On a reactor trip, all RCCAs (shutdown banks and control banks exclusive of the GRCAs), except the most reactive RCCA, are assumed to insert into the core. The shutdown banks shall be at or above their insertion limits and available to insert the maximum amount of negative reactivity on a reactor trip signal. The control banks may be partially inserted in the core as allowed by LCO 3.1.6, “Control Bank Insertion Limits.” The shutdown bank and control bank insertion limits are established to ensure that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM (see LCO 3.1.1, “SHUTDOWN MARGIN (SDM)”) following a reactor trip from full power. The combination of control banks and shutdown banks (less the most reactive RCCA which is assumed to be fully withdrawn) is sufficient to take the reactor from full power conditions at rated temperature to zero power, and to maintain the required SDM at the rated no load temperature (Ref. 3). The shutdown bank insertion limit also limits the reactivity worth of an ejected shutdown bank rod.

The acceptance criteria for addressing shutdown and control rod bank insertion limits and inoperability or misalignment is that:

a. There be no violations of:

   1. specified acceptable fuel design limits, or,

   2. RCS pressure boundary integrity; and

b. The core remains subcritical after accident transients.

As such, the shutdown bank insertion limits affect safety analysis involving core reactivity and SDM (Ref. 3).

The shutdown bank insertion limits preserve an initial condition assumed in the safety analyses and satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The shutdown banks must be within their insertion limits any time the reactor is critical or approaching criticality. This in conjunction with LCO 3.1.6, “Control Bank Insertion Limits,” and 3.2.5.d, Online Power Distribution Monitoring System (OPDMS) Monitored Parameters, “SDM,” ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip.

The shutdown bank insertion limits are defined in the COLR.

APPLICABILITY

The shutdown banks must be within their insertion limits with the reactor in MODE 1 and MODE 2. The shutdown banks do not have to be within their insertion limits in MODE 3, unless an approach to criticality is being made. In MODE 3, 4, 5, or 6 the shutdown banks are fully inserted in the Core and contribute to the SDM. Refer to LCO 3.1.1 for SDM requirements in MODES 3, 4, and 5. LCO 3.9.1, “Boron Concentration” ensures adequate SDM in MODE 6.

The Applicability requirements have been modified by a Note indicating that the LCO requirement is suspended during SR 3.1.4.2. This SR verifies the freedom of the rods to move, and requires the shutdown bank to move below the LCO limits, which would normally violate the LCO.

ACTIONS

A.1.1, A.1.2, and A.2

When one or more shutdown banks is not within insertion limits, 2 hours are allowed to restore the shutdown banks to within the insertion limits. This is necessary because the available SDM may be significantly reduced with one or more of the shutdown banks not within their insertion limits. Also, verification of SDM or initiation of boration within 1 hour is required, since the SDM in MODES 1 and 2 is ensured by the continuous monitoring of SDM by the OPDMS (see LCO 3.2.5) and adhering to the control and shutdown bank insertion limits (see LCO 3.1.1). If shutdown banks are not within their insertion limits, then SDM will be verified by the OPDMS or by performing a reactivity balance calculation, considering the effects listed in the BASES for SR 3.1.1.1.

The allowed Completion Time of 2 hours provides an acceptable time for evaluating and repairing minor problems without allowing the plant to remain in an unacceptable condition for an extended period of time.

BASES

ACTIONS (continued)

B.1

If the shutdown banks cannot be restored to within their insertion limits within 2 hours, the unit must be brought to a MODE where the LCO is not applicable. The allowed Completion Time of 6 hours is reasonable based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.5.1

Verification that the shutdown banks are within their insertion limits prior to an approach to criticality ensures that when the reactor is critical, or being taken critical, the shutdown banks will be available to shut down the reactor, and the required SDM will be maintained following a reactor trip. This SR and Frequency ensure that the shutdown banks are withdrawn before the control banks are withdrawn during a unit startup.

Since the shutdown banks are positioned manually by the main control room operator, a verification of shutdown bank position at a Frequency of 12 hours, after the reactor is taken critical, is adequate to ensure that they are within their insertion limits. Also, the 12 hours Frequency takes into account other information available in the main control room for the purpose of monitoring the status of shutdown rods.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.6 Control Bank Insertion Limits

BASES

BACKGROUND

The insertion limits of the shutdown and control rods are initial assumptions in the safety analyses that assume rod insertion upon reactor trip. The insertion limits directly affect core power and fuel burnup distributions and assumptions of available SDM, and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, “Reactor Design,” GDC 26, “Reactivity Control System Redundancy and Protection,” GDC 28, “Reactivity Limits” (Ref. 1) and 10 CFR 50.46, “Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors” (Ref. 2). Limits on control rod insertion have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

The rod cluster control assemblies (RCCAs) are divided among control banks and shutdown banks, gray rod cluster assemblies (GRCAs) are limited to control banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A group consists of two or more RCCAs or GRCAs that are electrically paralleled to step simultaneously. A bank of RCCAs consists of two groups that are moved in a staggered fashion, but always within 1 step of each other. The AP1000 design has seven control banks and four shutdown banks. See LCO 3.1.4, “Rod Group Alignment Limits,” for control and shutdown rod OPERABILITY and alignment requirements, and LCO 3.1.7, “Rod Position Indication,” for position indication requirements.

The control bank insertion sequence and overlap limits are specified in the COLR. The control banks are required to be at or above the applicable insertion limit lines. There will be two insertion limit lines. Which is applicable will depend on the operability of the Online Power Distribution Monitoring System (OPDMS).

The control banks are used for precise reactivity control of the reactor. The positions of the control banks are normally controlled automatically by the Plant Control System (PLS), but can also be manually controlled. They are capable of adding reactivity very quickly (compared to borating or diluting).

BASES

BACKGROUND (continued)

The power density at any point in the core must be limited so that the fuel design criteria are maintained. Together, LCO 3.1.4, “Rod Group Alignment Limits,” LCO 3.1.5, “Shutdown Bank Insertion Limits,” LCO 3.1.6, “Control Bank Insertion Limits,” and LCO 3.2.5, “OPDMS – Monitored Parameters,” when the OPDMS is OPERABLE, or LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD),” and LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” when the OPDMS is inoperable, provide limits on control component operation and on monitored process variables which ensure that the core operates within the fuel design criteria.

The shutdown and control bank insertion and alignment limits and power distribution limits are process variables that together characterize and control the three dimensional power distribution of the reactor core. Additionally, the control bank insertion limits control the reactivity that could be added in the event of a rod ejection accident, and the shutdown and control bank insertion limits assure the required SDM is maintained when the OPDMS is inoperable.

Operation within the subject LCO limits will prevent fuel cladding failures that would breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow, ejected rod, or other accident requiring termination by a Reactor Trip System (RTS) trip function.

APPLICABLE SAFETY ANALYSES

The shutdown and applicable control bank insertion limits, AFD and QPTR LCOs, are required when the OPDMS is inoperable, to prevent power distributions that could result in fuel cladding failures in the event of a LOCA, loss of flow, ejected rod, or other accident requiring termination by an RTS trip function.

The acceptance criteria for addressing shutdown and control bank insertion limits and inoperability or misalignment are that:

a. There be no violations of:

   1. specified fuel design limits, or

   2. Reactor Coolant System (RCS) pressure boundary integrity; and

b. The core remains subcritical after accident transients.

BASES

APPLICABLE SAFETY ANALYSES (continued)

As such, the shutdown and control bank insertion limits affect safety analysis involving core reactivity and power distributions (Ref. 3).

The SDM requirement is ensured by the continuous monitoring of the OPDMS and by limiting the control and shutdown bank insertion limits when the OPDMS is inoperable, so that allowable inserted worth of the RCCAs is such that sufficient reactivity is available in the rods to shut down the reactor to hot zero power with a reactivity margin which assumes the maximum worth RCCA remains fully withdrawn upon trip (Ref. 3).

Operation at the insertion limits or AFD limits may approach the maximum allowable linear heat generation rate or peaking factor, with the allowed QPTR present. Operation at the insertion limit may also indicate the maximum ejected RCCA worth could be equal to the limiting value in fuel cycles that have sufficiently high ejected RCCA worth.

The control and shutdown bank insertion limits ensure that safety analyses assumptions for SDM (with OPDMS inoperable), ejected rod worth, and power distribution peaking factors are preserved (Ref. 3).

The insertion limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii) in that they are initial conditions assumed in the safety analysis.

LCO

The limits on control banks sequence, overlap, and physical insertion as defined in the COLR, must be maintained because they serve the function of preserving power distribution, ensuring that the SDM is maintained (when OPDMS is inoperable), ensuring that ejected rod worth is maintained, and ensuring adequate negative reactivity insertion is available on trip. The overlap between control banks provides more uniform rates of reactivity insertion and withdrawal and is imposed to maintain acceptable power peaking during control bank motion.

APPLICABILITY

The control bank sequence, overlap, and physical insertion limits shall be maintained with the reactor in MODES 1 and 2 with $k_{eff} \geq 1.0$. There will be two sets of insertion limits applicable to the control banks depending on OPDMS operability. With OPDMS inoperable, these limits must be maintained since they preserve the assumed power distribution, ejected rod worth, SDM, and reactivity rate insertion assumptions. With OPDMS operable and continuously monitoring power distribution and SDM, the applicable insertion limits must be maintained since they preserve the accident analysis assumptions.

BASES

APPLICABILITY (continued)

Applicability in MODES 3, 4, and 5 is not required, since neither the power distribution nor ejected rod worth assumptions would be exceeded in these MODES.

The applicability requirements are modified by a Note indicating the LCO requirements are suspended during the performance of SR 3.1.4.2. This SR verifies the freedom of the rods to move, and requires the control bank to move below the LCO limits, which would violate the LCO.

The second Note suspends LCO applicability during GRCA bank sequence exchange operations. The two exchanging banks will move out of sequence and overlap limits for several minutes during the sequence exchange. This operation, which occurs frequently throughout the fuel cycle, would normally violate the LCO. GRCA bank sequence exchange is only allowed with the OPDMS OPERABLE to monitor the parameters of LCO 3.2.5, “OPDMS Monitored Parameters.”

ACTIONS A.1.1, A.1.2, A.2, B.1.1, B.1.2, and B.2

When the control banks are outside the acceptable insertion limits, they must be restored to within those limits. This restoration can occur in two ways:

a. Reducing power to be consistent with rod position; or

b. Moving rods to be consistent with power.

Also, verification of SDM or initiation of boration to regain SDM is required within 1 hour, since with OPDMS inoperable, the SDM in MODES 1 and 2, ensured by adhering to the control and shutdown bank insertion limits (see LCO 3.1.1, “SHUTDOWN MARGIN (SDM)”), has been upset. If control banks are not within their insertion limits, then SDM will be verified by the OPDMS or if the OPDMS is inoperable, by performing a reactivity balance calculation, considering the effects listed in the BASES for SR 3.1.1.1.

Similarly, if the control banks are found to be out of sequence or in the wrong overlap configuration, they must be restored to meet the limits.

Operation beyond the LCO limits is allowed for a short time period in order to take conservative action because the simultaneous occurrence of either a LOCA, loss of flow accident, ejected rod accident, or other accident during this short time period, together with an inadequate power distribution or reactivity capability, has an acceptably low probability.

BASES

ACTIONS (continued)

The allowed Completion Time of 2 hours for restoring the banks to within the insertion, sequence and overlap limits provides an acceptable time for evaluating and repairing minor problems without allowing the plant to remain outside the insertion limits for an extended period of time.

C.1

If Required Actions A.1 and A.2, or B.1 and B.2 cannot be completed within the associated Completion Times, the plant must be brought to MODE 2 with $k_{eff} < 1.0$, where the LCO is not applicable. The allowed Completion Time of 6 hours is reasonable based on operating experience for reaching the required MODE from full power condition in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.6.1

This Surveillance is required to ensure that the reactor does not achieve criticality with the control banks below their insertion limits.

The estimated critical position (ECP) depends upon a number of factors, one of which is xenon concentration. If the ECP was calculated long before criticality, xenon concentration could change to make the ECP substantially in error. Conversely, determining the ECP immediately before criticality could be an unnecessary burden. There are a number of unit parameters requiring operator attention at that point. Performing the ECP calculation within 4 hours prior to criticality avoids a large error from changes in xenon concentration, but allows the operator some flexibility to schedule the ECP calculation with other startup activities.

SR 3.1.6.2

Verification of the control banks insertion limits at a Frequency of 12 hours is sufficient to detect control banks that may be approaching the insertion limits since the insertion limits are monitored and alarms will occur on approach to and/or the exceeding of the limit and, normally, very little rod motion occurs in 12 hours.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.1.6.3

When control banks are maintained within their insertion limits as checked by SR 3.1.6.2 above, it is unlikely that their sequence and overlap will not be in accordance with requirements provided in the COLR. A Frequency of 12 hours is consistent with the insertion limit check above in SR 3.1.6.2.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.7 Rod Position Indication

BASES

BACKGROUND

According to GDC 13 (Ref. 1), instrumentation to monitor variables and systems over their operating ranges during normal operation, anticipated operational occurrences (AOOs), and accident conditions must be OPERABLE. LCO 3.1.7 is required to ensure OPERABILITY of the control rod position indicators to determine control rod positions and thereby ensure compliance with the control rod alignment and insertion limits.

The OPERABILITY, including position indication, of the shutdown and control rods is an initial assumption in the safety analyses that assume rod insertion upon reactor trip. Maximum rod misalignment is an initial assumption in the rod cluster control assembly (RCCA) misalignment safety analysis that directly affects core power distributions and assumptions of available SDM. Rod position indication is required to assess OPERABILITY and misalignment.

Mechanical or electrical failures may cause a control rod to become inoperable or to become misaligned from its group. Control rod inoperability or misalignment may cause increased power peaking due to the asymmetric reactivity distribution and a reduction in the total available rod worth for reactor shutdown. Therefore, control rod alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on control rod alignment and OPERABILITY have been established, and rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

RCCAs, or rods, are moved out of the core (up or withdrawn) or into the core (down or inserted) by their control rod drive mechanisms. The RCCAs are divided among control banks and shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control.

The axial position of shutdown rods and control rods are determined by two separate and independent systems: the Bank Demand Position Indication System (commonly called group step counters) and the Digital Rod Position Indication (DRPI) System.

BASES

BACKGROUND (continued)

The Bank Demand Position Indication System counts the pulses from the Rod Control System that move the rods. There is one step counter for each group of rods. Individual rods in a group receive the same signal to move and should, therefore, be at the same position indicated by the group step counter for that group. The Bank Demand Position Indication System is considered highly precise (± 1 step or ± 5/8 inch). If a rod does not move one step for each demand pulse, the step counter will still count the pulse and incorrectly reflect the position of the rod.

The DRPI System provides a highly accurate indication of actual control rod position, at a lower precision than the step counters. This system is based on inductive analog signals from a series of coils spaced along a hollow tube with a center to center distance of 3.75 inches, which is 6 steps. To increase the reliability of the system, the inductive coils are connected alternately to data system A or B. Thus, if one system fails, the DRPI will function at half accuracy with an effective coil spacing of 7.5 inches, which is 12 steps. Therefore, the normal indication accuracy of the DRPI System is ± 6 steps (± 3.75 inches), and the maximum uncertainty is ± 12 steps (± 7.5 inches). With an indicated deviation of 12 steps between the group step counter and DRPI, the maximum deviation between actual rod position and the demand position could be 24 steps, or 15 inches.

APPLICABLE SAFETY ANALYSES

Control and shutdown rod position accuracy is essential during power operation. Power peaking, ejected rod worth, or SDM limits may be violated in the event of a Design Basis Accident (Ref. 2), with control or shutdown rods operating outside their limits undetected. Therefore, the acceptance criteria for rod position indication is that rod positions must be known with sufficient accuracy in order to verify the core is operating within the group sequence, overlap, design peaking limits, ejected rod worth, and with minimum SDM (LCO 3.1.5, “Shutdown Bank Insertion Limits,” LCO 3.1.6, “Control Bank Insertion Limits”). The rod positions must also be known in order to verify the alignment limits are preserved (LCO 3.1.4, “Rod Group Alignment Limits”). Control rod positions are continuously monitored to provide operators with information that assures the plant is operating within the bounds of the accident analysis assumptions.

The control rod position indicator channels satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii). The control rod position indicators monitor control rod position, which is an initial condition of the accident.

BASES

LCO

LCO 3.1.7 specifies that one DRPI System and one Bank Demand Position Indication System be OPERABLE for each control rod. For the control rod position indicators to be OPERABLE requires meeting the SR of the LCO and the following:

a. The DRPI System indicates within 12 steps of the group step counter demand position as required by LCO 3.1.4, “Rod Group Alignment Limits”;

b. For the DRPI System there are no failed coils; and

c. The Bank Demand Indication System has been calibrated either in the fully inserted position or to the DRPI System.

The 12 step agreement limit between the Bank Demand Position Indication System and the DRPI System indicates that the Bank Demand Position Indication System is adequately calibrated and can be used for indication of the measurement of control rod bank position.

A deviation of less than the allowable limit given in LCO 3.1.4 in position indication for a single control rod ensures high confidence that the position uncertainty of the corresponding control rod group is within the assumed values used in the analysis (that specified control rod group insertion limits).

These requirements provide adequate assurance that control rod position indication during power operation and PHYSICS TESTS is accurate, and that design assumptions are not challenged. OPERABILITY of the position indicator channels ensures that inoperable, misaligned, or mispositioned control rods can be detected. Therefore, power peaking, ejected rod worth, and SDM can be controlled within acceptable limits.

APPLICABILITY

The requirements on the DRPI and step counters are only applicable in MODES 1 and 2 (consistent with LCOs 3.1.4, 3.1.5, and 3.1.6), because these are the only MODES in which power is generated, and the OPERABILITY and alignment of rods has the potential to affect the safety of the plant. In the shutdown MODES, the OPERABILITY of the shutdown and control banks has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the Reactor Coolant System (RCS).

ACTIONS

The ACTIONS table is modified by a Note indicating that a separate Condition entry is allowed for each inoperable rod position indicator per group and each demand position indicator per bank. This is acceptable because the Required Actions for each Condition provide appropriate compensatory actions for each inoperable position indicator.

BASES

ACTIONS (continued)

A.1

When one DRPI channel per group fails, the position of the rod can still be determined by use of the On-line Power Distribution Monitoring System (OPDMS). Based on experience, normal power operation does not require excessive movement of banks. If a bank has been significantly moved, the Actions of C.1 or C.2 below are required. Therefore, verification of RCCA position within the Completion Time of 8 hours is adequate to allow continued full power operation, since the probability of simultaneously having a rod significantly out of position and an event sensitive to that rod position is small.

A.2

Reduction of THERMAL POWER to ≤ 50% RTP puts the core into a condition where rod position is not significantly affecting core peaking factors (Ref. 2).

The allowed Completion Time of 8 hours is reasonable, based on operating experience, for reducing power to ≤ 50% RTP from full power conditions without challenging plant systems and allowing for rod position determination by Required Action A.1 above.

B.1, B.2, B.3, and B.4

When more than one DRPI per group fail, additional actions are necessary to ensure that acceptable power distribution limits are maintained, minimum SDM is maintained, and the potential effects of rod misalignment on associated accident analyses are limited. Placing the Rod Control System in manual assures unplanned rod motion will not occur. Together with the indirect position determination available via incore detectors will minimize the potential for rod misalignment. The immediate Completion Time for placing the Rod Control System in manual reflects the urgency with which unplanned rod motion must be prevented while in this Condition.

Monitoring and recording reactor coolant T_{avg} help assure that significant changes in power distribution and SDM are avoided. The once per hour Completion Time is acceptable because only minor fluctuations in RCS temperature are expected at steady state plant operating conditions.

The position of the rods may be determined indirectly by use of the incore detectors. The Required Action may also be satisfied by ensuring at least once per 8 hours that F_Q satisfies LCO 3.2.1, $F^N_{\Delta H}$ satisfies LCO 3.2.2, and SDM is within the limits provided in the COLR,

BASES

ACTIONS (continued)

provided the nonindicating rods have not been moved. Verification of control rod position once per 8 hours is adequate for allowing continued full power operation for a limited, 24 hour period, since the probability of simultaneously having a rod significantly out of position and an event sensitive to that rod position is small. The 24 hour Completion Time provides sufficient time to troubleshoot and restore the DRPI system to operation while avoiding the plant challenges associated with the shutdown without full rod position indication.

Based on operating experience, normal power operation does not require excessive rod movement. If one or more rods has been significantly moved, the Required Action of C.1 and C.2 below is required.

C.1 and C.2

These Required Actions clarify that when one or more rods with inoperable position indicators have been moved in excess of 24 steps in one direction since the position was last determined, the Required Actions of A.1 and A.2 or B.1 are still appropriate but must be initiated promptly under Required Action C.1 to begin verifying that these rods are still properly positioned relative to their group positions.

If, within 4 hours, the rod positions have not been determined, THERMAL POWER must be reduced to ≤ 50% RTP within 8 hours to avoid undesirable power distributions that could result from continued operation at > 50% RTP, if one or more rods are misaligned by more than 24 steps. The allowed Completion Time of 4 hours provides an acceptable period of time to verify the rod positions.

D.1.1 and D.1.2

With one demand position indicator per bank inoperable, the rod positions can be determined by the DRPI System. Since normal power operation does not require excessive movement of rods, verification by administrative means that the rod position indicators are OPERABLE and the most withdrawn rod and the least withdrawn rod are ≤ 12 steps apart within the allowed Completion Time of once every 8 hours is adequate.

D.2

Reduction of THERMAL POWER to ≤ 50% RTP puts the core into a condition where rod position is not significantly affecting core peaking factor limits (Ref. 2). The allowed Completion Time of 8 hours provides an acceptable period of time to verify the rod positions per Required Actions D.1.1 and D.1.2 or reduce power to ≤ 50% RTP.

BASES

ACTIONS (continued)

E.1

If the Required Actions cannot be completed within the associated Completion Time, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The allowed Completion Time is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.7.1

Verification that the DRPI agrees with the demand position within 12 steps provides assurance that the DRPI is operating correctly. Since the DRPI does not display the actual shutdown rod positions between 18 and 249 steps, only points within the indicated ranges are compared.

This surveillance is performed prior to reactor criticality after each removal of the reactor head, as there is the potential for unnecessary plant transients if the SR were performed with the reactor at power.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.8 PHYSICS TESTS Exceptions – MODE 2

BASES

BACKGROUND

The primary purpose of the MODE 2 PHYSICS TESTS exceptions is to permit relaxations of existing LCOs to allow certain PHYSICS TESTS to be performed.

Section XI of 10 CFR 50, Appendix B, (Ref. 1) requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that the specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. This testing is an integral part of the design, construction, and operation of the plant. Requirements for notification of the NRC, for the purpose of conducting tests and experiments, are specified in 10 CFR 50.59 (Ref. 2).

The key objectives of a test program are to (Ref. 3):

a. Ensure that the facility has been adequately designed;

b. Validate the analytical models used in the design and analysis;

c. Verify the assumptions used to predict unit response;

d. Ensure that installation of equipment in the facility has been accomplished in accordance with the design; and

e. Verify that the operating and emergency procedures are adequate.

To accomplish these objectives, testing is performed prior to initial criticality, during startup, during low power operations, during power ascension, at high power and after each refueling. The PHYSICS TEST requirements for reload fuel cycles assure that the operating characteristics of the core are consistent with the design predictions and that the core can be operated as designed (Ref. 4).

PHYSICS TEST procedures are written and approved in accordance with established formats. The procedures include information necessary to permit a detailed execution of the testing required, to ensure that the design intent is met. PHYSICS TESTS are performed in accordance with these procedures and test results are approved prior to continued power escalation and long-term power operation.

BASES

BACKGROUND (continued)

The typical PHYSICS TESTS performed for reload fuel cycles (Ref. 4) in MODE 2 are listed below:

a. Critical Boron Concentration – Control Rods Withdrawn;

b. Control Rod Worth;

c. Isothermal Temperature Coefficient (ITC).

These tests are performed in MODE 2. These and other supplementary tests may be required to calibrate the nuclear instrumentation or to diagnose operational problems. These tests may cause the operating controls and process variables to deviate from their LCO requirements during their performance.

a. The Critical Boron Concentration – Control Rods Withdrawn Test measures the critical boron concentration at hot zero power (HZP). With rods out, the lead control bank is at or near its fully withdrawn position. HZP is where the core is critical (k_{eff} = 1.0), and the Reactor Coolant System (RCS) is at design temperature and pressure for zero power. Performance of this test should not violate any of the referenced LCOs.

b. The Control Rod Worth Test is used to measure the reactivity worth of selected control banks. This test is performed at HZP and has four alternative methods of performance. The first method, the Boron Exchange Method, varies the reactor coolant boron concentration and moves the selected control bank in response to the changing boron concentration. The reactivity changes are measured with a reactivity computer. This sequence is repeated for the remaining control banks. The second method, the Rod Swap Method, measures the worth of a predetermined reference bank using the Boron Exchange Method above. The reference bank is then nearly fully inserted into the core. The selected bank is then inserted into the core as the reference bank is withdrawn. The HZP critical conditions are then determined with the selected bank fully inserted into the core. The worth of the selected bank is calculated based on the position of the reference bank with respect to the selected bank. This sequence is repeated as necessary for the remaining control banks. The third method, the Boron Endpoint Method, moves the selected control bank over its entire length of travel and while varying the reactor coolant boron concentration to maintain HZP criticality again. The difference in boron concentration is the worth of the selected control bank. This sequence is repeated for the remaining control banks. The fourth method, Dynamic Rod

BASES

BACKGROUND (continued)

Worth Measurement (DRWM), moves each bank, individually, into the core to determine its worth. The bank is dynamically inserted into the core while data is acquired from the excore channel. While the bank is being withdrawn, the data is analyzed to determine the worth of the bank. This is repeated for each control and shutdown bank. Performance of this test will violate LCO 3.1.4, “Rod Group Alignment Limits,” LCO 3.1.5, “Shutdown Bank Insertion Limits,” or LCO 3.1.6, “Control Bank Insertion Limits.”

c. The ITC Test measures the ITC of the reactor. This test is performed at HZP. The method is to vary the RCS temperature in a slow and continuous manner. The reactivity change is measured with a reactivity computer as a function of the temperature change. The ITC is the slope of the reactivity versus the temperature plot. The test is repeated by reversing the direction of the temperature change and the final ITC is the average of the two calculated ITCs. Performance of this test could violate LCO 3.4.2, “RCS Minimum Temperature for Criticality.”

APPLICABLE SAFETY ANALYSES

The fuel is protected by LCOs that preserve the initial conditions of the core assumed during the safety analyses. The methods for development of the LCOs that are excepted by this LCO are described in the Westinghouse Reload Safety Evaluation Methodology report (Ref. 5). The above mentioned PHYSICS TESTS, and other tests that may be required to calibrate nuclear instrumentation or to diagnose operational problems, may require the operating control or process variables to deviate from their LCO limitations.

Chapter 14 defines requirements for initial testing of the facility, including low power PHYSICS TESTS. Sections 14.2.10.2 and 14.2.10.3 (Ref. 6) summarize the initial criticality and low power tests.

Requirements for reload fuel cycle PHYSICS TESTS are defined in ANSI/ANS-19.6.1-2005 (Ref. 4). Although these PHYSICS TESTS are generally accomplished within the limits for the LCOs, conditions may occur when one or more LCOs must be suspended to make completion of PHYSICS TESTS possible or practical. This is acceptable as long as the fuel design criteria are not violated. When one or more of the requirements specified in:

LCO 3.1.3 “Moderator Temperature Coefficient (MTC),”
LCO 3.1.4 “Rod Group Alignment Limits,”
LCO 3.1.5 “Shutdown Bank Insertion Limits,”

BASES

APPLICABLE SAFETY ANALYSES (continued)

LCO 3.1.6 "Control Bank Insertion Limits," and
LCO 3.4.2 "Minimum Temperature for Criticality,"

are suspended for PHYSICS TESTS, the fuel design criteria are preserved as long as the power level is limited to ≤ 5% RTP, the reactor coolant temperature is kept ≥ 541°F, and SDM is within the limits provided in the COLR.

PHYSICS TESTS include measurement of core nuclear parameters or the exercise of control components that affect process variables. Also involved are the movable control components (control and shutdown rods), which are required to shut down the reactor. The limits for these variables are specified for each fuel cycle in the COLR.

As described in LCO 3.0.7, compliance with Test Exception LCOs is optional, and therefore no criteria of 10 CFR 50.36(c)(2)(ii) apply. Test Exception LCOs provide flexibility to perform certain operations by appropriately modifying requirements of other LCOs. A discussion of the criteria satisfied for the other LCOs is provided in their respective Bases.

Reference 7 allows special test exceptions (STE) to be included as part of the LCO that they affect. It was decided, however, to retain this STE as a separate LCO because it was less cumbersome and provided additional clarity.

LCO

This LCO allows the reactor parameters of MTC and minimum temperature for criticality to be outside their specified limits. In addition, it allows selected control and shutdown rods to be positioned outside of their specified alignment and insertion limits. Operation beyond specified limits is permitted for the purpose of performing PHYSICS TESTS and poses no threat to fuel integrity, provided the SRs are met.

The requirements of LCO 3.1.3, LCO 3.1.4, LCO 3.1.5, LCO 3.1.6, and LCO 3.4.2 may be suspended during the performance of PHYSICS TESTS provided:

a. RCS lowest loop average temperature is ≥ 541°F,

b. SDM is within the limits provided in the COLR, and

c. THERMAL POWER is ≤ 5% RTP.

BASES

APPLICABILITY

This LCO is applicable when performing low power PHYSICS TESTS. The Applicability is stated as “During PHYSICS TESTS initiated in MODE 2” to ensure that the 5% RTP maximum power level is not exceeded. Should the THERMAL POWER EXCEED 5% RTP, and consequently the unit enter MODE 1, this Applicability statement prevents exiting this Specification and its Required Actions.

ACTIONS

A.1 and A.2

If the SDM requirement is not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. The operator should begin boration with the best source available for the plant conditions. Boration will be continued until SDM is within limit.

Suspension of PHYSICS TESTS exceptions requires restoration of each of the applicable LCOs to within specification.

B.1

When THERMAL POWER is > 5% RTP, the only acceptable action is to open the reactor trip breakers (RTBs) to prevent operation of the reactor beyond its design limits. Immediately opening the RTBs will shut down the reactor and prevent operation of the reactor outside of its design limits.

C.1

When the RCS lowest T_{avg} is < 541°F, the appropriate action is to restore T_{avg} to within its specified limit. The allowed Completion Time of 15 minutes provides time for restoring T_{avg} to within limits without allowing the plant to remain in an unacceptable condition for an extended period of time. Operation with the reactor critical and with temperature below 541°F could violate the assumptions for accidents analyzed in the safety analyses.

D.1

If the Required Action of Condition C cannot be completed within the associated Completion Time, the plant must be placed in a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within an additional 15 minutes. The Completion Time of 15 additional minutes is reasonable, based on operating experience, to reach MODE 3 from MODE 2 HZP conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.8.1

The power range and intermediate range neutron detectors must be verified to be OPERABLE in MODE 2 by LCO 3.3.1 “Reactor Trip System (RTS) Instrumentation.” A REACTOR TRIP CHANNEL OPERATIONAL TEST is performed on each power range (Functions 2.a and 2.b) and intermediate range (Function 4) channel prior to initiation of the PHYSICS TESTS. This will ensure that the RTS is properly aligned to provide the required degree of core protection during the performance of the PHYSICS TESTS.

SR 3.1.8.2

Verification that the RCS lowest loop T_{avg} is ≥ 541°F will ensure that the unit is not operating in a condition that could invalidate the safety analyses. Verification of the RCS temperature at a Frequency of 30 minutes during the performance of the PHYSICS TESTS will provide assurance that the initial conditions of the safety analyses are not violated.

SR 3.1.8.3

Verification that the THERMAL POWER is ≤ 5% RTP will ensure that the plant is not operating in a condition that could invalidate the safety analyses. Verification of the THERMAL POWER at a Frequency of 30 minutes during the performance of the PHYSICS TESTS will ensure that the initial conditions of the safety analyses are not violated.

SR 3.1.8.4

The SDM is verified by performing a reactivity balance calculation, considering the following reactivity effects:

a. RCS boron concentration;

b. Control bank position;

c. RCS average temperature;

d. Fuel burnup based on gross thermal energy generation;

e. Xenon concentration;

f. Samarium concentration; and

g. Isothermal temperature coefficient (ITC).

BASES

SURVEILLANCE REQUIREMENTS (continued)

Using the ITC accounts for Doppler reactivity in this calculation because the reactor is subcritical, and the fuel temperature will be changing at the same rate as the RCS.

The Frequency of 24 hours is based on the generally slow change in required boron concentration and on the low probability of an accident occurring without the required SDM.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.9 Chemical and Volume Control System (CVS) Demineralized Water Isolation Valves and Makeup Line Isolation Valves

BASES

BACKGROUND

One of the principle functions of the CVS system is to maintain the reactor coolant chemistry conditions by controlling the concentration of boron in the coolant for plant startups, normal dilution to compensate for fuel depletion, and shutdown boration. In the dilute mode of operation, unborated demineralized water may be supplied directly to the reactor coolant system.

Although the CVS is not considered a safety related system, certain functions of the system are considered safety related functions. The appropriate components have been classified and designed as safety related. The safety related functions provided by the CVS include containment isolation of chemical and volume control system lines penetrating containment, termination of inadvertent boron dilution, and preservation of the Reactor Coolant System (RCS) pressure boundary, including isolation of CVS letdown from the RCS.

APPLICABLE SAFETY ANALYSES

One of the initial assumptions in the analysis of an inadvertent boron dilution event (Ref. 1) is the assumption that the increase in core reactivity, created by the dilution event, can be detected by the source range instrumentation. The source range instrumentation will then supply a signal to the demineralized water isolation valves and the makeup line isolation valves in the CVS causing these valves to close and terminate the boron dilution event. Thus the makeup line isolation valves and the demineralized water isolation valves are components which function to mitigate or prevent an AOO.

CVS isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that at least two demineralized water isolation valves and two makeup line isolation valves be OPERABLE assures that there will be redundant means available to terminate or prevent an inadvertent boron dilution event.

APPLICABILITY

The requirement that at least two demineralized water isolation valves and two makeup line isolation valves be OPERABLE is applicable in MODES 1, 2, 3, 4, and 5 because a boron dilution event is considered

BASES

APPLICABILITY (continued)

possible in these MODES, and the automatic closure of these valves is assumed in the safety analysis.

In MODES 1 and 2, the detection and mitigation of a boron dilution event does not assume the detection of the event by the source range instrumentation. In these MODES, the event would be signaled by an intermediate range trip, a trip on the Power Range Neutron Flux - High (low setpoint nominally at 25% RTP), or Overtemperature delta T. The two demineralized water isolation valves close automatically upon reactor trip.

In MODE 6, a dilution event is precluded by the requirement in LCO 3.9.2 to close, lock and secure at least one valve in each unborated water source flow path.

ACTIONS

A.1

If only one of the demineralized water isolation valve and/or the makeup line isolation valve is/are OPERABLE, the redundant valve must be restored to OPERABLE status in 72 hours. The allowed Completion Time assures expeditious action will be taken, and is acceptable because the safety function of automatically isolating the clean water source can be accomplished by the redundant isolation valve(s).

B.1

If the Required Actions and associated Completion Time of Condition A are not met, or if both CVS demineralized water isolation valves or both makeup line isolation valves are not OPERABLE (i.e., not able to be closed automatically), then the demineralized water supply flow path to the RCS must be isolated. Isolation can be accomplished by manually isolating the CVS demineralized water isolation valve(s) or by positioning the 3-way blend valve to only take suction from the boric acid tank. Alternatively, the dilution path may be isolated by closing appropriate isolation valve(s) in the flow path(s) from the demineralized water storage tank to the reactor coolant system.

The Action is modified by a Note allowing the flow path to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the main control room. In this way, the flow path can be rapidly isolated when a need for isolation is indicated.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.9.1

Verification that the CVS demineralized water isolation valves and makeup line isolation valves are OPERABLE, by stroking each valve closed, demonstrates that the valves can perform their safety related function. The Frequency is in accordance with the Inservice Testing Program.

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.1 Heat Flux Hot Channel Factor ($F_Q(Z)$) (F_Q Methodology)

BASES

BACKGROUND

The purpose of the limits on the values of $F_Q(Z)$ is to limit the local (i.e., pellet) peak power density. The value of $F_Q(Z)$ varies along the axial height (Z) of the core.

$F_Q(Z)$ is defined as the maximum local fuel rod linear power density divided by the average fuel rod linear power density, assuming nominal fuel pellet and fuel rod dimensions. Therefore, $F_Q(Z)$ is a measure of the peak fuel pellet power within the reactor core.

During power operation with the On-line Power Distribution Monitoring System (OPDMS) inoperable, the global power distribution is limited by LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD),” and LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” which are directly and continuously measured process variables. These LCOs along with LCO 3.1.6, “Control Bank Insertion Limits,” maintain the core limits on power distributions on a continuous basis.

$F_Q(Z)$ varies with fuel loading patterns, control bank insertion, fuel burnup, and changes in axial power distribution.

With the OPDMS OPERABLE, peak kw/ft (Z) (which is proportional to $F_Q(Z)$) is measured continuously. With the OPDMS inoperable, $F_Q(Z)$ is measured periodically using the incore detector system. These measurements are generally taken with the core at or near steady state conditions.

With the measured three dimensional power distributions, it is possible to derive a measured value for $F_Q(Z)$ with the OPDMS inoperable. However, because this value represents a steady state condition, it does not include the variations in the value of $F_Q(Z)$ which are present during a nonequilibrium situation such as load following.

To account for these possible variations, the steady state value of $F_Q(Z)$ is adjusted by an elevation dependent factor to account for the calculated worst case transient conditions.

Core monitoring and control under non-equilibrium conditions and the OPDMS inoperable are accomplished by operating the core within the limits of the appropriate LCOs, including the limits on AFD, QPTR, and control rod insertion.

BASES

APPLICABLE SAFETY ANALYSES

This LCO precludes core power distributions that violate the following fuel design criteria:

a. During a large break loss of coolant accident (LOCA), the peak cladding temperature must not exceed a limit of 2200°F (Ref. 1);

b. During a loss of forced reactor coolant flow accident, there must be at least a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a departure from nucleate boiling (DNB) condition;

c. During an ejected rod accident, the energy deposition to the fuel must not exceed 280 cal/gm (Ref. 2); and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. 3).

Limits on $F_Q(Z)$ ensure that the value of the initial total peaking factor assumed in the accident analyses remains valid. Other criteria must also be met (e.g., maximum cladding oxidation, maximum hydrogen generation, coolable geometry, and long term cooling). However, the peak cladding temperature is typically most limiting.

$F_Q(Z)$ limits assumed in the LOCA analysis are typically limiting (i.e., lower than) relative to the $F_Q(Z)$ assumed in safety analyses for other postulated accidents. Therefore, this LCO provides conservative limits for other postulated accidents.

$F_Q(Z)$ satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The Heat Flux Hot Channel Factor, $F_Q(Z)$, shall be limited by the following relationships:

$$F_Q(Z) \leq \frac{CFQ}{P} \qquad \text{for } P > 0.5$$

$$F_Q(Z) \leq \frac{CFQ}{0.5} \qquad \text{for } P \leq 0.5$$

where: CFQ is the $F_Q(Z)$ limit at RTP provided in the COLR,

$$P = \frac{\text{THERMAL POWER}}{\text{RTP}}$$

BASES

LCO (continued)

The actual values of CFQ are given in the COLR; however, CFQ is normally a number on the order of 2.60. For the AP1000, the normalized $F_Q(Z)$ as a function of core height is 1.0.

For RAOC operation, $F_Q(Z)$ is approximated by $F_Q^C(Z)$ and $F_Q^W(Z)$. Thus, both $F_Q^C(Z)$ and $F_Q^W(Z)$ must meet the preceding limits on $F_Q(Z)$.

An $F_Q^C(Z)$ evaluation requires obtaining an incore flux map in MODE 1. From the incore flux map results the measured value of $F_Q(Z)$, called $F_Q^M(Z)$ is obtained. Then,

$$F_Q^C(Z) = F_Q^M(Z) * F_Q^{MU}(Z)$$

where $F_Q^{MU}(Z)$ is a factor that accounts for fuel manufacturing tolerances and flux map measurement uncertainty. $F_Q^{MU}(Z)$ is provided in the COLR.

$F_Q^C(Z)$ is an excellent approximation for $F_Q(Z)$ when the reactor is at the steady state power at which the incore flux map was taken.

The expression for $F_Q^W(Z)$ is:

$$F_Q^W(Z) = F_Q^C(Z) * W(Z)$$

where W(Z) is a cycle-dependent function that accounts for power distribution transients encountered during normal operation. W(Z) is included in the COLR.

The $F_Q(Z)$ limits define limiting values for core power peaking that precludes peak cladding temperatures above 2200°F during either a large or small break LOCA.

This LCO requires operation within the bounds assumed in the safety analyses. Calculations are performed in the core design process to confirm that the core can be controlled in such a manner during operation that it can stay within the LOCA $F_Q(Z)$ limits. If $F_Q(Z)$ cannot be maintained within the LCO limits, reduction of the core power is required and if $F_Q^W(Z)$ cannot be maintained within LCO limits, reduction of the AFD limits will also result in a reduction of the core power.

BASES

LCO (continued)

Violating the LCO limits for $F_Q(Z)$ may result in an unanalyzed condition while $F_Q(Z)$ is outside its specified limits.

APPLICABILITY

When the OPDMS is inoperable and core power distribution parameters cannot be continuously monitored, it is necessary to determine $F_Q(Z)$ on a periodic basis. Furthermore, the $F_Q(Z)$ limits must be maintained in MODE 1 to prevent core power distributions from exceeding the limits assumed in the safety analyses. Applicability in other MODES is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the reactor coolant to require a limit on the distribution of core power.

ACTIONS

A.1

Reducing THERMAL POWER by ≥ 1% of RTP for each 1% by which $F_Q^C(Z)$ exceeds its limit, maintains an acceptable absolute power density. $F_Q^C(Z)$ is $F_Q^M(Z)$ multiplied by a factor accounting for fuel manufacturing tolerances and flux map measurement uncertainties. $F_Q^M(Z)$ is the measured value of $F_Q(Z)$. The Completion Time of 15 minutes provides an acceptable time to reduce power in an orderly manner without allowing the plant to remain in an unacceptable condition for an extended period of time. The maximum allowable power level initially determined by Required Action A.1 may be affected by subsequent determinations of $F_Q^C(Z)$ and would require power reductions within 15 minutes of the $F_Q^C(Z)$ determination, if necessary to comply with the decreased maximum allowable power level. Decreases in $F_Q^C(Z)$ would allow increasing the maximum allowable power level and increasing power up to this revised limit.

A.2

A reduction of the Power Range Neutron Flux – High Trip setpoints by ≥ 1% for each 1% by which $F_Q^C(Z)$ exceeds its limit is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period and the prompt reduction in THERMAL POWER in accordance with Required Action A.1. The maximum allowable Power Range

BASES

ACTIONS (continued)

Neutron Flux – High trip setpoints initially determined by Required Action A.2 may be affected by subsequent determinations of $F_Q^C(Z)$ and would require Power Range Neutron Flux – High trip setpoint reductions within 8 hours of the $F_Q^C(Z)$ determination, if necessary to comply with the decreased maximum allowable Power Range Neutron Flux – High trip setpoints. Decreases in $F_Q^C(Z)$ would allow increasing the maximum allowable Power Range Neutron Flux – High trip setpoints.

A.3

Reduction in the Overpower ΔT Trip setpoints (value of K_4) by ≥ 1% for each 1% by which $F_Q^C(Z)$ exceeds its limit is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period and the prompt reduction in THERMAL POWER in accordance with Required Action A.1. The maximum allowable Overpower ΔT trip setpoints initially determined by Required Action A.3 may be affected by subsequent determinations of $F_Q^C(Z)$ and would require Overpower ΔT trip setpoint reductions within 72 hours of the $F_Q^C(Z)$ determination, if necessary to comply with the decreased maximum allowable Overpower ΔT trip setpoints. Decreases in $F_Q^C(Z)$ would allow increasing the maximum allowable Overpower ΔT trip setpoints.

A.4

Verification that $F_Q^C(Z)$ has been restored to within its limit by performing SR 3.2.1.1 and SR 3.2.1.2 prior to increasing THERMAL POWER above the limit imposed by Required Action A.1, assures that core conditions during operation at higher power levels and future operation are consistent with safety analyses assumptions.

Condition A is modified by a Note that requires Required Action A.4 to be performed whenever the Condition is entered. This ensures that SR 3.2.1.1 and SR 3.2.1.2 will be performed prior to increasing THERMAL POWER above the limit of Required Action A.1, even when Condition A is exited prior to performing Required Action A.4. Performance of SR 3.2.1.1 and SR 3.2.1.2 are necessary to assure $F_Q(Z)$ is properly evaluated prior to increasing THERMAL POWER.

BASES

ACTIONS (continued)

B.1

If it is found that the maximum calculated value of $F_Q(Z)$ which can occur during normal maneuvers, $F_Q^W(Z)$, exceeds its specified limits, there exists a potential for $F_Q^C(Z)$ to become excessively high if a normal operational transient occurs. Reducing the AFD by ≥ 1% for each 1% by which $F_Q^W(Z)$ exceeds its limit within the allowed Completion Time of 4 hours restricts the axial flux distribution such that even if a transient occurred, core peaking factors would not be exceeded.

The implicit assumption is that if W(Z) values were recalculated (consistent with the reduced AFD limits), then $F_Q^C(Z)$ times the recalculated W(Z) values would meet the $F_Q(Z)$ limit. Note that complying with this action (of reducing AFD limits) may also result in a power reduction. Hence the need for B.2, B.3, and B.4.

B.2

A reduction of the Power Range Neutron Flux-High trip setpoints by ≥ 1% for each 1% by which the maximum allowable power is reduced, is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period and the preceding prompt reduction in THERMAL POWER as a result of reducing AFD limits in accordance with Required Action B.1.

B.3

Reduction in the Overpower ΔT trip setpoints value of K_4 by ≥ 1% for each 1% by which the maximum allowable power is reduced, is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period, and the preceding prompt reduction in THERMAL POWER as a result of reducing AFD limits in accordance with Required Action B.1.

BASES

ACTIONS (continued)

B.4

Verification that $F_Q^W(Z)$ has been restored to within its limit, by performing SR 3.2.1.1 and SR 3.2.1.2 prior to increasing THERMAL POWER above the maximum allowable power limit imposed by Required Action B.1 ensures that core conditions during operation at higher power levels and future operation are consistent with safety analyses assumptions.

Condition B is modified by a Note that requires Required Action B.4 to be performed whenever the Condition is entered. This ensures that SR 3.2.1.1 and SR 3.2.1.2 will be performed prior to increasing THERMAL POWER above the limit of Required Action B.1, even when Condition A is exited prior to performing Required Action B.4. Performance of SR 3.2.1.1 and SR 3.2.1.2 are necessary to assure $F_Q(Z)$ is properly evaluated prior to increasing THERMAL POWER.

C.1

If Required Actions A.1 through A.4 or B.1 through B.4 are not met within their associated Completion Times, the plant must be placed in a MODE or condition in which the LCO requirements are not applicable. This is done by placing the plant in at least MODE 2 within 6 hours.

This allowed Completion Time is reasonable based on operating experience regarding the amount of time it takes to reach MODE 2 from full power operation in an orderly manner without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.1.1 and SR 3.2.1.2 are modified by two Notes. The first note applies to the situation where the OPDMS is inoperable at the beginning of cycle startup. Note 1 applies during the first power ascension after a refueling. It states that THERMAL POWER may be increased until an equilibrium power level has been achieved at which a power distribution map can be obtained. This allowance is modified, however, by one of the Frequency conditions that requires verification that $F_Q^C(Z)$ and $F_Q^W(Z)$ are within their specified limits after a power rise of more than 10% of RTP over the THERMAL POWER at which they were last verified to be within specified limits. Because $F_Q^C(Z)$ and $F_Q^W(Z)$ could not have previously been measured in this reload core, there is a second Frequency condition, applicable only for reload cores, that requires determination of these parameters before exceeding 75% RTP. This ensures that some determination of $F_Q^C(Z)$ and $F_Q^W(Z)$ are made at a lower power level at

BASES

SURVEILLANCE REQUIREMENTS (continued)

which adequate margin is available before going to 100% RTP. Also, this Frequency condition, together with the Frequency condition requiring verification of $F_Q^C(Z)$ and $F_Q^W(Z)$ following a power increase of more than 10%, ensures that they are verified as soon as RTP (or any other level for extended operation) is achieved. In the absence of these Frequency conditions, it is possible to increase power to RTP and operate for 31 days without verification of $F_Q^C(Z)$ and $F_Q^W(Z)$. The Frequency condition is not intended to require verification of these parameters after every 10% increase in power level above the last verification. It only requires verification after a power level is achieved for extended operation that is 10% higher than that power at which $F_Q(Z)$ was last measured.

The second Note applies to the situation where the OPDMS becomes inoperable while the plant is in MODE 1. Without the continuous monitoring capability of the OPDMS, F_Q limits must be monitored on a periodic basis. The first measurement must be made within 31 days of the most recent date where the OPDMS data has verified peak kw/ft (Z) (and therefore also F_Q) to be within its limit. This is consistent with the 31 day Surveillance Frequency.

SR 3.2.1.1

Verification that $F_Q^C(Z)$ is within its specified limits involves increasing the measured values of $F_Q^C(Z)$ to allow for manufacturing tolerance and measurement uncertainties in order to obtain $F_Q^C(Z)$. Specifically, $F_Q^M(Z)$ is the measured value of $F_Q(Z)$ obtained from incore flux map results and $F_Q^C(Z) = F_Q^M(Z) * F_Q^{MU}(Z)$. $F_Q^C(Z)$ is then compared to its specified limits.

The limit to which $F_Q^C(Z)$ is compared varies inversely with power above 50% RTP.

Performing the Surveillance in MODE 1 prior to exceeding 75% RTP assures that the $F_Q^C(Z)$ limit is met when RTP is achieved because Peaking Factors generally decrease as power level is increased.

BASES

SURVEILLANCE REQUIREMENTS (continued)

If THERMAL POWER has been increased by ≥ 10% RTP since the last determination of $F_Q^C(Z)$, another evaluation of this factor is required 12 hours after achieving equilibrium conditions at this higher power level (to assure that $F_Q^C(Z)$ values are being reduced sufficiently with power increase to stay within the LCO limits).

The Frequency of 31 effective full power days (EFPDs) is adequate to monitor the change of power distribution with core burnup because such changes are slow and well controlled when the plant is operated in accordance with Technical Specifications.

SR 3.2.1.2

The nuclear design process includes calculations performed to determine that the core can be operated within the $F_Q(Z)$ limits. Because flux maps are taken in steady state conditions, the variations in power distribution resulting from normal operational maneuvers are not present in the flux map data. These variations are, however, conservatively calculated by considering a wide range of unit maneuvers in normal operation. The maximum peaking factor increase over steady state values, calculated as a function of core elevation, Z, is called W(Z). Multiplying the measured total peaking factor, $F_Q^C(Z)$, by W(Z) gives the maximum $F_Q(Z)$ calculated to occur in normal operation, $F_Q^W(Z)$.

The limit to which $F_Q^W(Z)$ is compared varies inversely with power.

The W(Z) curve is provided in the COLR for discrete core elevations. $F_Q^W(Z)$ evaluations are not applicable for the following axial core regions, measured in percent of core height:

a. Lower core region, from 0% to 15% inclusive; and

b. Upper core region, from 85% to 100% inclusive.

The top and bottom 15% of the core are excluded from the evaluation because of the difficulty of making a precise measurement in these regions and because of the low probability that these regions would be more limiting than the safety analyses.

This Surveillance has been modified by a Note, which may require that more frequent surveillances be performed. If $F_Q^W(Z)$ is evaluated and found to be within its limit, an evaluation of the expression below is

BASES

SURVEILLANCE REQUIREMENTS (continued)

required to account for any increase to $F_Q^M(Z)$ which could occur and cause the $F_Q(Z)$ limit to be exceeded before the next required $F_Q(Z)$ evaluation.

If the two most recent FQ(Z) evaluations show an increase in $F_Q^C(Z)$, it is required to meet the $F_Q(Z)$ limit with the last $F_Q^W(Z)$ increased by the greater of a factor of 1.02 or by an appropriate factor as specified in the COLR or to evaluate $F_Q(Z)$ more frequently, each 7 EFPDs. These alternative requirements will prevent $F_Q(Z)$ from exceeding its limit for any significant period of time without detection.

Performing the Surveillance in MODE 1 prior to exceeding 75% of RTP ensures that the $F_Q(Z)$ limit will be met when RTP is achieved, because peaking factors are generally decreased as power level is increased.

The Surveillance Frequency of 31 EFPDs is adequate to monitor the change of power distribution because such a change is sufficiently slow, when the plant is operated in accordance with Technical Specifications, to preclude the occurrence of adverse peaking factors between 31 EFPD Surveillances. The Surveillance may be done more frequently if required by the results of $F_Q(Z)$ evaluations.

$F_Q(Z)$ is verified at power increases of at least 10% RTP above the THERMAL POWER of its last verification, 12 hours after achieving equilibrium conditions, to assure that $F_Q(Z)$ will be within its limit at higher power levels.

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.2 Nuclear Enthalpy Rise Hot Channel Factor ($F^N_{\Delta H}$)

BASES

BACKGROUND

The purpose of this LCO is to establish limits on the power density at any point in the core so that the fuel design criteria are not exceeded and the accident analysis assumptions remain valid. The design limits on local (pellet) and integrated fuel rod peak power density are expressed in terms of hot channel factors. Control of the core power distribution with respect to these factors assures that local conditions in the fuel rods and coolant channels do not challenge core integrity at any location during either normal operation or a postulated accident analyzed in the safety analyses.

$F^N_{\Delta H}$ is defined as the ratio of the integral of the linear power along the fuel rod with the highest integrated power to the average integrated fuel rod power. Therefore, $F^N_{\Delta H}$ is a measure of the maximum total power produced in a fuel rod.

$F^N_{\Delta H}$ is sensitive to fuel loading patterns, bank insertion and fuel burnup. $F^N_{\Delta H}$ typically increases with control bank insertion and typically decreases with fuel burnup.

With the On-line Power Distribution Monitoring System (OPDMS) OPERABLE, $F^N_{\Delta H}$ is determined continuously by the OPDMS. When the OPDMS is inoperable, $F^N_{\Delta H}$ is not directly measurable but is inferred from a power distribution map obtained with the incore detector system. Specifically, the results of the three dimensional power distribution map are analyzed to determine $F^N_{\Delta H}$. This factor is calculated at least every 31 effective full power days (EFPDs). Also, during power operation with the OPDMS inoperable, the global power distribution is monitored by LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD),” and LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” which are directly and continuously measured process variables.

The COLR provides peaking factor limits that ensure that the design basis value of the departure from nucleate boiling (DNB) is met for normal operation, operational transients, and any transient condition arising from events of moderate frequency. The DNB design basis precludes DNB and is met by limiting the minimum local DNB heat flux ratio. Transient

BASES

BACKGROUND (continued)

events that may be DNB limited are assumed to begin with a $F^N_{\Delta H}$ that satisfies the LCO requirements.

Operation outside the LCO limits may produce unacceptable consequences if a DNB limiting event occurs. The DNB design basis ensures that there is no overheating of the fuel that results in possible cladding perforation with the release of fission products to the reactor coolant.

APPLICABLE SAFETY ANALYSES

Limits on $F^N_{\Delta H}$ prevent core power distributions from occurring which would exceed the following fuel design limits:

a. There must be at least a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hottest fuel rod in the core does not experience a DNB condition;

b. During a large break loss of coolant accident (LOCA), the peak cladding temperature (PCT) must not exceed 2200°F;

c. During an ejected rod accident, the energy deposition to the fuel must not exceed 280 cal/gm (Ref. 1); and

d. Fuel design limits required by GDC 26 (Ref. 2) for the condition when the control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn.

For transients that may be DNB limited, the Reactor Coolant System (RCS) flow and $F^N_{\Delta H}$ are the core parameters of most importance. The limits on $F^N_{\Delta H}$ ensure that the DNB design basis is met for normal operation, operational transients, and any transients arising from events of moderate frequency. The DNB design basis is met by limiting the minimum DNB ratio (DNBR) to the 95/95 DNB criterion. This value provides a high degree of assurance that the hottest fuel rod in the core will not experience a DNB.

The allowable $F^N_{\Delta H}$ limit increases with decreasing power level. This functionality in $F^N_{\Delta H}$ is included in the analyses that provide the Reactor Core Safety Limits (SLs) of SL 2.1.1. Therefore, any DNB events in which the calculation of the core limits is modeled implicitly use this

BASES

APPLICABLE SAFETY ANALYSES (continued)

variable value of $F^N_{\Delta H}$ in the analyses. Likewise, all transients that may be DNB limited are assumed to begin with an initial $F^N_{\Delta H}$ as a function of power level defined by the COLR limit equation.

The LOCA safety analysis indirectly models $F^N_{\Delta H}$ as an input parameter. The Nuclear Heat Flux Hot Channel Factor ($F_Q(Z)$) and the axial peaking factors are inserted directly into the LOCA safety analyses that verify the acceptability of the resulting peak cladding temperature (Ref. 3).

The fuel is protected in part by Technical Specifications, which provide assurance that the initial conditions assumed in the safety and accident analyses remain valid. With the OPDMS OPERABLE, peak kw/ft(Z) and $F^N_{\Delta H}$ are directly monitored. Should the OPDMS become inoperable, the following LCOs assure that the conditions assumed for the safety analysis remain valid: LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD),” LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” LCO 3.1.6, “Control Bank Insertion Limits,” LCO 3.2.2, “Nuclear Enthalpy Rise Hot Channel Factor ($F^N_{\Delta H}$),” and LCO 3.2.1, “Heat Flux Hot Channel Factor ($F_Q(Z)$).”

When the OPDMS is not available to measure power distribution parameters continuously, $F^N_{\Delta H}$ and $F_Q(Z)$ are measured periodically using the incore detector system. Measurements are generally taken with the core at, or near, steady-state conditions. Without the OPDMS, core monitoring and control under transient conditions (Condition 1 events) are accomplished by operating the core within the limits of the LCOs on AFD, QPTR, and Bank Insertion Limits.

$F^N_{\Delta H}$ satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

$F^N_{\Delta H}$ shall be maintained within the limits of the relationship provided in the COLR.

The $F^N_{\Delta H}$ limit identifies the coolant flow channel with the maximum enthalpy rise. This channel has the least heat removal capability and thus the highest probability for a DNB.

BASES

LCO (continued)

The limiting value of $F^N_{\Delta H}$, described by the equation contained in the COLR, is the design radial peaking factor used in the unit safety analyses.

A power multiplication factor in this equation includes an additional margin for higher radial peaking from reduced thermal feedback and greater control rod insertion at low power levels. The limiting value of $F^N_{\Delta H}$ is allowed to increase 0.3% for every 1% RTP reduction in THERMAL POWER.

APPLICABILITY

When the OPDMS is inoperable and core power distribution parameters cannot be continuously monitored, it is necessary to monitor $F^N_{\Delta H}(Z)$ on a periodic basis. Furthermore, $F^N_{\Delta H}$ limits must be maintained in MODE 1 to preclude core power distributions from exceeding the fuel design limits for DNBR and peak cladding temperature (PCT). Applicability in other modes is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the coolant to require a limit on the distribution of core power. Specifically, the design bases events that are sensitive to $F^N_{\Delta H}$ in other modes (MODES 2 through 5) have significant margin to DNB, and therefore, there is no need to restrict $F^N_{\Delta H}$ in these modes.

ACTIONS

A.1.1

With $F^N_{\Delta H}$ exceeding its limit, the unit is allowed 4 hours to restore $F^N_{\Delta H}$ to within its limits. This restoration may, for example, involve realigning any misaligned rods or reducing power enough to bring $F^N_{\Delta H}$ within its power-dependent limit.

When the $F^N_{\Delta H}$ limit is exceeded, it is not likely that the DNBR limit would be violated in steady state operation, since events that could significantly perturb the $F^N_{\Delta H}$ value (e.g., static control rod misalignment) are considered in the safety analyses. However, the DNBR limit may be violated if a DNB limiting event occurs. Thus, the allowed Completion Time of 4 hours provides an acceptable time to restore $F^N_{\Delta H}$ to within its limits without allowing the plant to remain outside $F^N_{\Delta H}$ limits for an extended period of time.

BASES

ACTIONS (continued)

Condition A is modified by a Note that requires that Required Actions A.2 and A.3 must be completed whenever Condition A is entered. Thus, if power is not reduced because this Required Action is completed within the 4 hour time period, Required Action A.2 would nevertheless require another measurement and calculation of $F^N_{\Delta H}$ within 24 hours in accordance with SR 3.2.2.1.

However, if power were reduced below 50% RTP, Required Action A.3 requires that another determination of $F^N_{\Delta H}$ must be done prior to exceeding 50% RTP, prior to exceeding 75% RTP, and within 24 hours after reaching or exceeding 95% RTP. In addition, Required Action A.2 would be performed if power ascension were delayed past 24 hours.

A.1.2.1 and A.1.2.2

If the value of $F^N_{\Delta H}$ is not restored to within its specified limit either by adjusting a misaligned rod or by reducing THERMAL POWER, the alternative option is to reduce THERMAL POWER to < 50% RTP in accordance with Required Action A.1.2.1 and reduce the Power Range Neutron Flux - High to ≤ 55% RTP in accordance with Required Action A.1.2.2. The reduction in trip setpoints ensures that continuing operation remains at an acceptable low power level with adequate DNBR margin. The allowed Completion Time of 4 hours for Required Action A.1.2.1 is consistent with those specified in Required Action A.1.1 and provides an acceptable time to reach the required power level from full power operation without allowing the plant to remain in an unacceptable condition for an extended period of time. The Completion Time of 4 hours for Required Actions A.1.1 and A.1.2.1 are not additive.

The allowed Completion Time of 72 hours to reset the trip setpoints per Required Action A.1.2.2 recognizes that, once power is reduced, the safety analysis assumptions are satisfied and there is no urgent need to reduce the trip setpoints. This is a sensitive operation that may cause an inadvertent reactor trip.

A.2

Once the power level has been reduced to < 50% RTP per Required Action A.1.2.1, an incore flux map (SR 3.2.2.1) must be obtained and the measured value of $F^N_{\Delta H}$ verified not to exceed the allowed limit at the lower power level. The unit is provided 20 additional hours to perform this task over and above the 4 hours allowed by either Action A.1.1 or Action A.1.2.1. The Completion Time of 24 hours is acceptable because

BASES

ACTIONS (continued)

of the increase in the DNB margin, which is obtained at lower power levels, and the low probability of having a DNB limiting event within this 24 hour period. Additionally, operating experience has indicated that this Completion Time is sufficient to obtain the incore flux map, perform the required calculations, and evaluate $F^N_{\Delta H}$.

A.3

Verification that $F^N_{\Delta H}$ is within its specified limits after an out of limit occurrence assures that the cause that led to the $F^N_{\Delta H}$ exceeding its limit is corrected, and that subsequent operation will proceed within the LCO limit. This Action demonstrates that the $F^N_{\Delta H}$ limit is within the LCO limits prior to exceeding 50% of RTP, again prior to exceeding 75% RTP, and within 24 hours after THERMAL POWER is ≥ 95% RTP.

This Required Action is modified by a Note, that states that THERMAL POWER does not have to be reduced prior to performing this action.

B.1

When Required Actions A.1.1 through A.3 cannot be completed within their required Completion Times, the plant must be placed in a mode in which the LCO requirements are not applicable. This is done by placing the plant in at least MODE 2 within 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience regarding the time required to reach MODE 2 from full power conditions in an orderly manner without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.2.1

When the OPDMS is OPERABLE, the value of $F^N_{\Delta H}$ is directly and continuously monitored. With the OPDMS inoperable, the value of $F^N_{\Delta H}$ is determined by using the incore detector system to obtain a flux distribution map. A data reduction computer program then calculates the maximum value of $F^N_{\Delta H}$ from the measured flux distributions. The measured value of $F^N_{\Delta H}$ must be multiplied by a measurement uncertainty factor before making comparisons to the $F^N_{\Delta H}$ limit.

BASES

SURVEILLANCE REQUIREMENTS (continued)

After each refueling, with the OPDMS inoperable, $F^N_{\Delta H}$ must be determined prior to exceeding 75% RTP. This requirement ensures that $F^N_{\Delta H}$ limits are met at the beginning of each fuel cycle.

With the OPDMS inoperable, the 31 EFPDs Frequency is acceptable because the power distribution will change relatively slowly over this amount of fuel burnup. This Frequency is short enough so that the $F^N_{\Delta H}$ limit will not be exceeded for any significant period of operation.

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.3 AXIAL FLUX DIFFERENCE (AFD) (Relaxed Axial Offset Control (RAOC) Methodology)

BASES

BACKGROUND

The purpose of this LCO is to establish limits on the values of the AFD in order to limit the amount of axial power distribution skewing to either the top or bottom of the core when the On-Line Power Distribution Monitoring System (OPDMS) is inoperable. By limiting the amount of power distribution skewing, core peaking factors are consistent with the assumptions used in the safety analyses. Limiting power distribution skewing over time also minimizes the xenon distribution skewing which is a significant factor in axial power distribution control.

RAOC is a calculational procedure which defines the allowed operational space of the AFD versus THERMAL POWER. The AFD limits are selected by considering a range of axial xenon distributions that may occur as a result of large variations of the AFD. Subsequently, power peaking factors and power distributions are examined to assure that the loss of coolant accident (LOCA), loss of flow accident, and anticipated transient limits are met. Violation of the AFD limits invalidate the conclusions of the accident and transient analyses with regard to fuel cladding integrity.

The AFD is monitored on an automatic basis using the computer which has an AFD monitor alarm. The computer determines the 1 minute average of each of the OPERABLE excore detector outputs and provides an alarm message immediately if the AFD for two or more OPERABLE excore channels is outside its specified limits.

Although the RAOC defines limits that must be met to satisfy safety analyses, typically, without the OPDMS, an operating scheme, Constant Axial Offset Control (CAOC), is used to control axial power distribution in day-to-day operation (Ref. 1). CAOC requires that the AFD be controlled within a narrow tolerance band around a burnup-dependent target to minimize the variation of axial peaking factors and axial xenon distribution during unit maneuvers.

The CAOC operating space is typically smaller and lies within the RAOC operating space. Control within the CAOC operating space constrains the variation of axial xenon distributions and axial power distributions. RAOC calculations assume a wide range of xenon distributions and then confirm that the resulting power distributions satisfy the requirements of the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES

The AFD is a measure of the axial power distribution skewing SAFETY to either the top or bottom half of the core. The AFD is sensitive to many core related parameters such as control bank positions, core power level, axial burnup, axial xenon distribution, and, to a lesser extent, reactor coolant temperature and boron concentration.

The allowed range of the AFD is used in the nuclear design process to confirm that operation within these limits produces core peaking factors and axial power distributions that meet safety analysis requirements.

Three dimensional power distribution calculations are performed to demonstrate that normal operation power shapes are acceptable for the LOCA, the loss of flow accident, and for initial conditions of anticipated transients (Ref. 2). The tentative limits are adjusted as necessary to meet the safety analysis requirements.

With the OPDMS inoperable, the limits on the AFD ensure that the Heat Flux Hot Channel Factor ($F_Q(Z)$) is not exceeded during either normal operation or in the event of xenon redistribution following power changes. The limits on the AFD also restrict the range of power distributions that are used as initial conditions in the analyses of Condition 2, 3, or 4 events. This ensures that the fuel cladding integrity is maintained for these postulated accidents. The most important Condition 4 event is the LOCA. The most important Condition 3 event is the loss of flow accident. The most important Condition 2 events are uncontrolled bank withdrawal and boration or dilution accidents. Condition 2 accidents simulated to begin from within the AFD limits are used to confirm the adequacy of the Overpower ΔT and Overtemperature ΔT trip setpoints.

The limits on the AFD satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The shape of the power profile in the axial (i.e., the vertical) direction is largely under the control of the operator through the manual operation of the control banks or automatic motion of control banks. The automatic motion of the control banks is in response to temperature deviations resulting from manual operation of the Chemical and Volume Control System (CVS) to change boron concentration or from power level changes.

Signals are available to the operator from the Protection and Safety Monitoring System (PMS) excore neutron detectors (Ref. 3). Separate signals are taken from the top and bottom detectors. The AFD is defined as the difference in normalized flux signals between the top and bottom

BASES

LCO (continued)

excore detectors in each detector well. For convenience, this flux difference is converted to provide flux difference units expressed as a percentage and labeled as %Δ flux or %ΔI.

The AFD limits are provided in the COLR. Figure B 3.2.3-1 shows typical RAOC AFD limits. The AFD limits for RAOC do not depend on the target flux difference. However, the target flux difference may be used to minimize changes in the axial power distribution.

Violating this LCO on the AFD, with the OPDMS inoperable, could produce unacceptable consequences if a Condition 2, 3 or 4 event occurs while the AFD is outside its specified limits.

APPLICABILITY

The AFD requirements are applicable in MODE 1 greater than or equal to 50% RTP where the combination of THERMAL POWER and core peaking factors are of primary importance in safety analysis.

For AFD limits developed using RAOC methodology, the value of the AFD does not affect the limiting accident consequences with THERMAL POWER < 50% RTP and for lower operating power MODES. With the OPDMS inoperable, it is necessary to monitor AFD via the excore detectors to ensure that it remains within the RAOC limits.

ACTIONS

A.1

Required Action A.1 requires a THERMAL POWER reduction to < 50% RTP. This places the core in a condition where the value of the AFD is not important in the applicable safety analyses. A Completion Time of 30 minutes is reasonable, based on operating experience, to reach 50% RTP without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.3.1

This surveillance verifies that the AFD, as indicated by the PMS excore channel, is within its specified limits. The Surveillance Frequency of 7 days is adequate considering that the AFD is monitored by a computer and any deviation from requirements is alarmed.

AXIAL FLUX DIFFERENCE Limits as a Function
of RATED THERMAL POWER

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.4 QUADRANT POWER TILT RATIO (QPTR)

BASES

BACKGROUND

With the Online Power and Distribution Monitoring System (OPDMS) inoperable, the QPTR limit ensures that the gross radial power distribution remains consistent with the design values used in the safety analyses. Precise radial power distribution measurements are made during startup testing, after refueling, and periodically during power operation.

The power density at any point in the core must be limited so that the fuel design criteria are maintained. With the OPDMS OPERABLE, the peak kw/ft(Z) is continuously and directly monitored. With the OPDMS inoperable, LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD),” LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” and LCO 3.1.6, “Control Rod Insertion Limits,” provide limits on process variables that characterize and control the three dimensional power distribution of the reactor core. Control of these variables ensures that the core operates within the fuel design criteria and that the power distribution remains within the bounds used in the safety analyses.

APPLICABLE SAFETY ANALYSES

This LCO precludes core power distributions from occurring which would violate the following fuel design criteria:

a. During a large break loss of coolant accident (LOCA), the peak cladding temperature (PCT) must not exceed 2200°F (Ref. 1);

b. During a loss of forced reactor coolant flow accident, there must be at least a 95% probability at a 95% confidence level (the 95/95 departure from nucleate boiling (DNB) criterion) that the hot fuel rod in the core does not experience a DNB condition;

c. During an ejected rod accident, the energy deposition to the fuel must not exceed 280 cal/gm (Ref. 2); and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. 3).

The LCO limits on the AFD, the QPTR, the Heat Flux Hot Channel Factor ($F_Q(Z)$), the Nuclear Enthalpy Rise Hot Channel Factor ($F^N_{\Delta H}$), and control bank insertion are established to preclude core power distributions from occurring which would exceed the safety analyses limits.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Should the OPDMS become inoperable, the QPTR limits ensure that $F^N_{\Delta H}$ and $F_Q(Z)$ remain below their limiting values by preventing an undetected change in the gross radial power distribution.

In MODE 1, with the OPDMS inoperable, the $F^N_{\Delta H}$ and $F_Q(Z)$ limits must be maintained to preclude core power distributions from exceeding design limits assumed in the safety analyses.

The QPTR satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The QPTR limit of 1.02, where corrective action is required, provides a margin of protection for both the DNB ratio (DNBR) and linear heat generation rate contributing to excessive power peaks resulting from X-Y plane power tilts. A limiting QPTR of 1.02 can be tolerated before the margin for uncertainty in $F_Q(Z)$ and $F^N_{\Delta H}$ is possibly challenged.

APPLICABILITY

The QPTR limit must be maintained in MODE 1 with THERMAL POWER > 50% RTP to preclude core power distributions from exceeding the design limits. With the OPDMS inoperable, a continuous on-line indication of core peaking factors is not available. Therefore, QPTR must be monitored and the limits on QPTR ensure that peaking factors will be within design limits.

Applicability in MODE 1 ≤ 50% RTP and in other MODES is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the reactor coolant to require the implementation of a QPTR limit on the distribution of core power. The QPTR limit in these conditions is, therefore, not important. Note that the $F^N_{\Delta H}$ and $F_Q(Z)$ LCOs still apply, but allow progressively higher peaking factors at 50% RTP or lower.

ACTIONS

A.1

With the QPTR exceeding its limit, and the OPDMS inoperable, a power level reduction of 3% RTP for each 1% by which the QPTR exceeds 1.00 is a conservative tradeoff of total core power with peak linear power. The Completion Time of 2 hours allows sufficient time to identify the cause and correct the tilt. Note that the power reduction itself may cause a change in the tilted condition.

BASES

ACTIONS (continued)

The maximum allowable power level initially determined by Required Action A.1 may be affected by subsequent determinations of QPTR. Increases in QPTR would require power reduction within 2 hours of QPTR determination, if necessary to comply with the decreased maximum allowable power level and increasing power up to this revised limit.

A.2

After completion of Required Action A.1, the QPTR alarm may be in its alarmed state. As such, any additional changes in the QPTR are detected by requiring a check of the QPTR once per 12 hours thereafter. A 12 hour Completion Time is sufficient because any additional change in QPTR would be relatively slow.

A.3

The peaking factors $F_Q(Z)$, as approximated by $F_Q^C(Z)$ and $F_Q^W(Z)$, and $F_{\Delta H}^N$ are of primary importance in assuring that the power distribution remains consistent with the initial conditions used in the safety analyses. Performing SRs on $F_{\Delta H}^N$ and $F_Q(Z)$ within the Completion Time of 24 hours after achieving equilibrium conditions from a Thermal Power reduction power Required Action A.1 ensures that these primary indicators of power distribution are within their respective limits. A Completion Time of 24 hours after achieving equilibrium conditions from a Thermal Power reduction power Required Action A.1 takes into consideration the rate at which peaking factors are likely to change, and the time required to stabilize the plant and perform a flux map. If these peaking factors are not within their limits, the Required Actions of these Surveillances provide an appropriate response for the abnormal condition. If the QPTR remains above its specified limits, the peaking factor surveillances are required each 7 days thereafter to evaluate $F_{\Delta H}^N$ and $F_Q(Z)$ with changes in power distribution. Relatively small changes are expected due to either burnup and xenon redistribution or correction of the cause for exceeding the QPTR limit.

A.4

Although $F_{\Delta H}^N$ and $F_Q(Z)$ are of primary importance as initial conditions in the safety analyses, other changes in the power distribution may occur as the QPTR limit is exceeded and may have an impact on the validity of the safety analysis. A change in the power distribution can affect such

BASES

ACTIONS (continued)

reactor parameters as bank worths and peaking factors for rod malfunction accidents. When the QPTR exceeds its limit, it does not necessarily mean a safety concern exists. It does mean that there is an indication of a change in the gross radial power distribution that requires an investigation and evaluation that is accomplished by examining the incore power distribution. Specifically, the core peaking factors and the quadrant tilt must be evaluated because they are the factors which best characterize the core power distribution. This re-evaluation is required to assure that, before increasing THERMAL POWER to above the limit of Required Action A.1, the reactor core conditions are consistent with the assumptions in the safety analyses.

A.5

If the QPTR has exceeded the 1.02 limit and a re-evaluation of the safety analysis is completed and shows that safety requirements are met, the excore detectors are normalized to restore QPTR to within limits prior to increasing THERMAL POWER to above the limit of Required Action A.1. Normalization is accomplished in such a manner that the indicated QPTR following normalization is near 1.00. This is done to detect any subsequent significant changes in QPTR.

Required Action A.5 is modified by two Notes. Note 1 states that the QPTR is not restored to within limits until after the re-evaluation of the safety analysis has determined that core conditions at RTP are within the safety analysis assumptions (i.e., Required Action A.4). Note 2 states that if Required Action A.5 is performed, then Required Action A.6 shall be performed. Required Action A.5 normalizes the excore detectors to restore QPTR to within limits, which restores compliance with LCO 3.2.4. Thus, Note 2 prevents exiting the Actions prior to completing flux mapping to verify peaking factors, per Required Action A.6. These Notes are intended to prevent any ambiguity about the required sequence of actions.

A.6

Once the flux tilt is restored to within limits (i.e., Required Action A.5 is performed), it is acceptable to return to full power operation. However, as an added check that the core power distribution is consistent with the safety analysis assumptions, Required Action A.6 requires verification that $F_Q(Z)$ as approximated by $F_Q^C(Z)$ and $F_Q^W(Z)$, and $F_{\Delta H}^N$ are within their specified limits within 24 hours of achieving equilibrium conditions at RTP. As an added precaution, if the core power does not reach equilibrium conditions at RTP within 24 hours, but is increased slowly,

BASES

ACTIONS (continued)

then the peaking factor surveillances must be performed within 48 hours after increasing THERMAL POWER above the limit of Required Action A.1. These Completion Times are intended to allow adequate time to increase THERMAL POWER to above the limit of Required Action A.1, while not permitting the core to remain with unconfirmed power distributions for extended periods of time.

Required Action A.6 is modified by a Note that states that the peaking factor surveillances may only be done after the excore detectors have been calibrated to show zero tilt (i.e., Required Action A.5). The intent of this Note is to have the peaking factor surveillances performed at operating power levels, which can only be accomplished after the excore detectors are calibrated to show zero tilt and the core returned to power.

B.1

If Required Actions A.1 through A.6 are not completed within their associated Completion Times, the unit must be brought to a MODE or condition in which the requirements do not apply. To achieve the status, THERMAL POWER must be reduced to < 50% RTP within 4 hours. The allowed Completion Time of 4 hours is reasonable based on operating experience regarding the amount of time required to reach the reduced power level without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.4.1

SR 3.2.4.1 is modified by two Notes. Note 1 allows QPTR to be calculated with three power range channels if THERMAL POWER is < 75% RTP and the input from one Power Range Neutron Flux channel is inoperable. Note 2 allows performance of SR 3.2.4.2 in lieu of SR 3.2.4.1.

This Surveillance verifies that the QPTR as indicated by the Protection and Safety Monitoring System (PMS) excore channels is within its limits. The Frequency of 7 days takes into account other information and alarms available to the operator in the control room.

For those causes of QPT that occur quickly (a dropped rod), there are other indications of abnormality that prompt a verification of core power tilt.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.2.4.2

This Surveillance is modified by a Note, which states that it is not required until 12 hours after the input from one or more Power Range Neutron Flux channels are inoperable and the THERMAL POWER is ≥ 75% RTP.

With a PMS power range channel inoperable, tilt monitoring for a portion of the reactor core becomes degraded. Large tilts would likely be detected with the remaining channels, but the capability for detection of small power tilts in some quadrants is decreased. Performing SR 3.2.4.2 at a Frequency of 12 hours provides an accurate alternative means for assuring that any tilt remains within its limits.

For purposes of monitoring the QPTR when one power range channel is inoperable, the incore detectors are used to confirm that the normalized symmetric power distribution is acceptable.

With the OPDMS and one PMS channel inoperable, the surveillance of the incore power distribution on a 12 hour basis is sufficient to maintain peaking factors within their normal limits, especially, considering the other LCOs and ACTIONS required when the OPDMS is out of service.

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.5 OPDMS-Monitored Parameters

BASES

BACKGROUND

The On-line Power Distribution Monitoring System (OPDMS) for the AP1000 is an advanced core monitoring and support package. The OPDMS has the ability to continuously monitor core power distribution parameters. In addition, the OPDMS monitors SDM.

The purpose of the limits on the OPDMS-monitored power distribution parameters is to provide assurance of fuel integrity during Conditions I (Normal Operation) and II (incidents of Moderate Frequency) events by: (1) not exceeding the minimum departure from boiling ratio (DNBR) in the core, and (2) limiting the fission gas release, fuel pellet temperature, and cladding mechanical properties to within assumed design criteria. In addition, limiting the peak linear power density during Condition I events provides assurance that the initial conditions assumed for the LOCA analyses are met and the peak cladding temperature (PCT) limit of 2200°F is not exceeded.

The definition of certain quantities used in these specifications are as follows:

Peak kw/ft(Z)	Peak linear power density (axially dependent) as measured in kw/ft.
$F^N_{\Delta H}$	Ratio of the integral of linear power along the rod with the highest integrated power to the average rod power.
Minimum DNBR	Minimum ratio of the critical heat flux to actual heat flux at any point in the reactor that is allowed in order to assure that certain performance and safety criteria requirements are met over the range of plant conditions.

By continuously monitoring the core and following its actual operation, it is possible to significantly limit the adverse nature of power distribution initial conditions for transients which may occur at any time.

BASES

APPLICABLE SAFETY ANALYSES

The limits on the above parameters preclude core power distributions from occurring which would violate the following fuel design criteria:

a. During a large break loss of coolant accident (LOCA), the PCT must not exceed a limit of 2200°F (Ref. 1);

b. During a loss of forced reactor coolant flow accident, there must be at least a 95% probability at a 95% confidence level (the 95/95 departure from nucleate boiling (DNB) criterion) that the hot fuel rod in the core does not experience a DNB condition;

c. During an ejected rod accident, the energy deposition to the fuel must not exceed 280 cal/gm (Ref. 2); and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn.

Limits on linear power density or peak kw/ft assure that the peak linear power density assumed as a base condition in the LOCA analyses is not exceeded during normal operation.

Limits on $F_{\Delta H}$ ensure that the LOCA analysis assumptions and assumptions made with respect to the Overtemperature ΔT Setpoint are maintained.

The limit on DNBR ensures that if transients analyzed in the safety analyses initiate from the conditions within the limit allowed by the OPDMS, the DNB criteria will be met.

The OPDMS-monitored power distribution parameters of this LCO satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO ensures operation within the bounds assumed in the safety analyses. Calculations are performed in the core design process to confirm that the core can be controlled in such a manner during operation that it can stay within these limits. If the LCO limits cannot be maintained within limits, reduction of the core power is required.

Violating the OPDMS-monitored power distribution parameter limits could result in unanalyzed conditions should a design basis event occur while the parameters are outside their specified limits.

BASES

LCO (continued)

Peak kw/ft limits define limiting values for core power peaking that precludes peak cladding temperatures above 2200°F during either a large or small break LOCA. The highest calculated linear power densities in the core at specific core elevations are displayed for operator visual verification relative to the COLR values.

The determination of $F^N_{\Delta H}$ identifies the coolant flow channel with the maximum enthalpy rise. This channel has the least heat removal capability and thus the highest probability for DNB. Should $F^N_{\Delta H}$ exceed the limit given in the COLR, the possibility exists for DNBR to exceed the value used as a base condition for the safety analysis.

Two levels of alarms on power distribution parameters are provided to the operator. One serves as a warning before the three parameters (kw/ft(Z), $F^N_{\Delta H}$, DNBR) exceed their values used as a base condition for the safety analysis. The other alarm indicates when the parameters have reached their limits.

APPLICABILITY

The OPDMS-monitored power distribution parameter limits must be maintained in MODE 1 above 50% RTP to preclude core power distributions from exceeding the limits assumed in the safety analyses. Applicability in other MODES, and MODE 1 below 50% RTP, is not required because there is either insufficient stored energy in the fuel or insufficient energy transferred to the reactor coolant to require a limit on the distribution of core power. The OPDMS monitoring of SDM is applicable in MODES 1 and 2 with $k_{eff} \geq 1.0$.

Specifically for $F^N_{\Delta H}$, the design bases accidents (DBAs) that are sensitive to $F^N_{\Delta H}$ in other MODES (MODES 2 through 5) have significant margin to DNB, and therefore, there is no need to restrict $F^N_{\Delta H}$ in these modes.

In addition to the alarms discussed in the LCO section above (alarms on OPDMS-monitored power distribution parameters), there is an alarm indicating the potential inoperability of the OPDMS itself.

Should the OPDMS be determined to be inoperable for other than reasons of alarms inoperable, this LCO is no longer applicable and LCOs 3.2.1 through 3.2.4 become applicable.

BASES

ACTIONS

A.1

With any of the OPDMS-monitored power distribution parameters outside of their limits, the assumptions used as most limiting base conditions for the DBA analyses may no longer be valid. The 1 hour operator ACTION requirement to restore the parameter to within limits is consistent with the basis for the anticipated operational occurrences and provides time to assess if there are instrumentation problems. It also allows the possibility to restore the parameter to within limits by rod cluster control assembly (RCCA) motion if this is possible. The OPDMS will continuously monitor these parameters and provide an indication when they are approaching their limits.

B.1

If the OPDMS-monitored power distribution parameters cannot be restored to within their limits within the Completion Time of ACTION A.1, it is likely that the problem is not due to a failure of instrumentation. Most of these parameters can be brought within their respective limits by reducing THERMAL POWER because this will reduce the absolute power density at any location in the core thus providing margin to the limit.

If the parameters cannot be returned to within limits as power is being reduced, THERMAL POWER must be reduced to < 50% RTP where the LCOs are no longer applicable.

A Note has been added to indicate that if the power distribution parameters in violation are returned to within their limits during the power reduction, then power operation may continue at the power level where this occurs. This is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions.

The Completion Time of 4 hours provides an acceptable time to reduce power in an orderly manner and without allowing the plant to remain outside the $F^N_{\Delta H}$ limits for an extended period of time.

C.1

If the SDM requirements are not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. It is assumed that boration will be continued until the SDM requirements are met. In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon

BASES

ACTIONS (continued)

as possible, the boron concentration should be a concentrated solution. The operator should begin boration with the best source available for the plant conditions.

SURVEILLANCE REQUIREMENTS

With OPDMS operating, the power distribution parameters are continuously computed and displayed, and compared against their limit. Two levels of alarms are provided to the operator. The first alarm provides a warning before these parameters (kw/ft(Z), $F^N_{\Delta H}$, and DNBR) exceed their limits. The second alarm indicates when they actually reach their limits. A third alarm indicates trouble with the OPDMS system.

SR 3.2.5.1

This Surveillance requires the operator to verify that the power distribution parameters are within their limits. This confirmation is a verification in addition to the automated checking performed by the OPDMS system. A 24 hour Surveillance interval provides assurance that the system is functioning properly and that the core limits are met.

With the OPDMS parameter alarms inoperable, an increased Surveillance Frequency is provided to assure that parameters are not approaching the limits. A 12 hour Frequency is adequate to identify changes in these parameters that could lead to their exceeding their limits.

B 3.3 INSTRUMENTATION

B 3.3.1 Reactor Trip System (RTS) Instrumentation

BASES

BACKGROUND

The RTS initiates a unit shutdown, based upon the values of selected unit parameters, to protect against violating the core fuel design limits and Reactor Coolant System (RCS) pressure boundary during anticipated operational occurrences (AOOs) and to assist the Engineered Safety Feature Actuation System (ESFAS) in mitigating accidents.

The Protection and Safety Monitoring System (PMS) has been designed to assure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RTS, as well as specifying LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions. LSSS are defined by the regulation as “Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded.” The Safety Analysis Limit (SAL) is the limit of the process variable at which a protective action is initiated, as established by the safety analysis, to assure that a SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Safety Analysis Limit to account for instrument loop uncertainties related to the setting at which the automatic protective action would actually occur. The LSSS values are identified and maintained in the Setpoint Program (SP) and are controlled by 10 CFR 50.59.

BASES

BACKGROUND (continued)

The Nominal Trip Setpoint (NTS) specified in the SP is a predetermined field setting for a protection channel chosen to initiate automatic actuation prior to the process variable reaching the Safety Analysis Limit and, thus, assures that the SL is not exceeded. As such, the NTS accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the NTS assured that the SLs are not exceeded. Therefore, the NTS meets the 10 CFR 50.36 definition of an LSSS.

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety functions(s)." Relying solely on the NTS to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule which are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the NTS due to some drift of the setting may still be OPERABLE since drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the NTS, and thus, the automatic protective action would still have assured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE since it would have performed its safety function. If the as-found condition of the channel is near the as-found tolerance, recalibration is considered appropriate to allow for drift during the next surveillance interval.

During AOOs, which are those events expected to occur one or more times during the unit life, the acceptable limits are:

1. The Departure from Nucleate Boiling Ratio (DNBR) shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling (DNB);

2. Fuel centerline melt shall not occur; and

3. The RCS pressure SL of 2750 psia shall not be exceeded.

BASES

BACKGROUND (continued)

Operation within the SLs of Specification 2.0, “Safety Limits (SLs),” also maintains the above values and assures that offsite doses are within the acceptance criteria during AOOs.

Design Basis Accidents (DBA) are events that are analyzed even though they are not expected to occur during the unit life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of the limits. Different accident categories are allowed a different fraction of these limits, based on the probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

The RTS maintains surveillance on key process variables which are directly related to equipment mechanical limitations, such as pressure, and on variables which directly affect the heat transfer capability of the reactor, such as flow and temperature. Some limits, such as Overtemperature ΔT, are calculated in the protection and safety monitoring system cabinets from other parameters when direct measurement of the variable is not possible.

The RTS instrumentation is segmented into four distinct but interconnected modules as identified below:

- Field inputs from process sensors, nuclear instrumentation;
- Protection and Safety Monitoring System Cabinets;
- Voting Logic; and
- Reactor Trip Switchgear Interface.

Field Transmitters and Sensors

Normally, four redundant measurements using four separate sensors are made for each variable used for reactor trip. The use of four channels for protection functions is based on a minimum of two channels being required for a trip or actuation, one channel in test or bypass, and a single failure on the remaining channel. The signal selector algorithm in the Plant Control System (PLS) will function with only three channels. This includes two channels properly functioning and one channel having a single failure. For protection channels providing data to the control system, the fourth channel permits one channel to be in test or bypass. Minimum requirements for protection and control are achieved with only three channels OPERABLE. The fourth channel is provided to increase plant availability, and permits the plant to run for an indefinite time with a

BASES

BACKGROUND (continued)

single channel out of service. The circuit design is able to withstand both an input failure to the control system, which may then require the protection Function actuation, and a single failure in the other channels providing the protection Function actuation. Again, a single failure will neither cause nor prevent the protection Function actuation. These requirements are described in IEEE-603 (Ref. 5). The actual number of channels required for each plant parameter is specified in Reference 2.

Selected analog measurements are converted to digital form by digital converters within the protection and safety monitoring system cabinets. Signal conditioning may be applied to selected inputs following the conversion to digital form. Following necessary calculations and processing, the measurements are compared against the applicable setpoint for that variable. A partial trip signal for the given parameter is generated if one channel measurement exceeds its predetermined or calculation limit. Processing on all variables for reactor trip is duplicated in each of the four redundant divisions of the protection system. Each division sends its partial trip status to each of the other three divisions over isolated multiplexed links. Each division is capable of generating a reactor trip signal if two or more of the redundant channels of a single variable are in the partial trip state.

The reactor trip signal from each division is sent to the corresponding reactor trip actuation division. Each of the four reactor trip actuation divisions consists of two reactor trip circuit breakers. The reactor is tripped when two or more actuation divisions receive a reactor trip signal. This automatic trip demand initiates the following two actions:

1. It de-energizes the undervoltage trip attachment on each reactor trip breaker, and

2. It energizes the shunt trip device on each reactor trip breaker.

Either action causes the breakers to trip. Opening of the appropriate trip breakers removes power to the control rod drive mechanism (CRDM) coils, allowing the rods to fall into the core. This rapid negative reactivity insertion shuts down the reactor.

<u>Protection and Safety Monitoring System Cabinets</u>

The protection and safety monitoring system cabinets contain the necessary equipment to:

- Permit acquisition and analysis of the sensor inputs, including plant process sensors and nuclear instrumentation, required for reactor trip and ESF calculations;

BASES

BACKGROUND (continued)

- Perform computation or logic operations on variables based on these inputs;
- Provide trip signals to the reactor trip switchgear and ESF actuation data to the ESF coincidence logic as required;
- Permit manual trip or bypass of each individual reactor trip Function and permit manual actuation or bypass of each individual voted ESF Function;
- Provide data to other systems in the Instrumentation and Control (I&C) architecture;
- Provide separate input circuitry for control Functions that require input from sensors that are also required for protection Functions.

Each of the four divisions provides signal conditioning, comparable output signals for indications in the main control room, and comparison of measured input signals with established setpoints. The basis of the setpoints are described in References 3 and 4. If the measured value of a unit parameter exceeds the predetermined setpoint, an output is generated which is transmitted to the ESF coincidence logic for logic evaluation.

Within the PMS, redundancy is generally provided for active equipment such as processors and communication hardware. This redundancy is provided to increase plant availability and facilitate surveillance testing. A division or channel is OPERABLE if it is capable of performing its specified safety function(s) and all the required supporting functions or systems are also capable of performing their related support functions. Thus, a division or channel is OPERABLE as long as one set of redundant components within the division or channel is capable of performing its specified safety function(s).

Voting Logic

The voting logic provides a reliable means of opening the reactor trip switchgear in its own division as demanded by the individual protection functions.

BASES

BACKGROUND (continued)

Reactor Trip Switchgear Interface

The final stage of the voting logic provides the signal to energize the undervoltage trip attachment on each RTB within the reactor trip switchgear. Loss of the signal de-energizes the undervoltage trip attachments and results in the opening of those reactor trip switchgear. An additional external relay is de-energized with loss of the signal. The normally closed contacts of the relay energize the shunt trip attachments on each switchgear at the same time that the undervoltage trip attachment is de-energized. This diverse trip actuation is performed external to the PMS cabinets. The switchgear interface including the trip attachments and the external relay are within the scope of the PMS. Separate outputs are provided for each switchgear. Testing of the interface allows trip actuation of the breakers by either the undervoltage trip attachment or the shunt trip attachment.

Nominal Trip Setpoint (NTS)

The NTS is the nominal value at which the trip output is set. Any trip output is considered to be properly adjusted when the “as-left” value is within the band for CHANNEL CALIBRATION (i.e., ± rack calibration accuracy).

The trip setpoints used in the trip output are based on the Safety Analysis Limits stated in Reference 3. The determination of these NTSs is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrument drift, and severe environment errors for those RTS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 6), the NTSs specified in the SP are conservative with respect to the Safety Analysis Limits. A detailed description of the methodology used to calculate the NTSs, including their explicit uncertainties, is provided in the “Westinghouse Setpoint Methodology for Protection Systems” (Ref. 4). The as-left tolerance and as-found tolerance band methodology is provided in the SP. The as-found OPERABILITY limit for the purpose of the REACTOR TRIP CHANNEL OPERATIONAL TEST (RTCOT) is defined as the as-left limit about the NTS (i.e., ± rack calibration accuracy).

The NTSs listed in the SP are based on the methodology described in Reference 4, which incorporates all of the known uncertainties applicable for each channel. The magnitudes of these uncertainties are factored into the determination of each NTS. All field sensors and signal processing

BASES

BACKGROUND (continued)

equipment for these channels are assumed to operate within the allowances of these uncertainty magnitudes. Transmitter and signal processing equipment calibration tolerances and drift allowances must be specified in plant calibration procedures, and must be consistent with the values used in the setpoint methodology.

The OPERABILITY of each transmitter or sensor can be evaluated when its “as-found” calibration data are compared against the “as-left” data and are shown to be within the setpoint methodology assumptions. The basis of the setpoints is described in References 3 and 4. Trending of calibration results is required by the program description in Technical Specifications 5.5.14.d.

Note that the as-left and as-found tolerances listed in the SP define the OPERABILITY limits for a channel during a periodic CHANNEL CALIBRATION or RTCOT that requires trip setpoint verification.

The protection and safety monitoring system testing features are designed to allow for complete functional testing by using a combination of system self-checking features, functional testing features, and other testing features. Successful functional testing consists of verifying that the capability of the system to perform the safety function has not failed or degraded. For hardware functions this would involve verifying that the hardware components and connections have not failed or degraded. Since software does not degrade, software functional testing involves verifying that the software code has not changed and that the software code is executing. To the extent possible, protection and safety monitoring system functional testing will be accomplished with continuous system self-checking features and the continuous functional testing features.

The protection and safety monitoring system incorporates continuous system self-checking features wherever practical. Self-checking features include on-line diagnostics for the computer system and the hardware and communications tests. These self-checking tests do not interfere with normal system operation.

In addition to the self-checking features, the system includes functional testing features. Functional testing features include continuous functional testing features and manually initiated functional testing features. To the extent practical, functional testing features are designed not to interfere with normal system operation.

BASES

BACKGROUND (continued)

In addition to the system self-checking features and functional testing features, other test features are included for those parts of the system which are not tested with self-checking features or functional testing features. These test features allow for instruments/sensor checks, calibration verification, response time testing, setpoint verification and component testing. The test features again include a combination of continuous testing features and manual testing features.

All of the testing features are designed so that the duration of the testing is as short as possible. Testing features are designed so that the actual logic is not modified. To prevent unwanted actuation, the testing features are designed with either the capability to bypass a Function during testing and/or limit the number of signals allowed to be placed in test at one time.

Reactor Trip (RT) Channel

An RT Channel extends from the sensor to the output of the associated reactor trip subsystem in the protection and safety monitoring system cabinets, and includes the sensor (or sensors), the signal conditioning, any associated datalinks, and the associated reactor trip subsystem. For RT Channels containing nuclear instrumentation, the RT Channel also includes the nuclear instrument signal conditioning and the associated Nuclear Instrumentation Signal Processing and Control (NISPAC) subsystem.

Automatic Trip Logic

The Automatic Trip Logic extends from, but does not include, the outputs of the various RT Channels to, but does not include, the reactor trip breakers. Operator bypass of a reactor trip function is performed within the Automatic Trip Logic.

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY

The RTS functions to maintain the SLs during all AOOs and mitigates the consequences of DBAs in all MODES in which the RTBs are closed.

Each of the analyzed accidents and transients which require reactor trip can be detected by one of more RTS Functions. The accident analysis described in Reference 3 takes credit for most RTS trip Functions. RTS trip Functions not specifically credited in the accident analysis were qualitatively credited in the safety analysis and the NRC staff approved licensing basis for the plant. These RTS trip Functions may provide protection for conditions which do not require dynamic transient analysis to demonstrate function performance. These RTS trip Functions may also serve as backups to RTS trip Functions that were credited in the accident analysis.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Permissive and interlock functions are based upon the associated protection function instrumentation. Because they do not have to operate in adverse environmental conditions, the trip settings of the permissive and interlock functions use the normal environment, steady-state instrument uncertainties of the associated protection function instrumentation. This results in OPERABILITY criteria (i.e., as-found tolerance and as-left tolerance) that are the same as the associated protection function sensor and process rack modules. The NTSs for permissives and interlocks are based on the associated protection function OPERABILITY requirements; i.e., permissives and interlocks performing enabling functions must be set to occur prior to the specified trip setting of the associated protection function.

The LCO requires all instrumentation performing an RTS Function, listed in Table 3.3.1-1 in the accompanying LCO, to be OPERABLE. The as-left and as-found tolerances specified in the SP define the OPERABILITY limits for a channel during a CHANNEL CALIBRATION or RTCOT. As such, the as-left and as-found tolerances differ from the NTS by ± the PMS rack calibration accuracy and envelope the expected calibration accuracy and drift. In this manner, the actual setting of the channel (NTS) prevents exceeding an SL at any given point in time as long as the channel has not drifted beyond the expected tolerances during the surveillance interval. Note that the as-left and as-found recorded values must be confirmed to be operating within the assumptions of the statistical uncertainty calculations.

If the actual setting of the channel is found outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

A trip setpoint may be set more conservative than the NTS as necessary in response to plant conditions. However, in this case, the OPERABILITY of this instrument must be verified based on the actual field setting and not the NTS. Failure of any instrument renders the affected channel(s) inoperable and reduces the reliability of the affected Functions.

The LCO generally requires OPERABILITY of three channels in each instrumentation Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Reactor Trip System Functions

The safety analyses and OPERABILITY requirements applicable to each RTS Function are discussed below:

1. Manual Reactor Trip

The Manual Reactor Trip ensures that the main control room operator can initiate a reactor trip at any time by using either of two reactor trip actuation devices in the main control room. A Manual Reactor Trip accomplishes the same results as any one of the automatic trip Functions. It can be used by the reactor operator to shutdown the reactor whenever any parameter is rapidly trending toward its Trip Setpoint. The safety analyses do not take credit for the Manual Reactor Trip.

The LCO requires two Manual Reactor Trip actuation devices be OPERABLE in MODES 1 and 2 and in MODES 3, 4, and 5 with RTBs closed and PLS capable of rod withdrawal. Two independent actuation devices are required to be OPERABLE so that no single random failure will disable the Manual Reactor Trip Function.

In MODE 1 or 2, manual initiation of a reactor trip must be OPERABLE. These are the MODES in which the shutdown rods and/or control rods are partially or fully withdrawn from the core. In MODE 3, 4, or 5, the manual initiation Function must also be OPERABLE if the shutdown or control rods are withdrawn or the PLS is capable of withdrawing the shutdown or control rods. In MODES 3, 4, and 5, manual initiation of a reactor trip does not have to be OPERABLE if the PLS is not capable of withdrawing the shutdown or control rods. If the rods cannot be withdrawn from the core, there is no need to be able to trip the reactor because all of the rods are inserted. In MODE 6, neither the shutdown rods nor the control rods are permitted to be withdrawn and the CRDMs are disconnected from the control rods and shutdown rods. Therefore, the manual initiation Function does not have to be OPERABLE.

2. Power Range Neutron Flux

The PMS power range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The PMS power range detectors provide input to the PLS. Minimum requirements for protection and control is achieved with three channels OPERABLE. The fourth channel is provided to

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

increase plant availability, and permits the plant to run for an indefinite time with a single channel in trip or bypass. This Function also satisfies the requirements of IEEE 603 (Ref. 5) with 2/4 logic. This Function also provides a signal to prevent automatic and manual rod withdrawal prior to initiating a reactor trip. Limiting further rod withdrawal may terminate the transient and eliminate the need to trip the reactor.

a. Power Range Neutron Flux – High

The Power Range Neutron Flux – High trip Function ensures that protection is provided, from all power levels, against a positive reactivity excursion during power operations. Positive reactivity excursions can be caused by rod withdrawal or reductions in RCS temperature.

The LCO requires four Power Range Neutron Flux – High channels to be OPERABLE in MODES 1 and 2.

In MODE 1 or 2, when a positive reactivity excursion could occur, the Power Range Neutron Flux – High trip must be OPERABLE. This Function will terminate the reactivity excursion and shutdown the reactor prior to reaching a power level that could damage the fuel. In MODE 3, 4, 5, or 6, the Power Range Neutron Flux – High trip does not have to be OPERABLE because the reactor is shutdown and a reactivity excursion in the power range cannot occur. Other RTS Functions and administrative controls provide protection against reactivity additions when in MODE 3, 4, 5, or 6. In addition, the PMS power range detectors cannot detect neutron levels in this range.

b. Power Range Neutron Flux – Low

The LCO requirement for the Power Range Neutron Flux – Low trip Function ensures that protection is provided against a positive reactivity excursion from low power or subcritical conditions. The Trip Setpoint reflects only steady state instrument uncertainties as this Function does not provide primary protection for any event that results in a harsh environment.

The LCO requires four of the Power Range Neutron Flux – Low channels to be OPERABLE in MODE 1 below the Power Range Neutron Flux P-10 Setpoint and MODE 2.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

In MODE 1, below the Power Range Neutron Flux P-10 setpoint and in MODE 2, the Power Range Neutron Flux – Low trip must be OPERABLE. This Function may be manually blocked by the operator when the respective power range channel is greater than approximately 10% of RTP (P-10 setpoint). This Function is automatically unblocked when the respective power range channel is below the P-10 setpoint. Above the P-10 setpoint, positive reactivity additions are mitigated by the Power Range Neutron Flux – High trip Function.

In MODE 3, 4, 5, or 6, the Power Range Neutron Flux – Low trip Function does not have to be OPERABLE because the reactor is shutdown and the PMS power range detectors cannot detect neutron levels generated in MODES 3, 4, 5, and 6. Other RTS trip Functions and administrative controls provide protection against positive reactivity additions or power excursions in MODE 3, 4, 5, or 6.

3. Power Range Neutron Flux – High Positive Rate

The Power Range Neutron Flux – High Positive Rate trip Function ensures that protection is provided against rapid increases in neutron flux which are characteristic of a rod cluster control assembly (RCCA) drive rod housing rupture and the accompanying ejection of the RCCA. This Function compliments the Power Range Neutron Flux – High and Low trip Functions to ensure that the criteria are met for a rod ejection from the power range. The Power Range Neutron Flux Rate trip uses the same channels as discussed for Function 2 above.

The LCO requires four Power Range Neutron Flux – High Positive Rate channels to be OPERABLE. In MODE 1 or 2, when there is a potential to add a large amount of positive reactivity from a rod ejection accident (REA), the Power Range Neutron Flux – High Positive Rate trip must be OPERABLE. In MODE 3, 4, 5, or 6, the Power Range Neutron Flux – High Positive Rate trip Function does not have to be OPERABLE because other RTS trip Functions and administrative controls will provide protection against positive reactivity additions. Also, since only the shutdown banks may be withdrawn in MODE 3, 4, or 5, the remaining complement of control bank worth ensures a SDM in the event of an REA. In MODE 6, no rods are withdrawn and the SDM is increased during refueling operations. The reactor vessel head is also removed or the closure bolts are detensioned preventing any pressure buildup. In addition, the PMS power range detectors cannot detect neutron levels present in this MODE.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

4. Intermediate Range Neutron Flux

The Intermediate Range Neutron Flux trip Function ensures that protection is provided against an uncontrolled RCCA bank withdrawal accident from a subcritical condition during startup. This trip Function provides redundant protection to the Power Range Neutron Flux – Low Setpoint trip Function. The PMS intermediate range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The safety analyses do not take credit for the Intermediate Range Neutron Flux trip Function. Even though the safety analyses take no credit for the Intermediate Range Neutron Flux trip, the functional capability at the specified Trip Setpoint enhances the overall diversity of the RTS. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any events that result in a harsh environment. This trip can be manually blocked by the main control room operator when above the P-10 setpoint, which is the respective PMS power range channel greater than 10% power, and is automatically unblocked when below the P-10 setpoint, which is the respective PMS power range channel less than 10% power. This Function also provides a signal to prevent automatic and manual rod withdrawal prior to initiating a reactor trip. Limiting further rod withdrawal may terminate the transient and eliminate the need to trip the reactor.

The LCO requires four channels of Intermediate Range Neutron Flux to be OPERABLE. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 below the P-10 setpoint, and in MODE 2, when there is a potential for an uncontrolled rod withdrawal accident during reactor startup, the Intermediate Range Neutron Flux trip must be OPERABLE. Above the P-10 setpoint, the Power Range Neutron Flux – High Setpoint trip and the Power Range Neutron Flux – High Positive Rate trip provide core protection for a rod withdrawal accident. In MODE 3, 4, or 5, the Intermediate Range Neutron Flux trip does not have to be OPERABLE because the control rods must be fully inserted and only the shutdown rods may be withdrawn. The reactor cannot be started up in this condition. The core also has the required SDM to mitigate the consequences of a positive reactivity addition accident. In MODE 6, all rods are fully inserted and the core has a required increased SDM. Also, the PMS intermediate range detectors cannot detect neutron levels present in this MODE.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

5. Source Range Neutron Flux

The LCO requirement for the Source Range Neutron Flux trip Function ensures that protection is provided against an uncontrolled bank rod withdrawal accident from a subcritical condition during startup. This trip Function provides redundant protection to the Power Range Neutron Flux – Low Setpoint and Intermediate Range Neutron Flux trip Functions. In MODES 3, 4, and 5, administrative controls also prevent the uncontrolled withdrawal of rods. The PMS source range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The safety analyses do not take credit for the Source Range Neutron Flux trip Function. Even though the safety analyses take no credit for the Source Range Neutron Flux trip, the functional capability at the specified Trip Setpoint is assumed to be available and the trip is implicitly assumed in the safety analyses.

The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any events that result in a harsh environment. This trip can be manually blocked by the main control room operator when above the P-6 setpoint (Intermediate Range Neutron Flux interlock) and is automatically unblocked when below the P-6 setpoint. The manual block of the trip function also de-energizes the source range detectors. The source range detectors are automatically re-energized when below the P-6 setpoint. The trip is automatically blocked when above the P-10 setpoint (Power Range Neutron Flux interlock). The source range trip is the only RTS automatic protective Function required in MODES 3, 4, and 5. Therefore, the functional capability at the specified Trip Setpoint is assumed to be available.

The LCO requires four channels of Source Range Neutron Flux to be OPERABLE in MODE 2 below P-6 and in MODE 3, 4, or 5 with RTBs closed and Control Rod Drive System capable of rod withdrawal. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. In MODE 3, 4, or 5 with the RTBs open, the LCO does not require the Source Range Neutron Flux channels for reactor trip Functions to be OPERABLE.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

In MODE 2 when below the P-6 setpoint during a reactor startup, the Source Range Neutron Flux trip must be OPERABLE. Above the P-6 setpoint, the Intermediate Range Neutron Flux trip and the Power Range Neutron Flux – Low Setpoint trip will provide core protection for reactivity accidents. Above the P-6 setpoint, the PMS source range detectors are de-energized and inoperable as described above.

In MODE 3, 4, or 5 with the reactor shutdown, the Source Range Neutron Flux trip Function must also be OPERABLE. If the PLS is capable of rod withdrawal, the Source Range Neutron Flux trip must be OPERABLE to provide core protection against a rod withdrawal accident. If the PLS is not capable of rod withdrawal, the source range detectors are required to be OPERABLE to provide monitoring of neutron levels and provide protection for events like an inadvertent boron dilution. These Functions are addressed in LCO 3.3.2, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation." The requirements for the PMS source range detectors in MODE 6 are addressed in LCO 3.9.3, "Nuclear Instrumentation."

6. Overtemperature ΔT

The Overtemperature ΔT trip Function ensures that protection is provided to ensure that the design limit DNBR is met. This trip Function also limits the range over which the Overpower ΔT trip Function must provide protection. The inputs to the Overtemperature ΔT trip include all combinations of pressure, power, coolant temperature, and axial power distribution, assuming full reactor coolant flow. Protection from violating the DNBR limit is assured for those transients that are slow with respect to delays from the core to the measurement system. The Overtemperature ΔT trip Function uses the measured T_{HOT} and T_{COLD} in each loop, together with the measured pressurizer pressure, to compute the reactor core thermal power. Equations to fit the properties of density and enthalpy are programmed in the software, such that the ΔT power signal is presented as a percent of RTP for direct comparison with measured calorimetric power. The overtemperature ΔT setpoint is automatically varied for changes in the parameters that affect DNB as follows:

- reactor core inlet temperature – the Trip Setpoint is varied to correct for changes in core inlet temperature based on measured changes in cold leg temperature with dynamic compensation to account for cold leg-to-core transit time;

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

- pressurizer pressure – the Trip Setpoint is varied to correct for changes in system pressure; and

- axial power distribution – the Trip Setpoint is varied to account for imbalances in the axial power distribution as detected by the PMS upper and lower power range detectors. If axial peaks are greater than the design limit, as indicated by the difference between the upper and lower PMS power range detectors, the Trip Setpoint is reduced in accordance with algorithms documented in the SP.

Dynamic compensation of the ΔT power signal is included for system piping delays from the core to the temperature measurement system. The Overtemperature ΔT trip Function is calculated for each loop as described in the SP. A detailed description of this trip is provided in Reference 8. This Function also provides a signal to generate a turbine runback prior to reaching the Trip Setpoint. A turbine runback will reduce turbine power and reactor power. A reduction in power will normally alleviate the Overtemperature ΔT condition and may prevent a reactor trip. No credit is taken in the safety analyses for the turbine runback.

The LCO requires four channels (two per loop) of the Overtemperature ΔT trip Function to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. Note that the Overtemperature ΔT Function receives input from channels shared with other RTS Functions. Failures that affect multiple Functions require entry into the Conditions applicable to all affected Functions.

In MODE 1 or 2, the Overtemperature ΔT trip must be OPERABLE to prevent DNB. In MODE 3, 4, 5, or 6, this trip Function does not have to be OPERABLE because the reactor is not operating and there is insufficient heat production to be concerned about DNB.

7. <u>Overpower ΔT</u>

The Overpower ΔT trip Function ensures that protection is provided to ensure the integrity of the fuel (i.e., no fuel pellet melting and less than 1% cladding strain) under all possible overpower conditions. This trip Function also limits the required range of the Overtemperature ΔT trip function and provides a backup to the

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Power Range Neutron Flux – High Setpoint trip. The Overpower ΔT trip Function ensures that the allowable heat generation rate (kW/ft) of the fuel is not exceeded. It uses the same ΔT power signal generated for the Overtemperature ΔT. The setpoint is automatically varied with the following parameter:

- Axial power distribution – the Trip Setpoint is varied to account for imbalances in the axial power distribution as detected by the PMS upper and lower power range detectors. If axial peaks are greater than the design limit, as indicated by the difference between the upper and lower PMS power range detectors, the Trip Setpoint is reduced in accordance with algorithms documented in the SP.

The Overpower ΔT trip Function is calculated for each loop as described in the SP. A detailed description of this trip is provided in Reference 8. The Trip Setpoint reflects the inclusion of both steady state and adverse environmental instrument uncertainties as the detectors provide protection for a steam line break and may be in a harsh environment. Note that this Function also provides a signal to generate a turbine runback prior to reaching the Trip Setpoint. A turbine runback reduces turbine power and reactor power. A reduction in power normally alleviates the Overpower ΔT condition and may prevent a reactor trip.

The LCO requires four channels (two per loop) of the Overpower ΔT trip Function to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. The Overpower ΔT Function receives input from channels shared with other RTS Functions. Failures that affect multiple Functions require entry into the Conditions applicable to all affected Functions.

In MODE 1 or 2, the Overpower ΔT trip Function must be OPERABLE. These are the only times that enough heat is generated in the fuel to be concerned about the heat generation rates and overheating of the fuel. In MODE 3, 4, 5, or 6, this trip Function does not have to be OPERABLE because the reactor is not operating and there is insufficient heat production to be concerned about fuel overheating and fuel damage.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

8. Pressurizer Pressure

The same sensors provide input to the Pressurizer Pressure – High and – Low trips and the Overtemperature ΔT trip.

a. Pressurizer Pressure – Low

The Pressurizer Pressure – Low trip Function ensures that protection is provided against violating the DNBR limit due to low pressure. The Trip Setpoint reflects both steady state and adverse environmental instrument uncertainties as the detectors provide primary protection for an event that results in a harsh environment.

The LCO requires four channels of Pressurizer Pressure – Low to be OPERABLE in MODE 1 above P-10. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1, when DNB is a major concern, the Pressurizer Pressure – Low trip must be OPERABLE. This trip Function is automatically enabled on increasing power by the P-10 interlock. On decreasing power, this trip Function is automatically blocked below P-10. Below the P-10 setpoint, no conceivable power distributions can occur that would cause DNB concerns.

b. Pressurizer Pressure – High

The Pressurizer Pressure – High trip Function ensures that protection is provided against overpressurizing the RCS. This trip Function operates in conjunction with the safety valves to prevent RCS overpressure conditions. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any event that results in a harsh environment.

The LCO requires four channels of the Pressurizer Pressure – High to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

In MODE 1 or 2, the Pressurizer Pressure – High trip must be OPERABLE to help prevent RCS overpressurization and LCOs, and minimizes challenges to the safety valves. In MODE 3, 4, 5, or 6, the Pressurizer Pressure – High trip Function does not have to be OPERABLE because transients which could cause an overpressure condition will be slow to occur. Therefore, the operator will have sufficient time to evaluate plant conditions and take corrective actions. Additionally, low temperature overpressure protection systems provide overpressure protection when below MODE 4.

9. Pressurizer Water Level – High 3

The Pressurizer Water Level – High 3 trip Function provides a backup signal for the Pressurizer Pressure – High 3 trip and also provides protection against water relief through the pressurizer safety valves. These valves are designed to pass steam in order to achieve their design energy removal rate. A reactor trip is actuated prior to the pressurizer becoming water solid. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any event that results in a harsh environment. The level channels do not actuate the safety valves.

The LCO requires four channels of Pressurizer Water Level – High 3 to be OPERABLE in MODE 1 above P-10. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 when there is a potential for overfilling the pressurizer, the Pressurizer Water Level – High 3 trip must be OPERABLE. This trip Function is automatically enabled on increasing power by the P-10 interlock. On decreasing power, this trip Function is automatically blocked below P-10. Below the P-10 setpoint, transients which could raise the pressurizer water level will be slow and the operator will have sufficient time to evaluate plant conditions and take corrective actions.

10. Reactor Coolant Flow – Low

Reactor Coolant Flow

The Reactor Coolant Flow – Low trip Function ensures that protection is provided against violating the DNBR limit due to low flow in one or more RCS hot legs. Above the P-10 setpoint, a loss of flow in any RCS hot leg will actuate a Reactor trip.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Each RCS hot leg has four flow detectors to monitor flow. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any event that results in a harsh environment.

The LCO requires four Reactor Coolant Flow – Low channels per hot leg to be OPERABLE in MODE 1 above P-10. Four OPERABLE channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 above the P-10 setpoint, when a loss of flow in one RCS hot leg could result in DNB conditions in the core, the Reactor Coolant Flow – Low trip must be OPERABLE.

11. Reactor Coolant Pump (RCP) Bearing Water Temperature – High

RCP Bearing Water Temperature – High

The RCP Bearing Water Temperature – High reactor trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in one RCS cold leg. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any event that results in a harsh environment.

The LCO requires four RCP Bearing Water Temperature – High channels per RCP to be OPERABLE in MODE 1 or 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 or 2, when a loss of flow in any RCS cold leg could result in DNB conditions in the core, the RCP Bearing Water Temperature – High trip must be OPERABLE.

12. Reactor Coolant Pump Speed – Low

The RCP Speed – Low trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in two or more RCS cold legs. The speed of each RCP is monitored. Above the P-10 setpoint a low speed detected on two or more RCPs will initiate a reactor trip. The Trip Setpoint reflects only steady state instrument uncertainties as the detectors do not provide primary protection for any event that results in a harsh environment.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

The LCO requires four RCP Speed – Low channels (one per pump) to be OPERABLE in MODE 1 above P-10. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 above the P-10 setpoint, the RCP Speed – Low trip must be OPERABLE. Below the P-10 setpoint, all reactor trips on loss of flow are automatically blocked since no power distributions are expected to occur that would cause a DNB concern at this low power level. Above the P-10 setpoint, the reactor trip on loss of flow in two or more RCS cold legs is automatically enabled.

13. Steam Generator Water Level – Low

The SG Water Level – Low trip Function ensures that protection is provided against a loss of heat sink. The SGs are the heat sink for the reactor. In order to act as a heat sink, the SGs must contain a minimum amount of water. A narrow range low level in any steam generator is indicative of a loss of heat sink for the reactor. The Trip Setpoint reflects the inclusion of both steady state and adverse environmental instrument uncertainties as the detectors provide primary protection for an event that results in a harsh environment. This Function also contributes to the coincidence logic for the ESFAS Function of opening the Passive Residual Heat Removal (PRHR) discharge valves.

The LCO requires four channels of SG Water Level – Low per SG to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODE 1 or 2, when the reactor requires a heat sink, the SG Water Level – Low trip must be OPERABLE. The normal source of water for the SGs is the Main Feedwater System (non-safety related). The Main Feedwater System is normally in operation in MODES 1 and 2. PRHR is the safety related backup heat sink for the reactor. During normal startups and shutdowns, the Main and Startup Feedwater Systems (non-safety related) can provide feedwater to maintain SG level. In MODE 3, 4, 5, or 6, the SG Water Level – Low Function does not have to be OPERABLE because the reactor is not operating or even critical.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

14. Steam Generator Water Level – High 2

The SG Water Level – High 2 trip Function ensures that protection is provided against excessive feedwater flow by closing the main feedwater control valves, tripping the turbine, and tripping the reactor. While the transmitters (d/p cells) are located inside containment, the events which this function protects against cannot cause severe environment in containment. Therefore, the Trip Setpoint reflects only steady state instrument uncertainties.

The LCO requires four channels of SG Water Level – High 2 per SG to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODES 1 and 2 above the P-11 interlock, the SG Water Level – High 2 trip must be OPERABLE. The normal source of water for the SGs is the Main Feedwater System (non-safety related). The Main Feedwater System is only in operation in MODES 1 and 2. In MODE 3, 4, 5, or 6, the SG Water Level – High 2 Function does not have to be OPERABLE because the reactor is not operating or even critical. The P-11 interlock is provided on this Function to permit bypass of the trip Function when the pressure is below P-11. This bypass is necessary to permit rod testing when the steam generators are in wet layup.

15. Safeguards Actuation Signal from Engineered Safety Feature Actuation System

The Safeguards Actuation Signal from ESFAS ensures that if a reactor trip has not already been generated by the RTS, the ESFAS automatic actuation logic will initiate a reactor trip upon any signal which initiates the Safeguards Actuation signal. This is a condition of acceptability for the Loss of Coolant Accident (LOCA). However, other transients and accidents take credit for varying levels of ESFAS performance and rely upon rod insertion, except for the most reactive rod which is assumed to be fully withdrawn, to ensure reactor shutdown.

The LCO requires two manual and four automatic divisions of Safeguards Actuation Signal Input from ESFAS to be OPERABLE in MODES 1 and 2. Four automatic divisions are provided to permit one division bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

A reactor trip is initiated every time a Safeguards Actuation signal is present. Therefore, this trip Function must be OPERABLE in MODES 1 and 2, when the reactor is critical, and must be shutdown in the event of an accident. In MODE 3, 4, 5, or 6, the reactor is not critical.

16. Reactor Trip System Interlocks

Reactor protection interlocks are provided to ensure reactor trips are in the correct configuration for the current plant status. They back up operator actions to ensure protection system Functions are not blocked during plant conditions under which the safety analysis assumes the Functions are OPERABLE. Therefore, the interlock Functions do not need to be OPERABLE when the associated reactor trip Functions are outside the applicable MODES. These are:

a. Intermediate Range Neutron Flux, P-6

The Intermediate Range Neutron Flux, P-6 interlock is actuated when the respective PMS Intermediate Range Neutron Flux channel increases to approximately one decade above the channel lower range limit. The LCO requirement for the P-6 interlock ensures that the following Functions are performed:

(1) on increasing power, the P-6 interlock allows the manual block of the respective PMS Source Range, Neutron Flux reactor trip. This prevents a premature block of the source range trip and allows the operator to ensure that the intermediate range is OPERABLE prior to leaving the source range. When the source range trip is blocked, the high voltage to the detectors is also removed.

(2) on decreasing power, the P-6 interlock automatically energizes the PMS source range detectors and enables the PMS Source Range Neutron Flux reactor trip.

(3) on increasing power, the P-6 interlock provides a backup block signal to the source range neutron flux doubling circuit. Normally, this Function is manually blocked by the main control room operator during the reactor startup.

The LCO requires four channels of Intermediate Range Neutron Flux, P-6 interlock to be OPERABLE in MODE 2 when below the P-6 interlock setpoint.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

In MODE 2, when below the P-6 interlock setpoint, the P-6 interlock must be OPERABLE. Above the P-6 interlock setpoint, the PMS Source Range Neutron Flux reactor trip will be blocked; and this Function will no longer be necessary. In MODES 3, 4, 5, and 6, the P-6 interlock does not have to be OPERABLE because the PMS Source Range is providing core protection.

b. Power Range Neutron Flux, P-10

The Power Range Neutron Flux, P-10 interlock is actuated at approximately 10% power as determined by the respective PMS power-range detector. The LCO requirement for the P-10 interlock ensures that the following functions are performed:

(1) on increasing power, the P-10 interlock automatically enables reactor trips on the following Functions:

- Pressurizer Pressure – Low,
- Pressurizer Water Level – High 3,
- Reactor Coolant Flow – Low, and
- RCP Speed – Low.

These reactor trips are only required when operating above the P-10 setpoint (approximately 10% power). These reactor trips provide protection against violating the DNBR limit. Below the P-10 setpoint, the RCS is capable of providing sufficient natural circulation without any RCP running.

(2) on increasing power, the P-10 interlock allows the operator to manually block the Intermediate Range Neutron Flux reactor trip.

(3) on increasing power, the P-10 interlock allows the operator to manually block the Power Range Neutron Flux – Low Setpoint reactor trip.

(4) on increasing power, the P-10 interlock automatically provides a backup block signal to the Source Range Neutron Flux reactor trip and also to de-energize the PMS source range detectors.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

(5) on decreasing power, the P-10 interlock automatically blocks reactor trips on the following Functions:

- Pressurizer Pressure – Low,
- Pressurizer Water Level – High 3,
- Reactor Coolant Flow – Low, and
- RCP Speed – Low.

(6) on decreasing power, the P-10 interlock automatically enables the Power Range Neutron Flux – Low reactor trip and the Intermediate Range Neutron Flux reactor trip (and rod stop).

The LCO requires four channels of Power Range Neutron Flux, P-10 interlock to be OPERABLE in MODE 1 or 2.

In MODE 1, when the reactor is at power, the Power Range Neutron Flux, P-10 interlock must be OPERABLE. This Function must be OPERABLE in MODE 2 to ensure that core protection is provided during a startup or shutdown by the Power Range Neutron Flux – Low Setpoint and Intermediate Range Neutron Flux reactor trips. In MODE 3, 4, 5, or 6, this Function does not have to be OPERABLE because the reactor is not at power and the Source Range Neutron Flux reactor trip provides core protection.

c. Pressurizer Pressure, P-11

With pressurizer pressure channels less than the P-11 setpoint, the operator can manually block the Steam Generator Narrow Range Water Level – High 2 reactor Trip. This allows rod testing with the steam generators in cold wet layup. With pressurizer pressure channels > P-11 setpoint, the Steam Generator Narrow Range Water Level – High 2 reactor Trip is automatically enabled. The operator can also enable these actuations by use of the respective manual reset.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

17. Reactor Trip Breakers

This trip Function applies to the RTBs exclusive of individual trip mechanisms. There are eight reactor trip breakers with two breakers in each division. The reactor trip circuit breakers are arranged in a two-out-of-four logic configuration, such that the tripping of the two circuit breakers associated with one division does not cause a reactor trip. This circuit breaker arrangement is illustrated in DCD Figure 7.1-7. The LCO requires four divisions of the Reactor Trip Switchgear to be OPERABLE with two trip breakers associated with each required division. This logic is required to meet the safety function assuming a single failure.

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical. In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs are closed, and the PLS is capable of rod withdrawal.

18. Reactor Trip Breaker Undervoltage and Shunt Trip Mechanisms

The LCO requires both the Undervoltage and Shunt Trip Mechanisms to be OPERABLE for each RTB that is in service. The trip mechanisms are not required to be OPERABLE for trip breakers that are open, racked out, incapable of supplying power to the PLS, or declared inoperable under Function 17 above. OPERABILITY of both trip mechanisms on each breaker ensures that no single trip mechanism failure will prevent opening the breakers on a valid signal.

These trip Functions must be OPERABLE in MODES 1 and 2 when the reactor is critical. In MODES 3, 4, and 5, these RTS trip Functions must be OPERABLE when the RTBs are closed, and the PLS is capable of rod withdrawal.

19. Automatic Trip Logic

The LCO requirement for the RTBs (Functions 17 and 18) and Automatic Trip Logic (Function 19) ensures that means are provided to interrupt the power to the CRDMs and allow the rods to fall into the reactor core. Each RTB is equipped with an undervoltage coil and a shunt trip coil to trip the breaker open when needed.

The automatic trip logic includes the ESF coincidence logic and the voting logic.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

The LCO requires four divisions of RTS Automatic Trip Logic to be OPERABLE. Four OPERABLE divisions are provided to ensure that a random failure of a single logic channel will not prevent reactor trip.

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical. In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs are closed and the PLS is capable of rod withdrawal.

20. ADS Stages 1, 2 and 3 Actuation Input from Engineered Safety Feature Actuation System

The LCO requirement for this Function provides a reactor trip for any event that may initiate depressurization of the reactor.

The LCO requires four divisions of RTS Automatic Trip Logic to be OPERABLE. Four OPERABLE divisions are provided to ensure that a random failure of a single logic channel will not prevent reactor trip.

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical. In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs are closed and the PLS is capable of rod withdrawal.

21. Core Makeup Tank (CMT) Actuation Input from Engineered Safety Feature Actuation System

The LCO requirement for this Function provides a reactor trip for any event that may initiate CMT injection.

The LCO requires four divisions of RTS Automatic Trip Logic to be OPERABLE. Four OPERABLE divisions are provided to ensure that random failure of a single logic channel will not prevent reactor trip.

These trip Functions must be OPERABLE in MODES 1 and 2 when the reactor is critical. In MODE 3, 4, and 5 these RTS trip Functions must be OPERABLE when the RTBs are closed and the PLS is capable of rod withdrawal.

22. Passive Residual Heat Removal Actuation

The Passive Residual Heat Removal (PRHR) Actuation reactor trip ensures that a reactivity excursion due to cold water injection will be minimized upon an inadvertent operation of the PRHR discharge valves. The two discharge valves for the PRHR HX are monitored by PMS using valve position indicators as inputs into PMS.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

The LCO requires four channels of PRHR discharge valve position indication per valve to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

In MODES 1 and 2, the Passive Heat Removal Actuation reactor trip must be OPERABLE. In MODES 3, 4, 5, and 6, the Passive Heat Removal Initiation reactor trip Function does not have to be OPERATIONAL because the reactor is not operating or critical.

The RTS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

ACTIONS

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed on Table 3.3.1-1.

In the event a channel's as-found condition is outside the as-found tolerance described in the SP, or the channel is not functioning as required, or the transmitter, instrument loop, signal processing electronics, or trip output is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition(s) entered for the protection Function(s) affected.

When the number of inoperable channels in a trip Function exceed those specified in one or other related Conditions associated with a trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 must be immediately entered if applicable in the current MODE of operation.

A.1

Condition A applies to all RTS protection Functions. Condition A addresses the situation where one or more required channels for one or more Functions are inoperable at the same time. The Required Action is to refer to Table 3.3.1-1 and to take the Required Actions for the protection Functions affected. The Completion Times are those from the referenced Conditions and Required Actions.

B.1, B.2.1, and B.2.2

Condition B applies to the Manual Reactor Trip, Manual Safeguards Actuation, Manual ADS Stages 1, 2, and 3 Actuation and Manual Core Makeup Tank Actuation in MODES 1 and 2 and in MODES 3, 4, and 5 with the reactor trip breakers closed and the plant control system capable of rod withdrawal. These Required Actions address inoperability of one

BASES

ACTIONS (continued)

manual initiation device of the Manual Reactor Trip Function, Manual Safeguards Actuation Function, Manual ADS Stages 1, 2, and 3 Actuation Function and/or Manual Core Makeup Tank Actuation Function. One device consists of an actuation switch and the associated hardware (such as contacts and wiring) up to but not including the eight Reactor Trip Breakers. With one device inoperable, the inoperable device must be restored to OPERABLE status within 48 hours. In this Condition, the remaining OPERABLE device is adequate to perform the safety function.

If the manual Function(s) cannot be restored to OPERABLE status in the allowed 48 hour Completion Time, the unit must be brought to a MODE in which the requirement does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 additional hours (54 hours total time) followed by opening the RTBs within 1 additional hour (55 hours total time). The 6 additional hours to reach MODE 3 and the 1 hour to open the RTBs are reasonable, based on operating experience, to reach MODE 3 and open the RTBs from full power operation in an orderly manner and without challenging unit systems. With the RTBs open and the unit in MODE 3, this trip Function is no longer required to be OPERABLE.

C.1 and C.2

Condition C applies to the Manual Reactor Trip in MODES 3, 4, and 5 with the RTBs closed and the PLS capable of rod withdrawal. These Required Actions address inoperability of one manual initiation device of the Manual Reactor Trip Function. One device consists of an actuation switch and the associated hardware (such as contacts and wiring) up to but not including the eight Reactor Trip Breakers. With one device inoperable, the inoperable device must be restored to OPERABLE status within 48 hours. In this Condition, the remaining OPERABLE device is adequate to perform the safety function.

If the Manual Reactor Trip Function cannot be restored to OPERABLE status in the allowed 48 hour Completion Time, the unit must be placed in a MODE in which the requirement does not apply. To achieve this status, the RTBs must be opened within the next 1 hour. With the RTBs open, this Function is no longer required.

D.1.1, D.1.2, D.1.3, D.2.1, D.2.2, and D.3

Condition D applies to the Power Range Neutron Flux – High Function in MODES 1 and 2.

With one or two channels inoperable, one affected channel must be placed in a bypass or trip condition within 6 hours. If one channel is

BASES

ACTIONS (continued)

bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is bypassed and one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 6 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 7.

In addition to placing the inoperable channel(s) in the bypassed or tripped condition, THERMAL POWER must be reduced to ≤ 75% RTP within 12 hours. Reducing the power level prevents operation of the core with radial power distributions beyond the design limits. With one or two of the PMS power range detectors inoperable, partial radial power distribution monitoring capability is lost. However, the protective function would still function even with a single failure of one of the two remaining channels.

As an alternative to reducing power, the inoperable channel(s) can be placed in the bypassed or tripped condition within 6 hours and the QPTR monitored every 12 hours as per SR 3.2.4.2, QPTR verification. Calculating QPTR compensates for the lost monitoring capability and allows continued plant operation at power levels > 75% RTP. The 12 hour Frequency is consistent with LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR).”

Required Action D.2.2 has been modified by a Note which only requires SR 3.2.4.2 to be performed if OPDMS and the Power Range Neutron Flux input to QPTR become inoperable. Power distribution limits are normally verified in accordance with LCO 3.2.5, “OPDMS - Monitored Power Distribution Parameters.” However, if OPDMS becomes inoperable, then LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR),” becomes applicable. Failure of a component in the Power Range Neutron Flux Channel which renders the High Flux Trip Function inoperable may not affect the capability to monitor QPTR. If either OPDMS or the channel input to QPTR is OPERABLE, then performance of SR 3.2.4.2 once per 12 hours is not necessary.

As an alternative to the above Actions, the plant must be placed in a MODE where this Function is no longer required OPERABLE. Twelve hours are allowed to place the plant in MODE 3. This is a reasonable time, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. If Required Actions cannot be completed within their allowed Completion Times, LCO 3.0.3 must be entered.

BASES

ACTIONS (continued)

E.1.1, E.1.2, and E.2

Condition E applies to the following reactor trip Functions:

- Power Range Neutron Flux – Low;
- Overtemperature ΔT;
- Overpower ΔT;
- Power Range Neutron Flux – High Positive Rate;
- Pressurizer Pressure – High;
- RCP Bearing Water Temperature – High;
- SG Water Level – Low;
- SG Water Level – High 2; and
- Passive Residual Heat Removal Actuation.

With one or two channels inoperable, one affected channel must be placed in a bypass or trip condition within 6 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is bypassed and one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 6 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 7.

If the Required Actions described above cannot be met within the specified Completion Times, the unit must be placed in a MODE where this Function is no longer required to be OPERABLE. An additional 6 hours is allowed to place the unit in MODE 3. Six hours is a reasonable time, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

F.1.1, F.1.2, F.2, and F.3

Condition F applies to the Intermediate Range Neutron Flux trip when above the P-6 setpoint and below the P-10 setpoint. Above the P-6 setpoint and below the P-10 setpoint, the PMS intermediate range detector performs the monitoring functions.

With one or two channels inoperable, one affected channel must be placed in a bypass or trip condition within 2 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is bypassed and one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 2 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 7.

As an alternative to placing the channel(s) in bypass or trip if THERMAL POWER is greater than the P-6 setpoint but less than the P-10 setpoint, 2 hours are allowed to reduce THERMAL POWER below the P-6 setpoint or to increase the THERMAL POWER above the P-10 setpoint. The PMS Intermediate Range Neutron Flux channels must be OPERABLE when the power level is above the capability of the source range, P-6, and below the capability of the power range, P-10. If THERMAL POWER is greater than the P-10 setpoint, the PMS power range detectors perform the monitoring and protective functions and the intermediate range is not required. The Completion Times allow for a slow and controlled power adjustment below P-6, and takes into account the redundant capability afforded by the two remaining OPERABLE channels and the low probability of their failure during this period.

G.1 and G.2

Condition G applies to three Intermediate Range Neutron Flux trip channels inoperable in MODE 2 above the P-6 setpoint and below the P-10 setpoint. Required Actions specified in this Condition are only applicable when channel failures do not result in reactor trip. Above the P-6 setpoint and below the P-10 setpoint, the PMS intermediate range detector performs the monitoring Functions. With only one intermediate range channel OPERABLE, the Required Actions are to suspend operations involving positive reactivity additions immediately. This will preclude any power level increase since there are insufficient OPERABLE Intermediate Range Neutron Flux channels to adequately monitor the power escalation. The operator must also reduce THERMAL POWER

ACTIONS (continued)

below the P-6 setpoint within 2 hours. Below P-6, the Source Range Neutron Flux channels will be able to monitor the core power level. The Completion Time of 2 hours will allow a slow and controlled power reduction to less than the P-6 setpoint and takes into account the low probability of occurrence of an event during this period that may require the protection afforded by the PMS Intermediate Range Neutron Flux trip.

H.1

Condition H applies to the Intermediate Range Neutron Flux trip when THERMAL POWER is below the P-6 setpoint and one or two channels are inoperable. Below the P-6 setpoint, the PMS source range performs the monitoring and protective functions. At least three of the four PMS intermediate range channels must be returned to OPERABLE status prior to increasing power above the P-6 setpoint. With the unit in this Condition, below P-6, the PMS source range performs the monitoring and protection functions.

I.1

Condition I applies to one or two Source Range Neutron Flux trip channels inoperable when in MODE 2, below the P-6 setpoint, and performing a reactor startup. With the unit in this Condition, below P-6, the PMS source range performs the monitoring and protection functions. With one or two of the four channels inoperable, operations involving positive reactivity additions shall be suspended immediately.

This will preclude any power escalation. With only two source range channels OPERABLE, core protection is severely reduced and any actions that add positive reactivity to the core must be suspended immediately.

J.1

Condition J applies to three inoperable Source Range Neutron Flux channels when in MODE 2, below the P-6 setpoint, and performing a reactor startup, or in MODE 3, 4, or 5 with the RTBs closed and the CRD System capable of rod withdrawal. With the unit in this Condition, below P-6, the NIS source range performs the monitoring and protection functions. With three source range channels inoperable, the RTBs must be opened immediately. With the RTBs open, the core is in a more stable condition and the unit enters Condition T.

BASES

ACTIONS (continued)

K.1.1, K.1.2, and K.2

Condition K applies to the following reactor trip Functions:

- Pressurizer Pressure – Low;
- Pressurizer Water Level – High 3;
- Reactor Coolant Flow – Low; and
- RCP Speed – Low.

With one or two channels inoperable, one affected channel must be placed in a bypass or trip condition within 6 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is bypassed and one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 6 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 7.

If Required Actions described above cannot be met within the specified Completion Times, the unit must be placed in a MODE where this Function is no longer required to be OPERABLE. A Completion Time of an additional 6 hours is allowed to reduce power < P-10. Allowance of this time interval takes into consideration the redundant capability provided by the remaining two redundant OPERABLE channels and the low probability of occurrence of an event during this period that may require the protection afforded by the Functions associated with Condition K.

L.1 and L.2

Condition L applies to the Safeguards Actuation signal from ESFAS reactor trip, the RTS Automatic Trip Logic, automatic ADS Stages 1, 2, and 3 actuation, and automatic CMT injection in MODES 1 and 2.

BASES

ACTIONS (continued)

With one or two channels or divisions inoperable, the Required Action is to restore three of the four channels/divisions within 6 hours. Restoring all channels/divisions but one to OPERABLE status ensures that a single failure will neither cause nor prevent the protective function. The 6 hour Completion Time is considered reasonable since the protective function will still function.

If Required Actions described above cannot be met within the specified Completion Times, the unit must be placed in a MODE where this Function is no longer required to be OPERABLE. A Completion Time of an additional 6 hours is allowed to place the unit in MODE 3. The Completion Time is a reasonable time, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. Allowance of this time interval takes into consideration the redundant capability provided by the remaining two redundant OPERABLE channels/divisions and the low probability of occurrence of an event during this period that may require the protection afforded by this Function.

M.1, M.2.1, M.2.2, and M.3

Condition M applies to the P-6, P-10, and P-11 interlocks. With one or two channels inoperable, the associated interlock must be verified to be in its required state for the existing plant condition within 1 hour, or the Functions associated with inoperable interlocks placed in a bypassed or tripped condition within 7 hours, or the unit must be placed in MODE 3 within 13 hours. Verifying the interlock manually accomplishes the interlock condition.

If one interlock channel is inoperable, the associated Function(s) must be placed in a bypass or trip condition within 7 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.)

If two interlock channels are inoperable, one channel of the associated Function(s) must be bypassed and one channel of the associated Function(s) must be tripped. In this state, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 7 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 7.

BASES

ACTIONS (continued)

If placing the associated Functions in bypass or trip is impractical, for instance as the result of other channels in bypass or trip, the Completion Time of an additional 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems.

N.1, N.2.1, and N.2.2

Condition N applies to the RTBs, and RTB undervoltage and shunt trip mechanisms in MODES 1 and 2, and in MODES 3, 4, and 5 with the RTBs closed and the PLS capable of rod withdrawal. This Condition is primarily associated with mechanical damage that can prevent the RTBs from opening.

With one division inoperable, the reactor trip breakers in the inoperable division must be opened within 8 hours. A division is inoperable, if, within that division, one or both of the RTBs and/or one or both of the trip mechanisms is inoperable.

With one division inoperable (with its RTBs open) and with three OPERABLE divisions remaining, the trip logic becomes one-out-of-three. The one-out-of-three trip logic meets the single failure criterion. (A failure in one of the three remaining divisions will not prevent the protective function.) If, coincident with RTBs inoperable in one division, the automatic trip logic is inoperable in another division, the trip logic becomes one-out-of-two, which meets the single failure criterion. If Required Actions described above cannot be met within the specified Completion Times, the unit must be placed in a MODE where this Function is no longer required to be OPERABLE within an additional 6 hours. This is performed by opening all of the RTBs. With the RTBs open, these Functions are no longer required.

O.1, O.2.1, and O.2.2

Condition O applies to the RTBs in MODES 1 and 2, and in MODES 3, 4, and 5 with the RTBs closed and the PLS capable of rod withdrawal. With two divisions of RTBs and/or RTB Undervoltage and Shunt Trip Mechanisms inoperable, 1 hour is allowed to restore the three of the four divisions to OPERABLE status or the unit must be placed in MODE 3, 4 or 5 and the RTBs opened within the next 6 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging unit systems. The 1-hour and 6-hour Completion Times are equal to the time allowed by LCO 3.0.3 for shutdown actions in the event of a complete loss of RTS Function. Placing the unit in MODE 3 with the RTBs open removes the requirement for this particular Function.

BASES

ACTIONS (continued)

P.1 and P.2

Condition P applies to automatic ADS Stages 1, 2, and 3 Actuation, automatic CMT Actuation and the RTS Automatic Trip Logic in MODES 3, 4, and 5 with the RTBs closed and the PLS capable of rod withdrawal.

With one or two channels/divisions inoperable, three of the four channels/divisions must be restored to OPERABLE status in 48 hours. Restoring all channels but one to OPERABLE ensures that a single failure will neither cause nor prevent the protective function. The 48 hour Completion Time is considered reasonable since the protective function will still function.

If Required Actions described above cannot be met within the specified Completion Times, the unit must be placed in a MODE where this Function is no longer required to be OPERABLE. A Completion Time of an additional 1 hour is allowed to open the RTBs. With RTBs open, these Functions are no longer required.

Q.1 and Q.2

Condition Q applies to one or two inoperable Source Range Neutron Flux channels in MODE 3, 4, or 5 with the RTBs closed and the PLS capable of rod withdrawal. With the unit in this Condition, below P-6, the NIS source range performs the monitoring and protection functions. With one or two of the source range channels inoperable, 48 hours is allowed to restore three of the four channels to an OPERABLE status. If the channels cannot be returned to an OPERABLE status, 1 additional hour is allowed to open the RTBs. Once the RTBs are open, the core is in a more stable condition and the unit enters Condition R. The allowance of 48 hours to restore the channel to OPERABLE status, and the additional hour to open the RTBs, are justified in Reference 7.

R.1, R.2, and R.3

Condition R applies when the required Source Range Neutron Flux channel is inoperable in MODE 3, 4, or 5 with the RTBs open. With the unit in this Condition, the NIS source range performs the monitoring and protection functions. With the required source range channel inoperable, operations involving positive reactivity additions shall be suspended immediately. This will preclude any power escalation. In addition to suspension of positive reactivity additions, all valves that could add unborated water to the RCS must be closed within 1 hour as specified in LCO 3.9.2. The isolation of unborated water sources will preclude a boron dilution accident.

BASES

ACTIONS (continued)

Also, the SDM must be verified within 1 hour and once every 12 hours thereafter as per SR 3.1.1.1, SDM verification. With no source range channels OPERABLE, core protection is severely reduced. Verifying the SDM within 1 hour allows sufficient time to perform the calculations and determine that the SDM requirements are met. The SDM must also be verified once per 12 hours thereafter to ensure that the core reactivity has not changed. Required Action R.3 precludes any positive reactivity additions; therefore, core reactivity should not be increasing, and a 12 hour Frequency is adequate. The Completion Times of within 1 hour and once per 12 hours are based on operating experience in performing the Required Actions and the knowledge that unit conditions will change slowly.

SURVEILLANCE REQUIREMENTS

The SRs for each RTS Function are identified in the SRs column of Table 3.3.1-1 for that Function.

A Note has been added to the SR table stating that Table 3.3.1-1 determines which SRs apply to which RTS Functions.

The CHANNEL CALIBRATION and RTCOT are performed in a manner that is consistent with the assumptions used in analytically calculating the required channel accuracies. For channels that include dynamic transfer functions, such as, lag, lead/lag, rate/lag, the response time test may be performed with the transfer function set to one, with the resulting measured response time compared to the appropriate Chapter 7 response time (Ref. 2). Alternately, the response time test can be performed with the time constants set to their nominal value provided the required response time is analytically calculated assuming the time constants are set at their nominal values. The response time may be measured by a series of overlapping tests such that the entire response time is measured.

SR 3.3.1.1

Performance of the CHANNEL CHECK once every 12 hours ensures that gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of even something more serious. A CHANNEL

BASES

SURVEILLANCE REQUIREMENTS (continued)

CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment have drifted outside their corresponding limits.

The channels to be checked are:

Power Range Neutron Flux
Intermediate Range Neutron Flux
Source Range Neutron Flux (below P-6)
Overtemperature Delta T
Overpower Delta T
Pressurizer Pressure Pressurizer Water Level
Reactor Coolant Flow – each hot leg
RCP Bearing Water Temperature – each RCP
RCP Speed
SG Narrow Range Level – each SG
RCS Loop T-cold – each cold leg
RCS Loop T-hot – each cold leg

The Frequency is based on operating experience that demonstrates that channel failure is rare. Automated operator aids may be used to facilitate the performance of the CHANNEL CHECK.

SR 3.3.1.2

SR 3.3.1.2 compares the calorimetric heat balance to the nuclear instrumentation channel output every 24 hours. If the calorimetric measurement between 70% and 100% RTP, differs from the nuclear instrument channel output by > 1% RTP, the nuclear instrument channel is not declared inoperable, but must be adjusted. If the nuclear instrument channel output cannot be properly adjusted, the channel is declared inoperable.

Three Notes modify SR 3.3.1.2. The first Note indicates that the nuclear instrument channel output shall be adjusted consistent with the calorimetric results if the absolute difference between the nuclear instrument channel output and the calorimetric measurement between 70% and 100% RTP is > 1% RTP. The second Note clarifies that this Surveillance is required only if reactor power is ≥ 15% RTP and that 12 hours is allowed for performing the first Surveillance after reaching

BASES

SURVEILLANCE REQUIREMENTS (continued)

15% RTP. At lower power levels the calorimetric data from feedwater flow venturi measurements are less accurate. The third Note is required because, at power levels between 15% and 70% calorimetric uncertainty and control rod insertion create the potential for miscalibration of the nuclear instrumentation channel in cases where the channel is adjusted downward to match the calorimetric power. Therefore, if the calorimetric heat measurement is less than 70% RTP, and if the nuclear instrumentation channel indicated power is lower than the calorimetric measurement by > 1%, then the nuclear instrumentation channel shall be adjusted upward to match the calorimetric measurement. No nuclear instrumentation channel adjustment is required if the nuclear instrumentation channel is higher than the calorimetric measurement (see Westinghouse Technical Bulletin NSD-TB-92-14, Rev. 1.)

The Frequency of every 24 hours is adequate based on plant operating experience, considering instrument reliability and operating history data for instrument drift.

Together, these factors demonstrate the change in the absolute difference between nuclear instrumentation and heat balance calculated powers rarely exceeds 1% RTP in any 24 hours period.

In addition, main control room operators periodically monitor redundant indications and alarms to detect deviations in channel outputs.

SR 3.3.1.3

SR 3.3.1.3 compares the calorimetric heat balance to the calculated ΔT power ($q_{\Delta T}$) in each Division every 24 hours. If the calorimetric measurement between 70% and 100% RTP, differs from the calculated ΔT power by > 1% RTP, the Function is not declared inoperable, but the conversion factor, ΔT°, must be adjusted. If ΔT° cannot be properly adjusted, the Function is declared inoperable in the affected Division(s).

Three Notes modify SR 3.3.1.3. The first Note indicates that ΔT° shall be adjusted consistent with the calorimetric results if the absolute difference between the calculated ΔT power and the calorimetric measurement between 70% and 100% RTP is > 1% RTP.

The second Note clarifies that this Surveillance is required only if reactor power is ≥ 50% RTP and that 12 hours is allowed for performing the first Surveillance after reaching 50% RTP. At lower power levels, the calorimetric data from feedwater flow venturi measurements are less accurate. The calculated ΔT power is normally stable (less likely to need adjustment or to be grossly affected by changes in the core loading

BASES

SURVEILLANCE REQUIREMENTS (continued)

pattern than the nuclear instrumentation), and its calibration should not be unnecessarily altered by a possibly inaccurate calorimetric measurement at low power.

The third Note is required because at power levels below 70%, calorimetric uncertainty creates the potential for non-conservative adjustment of the ΔT° conversion factor, in cases where the calculated ΔT power would be reduced to match the calorimetric power. Therefore, if the calorimetric heat measurement is less than 70% RTP, and if the calculated ΔT power is lower than the calorimetric measurement by > 5%, then the ΔT° conversion factor shall be adjusted so that the calculated ΔT power matches the calorimetric measurement. No ΔT° conversion factor adjustment is required if the calculated ΔT power is higher than the calorimetric measurement.

The Frequency of every 24 hours is based on plant operating experience, considering instrument reliability and the limited effects of fuel burnup and rod position changes on the accuracy of the calculated ΔT power.

SR 3.3.1.4

SR 3.3.1.4 compares the AXIAL FLUX DIFFERENCE determined using the incore system to the nuclear instrument channel AXIAL FLUX DIFFERENCE every 31 effective full power days (EFPD).

If the absolute difference is ≥ 3% AFD the nuclear instrument channel is still OPERABLE, but must be readjusted. If the nuclear instrument channel cannot be properly readjusted, the channel is declared inoperable. This surveillance is performed to verify the f(ΔI) input to the overtemperature ΔT function.

Two Notes modify SR 3.3.1.4. The first Note indicates that the excore nuclear instrument channel shall be adjusted if the absolute difference between the incore and excore AFD is ≥ 3% AFD. Note 2 clarifies that the Surveillance is required only if reactor power is ≥ 20% RTP and that 24 hours is allowed for performing the first Surveillance after reaching 20% RTP. Below 20% RTP, the design of the incore detector system, low core power density, and detector accuracy make use of the incore detectors inadequate for use as a reference standard for comparison to the excore channels.

The Frequency of every 31 EFPD is adequate based on plant operating experience, considering instrument reliability and operating history data for instrument drift. Also, the slow changes in neutron flux during the fuel cycle can be detected during this interval.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.1.5

SR 3.3.1.5 is a calibration of the excore channels to the incore channels. If the measurements do not agree, the excore channels are not declared inoperable but must be adjusted to agree with the incore detector measurements. If the excore channels cannot be adjusted, the channels are declared inoperable. This Surveillance is performed to verify the f(ΔI) input to the overtemperature ΔT Function.

A Note modifies SR 3.3.1.5. The Note states that this Surveillance is required only if reactor power is > 50% RTP and that 24 hours is allowed for performing the first surveillance after reaching 50% RTP.

The Frequency of 92 EFPD is adequate based on industry operating experience, considering instrument reliability and operating history data for instrument drift.

SR 3.3.1.6

SR 3.3.1.6 is the performance of a TADOT every 92 days on a STAGGERED TEST BASIS. This test shall verify OPERABILITY by actuation of the end devices.

The Reactor Trip Breaker (RTB) test shall include separate verification of the undervoltage and shunt trip mechanisms. Each RTB in a division shall be tested separately in order to minimize the possibility of an inadvertent trip.

The Frequency of every 92 days on a STAGGERED TEST BASIS is adequate based on industry operating experience, considering instrument reliability and operating history data. In addition, the AP1000 design provides additional breakers to enhance reliability.

The SR is modified by a Note to clarify that both breakers in a single division are to be tested during each STAGGERED TEST.

SR 3.3.1.7 and SR 3.3.1.8

SR 3.3.1.7 and SR 3.3.1.8 are the performance of a REACTOR TRIP CHANNEL OPERATIONAL TEST (RTCOT) every 92 days. The SR 3.3.1.8 testing is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is

BASES

SURVEILLANCE REQUIREMENTS (continued)

functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

A RTCOT is performed on each required channel to provide reasonable assurance that the entire channel will perform the intended Function.

A test subsystem is provided with the protection and safety monitoring system to aid the plant staff in performing the RTCOT. The test subsystem is designed to allow for complete functional testing by using a combination of system self checking features, functional testing features, and other testing features. Successful functional testing consists of verifying that the capability of the system to perform the safety function has not failed or degraded.

For hardware functions this would involve verifying that the hardware components and connections have not failed or degraded. Generally this verification includes a comparison of the outputs from two or more redundant subsystems or channels.

Since software does not degrade, software functional testing involves verifying that the software code has not changed and that the software code is executing.

To the extent possible, protection and safety monitoring system functional testing is accomplished with continuous system self-checking features and the continuous functional testing features. The RTCOT shall include a review of the operation of the test subsystem to verify the completeness and adequacy of the results.

If the RTCOT can not be completed using the built-in test subsystem, either because of failures in the test subsystem or failures in redundant channel hardware used for functional testing, the RTCOT can be performed using portable test equipment.

This test frequency of 92 days is justified based on Reference 7 and the use of continuous diagnostic test features, such as deadman timers, cross-check of redundant channels, memory checks, numeric coprocessor checks, and tests of timers, counters and crystal time bases, which will report a failure within the protection and safety monitoring system cabinets to the operator within 10 minutes of a detectable failure.

SR 3.3.1.8 is modified by a note that provides a 4 hour delay in the requirement to perform this Surveillance for source range instrumentation

BASES

SURVEILLANCE REQUIREMENTS (continued)

when entering MODE 3 from MODE 2. This note allows a normal shutdown to proceed without a delay for testing in MODE 2 and for a short time in MODE 3 until the RTBs are open and SR 3.3.1.8 is no longer required to be performed. If the unit is to be in MODE 3 with the RTBs closed for a time greater than 4 hours, this Surveillance must be performed prior to 4 hours after entry into MODE 3.

During the RTCOT, the protection and safety monitoring system cabinets in the division under test may be placed in bypass.

SR 3.3.1.9

SR 3.3.1.9 is the performance of a RTCOT as described in SR 3.3.1.7 and SR 3.3.1.8, except it is modified by a Note that this test shall include verification that the P-6 and P-10 interlocks are in their required state for the existing unit condition. The test is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

The Frequency is modified by a Note that allows this surveillance to be satisfied if it has been performed within 92 days of the Frequencies prior to reactor startup and four hours after reducing power below P-10 and P-6. The Frequency of "prior to startup" ensures this surveillance is performed prior to critical operations and applies to the source, intermediate and power range low instrument channels. The Frequency of "4 hours after reducing power below P-10" (applicable to intermediate and power range low channels) and "4 hours after reducing power below P-6" (applicable to source range channels) allows a normal shutdown to be completed and the unit removed from the MODE of Applicability for this surveillance without a delay to perform the testing required by this surveillance. The Frequency of every 92 days thereafter applies if the plant remains in the MODE of Applicability after the initial performances of prior to reactor startup and four hours after reducing power below P-10 or P-6. The MODE of Applicability for this surveillance is < P-10 for the power range low and intermediate range channels and < P-6 for the source range channels. Once the unit is in MODE 3, this surveillance is no longer required. If power is to be maintained < P-10 or < P-6 for more than 4 hours, then the testing required by this surveillance must be

BASES

SURVEILLANCE REQUIREMENTS (continued)

performed prior to the expiration of the 4 hour limit. Four hours is a reasonable time to complete the required testing or place the unit in a MODE where this surveillance is no longer required. This test ensures that the NIS source, intermediate, and power range low channels are OPERABLE prior to taking the reactor critical and after reducing power into the applicable MODE (< P-10 or < P-6) for periods > 4 hours.

SR 3.3.1.10

A CHANNEL CALIBRATION is performed every 24 months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

The test is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation. Transmitter calibration must be performed consistent with the assumptions of the setpoint methodology. The differences between the current as-found values and the previous as-left values must be consistent with the transmitter drift allowance used in the setpoint methodology.

The setpoint methodology requires that 30 months drift be used (1.25 times the surveillance calibration interval, 24 months).

SR 3.3.1.10 is modified by a Note stating that this test shall include verification that the time constants are adjusted to the prescribed values where applicable.

SR 3.3.1.11

SR 3.3.1.11 is the performance of a CHANNEL CALIBRATION every 24 months. This SR is modified by a Note stating that neutron detectors are excluded from the CHANNEL CALIBRATION. The test is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

The CHANNEL CALIBRATION for the power range neutron detectors consists of a normalization of the detectors based on a power calorimetric and flux map performed above 20% RTP. Below 20% RTP, the design of the incore detector system, low core power density, and detector accuracy make use of the incore detectors inadequate for use as a reference standard for comparison to the excore channels. The CHANNEL CALIBRATION for the source range and intermediate range neutron detectors consists of obtaining the detector plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to the manufacturer's data. This Surveillance is not required for the power range detectors for entry into MODES 2 and 1, and is not required for the intermediate range detectors for entry into MODE 2, because the plant must be in at least MODE 2 to perform the test for the intermediate range detectors and MODE 1 for the power range detectors.

The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed on the 24 month Frequency.

SR 3.3.1.12

SR 3.3.1.12 is the performance of a TADOT of the Manual Reactor Trip, and the SI, ADS Actuation, CMT Injection inputs from the ESF logic, and Passive Residual Heat Removal Actuation. This TADOT is performed every 24 months. The test shall independently verify the OPERABILITY of the undervoltage and shunt trip mechanisms for the Manual Reactor Trip Function for the Reactor Trip Breakers.

The Frequency is based on the known reliability of the Functions and the multichannel redundancy available, and has been shown to be acceptable through operating experience.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The SR is modified by a Note that excludes verification of setpoints from the TADOT. The Functions affected have no setpoints associated with them.

SR 3.3.1.13

This SR 3.3.1.13 verifies that the individual channel/division actuation response times are less than or equal to the maximum values assumed in the accident analysis. Response Time testing criteria are included in Reference 2.

For channels that include dynamic transfer Functions (e.g., lag, lead/lag, rate/lag, etc.), the response time test may be performed with the transfer Function set to one, with the resulting measured response time compared to the appropriate DCD Chapter 7 response time. Alternately, the response time test can be performed with the time constants set to their nominal value, provided the required response time is analytically calculated assuming the time constants are set at their nominal values. The response time may be measured by a series of overlapping tests such that the entire response time is measured.

Response time may be verified by actual response time tests in any series of sequential, overlapping or total channel measurements, or by the summation of allocated sensor, signal processing and actuation logic response times with actual response time tests on the remainder of the channel. Allocations for sensor response times may be obtained from: (1) historical records based on acceptable response time tests (hydraulic, noise, or power interrupt tests), (2) in place, onsite, or offsite (e.g. vendor) test measurements, or (3) utilizing vendor engineering specifications. WCAP-13632-P-A, Revision 2, “Elimination of Pressure Sensor Response Time Testing Requirements” (Ref. 9), provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the WCAP. Response time verification for other sensor types must be demonstrated by test.

Each division response must be verified every 24 months on a STAGGERED TEST BASIS (i.e., all four Protection Channel Sets would be tested after 96 months). Response times cannot be determined during plant operation because equipment operation is required to measure response times. Experience has shown that these components usually pass this surveillance when performed on a refueling frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The SR 3.3.1.13 is modified by a note exempting neutron detectors from response time testing. A Note to the Surveillance indicates that neutron detectors may be excluded from RTS RESPONSE TIME testing. This Note is necessary because of the difficulty in generating an appropriate detector input signal. Excluding the detectors is acceptable because the principles of detector operation ensure a virtually instantaneous response.

B 3.3 INSTRUMENTATION

B 3.3.2 Engineered Safety Feature Actuation System (ESFAS) Instrumentation

BASES

BACKGROUND

The ESFAS initiates necessary safety systems, based upon the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary, and to mitigate accidents. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the ESFAS, as well as specifying LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions. LSSS are defined by the regulation as “Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded.” The Safety Analysis Limit (SAL) is the limit of the process variable at which a protective action is initiated, as established by the safety analysis, to ensure that an SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Safety Analysis Limit to account for instrument loop uncertainties related to the setting at which the automatic protective action would actually occur. The LSSS values are identified and maintained in the Setpoint Program (SP) and are controlled by 10.CFR.50.59.

The Nominal Trip Setpoint (NTS) specified in the SP is a predetermined field setting for a protection channel chosen to initiate automatic actuation prior to the process variable reaching the Safety Analysis Limit and, thus, ensuring that the SL is not exceeded. As such, the NTS accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how

BASES

BACKGROUND (continued)

the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the NTS ensures that the SL is not exceeded. Therefore, the NTS meets the 10 CFR 50.36 definition of an LSSS.

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety functions(s)." Relying solely on the NTS to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule that are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the NTS due to some drift of the setting may still be OPERABLE since drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the NTS, and thus, the automatic protective action would still have ensured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE since it would have performed its safety function. If the as-found condition of the channel is near the as-found tolerance, recalibration is considered appropriate to allow for drift during the next surveillance interval.

During AOOs, which are those events expected to occur one or more times during the unit life, the acceptable limits are:

1. The Departure from Nucleate Boiling Ratio (DNBR) shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling (DNB),

2. Fuel centerline melt shall not occur, and

3. The RCS pressure SL of 2750 psia shall not be exceeded.

Operation within the SLs of Specification 2.0, "Safety Limits (SLs)," also maintains the above values and ensures that offsite dose will be within the acceptance criteria during AOOs.

BASES

BACKGROUND (continued)

Design Basis Accidents (DBAs) are events that are analyzed even though they are not expected to occur during the unit life. The acceptable limit during accidents is that offsite dose shall be maintained within an acceptable fraction of the limits. Different accident categories are allowed a different fraction of these limits, based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

The ESFAS instrumentation is segmented into distinct but interconnected modules.

Field Transmitters and Sensors

Normally, four redundant measurements using four separate sensors, are made for each variable used for actuation of ESF. The use of four channels for protection Functions is based on a minimum of two channels being required for a trip or actuation, one channel in test or bypass, and a single failure on the remaining channel. The signal selector in the Plant Control System will function correctly with only three channels. This includes two channels properly functioning and one channel having a single failure. Minimum requirements for protection and control are achieved only with three channels OPERABLE. The fourth channel is provided to increase plant availability, and permits the plant to run for an indefinite time with a single channel out of service. The circuit design is able to withstand both an input failure to the control system, which may then require the protection Function actuation, and a single failure in the other channels providing the protection Function actuation. Again, a single failure will neither cause nor prevent the protection Function actuation. These requirements are described in IEEE-603 (Ref. 4). The actual number of channels provided for each plant parameter is specified in Reference 2.

Engineered Safety Features (ESF) Channel

An ESF channel extends from the sensor to the output of the associated ESF subsystem and shall include the sensor (or sensors), the signal conditioning, any associated data links, and the associated ESF subsystem. For ESF channels containing nuclear instrumentation, the ESF channel shall also include the nuclear instrument signal conditioning and the associated Nuclear Instrumentation Signal Processing and Control (NISPAC) subsystem. Any manual ESF controls that are associated with a particular ESF channel are also included in that ESF channel.

BASES

BACKGROUND (continued)

Plant Protection Subsystem

The Plant Protection contains the necessary equipment to:

- Permit acquisition and analysis of the sensor inputs, including plant process sensors and nuclear instrumentation, required for reactor trip and ESF calculations;
- Perform computation or logic operations on variables based on these inputs;
- Provide trip signals to the reactor trip switchgear and ESF actuation data to the ESF coincidence logic as required;
- Permit manual trip or bypass of each individual reactor trip Function and permit manual actuation or bypass of each individual voted ESF Function;
- Provide data to other systems in the Instrumentation and Control (I&C) architecture; and
- Provide separate input circuitry for control Functions that require input from sensors that are also required for protection Functions.

Each of the four divisions of plant protection provides signal conditioning, comparable output signals for indications in the main control room, and comparison of measured input signals with established setpoints. The basis of the setpoints are described in References 3 and 9. If the measured value of a unit parameter exceeds the predetermined setpoint, an output is generated which is transmitted to the ESF coincidence logic for logic evaluation.

Within the Protection and Safety Monitoring System (PMS), redundancy is generally provided for active equipment such as processors and communication hardware. This redundancy is provided to increase plant availability and facilitate surveillance testing. A division or channel is OPERABLE if it is capable of performing its specified safety function(s) and all the required supporting functions or systems are also capable of performing their related support functions. Thus, a division or channel is OPERABLE as long as one set of redundant components within the division or channel are capable of performing its specified safety function(s).

BASES

BACKGROUND (continued)

ESF Coincidence Logic

The ESF coincidence logic contains the necessary equipment to:

- Permit reception of the data supplied by the four divisions of plant protection and perform voting on the trip outputs;
- Perform system level logic using the input data from the plant protection subsystems and transmit the output to the ESF actuation subsystems; and
- Provide redundant hardware capable of providing system level commands to the ESF actuation subsystems.

ESF Actuation Subsystems

The ESF actuation subsystems contain the necessary equipment to:

- Receive automatic system level signals supplied by the ESF coincidence logic;
- Receive and transmit data to/from main control room multiplexers;
- Receive and transmit data to/from other PLCs on the same logic bus;
- Receive status data from component position switches (such as limit switches and torque switches); and
- Perform logic computations on received data, generate logic commands for final actuators (such as START, STOP, OPEN, and CLOSE).

ESF Coincidence Logic and ESF Actuation Subsystem OPERABILITY Background

Each ESF coincidence logic and ESF actuation subsystem has two subsystems that communicate by means of redundant halves of the logic bus. This arrangement is provided to facilitate testing. If one subsystem is removed from service, the remaining subsystem continues to function and the ESF division continues to provide full protection. At least one of these redundant halves is connected to the battery backed portion of the power system. This provides full functionality of the ESF division even when all ac power sources are lost. As long as one battery subsystem within an ESF coincidence logic or ESF actuation subsystem continues to

BACKGROUND (continued)

operate, the ESF division is unaffected. An ESF division is only affected when all battery backed subsystems within that division's ESF coincidence logic or ESF actuation subsystem are not OPERABLE.

Nominal Trip Setpoints (NTSs)

The NTS is the nominal value at which the trip output is set. Any trip output is considered to be properly adjusted when the "as-left" value is within the band for CHANNEL CALIBRATION, i.e., ± rack calibration accuracy.

The trip setpoints used in the trip output are based on the Safety Analysis Limits stated in Reference 3. The determination of these NTSs is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrument drift, and severe environment errors for those ESFAS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 5), the NTSs specified in the SP are conservative with respect to the Safety Analysis Limits. A detailed description of the methodology used to calculate the NTSs, including their explicit uncertainties, is provided in the "Westinghouse Setpoint Methodology for Protection Systems" (Ref. 9). The as-left tolerance and as-found tolerance band methodology is provided in the SP. The as-found OPERABILITY limit for the purpose of the CHANNEL OPERATIONAL TEST (COT) is defined as the as-left limit about the NTS (i.e., ± rack calibration accuracy).

The NTSs listed in the SP are based on the methodology described in Reference 9, which incorporates all of the known uncertainties applicable for each channel. The magnitudes of these uncertainties are factored into the determination of each NTS. All field sensors and signal processing equipment for these channels are assumed to operate within the allowances of these uncertainty magnitudes. Transmitter and signal processing equipment calibration tolerances and drift allowances must be specified in plant calibration procedures, and must be consistent with the values used in the setpoint methodology.

The OPERABILITY of each transmitter or sensor can be evaluated when its "as-found" calibration data are compared against the "as-left" data and are shown to be within the setpoint methodology assumptions. The basis of the setpoints is described in References 3 and 9. Trending of calibration results is required by the program description in Technical Specification 5.5.14.d.

BASES

BACKGROUND (continued)

Note that the as-left and as-found tolerances listed in the SP define the OPERABILITY limits for a channel during a periodic CHANNEL CALIBRATION, CHANNEL OPERATIONAL TESTS, or a TRIP ACTUATING DEVICE OPERATIONAL TEST that requires trip setpoint verification.

The protection and safety monitoring system testing features are designed to allow for complete functional testing by using a combination of system self-checking features, functional testing features, and other testing features. Successful functional testing consists of verifying that the capability of the system to perform the safety function has not failed or degraded. For hardware functions this would involve verifying that the hardware components and connections have not failed or degraded. Since software does not degrade, software functional testing involves verifying that the software code has not changed and that the software code is executing. To the extent possible, protection and safety monitoring system functional testing will be accomplished with continuous system self-checking features and the continuous functional testing features.

The protection and safety monitoring system incorporates continuous system self-checking features wherever practical. Self-checking features include on-line diagnostics for the computer system and the hardware and communications tests. These self-checking tests do not interfere with normal system operation.

In addition to the self-checking features, the system includes functional testing features. Functional testing features include continuous functional testing features and manually initiated functional testing features. To the extent practical, functional testing features are designed not to interfere with normal system operation.

In addition to the system self-checking features and functional testing features, other test features are included for those parts of the system which are not tested with self-checking features or functional testing features. These test features allow for instruments/sensor checks, calibration verification, response time testing, setpoint verification and component testing. The test features again include a combination of continuous testing features and manual testing features.

All of the testing features are designed so that the duration of the testing is as short as possible. Testing features are designed so that the actual logic is not modified. To prevent unwanted actuation, the testing features are designed with either the capability to bypass a Function during testing and/or limit the number of signals allowed to be placed in test at one time.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY

Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. For example, Pressurizer Pressure – Low is a primary actuation signal for small loss of coolant accidents (LOCAs) and a backup actuation signal for steam line breaks (SLBs) outside containment. Functions such as manual initiation not specifically credited in the accident safety analysis are qualitatively credited in the safety analysis and the NRC staff approved licensing basis for the plant. These Functions may provide protection for conditions which do not require dynamic transient analysis to demonstrate Function performance. These Functions may also serve as backups to Functions that were credited in the accident analysis (Ref. 3).

Permissive and interlock functions are based upon the associated protection function instrumentation. Because they do not have to operate in adverse environmental conditions, the trip settings of the permissive and interlock functions use the normal environment, steady-state instrument uncertainties of the associated protection function instrumentation. This results in OPERABILITY criteria (i.e., as-found tolerance and as-left tolerance) that are the same as the associated protection function sensor and process rack modules. The NTSs for permissives and interlocks are based on the associated protection function OPERABILITY requirements; i.e., permissives and interlocks performing enabling functions must be set to occur prior to the specified trip setting of the associated protection function.

The LCO requires all instrumentation performing an ESFAS Function, listed in Table 3.3.2-1 in the accompanying LCO, to be OPERABLE. The as-left and as-found tolerances specified in the SP define the OPERABILITY limits for a channel during the CHANNEL CALIBRATION or CHANNEL OPERATIONAL TEST (COT). As such, the as-left and as-found tolerances differ from the NTS by ± the PMS rack calibration accuracy and envelope the expected calibration accuracy and drift. In this manner, the actual setting of the channel (NTS) prevents exceeding an SL at any given point in time as long as the channel has not drifted beyond the expected tolerances during the surveillance interval. Note that the as-left and as-found recorded values must be confirmed to be operating within the assumptions of the statistical uncertainty calculations.

If the actual setting of the channel is found outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance) and evaluating the channel's response. If the

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

channel is functioning as required and expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

A trip setpoint may be set more conservative than the NTS as necessary in response to plant conditions. However, in this case, the OPERABILITY of this instrument must be verified based on the actual field setting and not the NTS. Failure of any instrument renders the affected channel(s) inoperable and reduces the reliability of the affected Functions.

The LCO generally requires OPERABILITY of four channels in each instrumentation/logic Function and two devices for each manual initiation Function. The two-out-of-four configurations allow one channel to be bypassed during maintenance or testing without causing an ESFAS initiation. Two manual initiation channels are required to ensure no single random failure disables the ESFAS.

The required channels of ESFAS instrumentation provide plant protection in the event of any of the analyzed accidents. ESFAS protective functions are as follows:

1. Safeguards Actuation

   The Safeguards Actuation signal actuates the alignment of the Core Makeup Tank (CMT) valves for passive injection to the RCS. The Safeguards Actuation signal provides two primary Functions:

   - Primary side water addition to ensure maintenance or recovery of reactor vessel water level (coverage of the active fuel for heat removal and clad integrity, peak clad temperature < 2200°F); and
   - Boration to ensure recovery and maintenance of SHUTDOWN MARGIN (k_{eff} < 1.0).

   These Functions are necessary to mitigate the effects of high energy line breaks (HELBs) both inside and outside of containment. The Safeguards Actuation signal is also used to initiate other Functions such as:

   - Containment Isolation;
   - Reactor Trip;

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

- Close Main Feedwater Control Valves;
- Trip Main Feedwater Pumps and Closure of Isolation and Crossover Valves; and
- Reactor Coolant Pump Trip.

These other Functions ensure:

- Isolation of nonessential systems through containment penetrations;
- Trip of the turbine and reactor to limit power generation;
- Isolation of main feedwater to limit secondary side mass losses;
- Trip of the reactor coolant pumps to ensure proper CMT actuation;
- Enabling automatic depressurization of the RCS on CMT Level – Low 1 to ensure continued safeguards actuated injection.

Manual and automatic initiation of Safeguards Actuation must be OPERABLE in MODES 1, 2, 3, and 4. In these MODES there is sufficient energy in the primary and secondary systems to warrant automatic initiation of ESF systems. Automatic actuation in MODE 4 is provided by the high containment pressure signal.

Manual initiation is required in MODE 5 to support system level initiation. Automatic initiation is not required to be OPERABLE in MODE 5 because parameters are not available to provide automatic actuation, and manual initiation is sufficient to mitigate the consequences of an accident.

These Safeguards Actuation Functions are not required to be OPERABLE in MODE 6 because there is adequate time for the operator to evaluate plant conditions and respond by manually starting individual systems, pumps, and other equipment to mitigate the consequences of an abnormal condition or accident. Plant pressure and temperature are very low and many ESF components are administratively locked out or otherwise prevented from actuating to prevent inadvertent overpressurization of plant systems.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

1.a. Manual Initiation

The LCO requires that two manual initiation devices are OPERABLE. The operator can initiate the Safeguards Actuation signal at any time by using either of two switches in the main control room. This action will cause actuation of all components in the same manner as any of the automatic actuation signals.

The LCO on Manual Initiation ensures the proper amount of redundancy is maintained in the manual ESFAS actuation circuitry to ensure the operator has manual ESFAS initiation capability.

Each device consists of one switch and the interconnecting wiring to all four divisions. Each manual initiation device actuates all four divisions. This configuration does not allow testing at power.

1.b. Containment Pressure – High 2

This signal provides protection against the following accidents:

- SLB inside containment;
- LOCA; and
- Feed line break inside containment.

The transmitters (d/p cells) and electronics are located outside of containment. Since the transmitters and electronics are located outside of containment, they will not experience adverse environmental conditions. The Containment Pressure – High 2 setpoint has been specified as low as reasonable, without creating potential for spurious trips during normal operations, consistent with the TMI action item (NUREG-0933, Item II.E.4.2) guidance.

The LCO requires four channels of Containment Pressure – High 2 to be OPERABLE in MODES 1, 2, 3, and 4. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

1.c. Pressurizer Pressure – Low

This signal provides protection against the following accidents:

- Inadvertent opening of a steam generator (SG) safety valve;
- SLB;
- A spectrum of rod cluster control assembly ejection accidents (rod ejection);
- Inadvertent opening of a pressurizer safety valve;
- LOCAs; and
- Steam Generator Tube Rupture (SGTR).

The transmitters are located inside containment, with the taps in the vapor space region of the pressurizer, and thus possibly experiencing adverse environmental conditions (LOCA, SLB inside containment). Therefore, the NTS reflects the inclusion of both steady state and adverse environmental instrument uncertainties.

The LCO requires four channels of Pressurizer Pressure – Low to be OPERABLE in MODES 1, 2, and 3 (above P-11, when the RCS boron concentration is below that necessary to meet the SDM requirements at an RCS temperature of 200°F), to mitigate the consequences of a high energy line rupture inside containment. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. This signal may be manually blocked by the operator below the P-11 setpoint. Automatic actuation below this pressure is then performed by the Containment Pressure – High 2 signal.

This Function is not required to be OPERABLE in MODE 3 below the P-11 setpoint. Other ESF Functions are used to detect accident conditions and actuate the ESF systems in this MODE. In MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

1.d. Steam Line Pressure – Low

Steam Line Pressure – Low provides protection against the following accidents:

- SLB;
- Feed line break; and
- Inadvertent opening of an SG relief or an SG safety valve.

It is possible for the transmitters to experience adverse environmental conditions during a secondary side break. Therefore, the NTS reflects both steady state and adverse environmental instrument uncertainties.

This Function is anticipatory in nature and has a typical lead/lag ratio of 50/5.

The LCO requires four channels of Steam Line Pressure – Low to be OPERABLE in MODES 1, 2, and 3 (above P-11, when the RCS boron concentration is below that necessary to meet the SDM requirements at an RCS temperature of 200°F). At these conditions, a secondary side break or stuck open valve could result in the rapid depressurization of the steam lines. Four channels are provided in each steam line to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. This signal may be manually blocked by the operator below the P-11 setpoint. Below P-11, feed line break is not a concern, inside containment SLB will be terminated by automatic actuation via Containment Pressure – High 2, and outside containment SLB will be terminated by the Steam Line Pressure-Negative Rate – High signal for steam line isolation. In MODE 4, 5, or 6, this Function is not needed for accident detection and mitigation because the steam line pressure is below the actuation setpoint. Low steam line pressure in these MODES is not an adequate indication of a feed line or steam line break.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

1.e. RCS Cold Leg Temperature (T_{cold}) – Low

This signal provides protection against the following accidents:

- SLB;
- Feed line break; and
- Inadvertent opening of an SG relief or an SG safety valve.

The LCO requires four channels of T_{cold} – Low to be OPERABLE in MODES 1 and 2, and in MODE 3 with any main steam isolation valve open and above P-11 when the RCS boron concentration is below that necessary to meet the SDM requirements at an RCS temperature of 200°F. At these conditions, a secondary side break or stuck open valve could result in the rapid cooldown of the primary side. Four channels are provided in each loop to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. In MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation because the cold leg temperature is reduced below the actuation setpoint.

2. Core Makeup Tank (CMT) Actuation

CMT Actuation provides the passive injection of borated water into the RCS. Injection provides RCS makeup water and boration during transients or accidents when the normal makeup supply from the Chemical and Volume Control System (CVS) is lost or insufficient. Two tanks are available to provide passive injection of borated water. CMT injection mitigates the effects of high energy line breaks by adding primary side water to ensure maintenance or recovery of reactor vessel water level following a LOCA, and by borating to ensure recovery or maintenance of SHUTDOWN MARGIN following a steam line break. CMT Valve Actuation is initiated by the Safeguards Actuation signal, Pressurizer Level – Low 2, ADS Stages 1, 2 and 3 Actuation, or manually.

The LCO requires that manual and automatic CMT Valve Actuation be OPERABLE in MODES 1 through 4. Manual and Automatic actuation of the CMT valves is additionally required in MODE 5 with the RCS pressure boundary intact. Actuation of this Function is not required in MODE 5 with the RCS pressure boundary open, or

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

MODE 6 because the CMTs are not required to be OPERABLE in these MODES.

2.a. Manual Initiation

Manual CMT Valve Actuation is accomplished by either of two switches in the main control room. Either switch activates all four divisions.

2.b. Pressurizer Water Level – Low 2

This Function also initiates CMT Valve Actuation from the coincidence of pressurizer level below the Low 2 Setpoint in any two of the four divisions. This function can be manually blocked when the pressurizer water level is below the P-12 Setpoint. This Function is automatically unblocked when the pressurizer water level is above the P-12 Setpoint. The Setpoint reflects both steady state and adverse environmental instrument uncertainties as the detectors provide protection for an event that results in a harsh environment.

2.c. Safeguards Actuation (Function 1)

CMT Valve Actuation is also initiated by all Functions that initiate the Safeguards Actuation signal. The CMT Valve Actuation Function requirements are the same as the requirements for the Safeguards Actuation Functions, but only apply in MODES 1 through 4, and in MODE 5 with the RCS pressure boundary intact. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 1 is referenced for all initiating Functions and requirements.

2.d. ADS Stages 1, 2, and 3 Actuation (Function 9)

The CMTs are actuated on an ADS Stages 1, 2, and 3 actuation. The CMT Actuation Function requirements are the same as the requirements for the ADS Stages 1, 2, and 3 Actuation Function, but only apply in MODES 1 through 4, and in MODE 5 with the RCS pressure boundary intact. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 9 is referenced for all initiating functions and requirements.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

3. Containment Isolation

Containment Isolation provides isolation of the containment atmosphere and selected process systems which penetrate containment from the environment. This Function is necessary to prevent or limit the release of radioactivity to the environment in the event of a large break LOCA.

Containment Isolation is actuated by the Safeguards Actuation signal, manual actuation of containment cooling, or manually.

Manual and automatic initiation of Containment Isolation must be OPERABLE in MODES 1, 2, 3, and 4, when containment integrity is required. Manual initiation is required in MODE 5 and MODE 6 for closure of open penetrations providing direct access from the containment atmosphere to the outside atmosphere. Manual initiation of this Function in MODES 5 and 6 is not applicable if the direct access lines penetrating containment are isolated. Initiation of containment isolation by manual initiation of passive containment cooling in MODE 5 or 6 with decay heat ≤ 6.0 MWt is not required because OPERABILITY of the passive containment cooling system is not required when air cooling is sufficient. This provides the capability to manually initiate containment isolation during all MODES. Automatic Safeguards Actuation is required in MODE 5 for closure of open penetrations providing direct access from the containment atmosphere to the outside atmosphere. Automatic Safeguards Actuation is not required in MODE 6 because manual initiation is sufficient to mitigate the consequences of an accident in this MODE.

3.a. Manual Initiation

Manual Containment Isolation is accomplished by either of two switches in the main control room. Either switch actuates all four ESFAC divisions.

3.b. Manual Initiation of Passive Containment Cooling (Function 12.a)

Containment Isolation is also initiated by Manual Initiation of Passive Containment Cooling. This is accomplished as described for ESFAS Function 12.a, but are not applicable if the direct access flow paths are isolated.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

3.c. Safeguards Actuation (Function 1)

Containment Isolation is also initiated by all Functions that initiate the Safeguards Actuation signal. The Containment Isolation Function requirements are the same as the requirements for the Safeguards Actuation Function, but are not applicable if the direct access flow paths are isolated. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 1 is referenced for all initiating functions and requirements.

4. Steam Line Isolation

Isolation of the main steam lines provides protection in the event of an SLB inside or outside containment. Rapid isolation of the steam lines will limit the steam break accident to the blowdown from one SG at most. For an SLB upstream of the isolation valves, inside or outside of containment, closure of the isolation valves limits the accident to the blowdown from only the affected SG. For a SLB downstream of the isolation valves, closure of the isolation valves terminates the accident as soon as the steam lines depressurize.

Closure of the turbine stop and control valves and the main steam branch isolation valves is initiated by this Function. Closure of these valves limits the accidental depressurization of the main steam system associated with an inadvertent opening of a single steam dump, relief, safety valve, or a rupture of a main steam line. Closure of these valves also supports a steam generator tube rupture event by isolating the faulted steam generator.

4.a. Manual Initiation

Manual initiation of Steam Line Isolation can be accomplished from the main control room. There are two switches in the main control room and either switch can initiate action to immediately close all main steam isolation valves (MSIVs). The LCO requires two OPERABLE channels in MODES 1, 2, 3, and 4 with any main steam valve open, when there is sufficient energy in the RCS and SGs to have an SLB or other accident resulting in the release of significant quantities of energy to cause a cooldown of the primary system. In MODES 5 and 6, this Function is not required to be OPERABLE because there is insufficient energy in the secondary side of the unit to cause an accident.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

4.b. Containment Pressure – High 2

This Function actuates closure of the MSIVs in the event a SLB inside containment to limit the mass and energy release to containment and limit blowdown to a single SG.

The transmitters and electronics are located outside containment; thus, they will not experience harsh environmental conditions.

The Containment Pressure – High 2 setpoint has been specified as low as reasonable, without creating potential for spurious trips during normal operations, consistent with the TMI action item (NUREG-0933, Item II.E.4.2) guidance. The LCO requires four channels of Containment Pressure – High 2 to be OPERABLE in MODES 1, 2, 3, and 4, with any main steam valve open, when there is sufficient energy in the primary and secondary side to pressurize the containment following a pipe break. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. There would be a significant increase in the containment pressure, thus allowing detection and closure of the MSIVs. In MODES 5 and 6, there is not enough energy in the primary and secondary sides to pressurize the containment to the Containment Pressure – High 2 setpoint.

4.c. Steam Line Pressure

(1) Steam Line Pressure – Low

Steam Line Pressure – Low provides closure of the MSIVs in the event of an SLB to limit the mass and energy release to containment and limit blowdown to a single SG.

The LCO requires four channels of Steam Line Pressure – Low Function to be OPERABLE in MODES 1, 2, and 3 (above P-11, when the RCS boron concentration is below that necessary to meet the SDM requirements at an RCS temperature of 200°F), with any main steam isolation valve open, when a secondary side break or stuck open valve could result in the rapid depressurization of the steam lines. Four channels are

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

provided in each steam line to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. This signal may be manually blocked by the operator below the P-11 setpoint. Below P-11, an inside containment SLB will be terminated by automatic actuation via Containment Pressure – High 2, and stuck open valve transients and outside containment steam line breaks will be terminated by the Steam Line Pressure-Negative Rate – High signal for Steam Line Isolation. In MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation.

(2) Steam Line Pressure-Negative Rate – High

Steam Line Pressure-Negative Rate – High provides closure of the MSIVs for an SLB, when less than the P-11 setpoint, to maintain at least one unfaulted SG as a heat sink for the reactor and to limit the mass and energy release to containment. When the operator manually blocks the Steam Line Pressure – Low when less than the P-11 setpoint, the Steam Line Pressure-Negative Rate – High signal is automatically enabled.

The LCO requires four channels of Steam Line Pressure-Negative Rate – High to be OPERABLE in MODE 3, with any main steam valve open, when less than the P-11 setpoint, when a secondary side break or stuck open valve could result in the rapid depressurization of the steam line(s). Four channels are provided in each steam line to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. In MODES 1 and 2, and in MODE 3 when above the P-11 setpoint with the RCS boron concentration below that necessary to meet the SDM requirements at an RCS temperature of 200°F, this signal is automatically disabled and the Steam Line Pressure – Low signal is automatically enabled.

In MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

While the transmitters may experience elevated ambient temperatures due to a steam line break, the Trip Function is on rate of change, not the absolute accuracy of the indicated steam pressure. Therefore, the NTS reflects only steady state instrument uncertainties.

4.d. T_{cold} – Low

This Function provides closure of the MSIVs during a SLB or inadvertent opening of a SG relief or a safety valve to maintain at least one unfaulted SG as a heat sink for the reactor and to limit the mass and energy release to containment.

This Function was discussed as Safeguards Actuation Function 1.e.

The LCO requires four channels of T_{cold} – Low to be OPERABLE in MODES 1 and 2, and in MODE 3 above P-11 when the RCS boron concentration is below that necessary to meet the SDM requirements at an RCS temperature of 200°F, with any main steam isolation valve open, when a secondary side break or stuck open valve could result in the rapid cooldown of the primary side. Four channels are provided in each loop to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. In MODE 3 below P-11 and in MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation because the cold leg temperature is reduced below the actuation setpoint.

5. Turbine Trip

The primary Function of the Turbine Trip is to prevent damage to the turbine due to water in the steam lines. This Function is necessary in MODES 1 and 2, and 3 above P-11 to mitigate the effects of a large SLB or a large Feedline Break (FLB). Failure to trip the turbine following a SLB or FLB can lead to additional mass and energy being delivered to the steam generators, resulting in excessive cooldown and additional mass and energy release in containment. In MODES 3, 4, 5, and 6, the turbine is not in operation and this function is not required to be OPERABLE.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

This Function is actuated by Steam Generator Water Level – High 2, by a Safeguards Actuation signal, or manually. The Reactor Trip Signal also initiates a turbine trip signal whenever a reactor trip (P-4) is generated.

5.a. Manual Main Feedwater Isolation

The Turbine Trip is also initiated by the Manual Main Feedwater Control Valve Isolation Function. The requirements for this Function are the same as the requirements for Manual Main Feedwater Control Valve Isolation (Function 6.a), but only apply in MODES 1 and 2. Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 6.a is referenced for all requirements.

5.b. Steam Generator Narrow Range Water Level – High 2

This signal provides protection against excessive feedwater flow by closing the main feedwater control, isolation and crossover valves, tripping of the main feedwater pumps, and tripping the turbine. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. The transmitters (d/p cells) are located inside containment.

However, the events which this Function protect against cannot cause severe environment in containment. Therefore, the Setpoint reflects only steady state instrument uncertainties.

5.c. Reactor Trip (Function 18.b)

Turbine Trip is also initiated by all functions that initiate Reactor Trip. The turbine trip function requirements are the same as the requirements for the Reactor Trip Function, but only apply in MODES 1 and 2. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 18.b, P-4 (Reactor Trip), is referenced for all initiating Functions and requirements.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

6. Main Feedwater Control Valve Isolation

The primary Function of Main Feedwater Control Valve Isolation is to prevent damage to the turbine due to water in the steam lines and to stop the excessive flow of feedwater into the SGs. This Function is actuated by Steam Generator Narrow Range Water Level – High 2, by a Safeguards Actuation signal, or manually. The Reactor Trip Signal also initiates closure of the main feedwater control valves coincident with a low RCS average temperature (T_{avg}) signal whenever a reactor trip (P-4) is generated.

Closing the Main Feedwater Control Valves on Manual Main Feedwater Isolation, SG Narrow Range Water Level-High 2, or Safeguards Actuation is necessary in MODES 1, 2, and 3 to mitigate the effects of a large SLB or a large FLB. This Function is also required to be OPERABLE in MODES 1 and 2 on T_{avg} Low-1 coincident with Reactor Trip (P-4). Failure to close the main feedwater control valves following a SLB or FLB can lead to additional mass and energy being delivered to the steam generators, resulting in excessive cooldown and additional mass and energy release in containment. Manual main feedwater isolation is required to be OPERABLE in MODE 4 when the main feedwater control valves are open. This Function is not applicable in MODE 4 for valve isolation if the main feedwater line is isolated. Automatic actuation on a Steam Generator Narrow Range Water Level – High 2 is required to be OPERABLE in MODE 4 when the RCS is not being cooled by the RNS. In MODES 5 and 6, the energy in the RCS and the steam generators is low and this function is not required to be OPERABLE.

6.a. Manual Main Feedwater Isolation

Manual Main Feedwater Isolation can be accomplished from the main control room. There are two switches in the main control room and either switch can initiate action in both divisions to close all main and startup feedwater control, isolation and crossover valves, trip all main and startup feedwater pumps, and trip the turbine.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

6.b. Steam Generator Narrow Range Water Level – High 2

This signal provides protection against excessive feedwater flow by closing the main feedwater control, isolation and crossover valves, tripping of the Main Feedwater Pumps, and tripping the turbine.

Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. The transmitters (d/p cells) are located inside containment. However, the events which this Function protect against cannot cause severe environment in containment. Therefore, the Setpoint reflects only steady state instrument uncertainties.

6.c. Safeguards Actuation (Function 1)

This Function is also initiated by all Functions that initiate the Safeguards Actuation signal. The Main Feedwater Control Valve Isolation Function requirements are the same as the requirements for the Safeguards Actuation Function, but do not apply in MODE 4 with the flow paths isolated. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead

Function 1 is referenced for all initiating Functions and requirements. The Safeguards Actuation signal closes all main feedwater control, isolation and crossover valves, trips all main feedwater pumps, and trips the turbine.

6.d. T_{avg} Low-1 Coincident with Reactor Trip (P-4)

This signal provides protection against excessive feedwater flow by closing the main feedwater control valves. This signal results from a coincidence of two of the four divisions of reactor loop average temperature below the Low 1 setpoint coincident with the P-4 permissive. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure that no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

7. Main Feedwater Pump Trip and Valve Isolation

The primary function of the Main Feedwater Pump Trip and Isolation is to prevent damage to the turbine due to water in the steam lines and to stop the excessive flow of feedwater into the SGs. Valve isolation includes closing the main feedwater isolation and crossover valves. Isolation of main feedwater is necessary to prevent an increase in heat removal from the reactor coolant system in the event of a feedwater system malfunction. Addition of excessive feedwater causes an increase in core power by decreasing reactor coolant temperature. This Function is actuated by Steam Generator Water Level – High 2, by a Safeguards Actuation signal, or manually. The Reactor Trip Signal also initiates a turbine trip signal whenever a reactor trip (P-4) is generated.

This Function is necessary in MODES 1, 2, 3, and 4 to mitigate the effects of a large SLB or a large FLB except T_{avg} Low 2 coincident with Reactor Trip (P-4) which is required to be OPERABLE in MODES 1 and 2. Failure to trip the turbine or isolate the main feedwater system following a SLB or FLB can lead to additional mass and energy being delivered to the steam generators, resulting in excessive cooldown and additional mass and energy release in containment. Manual main feedwater isolation is required to be OPERABLE in MODE 4 when the main feedwater isolation valves are open. This Function is not applicable in MODE 4 for valve isolation if the main feedwater line is isolated. Automatic actuation on a Steam Generator Narrow Range Water Level – High 2 is required to be OPERABLE in MODE 4 when the RCS is not being

cooled by the RNS. In MODES 5 and 6, the energy in the RCS and the steam generators is low and this Function is not required to be OPERABLE.

7.a. Manual Main Feedwater Isolation

The Main Feedwater Pump Trip and Valve Isolation is also initiated by the Manual Main Feedwater Control Valve Isolation Function. The requirements for this Function are the same as the requirements for Manual Main Feedwater Control Valve Isolation (Function 6.a). Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 6.a is referenced for all requirements.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

7.b. Steam Generator Narrow Range Water Level – High 2

This signal provides protection against excessive feedwater flow by closing the main feedwater control, isolation and crossover valves, tripping of the main feedwater pumps, and tripping the turbine. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. The transmitters (d/p cells) are located inside containment. However, the events which this Function protect against cannot cause severe environment in containment. Therefore, the Setpoint reflects only steady state instrument uncertainties.

7.c. Safeguards Actuation (Function 1)

This Function is also initiated by all Functions that initiate the Safeguards Actuation signal. The Main Feedwater Pump Trip and Valve Isolation Function requirements are the same as the requirements for their Safeguards Actuation Function, but do not apply in MODE 4 with the flow paths isolated. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 1 is referenced for all initiating Functions and requirements. The Safeguards Actuation signal closes all main feedwater control, isolation and crossover valves, trips all main feedwater pumps, and trips the turbine.

7.d. T_{avg} Low-2 Coincident with Reactor Trip (P-4)

This signal provides protection against excessive feedwater flow by closing the main feedwater isolation and crossover leg valves, and tripping of the main feedwater pumps. This signal results from a coincidence of two out of four divisions of reactor loop average temperature below the Low 2 setpoint coincident with the P-4 permissive. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure that no single random failure will disable this trip Function. This Function may be manually blocked when the pressurizer pressure is below the P-11 setpoint. The block is automatically removed when the pressurizer pressure is above the P-11 setpoint.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

8. Startup Feedwater Isolation

The primary Function of the Startup Feedwater Isolation is to stop the excessive flow of feedwater into the SGs. This Function is necessary in MODES 1, 2, 3, and 4 to mitigate the effects of a large SLB or a large FLB. Failure to isolate the startup feedwater system following a SLB or FLB can lead to additional mass and energy being delivered to the steam generators, resulting in excessive cooldown and additional mass and energy release in containment.

Startup feedwater isolation must be OPERABLE in MODES 1, 2, 3, and 4 when there is significant mass and energy in the RCS and the steam generators. This Function is not applicable in MODE 4 when the startup feedwater flow paths are isolated. In MODES 5 and 6, the energy in the RCS and the steam generators is low and this Function is not required to be OPERABLE.

8.a. Steam Generator (SG) Narrow Range Water Level – High 2

If steam generator narrow range level reaches the High 2 setpoint in either steam generator, then all startup feedwater control and isolation valves are closed and the startup feedwater pumps are tripped. Four channels are provided in each steam generator to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

8.b. T_{cold} – Low

This Function closes the startup feedwater control and isolation valves and trips the startup feedwater pumps if reactor coolant system cold leg temperature is below the T_{cold} setpoint in any loop. Startup feedwater isolation on this condition may be manually blocked when the pressurizer pressure is below the P-11 setpoint. This function is automatically unblocked when the pressurizer pressure is above the P-11 setpoint with the RCS boron concentration below that necessary to meet the SDM requirements at an RCS temperature of 200°F. Four channels are provided in each loop to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

8.c. Manual Main Feedwater Control Valve Isolation (Function 6.a)

The Startup Feedwater Isolation is also initiated by the Manual Main Feedwater Control Valve Isolation Function. The requirements for this Function are the same as the requirements for the Manual Main Feedwater Control Valve Isolation (Function 6.a). Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 6.a is referenced for all requirements.

8.d. Steam Generator Narrow Range Level – High Coincident with Reactor Trip (P-4)

If steam generator narrow range level reaches the High setpoint in either steam generator coincident with a Reactor Trip (P-4), then all startup feedwater control and isolation valves are closed and the startup feedwater pumps are tripped. Four channels are provided in each steam generator to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this function.

9. ADS Stages 1, 2, & 3 Actuation

The Automatic Depressurization System (ADS) provides a sequenced depressurization of the reactor coolant system to allow passive injection from the CMTs, accumulators, and the in-containment refueling water storage tank (IRWST) to mitigate the effects of a LOCA. The depressurization is accomplished in four stages, with the first three stages discharging into the IRWST and the last stage discharging into containment. Each of the first three stages consists of two parallel paths with each path containing an isolation valve and a depressurization valve.

The first stage isolation valves open on any ADS Stages 1, 2, and 3 actuation. The first stage depressurization valves are opened following a preset time delay after the actuation of the isolation valves. The second stage isolation valves are opened following a preset time delay after actuation of the first stage depressurization valves open. The second stage depressurization valves are opened following a preset time delay after the second stage isolation valves are actuated, similar to stage one. Similar to the second stage, the third stage isolation valves are opened following a preset time delay after the actuation of the second stage depressurization valves. The third stage depressurization valves are opened following a preset time delay after the third stage isolation valves are actuated.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

9.a. Manual Initiation

The first stage depressurization valves open on manual actuation. Any ADS Stages 1, 2, and 3 actuation also actuates PRHR and trips all reactor coolant pumps. The operator can initiate an ADS Stages 1, 2, and 3 actuation from the main control room by simultaneously actuating two ADS actuation devices in the same set. There are two sets of two switches each in the main control room. Simultaneously actuating the two devices in either set will actuate ADS Stages 1, 2, and 3. This Function must be OPERABLE in MODES 1, 2, 3, and 4. This Function must also be OPERABLE in MODES 5 and 6 when the required ADS valves are not open, and in MODE 6 with the upper internals in place. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS - Shutdown, RCS Intact and LCO 3.4.13, ADS - Shutdown, RCS Open.

9.b. CMT Level – Low 1 Coincident with CMT Actuation

This Function ensures continued passive injection or borated water to the RCS following a small break LOCA. ADS Stages 1, 2 and 3 actuation is initiated when the CMT Level reaches its Low 1 Setpoint coincident with any CMT Actuation signal (Function 2). Four channels are provided in each CMT to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

The ADS Stages 1, 2, and 3 Actuation Function requirements are the same as the requirements discussed in Function 2 (CMT Actuation). Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 2 is referenced for all initiating functions and requirements. This Function must be OPERABLE in MODES 1, 2, 3, and 4.

This Function must also be OPERABLE in MODE 5 with pressurizer level ≥ 20% and the required ADS valves not open. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS - Shutdown, RCS Intact and LCO 3.4.13, ADS - Shutdown, RCS Open. In MODE 5, only one CMT is required to be OPERABLE in accordance with LCO 3.5.3, CMTs - Shutdown, RCS Intact; therefore, CMT level channels are only required on an OPERABLE CMT.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

10. ADS Stage 4 Actuation

The ADS provides a sequenced depressurization of the reactor coolant system to allow passive injection from the CMTs, accumulators, and the IRWST to mitigate the effects of a LOCA. The depressurization is accomplished in four stages, with the first three stages discharging into the IRWST and the fourth stage discharging into containment.

The fourth stage of the ADS consists of four parallel paths. Each of these paths consists of a normally open isolation valve and a depressurization valve. The four paths are divided into two groups with two paths in each group. Within each group, one path is designated to be substage A and the second path is designated to be substage B.

The substage A depressurization valves are opened following a preset time delay after the substage A isolation valve confirmatory open signal. The sequence is continued with substage B. A confirmatory open signal is provided to the substage B isolation valves following a preset time delay after the substage A depressurization valve has been opened. The signal to open the substage B depressurization valve is provided following a preset time delay after the substage B isolation valves confirmatory open signal.

10.a. Manual Initiation Coincident with RCS Wide Range Pressure – Low or ADS Stages 1, 2, and 3 Actuation (Function 9)

The fourth stage depressurization valves open on manual actuation. The operator can initiate Stage 4 of ADS from the main control room. There are two sets of two switches each in the main control room. Actuating the two switches in either set will actuate all 4th stage ADS valves. This manual actuation is interlocked to actuate with either the low RCS pressure signal or with the ADS Stages 1, 2, & 3 actuation (Function 9). These interlocks minimize the potential for inadvertent actuation of this Function. This interlock with Function 9 allows manual actuation of this Function if automatic or manual actuation of the ADS Stages 1, 2, & 3 valves fails to depressurize the RCS due to common-mode failure. This consideration is important in PRA modeling to improve the reliability of reducing the RCS pressure following a small LOCA or transient event. This Function must be OPERABLE in MODES 1, 2, 3, and 4. This Function must also be OPERABLE in MODES 5 and 6 when the required ADS valves

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

are not open, and in MODE 6 with the upper internals in place. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS - Shutdown, RCS Intact and LCO 3.4.13, ADS - Shutdown, RCS Open.

10.b. CMT Level – Low 2 Coincident with RCS Wide Range Pressure – Low

The fourth stage depressurization valves open on CMT Level – Low 2 in two-out-of-four channels in either CMT. Actuation of the fourth stage depressurization valves is interlocked with the third stage depressurization signal such that the fourth stage is not actuated unless the third stage has been previously actuated following a preset time delay. Actuation of the fourth stage ADS valves are further interlocked with a low RCS pressure signal such that the ADS Stage 4 actuation is not actuated unless the RCS pressure is below a predetermined setpoint. Four channels of CMT level are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. This Function must be OPERABLE in MODES 1, 2, 3, and 4. This Function must also be OPERABLE in MODE 5 when the required ADS valves are not open and with the pressurizer level ≥ 20%. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS - Shutdown, RCS Intact and LCO 3.4.13, ADS - Shutdown, RCS Open. In MODE 5, only one CMT is required to be OPERABLE in accordance with LCO 3.5.3, CMTs - Shutdown, RCS Intact; therefore, CMT level channels are only required on an OPERABLE CMT.

10.c. Coincident RCS Loop 1 and 2 Hot Leg Level – Low

A signal to automatically open the ADS Stage 4 is also generated when coincident loop 1 and 2 reactor coolant system hot leg level indication decreases below an established setpoint for a duration exceeding an adjustable time delay. This Function is required to be OPERABLE in MODE 4 with the RCS being cooled by the RNS. This Function is also required to be OPERABLE in MODE 5 and in MODE 6 when the required ADS valves are not open. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS - Shutdown, RCS Intact and LCO 3.4.13, ADS - Shutdown, RCS Open.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

11. Reactor Coolant Pump Trip

Reactor Coolant Pump (RCP) Trip allows the passive injection of borated water into the RCS. Injection provides RCS makeup water and boration during transients or accidents when the normal makeup supply from the CVS is lost or insufficient. Two tanks provide passive injection of borated water by gravity when the reactor coolant pumps are tripped. CMT injection mitigates the effects of high energy line breaks by adding primary side water to ensure maintenance or recovery of reactor vessel water level following a LOCA, and by borating to ensure recovery or maintenance of SHUTDOWN MARGIN following a steam line break. RCP trip on high bearing water temperature protects the RCP coast down. A high bearing water temperature trip signal will result in the tripping of all the RCPs. RCP trip is actuated by High RCP bearing water temperature, ADS Stages 1, 2, and 3 Actuation (Function 9), Manual CMT Actuation (Function 2.a), Pressurizer Water Level – Low 2, and Safeguards Actuation (Function 1).

11.a. ADS Stage 1, 2, and 3 Actuation (Function 9)

The RCPs are tripped any time ADS Stage 1, 2, and 3 actuation is initiated. The RCP trip Function requirements for the ADS Stage 1, 2, and 3 actuation are the same as the requirements for the ADS Function. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 9 is referenced for all initiating functions and requirements.

11.b. Reactor Coolant Pump Bearing Water Temperature – High

The RCPs are tripped if two-out-of-four sensors on any RCP indicate high bearing water temperature. This Function is required to be OPERABLE in MODES 1 and 2. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

11.c. Manual CMT Actuation (Function 2.a)

RCP trip is also initiated by the manual CMT actuation Function. The RCP trip Function requirements are the same as the requirements for the manual CMT actuation Function. Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 2.a is referenced for all requirements.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

11.d. Pressurizer Water Level – Low 2

The RCPs are tripped when the pressurizer water level reaches its Low 2 setpoint. This signal results from the coincidence of pressurizer water level below the Low 2 setpoint in any two-of-four divisions. This Function is required to be OPERABLE in MODES 1, 2, 3, and 4. This Function is also required to be OPERABLE in MODE 5 with pressurizer level ≥ 20%, when the RCS is not being cooled by the RNS. This Function can be manually blocked when the pressurizer water level is below the P-12 setpoint. This Function is automatically unblocked when the pressurizer water level is above the P-12 setpoint.

11.e. Safeguards Actuation (Function 1)

This Function is also initiated by all Functions that initiated the Safeguards Actuation signal. The requirements for the reactor trip Functions are the same as the requirements for the Safeguards Actuation Function. Therefore, the requirements are not repeated in Table 3.3.2.1. Instead, Function 1 is referenced for all initiating Functions and requirements.

12. Passive Containment Cooling Actuation

The Passive Containment Cooling System (PCS) transfers heat from the reactor containment to the environment. This Function is necessary to prevent the containment design pressure and temperature from being exceeded following any postulated DBA (such as LOCA or SLB). Heat removal is initiated automatically in response to a Containment Pressure – High 2 signal or manually.

A Passive Containment Cooling Actuation signal initiates water flow by gravity by opening the isolation valves. The water flows onto the containment dome, wetting the outer surface. The path for natural circulation of air along the outside walls of the containment structure is always open.

The LCO requires this Function to be OPERABLE in MODES 1, 2, 3, and 4 when the potential exists for a DBA that could require the operation of the Passive Containment Cooling System. In MODES 5 and 6, with decay heat more than 6.0 MWt, manual initiation of the PCS provides containment heat removal. Section B 3.6.7, Applicability, provides the basis for the decay heat limit.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

12.a. Manual Initiation

The operator can initiate Containment Cooling at any time from the main control room by actuating either of the two containment cooling actuation switches. There are two switches in the main control room, either of which will actuate containment cooling in all divisions. Manual Initiation of containment cooling also actuates containment isolation.

12.b. Containment Pressure – High 2

This signal provides protection against a LOCA or SLB inside containment. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

The transmitters and electronics are located outside containment; thus, they will not experience harsh environmental conditions. The Containment Pressure – High 2 setpoint has been specified as low as reasonable, without creating potential for spurious trips during normal operations, consistent with the TMI action item (NUREG-0933, Item II.E.4.2) guidance.

13. PRHR Heat Exchanger Actuation

The PRHR Heat Exchanger (HX) provides emergency core decay heat removal when the Startup Feedwater System is not available to provide a heat sink. PRHR is actuated when the discharge valves are opened in response to Steam Generator Narrow Range (NR) Level – Low coincident with Startup Feedwater Flow – Low, Steam Generator Wide Range (WR) Level – Low, ADS Stages 1, 2, and 3 Actuation, CMT Actuation, Pressurizer Water Level – High 3, or Manual Initiation.

13.a. Manual Initiation

Manual PRHR actuation is accomplished by either of two switches in the main control room. Either switch actuates all four ESFAC Divisions.

This Function is required to be OPERABLE in MODES 1, 2, 3, and 4, and MODE 5 with the RCS pressure boundary intact. This ensures that PRHR can be actuated in the event of a loss of the normal heat removal systems.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

13.b. Steam Generator Narrow Range Level – Low Coincident with Startup Feedwater Flow – Low

PRHR is actuated when the Steam Generator Narrow Range Level reaches its low setpoint coincident with an indication of low Startup Feedwater Flow.

The LCO requires four channels per steam generator to be OPERABLE to satisfy the requirements with a two-out-of-four logic. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. The Setpoint reflects both steady state and adverse environmental instrument uncertainties as the detectors provide protection for an event that results in a harsh environment.

Startup Feedwater Flow – Low uses a one-out-of-two logic on each of the two startup feedwater lines. This Function is required to be OPERABLE in MODES 1, 2, and 3 and in MODE 4 when the RCS is not being cooled by the Normal Residual Heat Removal System (RNS). This ensures that PRHR can be actuated in the event of a loss of the normal heat removal systems. In MODE 4 when the RCS is being cooled by the RNS, and in MODES 5 and 6, the SGs are not required to provide the normal RCS heat sink. Therefore, startup feedwater flow is not required, and PRHR actuation on low startup feedwater flow is not required.

13.c. Steam Generator Wide Range Level – Low

PRHR is also actuated when the SG Wide Range Level reaches its Low Setpoint. There are four wide range level channels for each steam generator and a two-out-of-four logic is used. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. This Function is required to be OPERABLE in MODES 1, 2, and 3 and in MODE 4 when the RCS is not being cooled by the RNS. This ensures that PRHR can be actuated in the event of a loss of the normal heat removal systems. In MODE 4 when the RCS is being cooled by the RNS, and in MODES 5 and 6, the SGs are not required to provide the normal RCS heat sink. Therefore, SG Wide Range Level is not required, and PRHR actuation on low wide range SG level is not required.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

13.d. ADS Stages 1, 2, and 3 Actuation

PRHR is also actuated any time ADS Stages 1, 2, and 3 Actuation is initiated. The PRHR actuation Function requirements for the ADS Stages 1, 2, and 3 actuation are the same as the requirements for the ADS Stages 1, 2, and 3 Actuation Function, but only in MODES 2, 3, and 4, and in MODE 5 with the RCS pressure boundary intact.

13.e. CMT Actuation (Function 2)

PRHR is also actuated by all the Functions that actuate CMT injection. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 2 (CMT Actuation) is referenced for all initiating functions and requirements.

13.f. Pressurizer Water Level – High 3

PRHR is actuated when the pressurizer water level reaches its High 3 setpoint. This signal provides protection against a pressurizer overfill following an inadvertent core makeup tank actuation with consequential loss of offsite power. This Function is automatically unblocked when RCS pressure is above the P-19 setpoint. This Function is required to be OPERABLE in MODES 1, 2, and 3, and in MODE 4 when the RCS is not being cooled by the RNS and above the P-19 (RCS pressure) interlock. This Function is not required to be OPERABLE in MODES 5 and 6 because it is not required to mitigate DBA in these MODES.

14. Steam Generator Blowdown Isolation

The primary Function of the steam generator blowdown isolation is to ensure that sufficient water inventory is present in the steam generators to remove the excess heat being generated until the decay heat has decreased to within the PRHR HX capability.

This Function closes the isolation valves of the Steam Generator Blowdown System in both steam generators when a signal is generated from the PRHR HX Actuation or Steam Generator Narrow Range Water Level – Low. This Function is required to be OPERABLE in MODES 1, 2, and 3, and in MODE 4 when the RCS is not being cooled by the RNS. This Function is not required to be

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

OPERABLE in MODE 4 if the steam generator blowdown line is isolated.

14.a. PRHR Heat Exchanger Actuation (Function 13)

Steam Generator Blowdown Isolation is also initiated by all Functions that initiate PRHR actuation. The Steam Generator Blowdown Isolation requirements for these Functions are the same as the requirements for the PRHR Actuation. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 13, PRHR HX Actuation, is referenced for all initiating Functions and requirements.

14.b. Steam Generator Narrow Range Level – Low

The Steam Generator Blowdown isolation is actuated when the Steam Generator Narrow Range Level reaches its Low Setpoint.

The LCO requires four channels per steam generator to be OPERABLE to satisfy the requirements with a two-out-of-four logic. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function. Setpoint reflects both steady state and adverse environmental instrument uncertainties as the detectors provide protection for an event that results in a harsh environment.

15. Boron Dilution Block

The block of boron dilution is accomplished by closing the CVS suction valves to demineralized water storage tanks, and aligning the boric acid tank to the CVS makeup pumps. This Function is actuated by Source Range Neutron Flux Doubling and Reactor Trip.

15.a. Source Range Neutron Flux Doubling

A signal to block boron dilution in MODES 2 or 3, when not critical or during an intentional approach to criticality, and MODES 4 or 5 is derived from source range neutron flow increasing at an excessive rate (source range flux doubling). This Function is not applicable in MODES 4 and 5 if the demineralized water makeup flow path is isolated. The source

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

range neutron detectors are used for this Function. The LCO requires four divisions to be OPERABLE. There are four divisions and two-out-of-four logic is used. On a coincidence of excessively increasing source range neutron flux in two of the four divisions, demineralized water is isolated from the makeup pumps and reactor coolant makeup is isolated from the reactor coolant system to preclude a boron dilution event. In MODE 6, a dilution event is precluded by the requirement in LCO 3.9.2 to close, lock and secure at least one valve in each unborated water source flow path.

15.b. Reactor Trip (Function 18.b)

Demineralized Water Makeup is also isolated by all the Functions that initiate a Reactor Trip. The isolation requirements for these Functions are the same as the requirements for the Reactor Trip Function. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 18.b, (P-4 Reactor Trip Breakers), is referenced for all initiating Functions and requirements.

16. Chemical Volume and Control System Makeup Line Isolation

The CVS makeup line is isolated following certain events to prevent overfilling of the RCS. In addition, this line is isolated on High 2 containment radioactivity to provide containment isolation following an accident. This line is not isolated on a containment isolation signal, to allow the CVS makeup pumps to perform their defense-in-depth functions. However, if very high containment radioactivity exists (above the High 2 setpoint) this line is isolated.

A signal to isolate the CVS is derived from two-out-of-four high steam generator levels on either steam generator, two-out-of-four channels of pressurizer level indicating high or two-out-of-four channels of containment radioactivity indicating high. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

16.a. Steam Generator Narrow Range Water Level – High 2

Four channels of steam generator level are provided for each steam generator. Two-out-of-four channels on either steam generator indicating level greater than the setpoint will close the isolation valves for the CVS. This Function prevents adding makeup water to the RCS during a SGTR. This Function is required to be OPERABLE in MODES 1, 2, 3, and 4 with the RCS not being cooled by the RNS. This Function is not applicable in MODES 3 and 4 if the CVS makeup flow path is isolated. This Function is not required to be OPERABLE in MODES 5 and 6 because the RCS pressure and temperature are reduced and a steam generator tube rupture event is not credible.

16.b. Pressurizer Water Level – High 1 Coincident with Safeguards Actuation

Four channels of pressurizer level are provided on the pressurizer. Two-out-of-four channels on indicating level greater than the High 1 setpoint coincident with a Safeguards Actuation signal (Function 1) will close the containment isolation valves for the CVS. This Function prevents the pressurizer level from reaching a level that could lead to water relief through the pressurizer safety valves during some DBAs. This Function is required to be OPERABLE in MODES 1, 2, and 3. This function is not required to be OPERABLE in MODES 4, 5, and 6, because it is not required to mitigate a DBA in these MODES. This Function is not applicable in MODE 3, if the CVS makeup flow path is isolated.

16.c. Pressurizer Water Level – High 2

A signal to close the CVS isolation valves is generated on Pressurizer Water Level – High 2. This Function results from the coincidence of pressurizer level above the High 2 setpoint in any two of the four divisions. This Function is automatically blocked when the pressurizer pressure is below the P-11 permissive setpoint to permit pressurizer water solid conditions with the plant cold and to permit level makeup during plant cooldowns. This Function is automatically unblocked when RCS pressure is above the P-19 setpoint. This Function is required to be OPERABLE in MODES 1, 2, and 3 and in MODE 4 when the RCS is not being cooled by the RNS. This Function is not required to be OPERABLE in MODE 4 if the

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

CVS makeup flow path is isolated. This Function is not required to be OPERABLE in MODES 5 and 6 because it is not required to mitigate a DBA in these MODES.

16.d. Containment Radioactivity – High 2

Four channels of Containment Radioactivity – High 2 are required to be OPERABLE in MODES 1, 2, and 3 when the potential exists for a LOCA, to ensure that the radioactivity inside containment is not released to the atmosphere. This Function is not required to be OPERABLE in MODE 3 if the associated flow path is isolated. This signal results from the coincidence of containment radioactivity above the High 2 Setpoint in any two of the four divisions. These Functions are not required to be OPERABLE in MODES 4, 5, and 6 because there is no credible release of radioactivity into the containment in these MODES that would result in a High 2 actuation.

16.e Manual Initiation

Manual Chemical Volume Control System Makeup Isolation is actuated by either of two switches in the main control room. Either switch closes Chemical Volume Control System Makeup valves. The LCO requires two switches to be OPERABLE.

16.f. Source Range Neutron Flux Doubling (Function 15.a)

Chemical Volume Control System Makeup Isolation is actuated by the Source Range Neutron Flux Doubling Function. The Source Range Neutron Flux Doubling Function requirements are the same as the requirements for Boron Dilution Block Function 15.a, Source Range Neutron Flux Doubling. Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 15.a is referenced for all requirements.

16.g. Steam Generator Narrow Range Water Level – High Coincident with Reactor Trip (P-4)

Four channels of steam generator level are provided for each steam generator. Two-out-of-four channels on either steam generator indicating level greater than the setpoint will close the isolation valves for the CVS. This Function prevents

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

adding makeup water to the RCS during an SGTR. This Function is required to be OPERABLE in MODES 1, 2, 3, and 4 with the RCS not being cooled by the RNS. This Function is not applicable in MODES 3 and 4 if the CVS makeup flow path is isolated. This Function is not required to be OPERABLE in MODES 5 and 6 because the RCS pressure and temperature are reduced and a steam generator tube rupture event is not credible.

17. Normal Residual Heat Removal System Isolation

The RNS suction line is isolated by closing the containment isolation valves on High 2 containment radioactivity to provide containment isolation following an accident. This line is isolated on a safeguards actuation signal. However, the valves may be reset to permit the RNS pumps to perform their defense-in-depth functions post accident. Should a high containment radiation signal (above the High 2 setpoint) develop following the containment isolation signal, the RNS valves would re-close. A high containment radiation signal is indicative of a high RCS source term and the valves would re-close to assure offsite doses do not exceed regulatory limits.

17.a. Containment Radioactivity – High 2

A signal to isolate the normal residual heat removal system is generated from the coincidence of containment radioactivity above the High 2 setpoint in two-out-of-four channels. Four channels of Containment Radioactivity – High 2 are required to be OPERABLE in MODES 1, 2, and 3 when the potential exists for a LOCA, to ensure that the radioactivity inside containment is not released to the atmosphere. This Function is not required to be OPERABLE in MODE 3 if the RNS suction line is isolated. These Functions are not required to be OPERABLE in MODES 4, 5, and 6 because no DBA that could release radioactivity into the containment is considered credible in these MODES.

17.b. Safeguards Actuation (Function 1)

This Function is also initiated by all Functions that initiated the Safeguards Actuation signal. The requirements to isolate the normal residual heat removal system are the same as the requirements for the Safeguards Actuation Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Therefore, the requirements are not repeated in Table 3.3.2.1. Instead, Function 1 is referenced for all initiating Functions and requirements.

17.c Manual Initiation

The operator can initiate RNS isolation at any time from the control room by simultaneously actuating two switches in the same actuation set. Because an inadvertent actuation of RNS isolation could have serious consequences, two switches must be actuated simultaneously to initiate isolation. There are two sets of two switches in the control room. Simultaneously actuating the two switches in either set will isolate the RNS in the same manner as the automatic actuation signal. Two Manual Initiation switches in each set are required to be OPERABLE to ensure no single failure disables the Manual Initiation Function.

18. ESFAS Interlocks

To allow some flexibility in unit operations, several interlocks are included as part of the ESFAS. These interlocks permit the operator to block some signals, automatically enable other signals, prevent some actions from occurring, and cause other actions to occur. The interlock Functions backup manual actions to ensure bypassable Functions are in operation under the conditions assumed in the safety analyses.

18.a. Reactor Trip Breaker Open, P-3

The P-3 interlock is provided to permit the block of automatic Safeguards Actuation after a predetermined time interval following automatic Safeguards Actuation.

The reactor trip breaker position switches that provide input to the P-3 interlock only function to energize or de-energize (open or close) contacts. Therefore, this Function does not have an adjustable trip setpoint.

18.b. Reactor Trip, P-4

There are eight reactor trip breakers with two breakers in each division. The P-4 interlock is enabled when the breakers in two-out-of-four divisions are open. Additionally, the P-4 interlock is enabled by all Automatic Reactor Trip Actuations. The Functions of the P-4 interlock are:

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

- Trip the main turbine
- Block boron dilution
- Isolate main feedwater coincident with low reactor coolant temperature (This function is not assumed in safety analysis therefore, it is not included in the technical specifications.)

The reactor trip breaker position switches that provide input to the P-4 interlock only function to energize or de-energize or open or close contacts. Therefore, this Function has no adjustable trip setpoint.

This Function must be OPERABLE in MODES 1, 2, and 3 when the reactor may be critical or approaching criticality. This Function does not have to be OPERABLE in MODE 4, 5, or 6 to trip the main turbine, because the main turbine is not in operation.

The P-4 Function does not have to be OPERABLE in MODE 4 or 5 to block boron dilution, because Function 15.a, Source Range Neutron Flux Doubling, provides the required block. In MODE 6, the P-4 interlock with the Boron Dilution Block Function is not required, since the unborated water source flow path isolation valves are locked closed in accordance with LCO 3.9.2.

18.c. Intermediate Range Neutron Flux, P-6

The Intermediate Range Neutron Flux, P-6 interlock is actuated when the respective NIS intermediate range channel increases to approximately one decade above the channel lower range limit. Below the setpoint, the P-6 interlock automatically unblocks the flux doubling function, permitting the block of boron dilution. Normally, this Function is blocked by the main control room operator during reactor startup. This Function is required to be OPERABLE in MODE 2.

18.d. Pressurizer Pressure, P-11

The P-11 interlock permits a normal unit cooldown and depressurization without Safeguards Actuation or main steam line and feedwater isolation. With pressurizer pressure channels less than the P-11 setpoint, the operator can manually block the Pressurizer pressure – Low, Steam Line

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Pressure – Low, and T_{cold} – Low Safeguards Actuation signals and the Steam Line Pressure – Low and T_{cold} – Low steam line isolation signals. When the Steam Line Pressure – Low is manually blocked, a main steam isolation signal on Steam Line Pressure-Negative Rate – High is enabled. This provides protection for an SLB by closure of the main steam isolation valves. Manual block of feedwater isolation on T_{avg} – Low 1, Low 2, and T_{cold} – Low is also permitted below P-11. With pressurizer pressure channels ≥ P-11 setpoint, the Pressurizer Pressure – Low, Steam Line Pressure – Low, and T_{cold} – Low Safeguards Actuation signals and the Steam Line Pressure Low and T_{cold} – Low steam line isolation signals are automatically enabled. The feedwater isolation signals on T_{cold} – Low, T_{avg} – Low 1 and Low 2 are also automatically enabled above P-11. The operator can also enable these signals by use of the respective manual reset buttons. When the Steam Line Pressure – Low and T_{cold} – Low steam line isolation signals are enabled, the main steam isolation on Steam Line Pressure-Negative Rate – High is disabled. The Setpoint reflects only steady state instrument uncertainties.

This Function must be OPERABLE in MODES 1, 2, and 3 to allow an orderly cooldown and depressurization of the unit without the Safeguards Actuation or main steam or feedwater isolation. This Function does not have to be OPERABLE in MODE 4, 5, or 6, because plant pressure must already be below the P-11 setpoint for the requirements of the heatup and cooldown curves to be met.

18.e. Pressurizer Level, P-12

The P-12 interlock is provided to permit midloop operation without core makeup tank actuation, reactor coolant pump trip, CVS letdown isolation, or purification line isolation. With pressurizer level channels less than the P-12 setpoint, the operator can manually block low pressurizer level signal used for these actuations. Concurrent with blocking CMT actuation on low pressurizer level, ADS 4^{th} Stage actuation on Low 2 RCS hot leg level is enabled. Also CVS letdown isolation on Low 1 RCS hot leg level is enabled. When the pressurizer level is above the P-12 setpoint, the pressurizer level signal is automatically enabled and a confirmatory open signal is issued to the isolation valves on the CMT cold leg balance lines. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

18.f. RCS Pressure, P-19

The P-19 interlock is provided to permit water solid conditions (i.e., when the pressurizer water level is >92%) in lower MODES without automatic isolation of the CVS makeup pumps. With RCS pressure below the P-19 setpoint, the operator can manually block CVS isolation on High 2 pressurizer water level, and block Passive RHR actuation and Pressurizer Heater Trip on High 3 pressurizer water level. When RCS pressure is above the P-19 setpoint, these Functions are automatically unblocked. This Function is required to be OPERABLE IN MODES 1, 2, 3, and 4 with the RCS not being cooled by the RNS. When the RNS is cooled by the RNS, the RNS suction relief valve provides the required overpressure protection (LCO 3.4.14).

19. Containment Air Filtration System Isolation

Some DBAs such as a LOCA may release radioactivity into the containment where the potential would exist for the radioactivity to be released to the atmosphere and exceed the acceptable site dose limits. Isolation of the Containment Air Filtration System provides protection to prevent radioactivity inside containment from being released to the atmosphere.

19.a. Containment Radioactivity – High 1

Three channels of Containment Radioactivity – High 1 are required to be OPERABLE in MODES 1, 2, 3, and 4 with the RCS not being cooled by the RNS, when the potential exists for a LOCA, to protect against radioactivity inside containment being released to the atmosphere. These Functions are not required to be OPERABLE in MODE 4 with the RCS being cooled by the RNS or MODES 5 and 6, because any DBA release of radioactivity into the containment in these MODES would not require containment isolation.

19.b. Containment Isolation (Function 3)

Containment Air Filtration System Isolation is also initiated by all Functions that initiate Containment Isolation. The Containment Air Filtration System Isolation requirements for these Functions are the same as the requirements for the Containment Isolation. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 3, Containment

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Isolation, is referenced for initiating Functions and requirements.

20. Main Control Room Isolation and Air Supply Initiation

Isolation of the main control room and initiation of the air supply provides a protected environment from which operators can control the plant following an uncontrolled release of radioactivity. This Function is required to be OPERABLE in MODES 1, 2, 3, and 4, and during movement of irradiated fuel because of the potential for a fission product release following a fuel handling accident, or other DBA.

20.a. Control Room Air Supply Radiation – High 2

Two radiation monitors are provided on the main control room air intake. If either monitor exceeds the High 2 setpoint, control room isolation is actuated.

21. Auxiliary Spray and Purification Line Isolation

The CVS maintains the RCS fluid purity and activity level within acceptable limits. The CVS purification line receives flow from the discharge of the RCPs. The CVS also provides auxiliary spray to the pressurizer. To preserve the reactor coolant pressure in the event of a break in the CVS loop piping, the purification line and the auxiliary spray line are isolated on a pressurizer water level Low 1 setpoint. This helps maintain reactor coolant system inventory.

21.a. Pressurizer Water Level – Low 1

A signal to isolate the purification line and the auxiliary spray line is generated upon the coincidence of pressurizer level below the Low 1 setpoint in any two-out-of-four divisions. This Function is required to be OPERABLE in MODES 1 and 2 to help maintain RCS inventory. In MODES 3, 4, 5, and 6, this Function is not needed for accident detection and mitigation.

21.b. Manual Chemical Volume Control System Makeup Isolation (Function 16.e)

The Auxiliary Spray and Purification Line Isolation is also initiated by the Manual Chemical Volume Control System Makeup Isolation Function. The requirements for this Function are the same as the requirements for Manual Chemical

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

Volume Control System Makeup Isolation (Function 16.e), but only apply in MODES 1 and 2. Therefore, the requirements are not repeated in Table 3.3.2-1, and Function 16.e is referenced for all requirements.

22. IRWST Injection Line Valve Actuation

The PXS provides core cooling by gravity injection and recirculation for decay heat removal following an accident. The IRWST has two injection flow paths. Each injection path includes a normally open motor operated isolation valve and two parallel lines, each isolated by one check valve and one squib valve in series. Manual initiation or automatic actuation on an ADS Stage 4 actuation signal or a coincident RCS Loops 1 and 2 Hot Leg Level-Low will generate a signal to open the IRWST injection line and actuate IRWST injection.

22.a. Manual Initiation

The operator can open IRWST injection line valves at any time from the main control room by actuating two IRWST injection actuation switches in the same actuation set. There are two sets of two switches each in the main control room. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6.

22.b. ADS Stage 4 Actuation (Function 10)

An open signal will be issued to the IRWST injection isolation valves when an actuation signal is issued to the ADS Stage 4 valves. The requirements for this function are the same as the requirements for the ADS Stage 4 Actuation Function. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 10 is referenced for all initiating functions and requirements.

23. IRWST Containment Recirculation Valve Actuation

The PXS provides core cooling by gravity injection and recirculation for decay heat removal following an accident. The PXS has two containment recirculation flow paths. Each path contains two parallel flow paths, one path is isolated by a motor operated valve in series with a squib valve and one path is isolated by a check valve in series with a squib valve. Manual initiation or automatic actuation on a Safeguards Actuation signal coincident with a Low 3 level signal in the IRWST will open these valves.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

23.a. Manual Initiation

The operator can open the containment recirculation valves at any time from the main control room by actuating two containment recirculation actuation switches in the same actuation set. There are two sets of two switches each in the main control room. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6.

23.b. ADS Stage 4 Actuation Coincident with IRWST Level – Low 3

A low IRWST level coincident with a ADS Stage 4 Actuation signal will open the containment recirculation valves. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure that no single random failure will disable this trip Function. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6, except when the ADS Stage 4 valves are open or an equivalent relief area is open. The required ADS valves or equivalent relief area are specified in LCO 3.4.12, ADS – Shutdown, RCS Intact and LCO 3.4.13, ADS – Shutdown, RCS Open.

24. Refueling Cavity Isolation

The containment isolation valves in the lines between the refueling cavity and the Spent Fuel Pool Cooling System are isolated on a Low spent fuel pool level.

24.a. Spent Fuel Pool Level – Low

In the event of a leak in the non-safety Spent Fuel Pool Cooling System, closure of the containment isolation valves on low spent fuel pool level in two of three channels will terminate draining of the refueling cavity. Since the transfer canal is open in MODE 6, the spent fuel pool level is the same as the refueling cavity.

Draining of the spent fuel pool, directly, through a leaking Spent Fuel Pool Cooling System is limited by the location of the suction piping, which is near the top of the pool. Therefore, closure of the containment isolation valves between the refueling cavity and the Spent Fuel Pool Cooling System is sufficient to terminate refueling cavity and spent fuel pool leakage through the Spent Fuel Pool Cooling System. This Function is required in MODE 6 to maintain water inventory in the refueling cavity.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

25. ESF Logic

This LCO requires four sets of ESF coincidence logic, each set with one battery backed logic group OPERABLE to support automatic actuation. These logic groups are implemented as processor based actuation subsystems. The ESF coincidence logic provides the system level logic interfaces for the divisions.

25.a. Coincidence Logic

If one division of battery backed coincidence logic is OPERABLE, an additional single failure will not prevent ESF actuations because three divisions will still be available to provide redundant actuation for all ESF Functions. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6.

26. ESF Actuation

This LCO requires that for each division of ESF actuation, one battery backed logic group be OPERABLE to support both automatic and manual actuation. The ESF actuation subsystems provide the logic and power interfaces for the actuated components.

26.a. Actuation Subsystem

If one battery backed logic group is OPERABLE for the ESF actuation subsystem in all four divisions, an additional single failure will not prevent ESF actuations because ESF actuation subsystems in the other three divisions are still available to provide redundant actuation for ESF Functions. The remaining cabinets in the division with a failed ESF actuation cabinet are still OPERABLE and will provide their ESF Functions. This Function is required to be OPERABLE in MODES 1, 2, 3, 4, 5, and 6.

27. Pressurizer Heater Trip

Pressurizer heaters are automatically tripped upon receipt of a core makeup tank operation signal or a Pressurizer Water Level – High 3 signal. This pressurizer heater trip reduces the potential for steam generator overfill and automatic ADS Stages 1, 2, and 3 actuation for a steam generator tube rupture event. Automatically tripping the pressurizer heaters reduces the pressurizer level swell for certain non-LOCA events such as loss of normal feedwater, inadvertent

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

CMT operation, and CVS malfunction resulting in an increase in RCS inventory. For small break LOCA analysis, tripping the pressurizer heaters supports depressurization of the RCS following actuation of the CMTs.

27.a. CMT Actuation (Function 2)

A signal to trip the pressurizer heaters is generated on a CMT actuation signal. The requirements for this function are the same as the requirements for the CMT Actuation Function, except this function is only required to be OPERABLE in MODES 1, 2, and 3, and in MODE 4 when the RCS is not being cooled by the RNS and above the P-19 (RCS pressure) interlock. Therefore, the requirements are not repeated in Table 3.3.2.1. Instead, Function 2 is referenced for initiating Functions and requirements and SR 3.3.2.9 also applies.

27.b. Pressurizer Water Level – High 3

A signal to trip the pressurizer heaters is generated when the pressurizer water level reaches its High 3 setpoint. This signal provides protection against a pressurizer overfill following an inadvertent core makeup tank actuation with consequential loss of offsite power. This Function is automatically unblocked when RCS pressure is above the P-19 setpoint. This Function is required to be OPERABLE in MODES 1, 2, and 3 and in MODE 4 when the RCS is not being cooled by the RNS and above the P-19 (RCS pressure) interlock. This Function is not required to be OPERABLE in MODES 5 and 6 because it is not required to mitigate DBA in these MODES.

28. Chemical and Volume Control System Letdown Isolation

The CVS provides letdown to the liquid radwaste system to maintain the pressurizer level. To help maintain RCS inventory in the event of a LOCA, the CVS letdown line is isolated on a Low 1 hot leg level signal in either of the RCS hot leg loops. This Function is required to be OPERABLE in MODE 4 with the RCS being cooled by the RNS. This Function is also required to be OPERABLE in MODE 5, and in MODE 6 with the water level < 23 feet above the top of the reactor vessel flange.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

28.a. Hot Leg Level – Low 1

A signal to isolate the CVS letdown valves is generated upon the occurrence of a Low 1 hot leg level in either of the two RCS hot leg loops. This helps to maintain reactor system inventory in the event of a LOCA. This function can be blocked in MODES 1, 2, and 3 and is automatically reset when P-12 is first activated. This function may be manually reset as well. These letdown valves are also closed by all of the initiating Functions and requirements that generate the Containment Isolation Function in Function 3.

29. SG Power Operated Relief Valve and Block Valve Isolation

The Function of the SG Power Operated Relief Valve and Block Valve Isolation is to ensure that the SG PORV flow paths can be isolated during a SG tube rupture (SGTR) event. The PORV flow paths must be isolated following a SGTR to minimize radiological releases from the ruptured steam generator into the atmosphere. The PORV flow path is assumed to open due to high secondary side pressure, during the SGTR. Dose analyses take credit for subsequent isolation of the PORV flow path by the PORV and/or the block valve which receive a close signal on low steam line pressure. Additionally, the PORV flow path can be isolated manually.

This Function is required to be OPERABLE in MODES 1, 2, 3, and 4 with the RCS cooling not being provided by the Normal Residual Heat Removal System (RNS). In MODE 4 with the RCS cooling being provided by the RNS and in MODES 5 and 6, the steam generators are not being used for RCS cooling and the potential for a SGTR is minimized due to the reduced mass and energy in the RCS and steam generators.

29.a. Manual Initiation

Manual initiation of SG Power Operated Relief Valve and Block Valve Isolation can be accomplished from the control room. There are two switches in the control room and either switch can close the SG PORVs and PORV block valves. The LCO requires two switches to be OPERABLE.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

29.b. Steam Line Pressure – Low

Steam Line Pressure – Low provides closure of the PORV flow paths in the event of SGTR in which the PORV(s) open, to limit the radiological releases from the ruptured steam generator into the atmosphere.

This Function is anticipatory in nature and has a typical leading/lag ratio of 50/5.

The LCO requires four channels of Steam Line Pressure – Low Function to be OPERABLE in MODES 1, 2, 3, and 4 with the RCS cooling not being provided by the RNS. Four channels are provided in each steam line to permit one channel to be in trip or bypass indefinitely and still ensure that no single random failure will disable this Function.

30. Component Cooling Water System Containment Isolation Valve Closure

The function of the Component Cooling Water System (CCS) containment isolation valve closure is to ensure that the CCS flow paths can be isolated during an RCP heat exchanger tube rupture event. The CCS flow paths must be isolated following an RCP heat exchanger tube rupture event to minimize radiological releases from the ruptured tube into the turbine building. The CCS flow path is isolated by the closure of the CCS containment isolation valves, which receive a close signal on high RCP bearing water temperature.

30.a. Reactor Coolant Pump Bearing Water Temperature – High

The CCS containment isolation valves are closed if two-out-of-four sensors on any RCP indicate high bearing water temperature. This Function is required to be OPERABLE in MODES 1, 2, 3, and 4. Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

BASES

APPLICABLE SAFETY ANALYSES, LCOs, and APPLICABILITY (continued)

31. Containment Vacuum Relief Valve Actuation

The purpose of the vacuum relief lines is to protect the containment vessel against damage due to a negative pressure (i.e., a lower pressure inside than outside).

Manual and automatic Containment Vacuum Relief Valve actuation must be OPERABLE in MODES 1 through 4 and in MODES 5 and 6 without an open containment air flow path ≥ 6 inches in diameter. With a 6 inch diameter or equivalent containment air flow path, the vacuum relief function is not needed to mitigate a low pressure event.

31.a. Containment Pressure – Low 2

This signal provides protection against a negative pressure in containment due to loss of ac power or inadvertent actuation of containment cooling and a low outside ambient air temperature in combination with limited containment heating that reduces the atmospheric temperature (and hence pressure) inside containment.

Four channels are provided to permit one channel to be in trip or bypass indefinitely and still ensure no single random failure will disable this trip Function.

31.b. Manual Initiation

The operator can open the vacuum relief valves at any time from the main control room by actuating either of the two vacuum relief actuation switches. There are two switches in the main control room, either of which will actuate vacuum relief in all divisions.

ESFAS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

ACTIONS

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this specification may be entered independently for each Function listed on Table 3.3.2-1. The Completion Time(s) of the inoperable equipment of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

BASES

ACTIONS (Continued)

A second Note has been added to provide clarification that, more than one Condition is listed for each of the Functions in Table 3.3.2-1. If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the second Condition shall be entered.

In the event a channel's as-found condition is outside the as-found tolerance described in the SP, or the channel is not functioning as required, or the transmitter, or the Protection and Safety Monitoring System Division, associated with a specific Function is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition(s) entered for the particular protection Function(s) affected. When the Required Channels are specified only on a per steam line, per loop, per SG, basis, then the Condition may be entered separately for each steam line, loop, SG, etc., as appropriate.

When the number of inoperable channels in a trip function exceed those specified in one or other related Conditions associated with a trip function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 in MODES 1 through 4 and LCO 3.0.8 for MODE 5 and 6 should be immediately entered if applicable in the current MODE of operation.

A.1

Condition A is applicable to all ESFAS protection Functions. Condition A addresses the situation where one or more channels/divisions for one or more functions are inoperable at the same time. The Required Action is to refer to Table 3.3.2-1 and to take the Required Actions for the protection Functions affected. The Completion Times are those from the referenced Conditions and Required Actions.

B.1 and B.2

With one or two channels or divisions inoperable, one affected channel or division must be placed in a bypass or trip condition within 6 hours. If one channel or division is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels or divisions will not prevent the protective function.) If one channel or division is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels or divisions will not prevent the protective function.) If one channel or division is bypassed and one channel or division is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 6 hours allowed to place the inoperable channel(s) or division(s) in the bypassed or tripped condition is justified in Reference 6.

BASES

ACTIONS (Continued)

C.1

With one channel inoperable, the affected channel must be placed in a bypass condition within 6 hours. The 6 hours allowed to place the inoperable channel in the bypass condition is justified in Reference 6. If one CVS isolation channel is bypassed, the logic becomes one-out-of-one. A single failure in the remaining channel could cause a spurious CVS isolation. Spurious CVS isolation, while undesirable, would not cause an upset plant condition.

D.1

With one required division inoperable, the affected division must be restored to OPERABLE status within 6 hours.

Condition D applies to one inoperable required division of the P-3 & P-4 Interlocks (Functions 18.a and 18.f). With one required division inoperable, the 2 remaining OPERABLE divisions are capable of providing the required interlock function, but without a single failure. The P-3 & P-4 Interlocks are enabled when RTBs in two divisions are detected as open. The status of the other inoperable, non-required P-3 & P-4 division is not significant, since P-3 & P-4 divisions cannot be tripped or bypassed. In order to provide single failure tolerance, 3 required divisions must be OPERABLE.

Condition D also applies to one inoperable division of ESF coincidence logic or ESF actuation (Functions 25 and 26). The ESF coincidence logic and ESF actuation divisions are inoperable when their associated battery-backed subsystem is inoperable. With one inoperable division, the 3 remaining OPERABLE divisions are capable of mitigating all DBAs, but without a single failure.

The 6 hours allowed to restore the inoperable division is reasonable based on the capability of the remaining OPERABLE divisions to mitigate all DBAs and the low probability of an event occurring during this interval.

E.1

Condition E is applicable to manual initiation of:

- Safeguards Actuation;
- CMT Actuation;
- Containment Isolation;

BASES

ACTIONS (Continued)

- Steam Line Isolation;
- Main Feedwater Control Valve Isolation;
- Main Feedwater Pump Trip and Valve Isolation;
- ADS Stages 1, 2, & 3 Actuation;
- ADS Stage 4 Actuation;
- Passive Containment Cooling Actuation;
- PRHR Heat Exchanger Actuation;
- CVS Makeup Line Isolation;
- IRWST Injection Line Valve Actuation;
- IRWST Containment Recirculation Valve Actuation;
- Steam Generator PORV Flow Path Isolation.

This Action addresses the inoperability of the system level manual initiation capability for the ESF Functions listed above. With one switch or switch set inoperable for one or more Functions, the system level manual initiation capability is reduced below that required to meet single failure criterion. Required Action E.1 requires the switch or switch set for system level manual initiation to be restored to OPERABLE status within 48 hours. The specified Completion Time is reasonable considering that the remaining switch or switch set is capable of performing the safety function.

F.1, F.2.1, and F.2.2

Condition F is applicable to the Main Control Room (MCR) isolation and air supply initiation function which has only two channels of the initiating process variable. With one channel inoperable, the logic becomes one-out-of-one and is unable to meet single failure criterion. Restoring all channels to OPERABLE status ensures that a single failure will not prevent the protective Function.

Alternatively, radiation monitor(s) which provide equivalent information and control room isolation and air supply initiation manual controls may be verified to be OPERABLE. These provisions for operator action can replace one channel of radiation detection and system actuation. The

BASES

ACTIONS (Continued)

72 hour Completion Time is reasonable considering that there is one remaining channel OPERABLE and the low probability of an event occurring during this interval.

G.1

With one switch, switch set, channel, or division inoperable, the system level initiation capability is reduced below that required to meet single failure criterion. Therefore, the required switch, switch set, channel, and division must be returned to OPERABLE status within 72 hours. The specified Completion Time is reasonable considering the remaining switch, switch set, channel, or division is capable of performing manual initiation.

H.1

With one channel inoperable, the inoperable channel must be placed in a trip condition within 6 hours.

Condition H is applicable to the PRHR heat exchangers actuation on SG Narrow Range Water Level Low coincident with Startup Feedwater Flow Low (Function 13.b). With one startup feedwater channel inoperable, the inoperable channel must be placed in a trip condition within 6 hours. If one channel is tripped, the interlock condition is satisfied. Condition H is also applicable to Refueling Cavity Isolation (Function 24.a). With one of the three spent fuel pool level channels inoperable, the inoperable channel must be placed in a trip condition within 6 hours. If one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The specified Completion Time is reasonable considering the time required to complete this action.

I.1 and I.2

Condition I applies to IRWST containment recirculation valve actuation on safeguards actuation coincident with IRWST Level Low 3 (Function 23.b). With one or two channels inoperable, one affected channel must be placed in a bypass or trip condition within 6 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is bypassed and one channel is tripped, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 6 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 6.

BASES

ACTIONS (Continued)

J.1 and J.2

Condition J applies to the P-6, P-11, P-12, and P-19 interlocks. With one or two required channel(s) inoperable, the associated interlock must be verified to be in its required state for the existing plant condition within 1 hour, or any Function channel associated with the inoperable interlock(s) placed in a bypassed condition within 7 hours. Verifying the interlock state manually accomplishes the interlock role.

If one interlock channel is inoperable, the associated Function(s) must be placed in a bypass or trip condition within 7 hours. If one channel is bypassed, the logic becomes two-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.) If one channel is tripped, the logic becomes one-out-of-three, while still meeting the single failure criterion. (A failure in one of the three remaining channels will not prevent the protective function.)

If two interlock channels are inoperable, one channel of the associated Function(s) must be bypassed and one channel of the associated Function(s) must be tripped. In this state, the logic becomes one-out-of-two, while still meeting the single failure criterion. The 7 hours allowed to place the inoperable channel(s) in the bypassed or tripped condition is justified in Reference 6.

K.1

LCO 3.0.8 is applicable while in MODE 5 or 6. Since irradiated fuel assembly movement can occur in MODE 5 or 6, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, the fuel movement is independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

Condition K is applicable to the MCR Isolation and Air Supply Initiation (Function 20), during movement of irradiated fuel assemblies. If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must suspend movement of the irradiated fuel assemblies immediately. The required action suspends activities with potential for releasing radioactivity that might enter the MCR. This action does not preclude the movement of fuel to a safe position.

BASES

ACTIONS (Continued)

L.1

If the required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 6 hours. The allowed time is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

M.1 and M.2

If the Required Action and associated Completion Time of the first condition listed in Table 3.3.2-1 is not met, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 6 hours and in MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

N.1 and N.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 6 hours and in MODE 4 with the RCS being cooled by the RNS within 24 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

O.1 and O.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 6 hours and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

P.1, P.2.1, and P.2.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 cannot be met, the plant must be placed in a condition where the instrumentation Function for valve isolation is no

BASES

ACTIONS (Continued)

longer needed. This is accomplished by isolating the affected flow path(s) within 24 hours. By isolating the flow path from the demineralized water storage tank to the RCS, the need for automatic isolation is eliminated.

To assure that the flow path remains closed, the flow path shall be isolated by the use of one of the specified means (P.2.1) or the flow path shall be verified to be isolated (P.2.2). A means of isolating the affected flow path(s) includes at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured within 7 days. If one of the P.2.1 specified isolation means is not used, the affected flow path shall be verified to be isolated once per 7 days.

This action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

Q.1, Q.2.1, and Q.2.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a condition where the instrumentation Function for valve isolation is no longer needed. This is accomplished by isolating the affected flow path by the use of at least one closed manual or closed and deactivated automatic valve within 6 hours.

If the flow path is not isolated within 6 hours the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 12 hours and in MODE 4 within 18 hours.

This action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

R.1, R.2.1.1, R.2.1.2, and R.2.2

If the Required Action and associated Completion Time of the first Condition given in Table 3.3.2-1 is not met the plant must be placed in a condition in which the likelihood and consequences of an event are minimized. This is accomplished by placing the plant in MODE 3 within

BASES

ACTIONS (Continued)

6 hours and isolating the affected flow path(s) within 12 hours. To assure that the flow path remains closed, the affected flow path shall be verified to be isolated once per 7 days.

If the flow path is not isolated within 12 hours the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 4 with the RCS cooling provided by the RNS within 30 hours. The allowed Completion Time is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

This action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

S.1, S.2.1.1, S.2.1.2, S.2.1.3, and S.2.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a condition in which the likelihood and consequences of an event are minimized. This is accomplished by placing the plant in MODE 3 within 6 hours and in MODE 4 with the RCS cooling provided by the RNS within 24 hours. Once the plant has been placed in MODE 4 the affected flow path must be isolated within 30 hours. To assure that the flow path remains closed, the affected flow path shall be verified to be isolated once per 7 days.

If the flow path is not isolated within 12 hours, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 5 within 42 hours. The allowed Completion Time is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

This action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

BASES

ACTIONS (Continued)

T.1.1, T.1.2.1, T.1.2.2, T.2.1, and T.2.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a Condition in which the likelihood and consequences of an event are minimized. This is accomplished by isolating the affected flow path within 6 hours and isolating the affected flow path(s) by the use of at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured within 7 days or verify the affected flow path is isolated once per 7 days.

If the flow path is not isolated within 6 hours the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 12 hours and in MODE 5 within 42 hours.

The allowed Completion Time is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

This action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

U.1 and U.2

If the Required Action and the associated Completion Time of the first Condition given in Table 3.3.2-1 is not met, and the required switch or switch set is not restored to OPERABLE status within 48 hours, the plant must be placed in a condition in which the likelihood and consequences of an event are minimized. This is accomplished by placing the plant in MODE 5 within 12 hours. Once in MODE 5, action shall be immediately initiated to open the RCS pressure boundary and establish ≥ 20% pressurizer level. The 12 hour Completion Time is a reasonable time to reach MODE 5 from MODE 4 with RCS cooling provided by the RNS (approximately 350°F) in an orderly manner without challenging plant systems. Opening the RCS pressure boundary assures that cooling water can be injected without ADS operation. Filling the RCS to provide ≥ 20% pressurizer level minimizes the consequences of a loss of decay heat removal event.

BASES

ACTIONS (Continued)

V.1, V.2.1, and V.2.2

If the Required Action and the associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met and the required channel(s) is not bypassed within 6 hours, the inoperable channel(s) must be restored within 168 hours. The 168 hour Completion Time is based on the ability of the two remaining OPERABLE channels to provide the protective Function even with a single failure.

If the channel(s) is not restored within the 168 hour Completion Time, the plant shall be placed in a condition in which the likelihood and consequences of an event are minimized. This is accomplished by placing the plant in MODE 5 within 180 hours (the next 12 hours). Once in MODE 5, action shall be initiated to open the RCS pressure boundary and establish ≥ 20% pressurizer level. The 12 hours is a reasonable time to reach MODE 5 from MODE 4 with RCS cooling provided by the RNS (approximately 350°F) in an orderly manner without challenging plant systems.

Opening the RCS pressure boundary assures that cooling water can be injected without ADS operation. Filling the RCS to provide ≥ 20% pressurizer level minimizes the consequences of a loss of decay heat removal event.

W.1, W.2, W.3, and W.4

If the Required Action and the associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met while in MODES 5 and 6, the plant must be placed in a MODE in which the likelihood and consequences of an event are minimized. This is accomplished by immediately initiating action to be in MODE 5 with the RCS open and ≥ 20% pressurizer level or to be in MODE 6 with the upper internals removed. The flow path from the demineralized water storage tank to the RCS shall also be isolated by the used of at least one closed and de-activated automatic valve or closed manual valve. These requirements minimize the consequences of the loss of decay heat removal by maximizing RCS inventory and maintaining RCS temperature as low as practical. Additionally, the potential for a criticality event is minimized by isolation of the demineralized water storage tank and by suspension of positive reactivity additions.

BASES

ACTIONS (Continued)

X.1, X.2, and X.3

If the Required Action and the associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met while in MODES 5 and 6, the plant must be placed in a MODE in which the likelihood and consequences of an event are minimized. This is accomplished by immediately initiating action to be in MODE 5 with the RCS open and ≥ 20% pressurizer level or to be in MODE 6 with the upper internals removed. These requirements minimize the consequences of the loss of decay heat removal by maximizing RCS inventory and maintaining RCS temperature as low as practical. Additionally, the potential for a criticality event is minimized by suspension of positive reactivity additions.

Y.1, Y.2, Y.3, and Y.4

If the Required Action and the associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met while in MODE 4, with RCS cooling provided by the RNS, MODE 5, or MODE 6, the plant must be placed in a MODE in which the likelihood and consequences of an event are minimized. If in MODE 4, this is accomplished by placing the plant in MODE 5 within 12 hours. The 12 hours is a reasonable time to reach MODE 5 from MODE 4 with RCS cooling provided by the RNS (approximately 350°F) in an orderly manner without challenging plant systems.

If in MODE 4 or 5, Required Action Y.3 requires initiation of action within 12 hours to close the RCS pressure boundary and establish ≥ 20% pressurizer level. The 12 hour Completion Time allows transition to MODE 5 in accordance with Y.2, if needed, prior to initiating action to open the RCS pressure boundary.

If in MODE 6, Required Action Y.4 requires the plant to be maintained in MODE 6 and initiation of action to establish the reactor cavity water level ≥ 23 feet above the top of the reactor vessel flange.

Required Actions Y.2, Y.3, and Y.4 minimize the consequences of a loss of decay heat removal event by optimizing conditions for RCS cooling in MODE 5 using the PRHR HX or in MODE 6 using IRWST injection.

Additionally, maximizing RCS inventory and maintaining RCS temperature as low as practical further minimize the consequences of a loss of decay heat removal event. Closing the RCS pressure boundary in MODE 5 assures that PRHR HX cooling is available. Additionally, the potential for a criticality event is minimized by suspension of positive reactivity additions.

BASES

ACTIONS (Continued)

Z.1, Z.2.1, and Z.2.2

If the Required Action and associated Completion Time of the first Condition listed in Table 3.3.2-1 is not met, the plant must be placed in a condition where the instrumentation Function for valve isolation is no longer needed. This is accomplished by isolating the affected flow path by the use of at least one closed manual or closed and deactivated automatic valve within 6 hours.

If the flow path is not isolated within 6 hours, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 12 hours and in MODE 4 with RCS cooling provided by the RNS within 30 hours.

This Action is modified by a Note allowing the flow path(s) to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

AA.1.1, AA.1.2.1, AA1.2.2, AA.2.1, AA.2.2, and AA.2.3

If the Required Action and associated Completion Time of the first condition listed in Table 3.3.2-1 is not met, the plant must be placed in a condition where the instrumentation Function for valve isolation is no longer needed. This is accomplished by isolating the affected flow path within 24 hours. By isolating the CVS letdown flow path from the RCS, the need for automatic isolation is eliminated.

To assure that the flow path remains closed, the flow path shall be isolated by the use of one of the specified means (AA.1.2.1) or the flow path shall be verified to be isolated (AA.1.2.2). A means of isolating the affected flow path includes at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured, within 7 days. If one of the P.2.1 specified isolation means is not used, the affected flow path shall be verified to be isolated once per 7 days.

This action is modified by a Note allowing the flow path to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way the flow path can be rapidly isolated when a need for flow path isolation is indicated.

BASES

ACTIONS (Continued)

If the flow path cannot be isolated in accordance with Required Actions AA.1.1, AA.1.2.1 and AA.1.2.2, the plant must be placed in a MODE in which the likelihood and consequences of an event are minimized. If in MODE 4, this is accomplished by placing the plant in MODE 5 within 12 hours. The 12 hours is a reasonable time to reach MODE 5 from MODE 4 with RCS cooling provided by the RNS (approximately 350°F) in an orderly manner without challenging plant systems.

If in MODE 4 or 5, Required Action AA.2.2 requires initiation of action, within 12 hours, to establish > 20% pressurizer level. The 12 hour Completion Time allows transition to MODE 5 in accordance with AA.2.1, if needed, prior to initiating action to establish the pressurizer level.

If in MODE 6, Required Action AA.2.3 requires the plant to be maintained in MODE 6 and initiation of action to establish the reactor cavity water level ≥ 23 feet above the top of the reactor vessel flange.

Required Actions AA.2.2 and AA.2.3 minimize the consequences of an event by optimizing conditions for RCS cooling in MODE 5 using the PRHR HX or in MODE 6 using IRWST injection.

BB.1 and BB.2

With one channel inoperable, the inoperable channel must be placed in bypass and the hot leg level continuously monitored.

If one channel is placed in bypass, automatic actuation will not occur. Continuous monitoring of the hot leg level provides sufficient information to permit timely operator action to ensure that ADS Stage 4 actuation can occur, if needed to mitigate events requiring RCS makeup, boration, or core cooling. Operator action to manually initiate ADS Stage 4 actuation is assumed in the analysis of shutdown events (Ref. 10). It is also credited in the shutdown PRA (Ref. 11) when automatic actuation is not available.

CC.1, CC.2, and CC.3

If the vacuum relief valve actuation function cannot be restored to OPERABLE status within the required Completion Time, the plant must be placed in a condition in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 or 6 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (Continued)

In MODE 5 or 6, a containment air flow path ≥ 6 inches in diameter shall be opened within 44 hours from Condition entry. Opening any flow path (or paths) with an area equivalent to 6 inches in diameter provides the required vacuum relief path in the event of a low pressure event.

The primary means of opening a containment air flow path is by establishing a VFS air flow path into containment. Manual actuation and maintenance as necessary to open a purge supply, purge exhaust, or vacuum relief flow path are available means to open a containment air flow path. In addition, opening of a spare penetration is an acceptable means to provide the necessary flow path. Opening of an equipment hatch or a containment airlock is acceptable. Containment air flow paths opened must comply with LCO 3.6.8, Containment Penetrations.

The 44 hour Completion Time is reasonable for opening a containment air flow path in an orderly manner.

SURVEILLANCE REQUIREMENTS

The Surveillance Requirements for each ESF Function are identified by the Surveillance Requirements column of Table 3.3.2-1. A Note has been added to the Surveillance Requirement table to clarify that Table 3.3.2-1 determines which Surveillance Requirements apply to which ESF Functions.

SR 3.3.2.1

Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or even something more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the match criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside their corresponding limits.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is based on operating experience that demonstrates that channel failure is rare. Automated operator aids may be used to facilitate performance of the CHANNEL CHECK.

SR 3.3.2.2

SR 3.3.2.2 is the performance of an ACTUATION LOGIC TEST. This test, in conjunction with the ACTUATION DEVICE TEST, demonstrates that the actuated device responds to a simulated actuation signal. The ESF coincidence logic and ESF actuation subsystems within a division are tested every 92 days on a STAGGERED TEST BASIS.

A test subsystem is provided with the protection and safety monitoring system to aid the plant staff in performing the ACTUATION LOGIC TEST. The test subsystem is designed to allow for complete functional testing by using a combination of system self-checking features, functional testing features, and other testing features. Successful functional testing consists of verifying that the capability of the system to perform the safety function has not failed or degraded.

For hardware functions this would involve verifying that the hardware components and connections have not failed or degraded. Generally this verification includes a comparison of the outputs from two or more redundant subsystems or channels.

Since software does not degrade, software functional testing involves verifying that the software code has not changed and that the software code is executing.

To the extent possible, protection and safety monitoring system functional testing is accomplished with continuous system self-checking features and the continuous functional testing features. The ACTUATION LOGIC TEST shall include a review of the operation of the test subsystem to verify the completeness and adequacy of the results.

If the ACTUATION LOGIC TEST can not be completed using the built-in test subsystem, either because of failures in the test subsystem or failures in redundant channel hardware used for functional testing, the ACTUATION LOGIC TEST can be performed using portable test equipment.

The Frequency of every 92 days on a STAGGERED TEST BASIS provides a complete test of all four divisions once per year. This frequency is adequate based on the inherent high reliability of the solid state devices which comprise this equipment; the additional reliability provided by the redundant subsystems; and the use of continuous diagnostic test features, such as deadman timers, memory checks,

BASES

SURVEILLANCE REQUIREMENTS (continued)

numeric coprocessor checks, cross-check of redundant subsystems, and tests of timers, counters, and crystal time basis, which will report a failure within these cabinets to the operator.

SR 3.3.2.3

SR 3.3.2.3 is the performance of a TADOT of the manual actuations, initiations, and blocks for various ESF Functions, the reactor trip breaker open (P-3), and the reactor trip (P-4) input from the IPCs. This TADOT is performed every 24 months.

The Frequency is based on the known reliability of the ESF Functions and the multichannel redundancy available, and has been shown to be acceptable through operating experience.

The SR is modified by a Note that excludes verification of setpoints from the TADOT. The functions have no setpoints associated with them.

SR 3.3.2.4

SR 3.3.2.4 is the performance of a CHANNEL CALIBRATION every 24 months or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor and the IPC. The test is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation. Transmitter calibration must be performed consistent with the assumptions of the setpoint methodology. The difference between the current as-found values and the previous as-left values must be consistent with the transmitter drift allowance used in the setpoint methodology.

The setpoint methodology requires that 30 months drift be used (1.25 times the surveillance calibration interval, 24 months).

The Frequency is based on operating experience and consistency with the refueling cycle.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This Surveillance Requirement is modified by a Note. The Note states that this test should include verification that the time constants are adjusted to the prescribed values where applicable.

SR 3.3.2.5

SR 3.3.2.5 is the performance of a CHANNEL OPERATIONAL TEST (COT) every 92 days. The test is performed in accordance with the SP. If the actual setting of the channel is found to be outside the as-found tolerance, the channel is considered inoperable. This condition of the channel will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTS (within the allowed tolerance), and evaluating the channel's response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

A COT is performed on each required channel to provide reasonable assurance that the entire channel will perform the intended ESF Function.

A test subsystem is provided with the protection and safety monitoring system to aid the plant staff in performing the COT. The test subsystem is designed to allow for complete functional testing by using a combination of system self-checking features, functional testing features, and other testing features. Successful functional testing consists of verifying that the capability of the system to perform the safety function has not failed or degraded.

For hardware functions this would involve verifying that the hardware components and connections have not failed or degraded. Generally this verification includes a comparison of the outputs from two or more redundant subsystems or channels.

Since software does not degrade, software functional testing involves verifying that the software code has not changed and that the software code is executing.

To the extent possible, protection and safety monitoring system functional testing is accomplished with continuous system self-checking features and the continuous functional testing features. The COT shall include a review of the operation of the test subsystem to verify the completeness and adequacy of the results.

BASES

SURVEILLANCE REQUIREMENTS (continued)

If the COT can not be completed using the built-in test subsystem, either because of failures in the test subsystem or failures in redundant channel hardware used for functional testing, the COT can be performed using portable test equipment.

The 92 day Frequency is based on Reference 6 and the use of continuous diagnostic test features, such as deadman timers, cross-check of redundant channels, memory checks, numeric coprocessor checks, and tests of timers, counters and crystal time bases, which will report a failure within the integrated protection cabinets to the operator.

During the COT, the protection and safety monitoring system cabinets in the division under test may be placed in bypass.

SR 3.3.2.6

This SR ensures the individual channel ESF RESPONSE TIMES are less than or equal to the maximum values assumed in the accident analysis. Individual component response times are not modeled in the analyses. The analyses model the overall or total elapsed time, from the point at which the parameter exceeds the NTS value at the sensor, to the point at which the equipment reaches the required functional state (e.g., valves in full open or closed position).

For channels that include dynamic transfer functions (e.g., lag, lead/lag, rate/lag, etc.), the response time test may be performed with the transfer functions set to one with the resulting measured response time compared to the appropriate Chapter 7 (Ref. 2) response time. Alternately, the response time test can be performed with the time constants set to their nominal value provided the required response time is analytically calculated assuming the time constants are set at their nominal values. The response time may be measured by a series of overlapping tests such that the entire response time is measured.

Response time may be verified by actual response time tests in any series of sequential, overlapping or total channel measurements, or by the summation of allocated sensor, signal processing and actuation logic response times with actual response time tests on the remainder of the channel. Allocations for sensor response times may be obtained from: (1) historical records based on acceptable response time tests (hydraulic, noise, or power interrupt tests), (2) in place, onsite, or offsite (e.g., vendor) test measurements, or (3) utilizing vendor engineering specifications. WCAP-13632-P-A, Revision 2, “Elimination of Pressure Sensor Response Time Testing Requirements” (Ref. 12), provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors

BASES

SURVEILLANCE REQUIREMENTS (continued)

identified in the WCAP. Response time verification for other sensor types must be demonstrated by test.

ESF RESPONSE TIME tests are conducted on a 24 month STAGGERED TEST BASIS. Testing of the devices, which make up the bulk of the response time, is included in the testing of each channel. The final actuation device in one train is tested with each channel. Therefore, staggered testing results in response time verification of these devices every 24 months. The 24 month Frequency is consistent with the typical refueling cycle and is based on unit operating experience, which shows that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.

SR 3.3.2.7

SR 3.3.2.7 is the performance of an ACTUATION DEVICE TEST. This test, in conjunction with the ACTUATION LOGIC TEST, demonstrates that the actuated device responds to a simulated actuation signal. This Surveillance Requirement is applicable to the equipment which is actuated by the Protection Logic Cabinets except squib valves. The OPERABILITY of the actuated equipment is checked by exercising the equipment on an individual basis.

The Frequency of 24 months is based on the need to perform this surveillance during periods in which the plant is shutdown for refueling to prevent any upsets of plant operation.

This Surveillance Requirement is modified by a Note that states that actuated equipment, that is included in the Inservice Test (IST) Program, is exempt from this surveillance. The IST Program provides for exercising of the safety related valves on a more frequent basis. The results from the IST Program can therefore be used to verify OPERABILITY of the final actuated equipment.

SR 3.3.2.8

SR 3.3.2.8 is the performance of an ACTUATION DEVICE TEST, similar to that performed in SR 3.3.2.7, except this Surveillance Requirement is specifically applicable to squib valves. This test, in conjunction with the ACTUATION LOGIC TEST, demonstrates that the actuated device responds to a simulated actuation signal. The OPERABILITY of the squib valves is checked by performing a continuity check of the circuit from the Protection Logic Cabinets to the squib valve.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Frequency of 24 months is based on the need to perform this surveillance during periods in which the plant is shutdown for refueling to prevent any additional risks associated with inadvertent operation of the squib valves.

SR 3.3.2.9

SR 3.3.2.9 is the performance of an ACTUATION DEVICE TEST. This test, in conjunction with the ACTUATION LOGIC TEST, demonstrates that the actuated device responds to a simulated actuation signal. This Surveillance Requirement is applicable to the circuit breakers which de-energize the power to the pressurizer heaters upon a pressurizer heater trip. The OPERABILITY of these breakers is checked by opening these breakers using the Plant Control System.

The Frequency of 24 months is based on the need to perform this surveillance during periods in which the plant is shutdown for refueling to prevent any upsets of plant operation. This Frequency is adequate based on the use of multiple circuit breakers to prevent the failure of any single circuit breaker from disabling the function and that all circuit breakers are tested.

B 3.3 INSTRUMENTATION

B 3.3.3 Post Accident Monitoring (PAM) Instrumentation

BASES

BACKGROUND

The primary purpose of the PAM Instrumentation is to display unit variables that provide information required by the main control room operators during accident situations. These plant variables provide the necessary information to assess the process of accomplishing or maintaining critical safety functions. The instruments which monitor these variables are designated in accordance with Reference 1.

The OPERABILITY of the PAM Instrumentation ensures that there is sufficient information available on selected plant parameters to monitor and assess plant status and behavior following an accident. This capability is consistent with the recommendations of Reference 1.

A PAM CHANNEL shall extend from the sensor up to the display device, and shall include the sensor (or sensors), the signal conditioning, any associated datalinks, the display device, any signal gathering or processing subsystems, and any data processing subsystems. Note that for digital PAM CHANNELs, the information may be displayed on multiple display devices. For this case, the PAM CHANNEL shall extend to any available qualified display device.

The instrument channels required to be OPERABLE by this LCO include two classes of parameters identified during unit specific implementation of Regulatory Guide 1.97 as Type A and Category 1 variables. The unit specific implementation of Regulatory Guide 1.97 has not identified any Type A variables, therefore, only Category 1 variables are specified.

APPLICABLE SAFETY ANALYSES

The PAM Instrumentation ensures that the main control room operating staff can:

- Determine whether systems important to safety are performing their intended functions;
- Determine the likelihood of a gross breach of the barriers to radioactivity release;
- Determine if a gross breach of a barrier has occurred; and
- Initiate action necessary to protect the public and to estimate the magnitude of any impending threat.

BASES

APPLICABLE SAFETY ANALYSES (continued)

PAM Instrumentation that is required in accordance with Regulatory Guide 1.97 satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The PAM instrumentation LCO provides OPERABILITY requirements for those monitors which provide information required by the control room operators to assess the process of accomplishing or maintaining critical safety functions. This LCO addresses those Regulatory Guide 1.97 instruments which are listed in Table 3.3.3-1.

The OPERABILITY of the PAM Instrumentation ensures there is sufficient information available on selected plant parameters to monitor and assess plant status following an accident. This capability is consistent with the recommendations of Reference 1.

Category 1 non-type A variables are required to meet Regulatory Guide 1.97 Category 1 (Ref. 1) design and qualification requirements for seismic and environmental qualification, single-failure criterion, utilization of emergency standby power, immediately accessible display, continuous readout, and recording of display.

Listed below are discussions of the specified instrument functions listed in Table 3.3.3-1. Each of these is a Category 1 variable.

1. Intermediate Range Neutron Flux

   Neutron Flux indication is provided to verify reactor shutdown. The neutron flux intermediate range is sufficient to cover the full range of flux that may occur post accident.

   Neutron flux is used for accident diagnosis, verification of subcriticality, and diagnosis of positive reactivity insertion.

2, 3. Reactor Coolant System (RCS) Wide Range Hot and Cold Leg Temperature

   RCS Hot and Cold Leg Temperatures are provided for verification of core cooling and long-term surveillance. The channels provide indication over a range of 50°F to 700°F.

   In addition to this, RCS cold leg temperature is used in conjunction with RCS hot leg temperature to verify the plant conditions necessary to establish natural circulation in the RCS.

BASES

LCO (continued)

4. RCS Pressure

   RCS wide range pressure is provided for verification of core cooling and RCS integrity long term surveillance.

5. Pressurizer Pressure and RCS Subcooling Monitor

   Pressurizer Pressure is used to determine RCS Subcooling. The RCS Subcooling Monitor is provided for verification of core cooling. Subcooling margin is available when the RCS pressure is greater than the saturation pressure corresponding to the core exit temperature. Inputs to the Subcooling Monitor are pressurizer pressure and RCS hot leg temperature.

6. Containment Water Level

   Containment Water Level is used to monitor the containment environment during accident conditions. The containment water level can also provide information to the operators that the various stages of safety injection along with system depressurization are progressing.

7. Containment Pressure

   The containment pressure transmitters monitor the containment pressure over the range of -5 to 10 psig. This provides information on post accident containment pressure and containment integrity.

8. Containment Pressure (Extended Range)

   The extended range containment pressure transmitters are instruments that operators use for monitoring the potential for breach of containment, a fission product barrier. The extended range sensors monitor containment pressure over the range of 0 to 240 psig.

9. Containment Area Radiation (High Range)

   Containment Area Radiation is provided to monitor for the potential of significant radiation releases and to provide release assessment for use by operators in determining the need to invoke site emergency plans.

BASES

LCO (continued)

10. Pressurizer Level and Associated Reference Leg Temperature

Pressurizer level is provided to monitor the RCS coolant inventory. During an accident, operation of the safeguards systems can be verified based on coolant inventory indicators.

The reference leg temperature is included in the Technical Specification since it is used to compensate the level signal.

11. In-Containment Refueling Water Storage Tank (IRWST) Water Level

The IRWST provides a long term heat sink for non-LOCA events and is a source of injection flow for LOCA events. When the IRWST is a heat sink, the level will change due to increased volume associated with the temperature increase. When saturation temperature is reached, the IRWST will begin steaming and initially lose mass to the containment atmosphere until condensation occurs on the steel containment shell which is cooled by the passive containment cooling system. The condensate is returned to the IRWST via a gutter.

During a LOCA, the IRWST is available for injection. Depending on the severity of the event, when a fully depressurized RCS has been achieved, the IRWST will inject by gravity flow.

12. Passive Residual Heat Removal (PRHR) Flow and PRHR Outlet Temperature

PRHR Flow is provided to monitor primary system heat removal during accident conditions when the steam generators are not available. PRHR provides primary protection for non-LOCA events when the normal heat sink is lost.

PRHR outlet temperature is provided to monitor primary system heat removal during accident conditions when the steam generators are not available. PRHR provides primary protection for non-LOCA events when the normal heat sink is lost.

13, 14, 15, 16. Core Exit Temperature

Core Exit Temperature is provided for verification and long term surveillance of core cooling.

BASES

LCO (continued)

An evaluation was made of the minimum number of valid core exit thermocouples necessary for In-Core Cooling (ICC) detection. The evaluation determined the reduced complement of core exit thermocouples necessary to detect initial core recovery and trend the ensuing core heatup. The evaluations account for core nonuniformities including incore effects of the radial decay power distribution and excore effects of condensate runback in the hot legs and nonuniform inlet temperatures. Based on these evaluations, adequate ICC detection is assured with two valid core exit thermocouples per quadrant. Core Exit Temperature is also used for plant stabilization and cooldown monitoring.

Two OPERABLE channels of Core Exit Temperature are required in each quadrant to provide indication of radial distribution of the coolant temperature rise across representative regions of the core. Power distribution symmetry was considered in determining the specific number and locations provided for diagnosis of local core problems. Two thermocouples in each of the two divisions ensure a single failure will not disable the ability to determine the temperature at two locations within a quadrant.

17. Passive Containment Cooling System (PCS) Storage Tank Level and PCS Flow

The PCS must be capable of removing the heat from the containment following a postulated LOCA or steam line break (SLB). The tank level instruments provide indication that sufficient water is available to meet this requirement. The PCS flow instrument provides a diverse indication of the PCS heat removal capability.

18. Remotely Operated Containment Isolation Valve Position

The Remotely Operated Containment Isolation Valve Position is provided for verification of containment OPERABILITY.

19. IRWST to RNS Suction Valve Status

The position of the motor-operated valve in the line from the IRWST to the pump suction header is monitored to verify that the valve is closed following postulated events. The valve must be closed to prevent loss of IRWST inventory into the RNS.

BASES

APPLICABILITY

The PAM instrumentation LCO is applicable in MODES 1, 2, and 3. These variables provide the information necessary to assess the process of accomplishing or maintaining critical safety functions following Design Basis Accidents (DBAs). The applicable DBAs are assumed to occur in MODES 1, 2, and 3. In MODES 4, 5, and 6, plant conditions are such that the likelihood of an event that would require PAM instrumentation is low; therefore, the PAM instrumentation is not required to be OPERABLE in these MODES.

ACTIONS

The ACTIONS Table has been modified by two Notes.

The first Note excludes the MODE change restriction of LCO 3.0.4. This exception allows entry into an applicable MODE while relying on the ACTIONS even though the ACTIONS may eventually require a plant shutdown. This exception is acceptable due to the passive function of the instruments, the operator's ability to respond to an accident using alternate instruments and methods, and low probability of an event requiring these instruments.

The second Note in the ACTIONS clarifies the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed on Table 3.3.3-1. The Completion Time(s) of the inoperable channel(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that function.

A.1

When one or more Functions have one required channel which is inoperable, the required inoperable channel must be restored to OPERABLE status within 30 days. The 30 day Completion Time is based on operating experience and takes into account the remaining OPERABLE channel (or in the case of a Function that has only one required channel, other non-Regulatory Guide 1.97 instrument channels to monitor the Function), the passive nature of the instrument (no critical automatic action is assumed to occur from these instruments), and the low probability of an event requiring PAM instrumentation during this interval.

B.1

The Required Action directs actions to be taken in accordance with Specification 5.6.7 immediately. Each time an inoperable channel has not met Required Action A.1, and the associated Completion Time has expired, Condition B is entered.

BASES

ACTIONS (continued)

C.1

When one or more Functions have two required channels which are inoperable, (two channels inoperable in the same Function), one channel in the Function should be restored to OPERABLE status within 7 days. The Completion Time of 7 days is based on the relatively low probability of an event requiring PAM instrument operation and the availability of alternate means to obtain the required information.

Continuous operation with two required channels inoperable in a Function is not acceptable because the alternate indications may not fully meet all performance qualification requirements applied to the PAM instrumentation. Therefore, requiring restoration of one inoperable channel of the Function limits the risk that the PAM function will be in a degraded condition should an accident occur.

D.1

This Required Action directs entry into the appropriate Condition referenced in Table 3.3.3-1. The applicable Condition referenced in the Table is Function dependent.

Each time an inoperable channel has not met any Required Action of Condition C, and the associated Completion Time has expired, Condition D is entered for that channel and provides for transfer to the appropriate subsequent Condition.

E.1 and E.2

If the Required Action and associated Completion Time of Condition C are not met for the Functions in Table 3.3.3-1, the plant must be placed in a MODE in which the LCO does not apply. This is done by placing the plant in at least MODE 3 within 6 hours and MODE 4 within 12 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

The following SRs apply to each PAM instrumentation function in Table 3.3.3-1:

SR 3.3.3.1

Performance of the CHANNEL CHECK once every 31 days verifies that a gross instrumentation failure has not occurred. A CHANNEL CHECK is a

BASES

SURVEILLANCE REQUIREMENTS (continued)

comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION. The high radiation instrumentation should be compared to similar plant instruments located throughout the plant.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the match criteria, it may be an indication that the sensor or the signal-processing equipment has drifted outside its limit. If the channels are within the match criteria, it is an indication that the channels are OPERABLE.

As specified in the SR, a CHANNEL CHECK is only required for those channels that are normally energized.

The Frequency of 31 days is based on operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given function in any 31 day interval is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of those displays associated with the required channels of this LCO.

SR 3.3.3.2

A CHANNEL CALIBRATION is performed every 24 months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop including the sensor. The test verifies that the channel responds to the measured parameter with the necessary range and accuracy. This SR is modified by a Note that excludes neutron detectors. The calibration method for neutron detectors is specified in the Bases of LCO 3.3.1, “Reactor Trip System (RTS) Instrumentation.” RTD and Thermocouple channels are to be calibrated in place using cross-calibration techniques. The Frequency is based on operating experience and consistency with the typical industry refueling cycle.

B 3.3 INSTRUMENTATION

B 3.3.4 Remote Shutdown Workstation (RSW)

BASES

BACKGROUND

The RSW provides the control room operator with sufficient displays and controls to place and maintain the unit in a safe shutdown condition from a location other than the control room. This capability is necessary to protect against the possibility that the control room becomes inaccessible. Passive residual heat removal (PRHR), the core makeup tanks (CMTs), and the in-containment refueling water storage tank (IRWST) can be used to remove core decay heat. The use of passive safety systems allows extended operation in MODE 4.

If the control room becomes inaccessible, the operators can establish control at the RSW and place and maintain the unit in MODE 4 with T_{avg} < 350°F. The unit can be maintained safely in MODE 4 with T_{avg} < 350°F for an extended period of time.

The OPERABILITY of the remote shutdown control and display functions ensures there is sufficient information available on selected unit parameters to place and maintain the unit in MODE 4 with T_{avg} < 350°F should the control room become inaccessible.

APPLICABLE SAFETY ANALYSES

The RSW is required to provide equipment at appropriate locations outside the control room with a capability to promptly shut down and maintain the unit in a safe condition in MODE 4 with T_{avg} < 350°F.

The criteria governing the design and the specific system requirements of the RSW are located in 10 CFR 50, Appendix A, GDC 19 (Ref. 1).

Since the passive safety systems alone can establish and maintain safe shutdown conditions for the unit, nonsafety systems are not required for safe shutdown of the unit. Therefore, no credit is taken in the safety analysis for nonsafety systems.

The RSW satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The RSW LCO provides the OPERABILITY requirements of the displays and controls necessary to place and maintain the unit in MODE 4 from a location other than the control room.

The RSW is OPERABLE if the display instrument and control functions needed to support the RSW are OPERABLE.

BASES

LCO (continued)

The RSW covered by this LCO does not need to be energized to be considered OPERABLE. This LCO is intended to ensure the RSW will be OPERABLE if unit conditions require that the RSW be placed in operation.

APPLICABILITY

The RSW LCO is applicable in MODES 1, 2, and 3 and in MODE 4 with $T_{avg} \geq 350°F$. This is required so that the facility can be placed and maintained in MODE 4 for an extended period of time from a location other than the control room.

This LCO is not applicable in MODE 4 with $T_{avg} < 350°F$ or in MODE 5 or 6. In these MODES, the unit is already subcritical and in a condition of reduced Reactor Coolant System (RCS) energy. Under these conditions, considerable time is available to restore necessary instrument control functions if control room instruments or controls become unavailable.

ACTIONS

The Note excludes the MODE change restriction of LCO 3.0.4. This exception allows entry into an applicable MODE while relying on the ACTIONS even though the ACTIONS may eventually require a unit shutdown. This exception is acceptable due to the low probability of an event requiring the RSW and because the equipment can generally be repaired during operation without significant risk of a spurious trip.

A.1

Condition A addresses the situation where the RSW is inoperable. The Required Action is to restore the RSW to OPERABLE status within 30 days. The Completion Time is based on operating experience and the low probability of an event that would require evacuation of the control room.

B.1 and B.2

If the Required Action and associated Completion Time of Condition A is not met, the unit must be brought to a MODE in which the LCO does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 with $T_{avg} < 350°F$ within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.3.4.1

SR 3.3.4.1 verifies that each required RSW transfer switch performs the required functions. This ensures that if the control room becomes inaccessible, the unit can be placed and maintained in MODE 4 with T_{avg} < 350°F from the RSW. The 24 month Frequency was developed considering it is prudent that these types of surveillances be performed during a unit outage. However, this surveillance is not required to be performed only during a unit outage. This is due to the unit conditions needed to perform the surveillance and the potential for unplanned transients if the surveillance is performed with the reactor at power. Operating experience demonstrates that RSW transfer switches usually pass the surveillance test when performed on the 24 month Frequency.

SR 3.3.4.2

This Surveillance verifies that the RSW communicates controls and indications with Divisions A, B, C, and D of the PMS. Communication is accomplished by use of separate multiplexers for each division. The operator can select the controls and indications available through each PMS division.

The Frequency is based on the known reliability of the Functions and the redundancy available, and has been shown to be acceptable through operating experience.

SR 3.3.4.3

SR 3.3.4.3 verifies the OPERABILITY of the RSW hardware and software by performing diagnostics to show that operator displays are capable of being called up and displayed to an operator at the RSW. The RSW has several video display units which can be used by the operator. The video display units are identical to that provided in the control room and the operator can display information on the video display units in a manner which is identical to the way the information is displayed in the control room. The operator normally selects an appropriate set of displays based on the particular operational goals being controlled by the operator at the time. Each display consists of static graphical and legend information which is contained within the display processor associated with each video display unit and dynamic data which is updated by the data display system.

The Frequency of 24 months is based on the use of the data display capability in the control room as part of the normal unit operation and the

BASES

SURVEILLANCE REQUIREMENTS (continued)

availability of multiple video display units at the RSW. The Frequency of 24 months is based upon operating experience and consistency with control room hardware and software.

SR 3.3.4.4

SR 3.3.4.4 is the performance of a TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT) every 24 months. This test should verify the OPERABILITY of the reactor trip breakers (RTBs) open and closed indication on the RSW by actuating the RTBs. The Frequency of 24 months was chosen because the RTBs may not be exercised while the facility is at power and is based on operating experience and consistency with the refueling outage.

B 3.3 INSTRUMENTATION

B 3.3.5 Diverse Actuation System (DAS) Manual Controls

BASES

BACKGROUND

The Diverse Actuation System (DAS) manual controls provide non-Class 1E backup controls in case of common-mode failure of the Protection and Safety Monitoring System (PMS) automatic and manual actuations evaluated in the AP1000 PRA. These DAS manual controls are not credited for mitigating accidents in the DCD Chapter 15 analyses.

The specific DAS controls were selected based on PRA risk importance as discussed in Reference 1. As noted in Reference 1, electrical power for these controls and instrument indications need not be covered by Technical Specifications. The rational is that these controls use the same nonsafety-related power supply used by the plant control system. This power is required to be available to support normal operation of the plant. With offsite power available, there are several sources to provide this power including AC power to non-Class 1E battery chargers, AC power to rectifiers, and non-Class 1E batteries. As a result, with offsite power available it is very likely that power will be available for these DAS controls. If offsite power is not available, then there is still the likelihood that the non-1E batteries or the non-1E diesel generators will be available. Even if these sources are unavailable, the desired actions will occur without operator action for the more probable events. The rods will insert automatically on loss of offsite power. The passive residual heat removal heat exchanger (PRHR HX), core makeup tanks (CMT), passive containment cooling system (PCS), and containment isolation features are initiated by operation of fail-safe, air-operated valves. If all offsite and onsite AC power is lost, the instrument air system will depressurize by the time these functions are needed in the 1-hour time frame.

Instrument readouts are expected to be available even in case of complete failure of the PMS due to common cause failure. These instruments include both DAS and PLS instruments. They are powered by DC sources for 24 or 72 hours following a loss of AC power, as described in DCD Section 8.3.2. As discussed above, it is expected that AC power will be available to power the instruments. Even if the operators have no instrument indications, they are expected to actuate the controls most likely to be needed (PRHR HX, CMT, PCS, and containment isolation). If all AC power fails, then the rods will drop and the air-operated valves will go to their fail-safe positions.

The DAS uses equipment from sensor output to the final actuated device that is diverse from the PMS to automatically initiate a reactor trip, or to manually actuate the identified safety-related equipment. DCD Section 7.7.1.11 (Ref. 2) provides a description of the DAS.

BASES

APPLICABLE SAFETY ANALYSES

The DAS manual controls are required to provide a diverse capability to manually trip the reactor and actuate the specified safety-related equipment, based on risk importance in the AP1000 PRA.

The DAS manual controls are not credited for mitigating accidents in the DCD Chapter 15 safety analyses.

The AP1000 PRA, Appendix A, provides additional information, including the thermal and hydraulic analyses of success sequences used in the PRA.

The DAS manual controls satisfy Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The DAS LCO provides the requirements for the OPERABILITY of the DAS manual trip and actuation controls necessary to place the reactor in a shutdown condition and to remove decay heat in the event that the PMS automatic actuation and manual controls are inoperable.

APPLICABILITY

The DAS manual controls are required to be OPERABLE in the MODES specified in Table 3.3.5-1.

The manual DAS reactor trip control is required to be OPERABLE in MODES 1 and 2 to mitigate the effects of an ATWS event occurring during power operation.

The other manual DAS actuation controls are required to be available in the plant MODES specified, based on the need for operator action to actuate the specified components during events that may occur in these various plant conditions, as identified in the AP1000 PRA.

ACTIONS

A.1

Condition A applies when one or more DAS manual controls are inoperable.

The Required Action A.1 to restore the inoperable DAS manual control(s) to OPERABLE status within 30 days is reasonable because the DAS is a separate and diverse non-safety backup system for the manual reactor trip and manual safety-related equipment actuation controls. The 30-day Completion Time allows sufficient time to repair an inoperable manual DAS control but ensures the control is repaired to provide backup protection.

BASES

ACTIONS (continued)

B.1 and B.2

Condition B applies when Required Action A cannot be completed for the DAS manual reactor trip control within the required completion time of 30 days.

Required Action B.1 requires SR 3.3.1.6, “Perform TADOT” for the reactor trip breakers, to be performed once per 31 days, instead of once every 92 days. Condition A of Example 1.3-6 illustrates the use of the Completion Time for Required Action B.1. The initial performance of SR 3.3.1.6 on the first division (since it is performed on a STAGGERED TEST BASIS) must be completed within 31 days of entering Condition B. The normal surveillance test frequency requirements for SR 3.3.1.6 must still be satisfied while performing SR 3.3.1.6 for Required Action B.1. The predominant failure requiring the DAS manual reactor trip control is common-mode failure of the reactor trip breakers. This change in surveillance frequency for testing the reactor trip breakers increases the likelihood that a common-mode failure of the reactor trip breakers would be detected while the DAS manual reactor trip control is inoperable. This reduces the likelihood that a diverse manual reactor trip is required. It is not required to perform a TADOT for the manual actuation control. The manual reactor trip control is very simple, highly reliable, and does not use software in the circuitry. Although the DAS manual controls are non-Class 1E, they have been shown to be PRA risk important as discussed in Reference 1. The impact of an inoperable DAS manual control is compensated for by increasing the reactor trip breaker surveillance frequency from once every 92 days to once every 31 days.

Action B.2 requires that the inoperable DAS manual reactor trip control be restored to OPERABLE status prior to entering MODE 2 following any plant shutdown to MODE 5 while the control is inoperable. This ACTION is provided to ensure that all DAS manual controls are restored to OPERABLE status following the next plant shutdown.

C.1 and C.2

Condition C applies when Required Action A cannot be completed for any DAS manual actuation control (other than reactor trip) within the required completion time of 30 days.

Required Action C.1 requires SR 3.3.2.2, “Perform ACTUATION LOGIC TEST,” to be performed once per 31 days, instead of once every 92 days. Condition A of Example 1.3-6 illustrates the use of the Completion Time for Required Action C.1. The initial performance of SR 3.3.2.2 on the first

BASES

ACTIONS (continued)

division (since it is performed on a STAGGERED TEST BASIS) must be completed within 31 days of entering Condition C. The normal surveillance test frequency requirements for SR 3.3.2.2 must still be satisfied while performing SR 3.3.2.2 for Required Action C.1. The predominant failure requiring the DAS manual actuation control is common-mode failure of the PMS actuation logic software or hardware. This change in surveillance frequency for actuation logic testing increases the likelihood that a common-mode failure of the PMS actuation logic from either cause would be detected while any DAS manual actuation control is inoperable. This reduces the likelihood that a diverse component actuation is required. It is not required to perform a TADOT for the manual actuation control device since the manual actuation control devices are very simple and highly reliable. Although the DAS manual controls are non-Class 1E, they have been shown to be PRA risk important as discussed in Reference 1. The impact of an inoperable DAS manual control is compensated for by increasing the automatic actuation surveillance frequency from once every 92 days to once every 31 days.

Action C.2 requires that the inoperable DAS manual actuation control(s) be restored to OPERABLE status prior to entering MODE 2 following any plant shutdown to MODE 5 while the control is inoperable. This ACTION is provided to ensure that all DAS manual controls are restored to OPERABLE status following the next plant shutdown.

D.1 and D.2

Condition D is entered if the Required Action associated with Condition B or C is not met within the required Completion Time.

Required Actions D.1 and D.2 ensure that the plant is placed in a condition where the probability and consequences of an event are minimized. The allowed Completion Times are reasonable based on plant operating experience, for reaching the required plant conditions from full power conditions in an orderly manner, without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.3.5.1

SR 3.3.5.1 is the performance of a TADOT of the DAS manual trip and actuation controls for the specified safety-related equipment. This TADOT is performed every 24 months.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Frequency is based on the known reliability of the DAS functions and has been shown to be acceptable through operating experience.

The SR is modified by a Note that excludes verification of the setpoints from the TADOT. The functions have no setpoints associated with them.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.1 RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits

BASES

BACKGROUND

These Bases address requirements for maintaining RCS pressure, temperature, and flow rate within the limits assumed in the safety analyses. The safety analyses (Ref. 1) of normal operating conditions and anticipated operational occurrences assume initial conditions within the normal steady state envelope of operating conditions. The limits placed on RCS pressure, temperature, and flow rate ensure that the minimum departure from nucleate boiling ratio (DNBR) will be met for each of the transients analyzed.

The RCS pressure limit is consistent with operation within the nominal operational envelope. Pressurizer pressure indications are averaged to come up with a value for comparison to the limit. A lower pressure will cause the reactor core to approach DNBR limits.

The RCS coolant average temperature limit is consistent with full power operation within the nominal operational envelope. Indications of temperature are averaged to determine a value for comparison to the limit. A higher average temperature will cause the core to approach DNB limits.

The RCS flow rate normally remains constant during an operational fuel cycle with all pumps running. The minimum RCS flow limit corresponds to that assumed for DNB analyses. At the beginning of the first fuel cycle, precision (calorimetric) flow measurements, augmented by hydraulic measurements in the reactor coolant loop and pump performance, provide a value for comparison to the limit, and to determine the calibration coefficients for future use with differential pressure measurements. The reactor coolant flow rate channels are normalized to these test measurements for 100-percent indication using these calibration coefficients and are frequently monitored to determine flow degradation. A lower RCS flow will cause the core to approach DNB limits.

Operation for significant periods of time outside these DNB limits increases the likelihood of a fuel cladding failure in a DNB limited event.

BASES

APPLICABLE SAFETY ANALYSES

The requirements of this LCO represent the initial conditions for DNB limited transients analyzed in the plant safety analyses (Ref. 1). The safety analyses have shown transients initiated within the requirements of this LCO will result in meeting the DNBR criterion. This is the acceptance limit for the RCS DNB parameters. Changes to the unit which could impact these parameters must be assessed for their impact on the DNBR criterion. The transients analyzed include loss of coolant flow events and dropped or stuck rod events. An assumption for the analysis of these events is that the core power distribution is within the limits of LCO 3.1.6, “Control Bank Insertion Limits”; LCO 3.2.3, “AXIAL FLUX DIFFERENCE (AFD)”; and LCO 3.2.4, “QUADRANT POWER TILT RATIO (QPTR).”

The pressurizer pressure limit and the RCS average temperature limit specified in the COLR correspond to analytical limits, with an allowance for steady state fluctuations and measurement errors. The RCS average temperature limit corresponds to the analytical limit with allowance for controller deadband and measurement uncertainty.

The RCS DNB parameters satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO specifies limits on the monitored process variables, pressurizer pressure, RCS average temperature, and RCS total flow rate to ensure the core operates within the limits assumed in the safety analyses. These variables are contained in the COLR to provide operating and analysis flexibility from cycle to cycle. However, the minimum RCS flow, usually based on maximum analyzed steam generator tube plugging, is retained in the TS LCO. Operating within these limits will result in meeting DNBR criterion in the event of a DNB limited transient.

The COLR RCS total flow rate limit is equal to or more restrictive than the ≥ 301,670 gpm limit specified in the LCO. The COLR limit reflects the cycle-specific core design and plant conditions as well as added margin.

Separate minimum RCS total flow rate limits are specified in the COLR for measurement by precision heat balance or by differential pressure instrumentation. Different flow limits may apply for each measurement method since the two methods have unique measurement errors and instrument allowances that are included in the COLR RCS flow rate limits.

The calibration coefficients for the differential pressure (hot-leg elbow and cold-leg bend) RCS total flow rate indication channels are established based on the comprehensive RCS flow measurements taken at the beginning of the first fuel cycle. These measurements include precision (calorimetric) flow, differential temperature, reactor coolant loop hydraulic tests, and pump performance. The differential pressure calibration

BASES

LCO (continued)

coefficients are not expected to change during plant life. Measurement errors associated with the method used to determine the calibration coefficients are included in the differential pressure COLR RCS flow rate limit.

The numerical values for pressure, temperature, and flow rate specified in the COLR are given for the measurement location but have been adjusted for instrument error.

APPLICABILITY

In MODE 1, the limits on pressurizer pressure, RCS coolant average temperature, and RCS flow rate must be maintained during steady state plant operation in order to ensure DNBR criterion will be met in the event of an unplanned loss of forced coolant flow or other DNB-limiting transient. In all other MODES, the power level is low enough that DNB is not a concern.

A Note has been added to indicate the limit on pressurizer pressure is not applicable during short term operational transients such as a THERMAL POWER ramp increase > 5% RTP per minute or a THERMAL POWER step increase > 10% RTP. These conditions represent short term perturbations where actions to control pressure variations might be counter productive. Also, since they represent transients initiated from power levels < 100% RTP, an increased DNBR margin exists to offset the temporary pressure variations.

The DNBR limit is provided in SL 2.1.1, “Reactor Core SLs.” The conditions which define the DNBR limit are less restrictive than the limits of this LCO, but violation of a Safety Limit (SL) merits a stricter, more severe Required Action. Should a violation of this LCO occur, the operator must check whether an SL may have been exceeded.

ACTIONS

A.1

RCS pressure and RCS average temperature are controllable and measurable parameters. With one or both of these parameters not within LCO limits, action must be taken to restore parameter(s).

RCS total flow rate is not a controllable parameter and is not expected to vary during steady state operation. If the indicated RCS total flow rate is below the LCO limit, power must be reduced, as required by Required Action B.1, to restore DNB margin and eliminate the potential for violation of the accident analysis bounds.

BASES

ACTIONS (continued)

The 2 hour Completion Time for restoration of the parameters provides sufficient time to adjust plant parameters, to determine the cause for the off normal condition, and to restore the readings within limits, and is based on plant operating experience.

B.1

If Required Action A.1 is not met within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 2 within 6 hours. In MODE 2, the reduced power condition eliminates the potential for violation of the accident analysis bounds. The Completion Time of 6 hours is reasonable to reach the required plant conditions in an orderly manner.

SURVEILLANCE REQUIREMENTS

SR 3.4.1.1

Since Required Action A.1 allows a Completion Time of 2 hours to restore parameters that are not within limits, the 12 hour Surveillance Frequency of pressurizer pressure is sufficient to ensure the pressure can be restored to a normal operation, steady state condition following load changes and other expected transient operations. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess for potential degradation and to verify operation is within safety analysis assumptions.

SR 3.4.1.2

Since Required Action A.1 allows a Completion Time of 2 hours to restore parameters that are not within limits, the 12 hour Surveillance Frequency for RCS average temperature is sufficient to ensure the temperature can be restored to a normal operation, steady state condition following load changes and other expected transient operations. The 12 hour Frequency has been shown by operating practice to be sufficient to regularly assess for potential degradation and to verify operation is within safety analysis assumptions.

SR 3.4.1.3

The 12 hour Surveillance Frequency for RCS total flow rate is performed using the installed differential pressure flow instrumentation. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess potential degradation and to verify operation within safety analysis assumptions.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.1.4

A CHANNEL CALIBRATION of the RCS total flow rate indication channels is performed every 24 months, at the beginning of each fuel cycle.

CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter with the necessary range and accuracy.

The Frequency is based on consistency with the refueling cycle.

SR 3.4.1.5

Measurement of RCS total flow rate by performance of precision test measurements once every 24 months, at the beginning of each fuel cycle, allows the installed RCS flow instrumentation to be normalized and verifies the actual RCS flow is greater than or equal to the minimum required RCS flow rate. These test measurements may be based on a precision heat balance, or by differential pressure measurements of static elements in the RCS piping (such as elbows) that have been calibrated by previous precision tests, or by a combination of those two methods. In all cases, the measured flow, less allowance for error, must exceed the corresponding value used in the safety analysis and specified in the COLR.

The Frequency of 24 months reflects the importance of verifying flow after a refueling outage when the core has been altered, which may have caused an alteration of flow resistance.

This SR is modified by a Note that allows entry into MODE 1, without having performed the SR, and placement of the unit in the best condition for performing the SR. The Note states that the SR is not required to be performed until after 24 hours after ≥ 90% RTP. This exception is appropriate since the heat balance requires the plant to be at a minimum of 90% RTP to obtain the stated RCS flow accuracies. The Surveillance shall be performed within 24 hours after reaching 90% RTP.

REFERENCES 1. Chapter 15, “Accident Analyses.”

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.2 RCS Minimum Temperature for Criticality

BASES

BACKGROUND

This LCO is based upon meeting several major considerations before the reactor can be made critical and while the reactor is critical.

The first consideration is moderator temperature coefficient (MTC), LCO 3.1.3, “Moderator Temperature Coefficient (MTC).” In the transient and accident analyses, the MTC is assumed to be in a range from zero to negative and the operating temperature is assumed to be within the nominal operating envelope while the reactor is critical. The LCO on minimum temperature for criticality helps ensure the plant is operated consistent with these assumptions.

The second consideration is the protective instrumentation. Because certain protective instrumentation (e.g., excore neutron detectors) can be affected by moderator temperature, a temperature value within the nominal operating envelope is chosen to ensure proper indication and response while the reactor is critical.

The third consideration is the pressurizer operating characteristics. The transient and accident analyses assume that the pressurizer is within its normal startup and operating range (i.e., saturated conditions and steam bubble present). It is also assumed that the RCS temperature is within its normal expected range for startup and power operation. Since the density of the water, and hence the response of the pressurizer to transients, depends upon the initial temperature of the moderator, a minimum value for moderator temperature within the nominal operating envelope is chosen.

The fourth consideration is that the reactor vessel is above its minimum nil-ductility reference temperature when the reactor is critical.

APPLICABLE SAFETY ANALYSES

Although the RCS minimum temperature for criticality is not itself an initial condition assumed in Design Basis Accidents (DBAs), the closely aligned temperature for hot zero power (HZP) is a process variable that is an initial condition of DBAs, such as the rod cluster control assembly (RCCA) withdrawal, RCCA ejection, and main steam line break accidents performed at zero power that either assume the failure of, or presents a challenge to, the integrity of a fission product barrier.

BASES

APPLICABLE SAFETY ANALYSES (continued)

All low power safety analyses assume initial RCS loop temperatures ≥ the HZP temperature of 557°F (Ref. 1). The minimum temperature for criticality limitation provides a small band, 6°F, for critical operation below HZP. This band allows critical operation below HZP during plant startup and does not adversely affect any safety analyses since the MTC is not significantly affected by the small temperature difference between HZP and the minimum temperature for criticality.

The RCS minimum temperature for criticality parameter satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

Compliance with the LCO ensures that the reactor will not be made or maintained critical (k_{eff} ≥ 1.0) at a temperature less than a small band below the HZP temperature, which is assumed in the safety analysis. Failure to meet the requirements of this LCO may produce initial conditions inconsistent with the initial conditions assumed in the safety analysis.

APPLICABILITY

In MODE 1 and MODE 2 with k_{eff} ≥ 1.0, LCO 3.4.2 is applicable since the reactor can only be critical (k_{eff} ≥ 1.0) in these MODES.

The special test exception of LCO 3.1.8, “MODE 2 PHYSICS TEST Exceptions,” permits PHYSICS TESTS to be performed at ≤ 5.0% RTP with RCS loop average temperatures slightly lower than normally allowed so that fundamental nuclear characteristics of the core can be verified. In order for nuclear characteristics to be accurately measured, it may be necessary to operate outside the normal restrictions of this LCO. For example, to measure the MTC at beginning of cycle, it is necessary to allow RCS loop average temperatures to fall below $T_{no\ load}$, which may cause RCS loop average temperatures to fall below the temperature limit of this LCO.

ACTIONS

A.1

If the parameters that are outside the limit cannot be restored, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 2 with k_{eff} < 1.0 within 30 minutes. Rapid reactor shutdown can be readily and practically achieved within a 30 minute period. The allowed time is reasonable, based on operating experience, to reach MODE 2 with k_{eff} < 1.0 in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.2.1

RCS loop average temperature is required to be verified at or above 551°F every 12 hours. The SR to verify RCS loop average temperatures every 12 hours takes into account indications and alarms that are continuously available to the operator in the control room and is consistent with other routine Surveillances which are typically performed once per shift. In addition, operators are trained to be sensitive to RCS temperature during approach to criticality and will ensure that the minimum temperature for criticality is met as criticality is approached.

REFERENCES

1. Chapter 15, “Accident Analyses.”

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.3 RCS Pressure and Temperature (P/T) Limits

BASES

BACKGROUND

All components of the RCS are designed to withstand effects of cyclic loads due to system pressure and temperature changes. These loads are introduced by startup (heatup) and shutdown (cooldown) operations, power transients, and reactor trips. This LCO limits the pressure and temperature changes during RCS heatup and cooldown, within the design assumptions and the stress limits for cyclic operation.

The PTLR contains P/T limit curves for heatup, cooldown, inservice leak and hydrostatic (ISLH) testing, and data for the maximum rate of change of reactor coolant temperature.

Each P/T limit curve defines an acceptable region for normal operation. The usual use of the curves is operational guidance during heatup or cooldown maneuvering, when pressure and temperature indications are monitored and compared to the applicable curve to determine that operation is within the allowable region.

The LCO establishes operating limits that provide a margin to brittle failure of the reactor vessel and piping of the reactor coolant pressure boundary (RCPB). The vessel is the component most subject to brittle failure, and the LCO limits apply mainly to the vessel. The limits do not apply to the pressurizer, which has different design characteristics and operating functions.

10 CFR 50, Appendix G (Ref. 1) requires the establishment of P/T limits for specific material fracture toughness requirements of the RCPB materials. An adequate margin to brittle failure must be provided during normal operation, anticipated operational occurrences, and system hydrostatic tests. Reference 1 mandates the use of the ASME Code, Section III, Appendix G (Ref. 2).

The neutron embrittlement effect on the material toughness is reflected by increasing the nil ductility reference temperature (RT_{NDT}) as exposure to neutron fluence increases.

The actual shift in the RT_{NDT} of the vessel material will be established periodically by removing and evaluating the irradiated reactor vessel material specimens, in accordance with ASTM E 185 (Ref. 3) and Appendix H of 10 CFR 50 (Ref. 4). The operating P/T limit curves will be adjusted, as necessary, based on the evaluation findings and the recommendations of Regulatory Guide 1.99 (Ref. 5).

BASES

BACKGROUND (continued)

The P/T limit curves are composite curves established by superimposing limits derived from stress analyses of those portions of the reactor vessel and head that are the most restrictive. At any specific pressure, temperature, and temperature rate of change, one location within the reactor vessel will dictate the most restrictive limit. Across the P/T span of the limit curves, different locations are more restrictive, and, thus, the curves are composites of the most restrictive regions.

The heatup curve represents a different set of restrictions than the cooldown curve because the directions of the thermal gradients through the vessel wall are reversed. The thermal gradient reversal alters the location of the tensile stress between the outer and inner walls.

The criticality limit curve includes the Reference 1 requirement that it be ≥ 40°F above the heatup curve or the cooldown curve, and not less than the minimum permissible temperature for ISLH Testing. However, the criticality curve is not operationally limiting; a more restrictive limit exists in LCO 3.4.2, “RCS Minimum Temperature for Criticality.”

The consequence of violating the LCO limits is that the RCS has been operated under conditions that can result in brittle failure of the RCPB, possibly leading to a nonisolable leak or loss of coolant accident. In the event these limits are exceeded, an evaluation must be performed to determine the effect on the structural integrity of the RCPB components. ASME Code, Section XI, Appendix E (Ref. 6) provides a recommended methodology for evaluating an operating event that causes an excursion outside the limits.

APPLICABLE SAFETY ANALYSES

The P/T limits are not derived from Design Basis Accident (DBA) analyses. They are prescribed during normal operation to avoid encountering pressure, temperature, and temperature rate of change conditions that might cause undetected flaws to propagate and cause nonductile failure of the RCPB, an unanalyzed condition. Reference 7 establishes the methodology for determining the P/T limits. Although the P/T limits are not derived from any DBA, the P/T limits are acceptance limits since they preclude operation in an unanalyzed condition.

RCS P/T limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The two elements of this LCO are:

a. The limit curves for heatup, cooldown, ISLH testing and criticality; and

b. Limits on the rate of change of temperature.

The LCO limits apply to all components of the RCS, except the pressurizer. These limits define allowable operating regions and permit a large number of operating cycles while providing a wide margin to nonductile failure.
The limits for the rate of change of temperature control the thermal gradient through the vessel wall and are used as inputs for calculating the heatup, cooldown, and ISLH testing P/T limit curves. Thus, the LCO for the rate of change of temperature restricts stresses caused by thermal gradients and also ensures the validity of the P/T limit curves.

Violating the LCO limits places the reactor vessel outside of the bounds of the stress analyses and can increase stresses in other RCPB components. The consequences depend on several factors, as follow:

a. The severity of the departure from the allowable operating P/T regime or the severity of the rate of change of temperature;

b. The length of time the limits were violated (longer violations allow the temperature gradient in the thick vessel walls to become more pronounced); and

c. The existences, sizes, and orientations of flaws in the vessel material.

APPLICABILITY

The RCS P/T limits LCO provides a definition of acceptable operation for prevention of nonductile (brittle) failure in accordance with 10 CFR 50, Appendix G (Ref. 1). Although the P/T limits were developed to provide guidance for operation during heatup or cooldown (MODES 3, 4, and 5) or ISLH testing, they are applicable at all times in keeping with the concern for nonductile failure. The limits do not apply to the pressurizer.

During MODES 1 and 2, other Technical Specifications provide limits for operation that can be more restrictive than or can supplement these P/T limits. LCO 3.4.1, “RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits”; LCO 3.4.2, “RCS Minimum Temperature for Criticality”; and Safety Limit 2.1, “Safety Limits,” also provide operational restrictions for pressure and temperature and

BASES

APPLICABILITY (continued)

maximum pressure. Furthermore, MODES 1 and 2 are above the temperature range of concern for nonductile failure, and stress analyses have been performed for normal maneuvering profiles, such as power ascension or descent.

ACTIONS

The actions of this LCO consider the premise that a violation of the limits occurred during normal plant maneuvering. Severe violations caused by abnormal transients, at times accompanied by equipment failures, may also require additional actions from emergency operating procedures.

A.1 and A.2

Operation outside the P/T limits must be restored to within the limits. The RCPB must be returned to a condition that has been verified by stress analyses. Restoration is in the proper direction to reduce RCPB stress.

The 30 minute Completion Time reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify the RCPB integrity remains acceptable and must be completed before continuing operation. Several methods may be used, including comparison with preanalyzed transients in the stress analyses, new analyses, or inspection of the components.

ASME Code, Section XI, Appendix E (Ref. 6) may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The 72 hour Completion Time is reasonable to accomplish the evaluation. The evaluation for a mild violation is possible within this time, but more severe violations may require special, event specific stress analyses or inspections. A favorable evaluation must be completed before continuing to operate.

Condition A is modified by a Note requiring Required Action A.2 be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration per Required Action A.1 alone is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

BASES

ACTIONS (continued)

B.1 and B.2

If a Required Action and associated Completion Time of Condition A are not met, the plant must be placed in a lower MODE because either the RCS remained in an unacceptable P/T region for an extended period of increased stress, or a sufficiently severe event caused entry into an unacceptable region. Either possibility indicates a need for more careful examination of the event, best accomplished with the RCS at reduced pressure and temperature. In reduced pressure and temperature conditions, the possibility of propagation with undetected flaws is decreased.

If the required restoration activity cannot be accomplished in 30 minutes, Required Action B.1 and Required Action B.2 must be implemented to reduce pressure and temperature.

If the required evaluation for continued operation cannot be accomplished within 72 hours or the results are indeterminate or unfavorable, action must proceed to reduce pressure and temperature as specified in Required Action B.1 and Required Action B.2. A favorable evaluation must be completed and documented before returning to operate pressure and temperature conditions.

Pressure and temperature are reduced by bringing the plant to MODE 3 within 6 hours and to MODE 4 within 24 hours, with RCS pressure < 500 psig.

The allowed Completion Times are reasonable based on operating experience, to reach the required plant conditions from full power condition in an orderly manner without challenging plant systems.

C.1 and C.2

Actions must be initiated immediately to correct operation outside of the P/T limits at times other than when in MODE 1, 2, 3, or 4, so that the RCPB is returned to a condition that has been verified by stress analysis.

The immediate Completion Time reflects the urgency of initiating action to restore the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify that the RCPB integrity remains acceptable and must be completed prior to

BASES

ACTIONS (continued)

entry into MODE 4. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, or inspection of the components.

ASME Code, Section XI, Appendix E (Ref. 6), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

Condition C is modified by a Note requiring Required Action C.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action C.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

SURVEILLANCE REQUIREMENTS

SR 3.4.3.1

Verification that operation is within PTLR limits is required every 30 minutes when RCS P/T conditions are undergoing planned changes. This Frequency is considered reasonable in view of the control room indication available to monitor RCS status. Also, since temperature rate of change limits are specified in hourly increments, 30 minutes permits assessment and correction for minor deviations within a reasonable time.

Surveillance for heatup, cooldown, or ISLH testing may be discontinued when the definition given in the relevant plant procedure for ending the activity is satisfied.

This SR is modified by a Note that only requires this surveillance to be performed during system heatup, cooldown, and ISLH testing. No SR is given for criticality operations because LCO 3.4.2, “RCS Minimum Temperature for Criticality,” contains a more restrictive requirement.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.4 RCS Loops

BASES

BACKGROUND

The primary function of the RCS is removal of the heat generated in the fuel due to the fission process, and transfer of this heat, via the steam generators (SGs) to the secondary plant.

The secondary functions of the RCS include:

a. Moderating the neutron energy level to the thermal state, to increase the probability of fission;

b. Improving the neutron economy by acting as a reflector;

c. Carrying the soluble neutron poison, boric acid;

d. Providing a second barrier against fission-product release to the environment; and

e. Removal of the heat generated in the fuel due to fission-product decay following a unit shutdown.

The reactor coolant is circulated through two loops connected in parallel to the reactor vessel, each containing a SG, two reactor coolant pumps (RCPs), and appropriate flow and temperature instrumentation for both control and protection. The reactor vessel contains the fuel. The SGs provide the heat sink to the isolated secondary coolant. The RCPs circulate the primary coolant through the reactor vessel and SGs at a sufficient rate to ensure proper heat transfer and prevent fuel damage. This forced circulation of the reactor coolant ensures mixing of the coolant for proper boration and chemistry control.

The RCPs must be started using the variable speed controller with the reactor trip breakers open. The controller shall be bypassed prior to closure of the reactor trip breakers.

APPLICABLE SAFETY ANALYSES

MODES 1 and 2

Safety analyses contain various assumptions for the design bases accident initial conditions including RCS pressure, RCS temperature, reactor power level, core parameters, and safety system setpoints. The important aspect for this LCO is the reactor coolant forced flow rate, which is represented by the number of RCS loops and RCPs in service.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Both transient and steady state analyses have been performed to establish the effect of flow on the departure from nucleate boiling (DNB). The transient and accident analyses for the plant have been performed assuming two RCS loops are initially in operation. The majority of the plant safety analyses are based on initial conditions at high core power or zero power. The accident analyses, where RCP operation is most important are the four pump coastdown, single pump locked rotor, single pump broken shaft or coastdown, and rod withdrawal events (Ref. 1).

Steady state DNB analysis has been performed for the two RCS loop operation. For two RCS loop operation, the steady state DNB analysis, which generates the pressure and temperature Safety Limit (SL) (i.e., the departure from nucleate boiling ratio (DNBR) limit) assumes a maximum power level of 100% RATED THERMAL POWER (RTP). This is the design overpower condition for two RCS loop operation. The value for the accident analysis setpoint of the nuclear overpower (high flux) trip is 118% and is based on an analysis assumption that bounds possible instrumentation errors. The DNBR limit defines a locus of pressure and temperature points which result in a minimum DNBR greater than or equal to the critical heat flux correlation limit.

The plant is designed to operate with both RCS loops in operation to maintain DNBR above the SL, during all normal operations and anticipated transients. By ensuring heat transfer in the nucleate boiling region, adequate heat transfer is provided between the fuel cladding and the reactor coolant.

MODES 3, 4, and 5

Whenever the reactor trip breakers are in the closed position and the control rod drive mechanisms (CRDMs) are energized, there is the possibility of an inadvertent rod withdrawal from subcritical, resulting in a power excursion in the area of the withdrawn rod. Such a transient could be caused by a malfunction of the Plant Control System (PLS). In addition, the possibility of a power excursion due to the ejection of an inserted control rod is possible with the breakers closed or open. Such a transient could be caused by the mechanical failure of a CRDM. The initial power rise is terminated by doppler broadening in the fuel pins, followed by rod insertion. During this event, if there is not adequate coolant flow along the clad surface of the fuel, there is a potential to exceed the departure from nucleate boiling ratio (DNBR) limit. Therefore, the required coolant flow is an initial condition of a design basis event that presents a challenge to the integrity of a fission product barrier.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Therefore, in MODE 3, 4 or 5 with the RTBs in the closed position and the PLS capable of rod withdrawal, accidental control rod withdrawal from subcritical is postulated and requires the RCPs to be OPERABLE and in operation to ensure that the accident analysis limits are met.

In MODES 3, 4 and 5 with the RTBs open, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. This is addressed in LCO 3.4.8, “Minimum RCS Flow.”

RCS Loops satisfy Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require an adequate forced flow rate for core heat removal. Flow is represented by the number of RCPs in operation for removal of heat by the SGs. To meet safety analysis acceptance criteria for DNB, four pumps are required in MODES 1 and 2. The requirement that at least four RCPs must be operating in MODES 3, 4 and 5 when the RTBs are closed provides assurance that, in the event of a rod withdrawal accident, there will be adequate flow in the core to avoid exceeding the DNBR limit. Bypass of the RCP variable speed control ensures that the pumps are operating at full flow.

With the RTBs in the open position, the PLS is not capable of rod withdrawal; therefore only a minimum RCS flow of 3,000 gpm is necessary to ensure removal of decay heat from the core in accordance with LCO 3.4.8, Minimum RCS Flow.

Note 1 prohibits startup of a RCP when the reactor trip breakers are closed. This requirement prevents startup of a RCP and the resulting circulation of cold and/or unborated water from an inactive loop into the core, precluding reactivity excursion events which are unanalyzed.

Note 2 prohibits startup of an RCP when the RCS temperature is $\geq$ 350°F unless pressurizer level is < 92%. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started.

Note 3 requires that the secondary side water temperature of each SG be ≤ 50°F above each of the RCS cold leg temperatures before the start of an RCP with any RCS cold leg temperature ≤ 350°F, and the RCP must be started at ≤ 25% of RCP speed. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started. This limitation also helps to ensure that the RNS system pressure remains below both the piping design pressure and the acceptable RNS relief valve inlet pressure.

BASES

LCO (continued)

Note 4 permits all RCPS to be de-energized in MODE 3, 4, or 5 for ≤ 1 hour per 8 hour period. The purpose of the Note is to permit tests that are designed to validate various accident analysis values. One of these tests is for the validation of the pump coastdown curve, used as input to a number of accident analyses including a loss of flow accident.

This test is generally performed in MODE 3 during the initial startup testing program, and as such should only be performed once. If, however, changes are made to the RCS that would cause a change to the flow characteristics of the RCS, the input values of the coastdown curve may need to be revalidated by conducting the test again.

Another test performed during the startup testing program is the validation of the rod drop times during cold conditions, both with and without flow.

The no-flow tests may be performed in MODE 3, 4, or 5, and require that the pumps be stopped for a short period of time. The Note permits the de-energizing of the pumps in order to perform this test and validate the assumed analysis values. As with the validation of the pump coastdown curve, this test should only be performed once, unless the flow characteristics of the RCS are changed. The 1 hour time period specified is adequate to perform the desired tests and experience has shown that boron stratification is not a problem during this short period with no forced flow.

Utilization of the Note is permitted provided the following conditions are met along with any other conditions imposed by initial startup test procedures:

a. No operations are permitted that would dilute the RCS boron concentration with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1, thereby maintaining the margin to criticality. Boron reduction with coolant at boron concentrations less than required to assure SDM is maintained is prohibited because a uniform concentration distribution throughout the RCS cannot be ensured when in natural circulation and

b. Core outlet temperature is maintained at least 10°F below saturation temperature, so that no vapor bubble may form and possibly cause natural circulation flow obstruction.

An OPERABLE RCS loop is composed of two OPERABLE RCPs in operation providing forced flow for heat transport and an OPERABLE SG.

BASES

APPLICABILITY

In MODES 1 and 2, the reactor is critical and thus has the potential to produce maximum THERMAL POWER. Thus, to ensure that the assumptions of the accident analyses remain valid, both RCS loops are required to be OPERABLE and in operation in these MODES to prevent DNB and core damage.

In MODES 3, 4 and 5, this LCO ensures forced circulation of the reactor coolant to remove decay heat from the core and to provide proper boron mixing. For these purposes and because the reactor trip breakers are closed, there is the possibility of an inadvertent rod withdrawal event. Four RCPs are required to be operating in MODES 3, 4 and 5, whenever the reactor trip breakers are closed.

ACTIONS

A.1

If the requirements of the LCO are not met while in MODE 1 or 2, the Required Action is to reduce power and bring the plant to MODE 3 with the reactor trip breakers open. This lowers power level and thus reduces the core heat removal needs and minimizes the possibility of violating DNB limits.

Condition A is modified by a Note which requires completion of Required Action A.1 whenever the Condition is entered. This ensures that no attempt is made to restart a pump with the reactor trip breakers closed, thus precluding events which are unanalyzed.

When all four reactor coolant pumps are operating, a loss of a single reactor coolant pump above power level P-10 will result in an automatic reactor trip.

The Completion Time of 6 hours is reasonable to allow for an orderly transition to MODE 3. The applicable safety analyses described above bound Design Basis Accidents (DBA) initiated with three reactor coolant pumps operating at power levels below P-10.

B.1

If the requirements of the LCO are not met while in MODE 3, 4 or 5, the Required Action is to remain in MODE 3, 4 or 5 and open the reactor trip breakers. This action eliminates the possibility of a rod withdrawal event with one or more pumps not operating and thus minimizing the possibility of violating DNB limits.

BASES

ACTIONS (continued)

Condition B is modified by a Note which requires completion of Required Action B.1 whenever the Condition is entered. This ensures that no attempt is made to restart a pump with the reactor trip breakers closed, thus precluding events which are unanalyzed.

The Completion Time of 1 hour is reasonable to allow for planned opening of the reactor trip breakers, since plant cool-down is not required.

SURVEILLANCE REQUIREMENTS

SR 3.4.4.1

This SR requires verification every 12 hours that each RCS loop is in operation with the pump variable speed control bypassed. Verification includes flow rate and temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal while maintaining the margin to DNB. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the main control room to monitor RCS loop performance.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.5 Pressurizer

BASES

BACKGROUND

The pressurizer provides a point in the RCS where liquid and vapor are maintained in equilibrium under saturated conditions for pressure control purposes to prevent bulk boiling in the remainder of the RCS. Key functions include maintaining required primary system pressure during steady state operation, and limiting the pressure changes caused by reactor coolant thermal expansion and contraction during normal load transients.

The normal level and pressure control components addressed by this LCO include the pressurizer water level, the heaters, their controls, and power supplies. Pressurizer safety valves and automatic depressurization valves are addressed by LCO 3.4.6, “Pressurizer Safety Valves,” and LCO 3.4.11, “Automatic Depressurization System (ADS) – Operating,” respectively.

The intent of the LCO is to ensure that a steam bubble exists in the pressurizer prior to power operation to minimize the consequences of potential overpressure transients. The presence of a steam bubble is consistent with analytical assumptions. Relatively small amounts of noncondensible gases can inhibit the condensation heat transfer between the pressurizer spray and the steam, and diminish the spray effectiveness for pressure control.

Electrical immersion heaters, located in the lower section of the pressurizer vessel, keep the water in the pressurizer at saturation temperature and maintain a constant operating pressure.

APPLICABLE SAFETY ANALYSES

In MODES 1, 2, and 3, the LCO requirement for a steam bubble is reflected implicitly in the accident analyses. Safety analyses performed for lower MODES are not limiting. All analyses performed from a critical reactor condition assume the existence of a steam bubble and saturated conditions in the pressurizer. In making this assumption, the analyses neglect the small fraction of noncondensible gases normally present.

Safety analyses presented in Chapter 15 (Ref. 1) do not take credit for pressurizer heater operation, however, an implicit initial condition assumption of the safety analyses is that the RCS is operating at normal pressure.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The maximum pressurizer water level limit satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requirement for the pressurizer water volume ≤ 92% of span, ensures that an adequate steam bubble exists. Limiting the LCO maximum operating water level preserves the steam space for pressure control. The LCO has been established to ensure the capability to establish and maintain pressure control for steady state operation and to minimize the consequences of potential overpressure transients. Requiring the presence of a steam bubble is also consistent with analytical assumptions.

APPLICABILITY

The need for pressure control is most pertinent when core heat can cause the greatest effect on RCS temperature, resulting in the greatest effect on pressurizer level and RCS pressure control. Thus, applicability has been designated for MODES 1 and 2. The applicability is also provided for MODE 3. The purpose is to prevent solid water RCS operation during heatup and cooldown to avoid rapid pressure rises caused by normal operational perturbation, such as reactor coolant pump startup.

ACTIONS

A.1 and A.2

Pressurizer water level control malfunctions or other plant evolutions may result in a pressurizer water level above the nominal upper limit, even with the plant at steady state conditions.

If the pressurizer water level is above the limit, action must be taken to restore the plant to operation within the bounds of the safety analyses. This is done by restoring the level to within limit, within 6 hours, or by placing the unit in MODE 3 with the reactor trip breakers open within 6 hours, and placing the unit in MODE 4 within 12 hours. This takes the unit out of the applicable MODES and restores the unit to operation within the bounds of the safety analyses.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.5.1

This SR requires that during steady state operation, pressurizer level is maintained below the nominal upper limit to provide a minimum space for a steam bubble. The Surveillance is performed by observing the indicated level. The Frequency of 12 hours corresponds to verifying the parameter each shift. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess the level for any deviation and verify that operation is within safety analyses assumptions. Alarms are also available for early detection of abnormal level indications.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.6 Pressurizer Safety Valves

BASES

BACKGROUND

The two pressurizer safety valves provide, in conjunction with the Protection and Safety Monitoring System (PMS), overpressure protection for the RCS. The pressurizer safety valves are totally enclosed, spring loaded, self actuated valves with backpressure compensation. The safety valves are designed to prevent the system pressure from exceeding the system Safety Limit (SL), 2733.5 psig, which is 110% of the design pressure.

Because the safety valves are totally enclosed and self actuating, they are considered independent components. The minimum relief capacity for each valve, 750,000 lb/hr, is based on postulated overpressure transient conditions resulting from a complete loss of steam flow to the turbine. This event results in the maximum surge rate into the pressurizer, which specifies the minimum relief capacity for the safety valves. The pressurizer safety valves discharge into the containment atmosphere. This discharge flow is indicated by an increase in temperature downstream of the pressurizer safety valves.

Overpressure protection is required in MODES 1, 2, 3, 4, 5, and 6 when the reactor vessel head is on; however, in MODE 4 with the RNS aligned, MODE 5, and MODE 6 with the reactor vessel head on, overpressure protection is provided by operating procedures and by meeting the requirements of LCO 3.4.14, “Low Temperature Overpressure Protection (LTOP) System.”

The upper and lower pressure limits are based on the ± 1% tolerance requirement (Ref. 1) for lifting pressures above 1000 psig. The lift setting is for the ambient conditions associated with MODES 1, 2, and 3. This requires either that the valves be set hot or that a correlation between hot and cold settings be established.

The pressurizer safety valves are part of the primary success path and mitigate the effects of postulated accidents. OPERABILITY of the safety valves ensures that the RCS pressure will be limited to 110% of design pressure.

The consequences of exceeding the ASME Code, Section III pressure limit (Ref. 1) could include damage to RCS components, increased LEAKAGE, or a requirement to perform additional stress analyses prior to resumption of reactor operation.

BASES

APPLICABLE SAFETY ANALYSES

All accident and safety analyses in Chapter 15 (Ref. 3) that require safety valve actuation assume operation of two pressurizer safety valves to limit increases in the RCS pressure. The overpressure protection analysis (Ref. 2) is also based on operation of the two safety valves. Accidents that could result in overpressurization if not properly terminated include:

a. Uncontrolled rod withdrawal from full power;

b. Loss of reactor coolant flow;

c. Loss of external electrical load;

d. Locked rotor; and

e. Loss of AC power/loss of normal feedwater

Detailed analyses of the above transients are contained in Reference 3. Compliance with this LCO is consistent with the design bases and accident analyses assumptions.

Pressurizer Safety Valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The two pressurizer safety valves are set to open at the RCS design pressure (2500 psia), and within the ASME specified tolerance, to avoid exceeding the maximum design pressure SL, to maintain accident analyses assumptions, and to comply with ASME requirements. The upper and lower pressure tolerance limits are based on the ± 1% tolerance requirements (Ref. 1) for lifting pressures above 1000 psig.

The limit protected by this specification is the Reactor Coolant Pressure Boundary (RCPB) SL of 110% of design pressure. Inoperability of one or more valves could result in exceeding the SL if a transient were to occur. The consequences of exceeding the ASME pressure limit could include damage to one or more RCS components, increased leakage, or additional stress analysis being required prior to resumption of reactor operation.

APPLICABILITY

In MODES 1, 2, and 3, and portions of MODE 4 with the Normal Residual Heat Removal System (RNS) isolated or with the RCS temperature ≥ 275°F, OPERABILITY of two valves is required because the combined capacity is required to keep reactor coolant pressure below 110% of its design value during certain accidents. MODE 3 and portions of MODE 4 are conservatively included although the listed accidents may not require the safety valves for protection.

BASES

APPLICABILITY (continued)

The LCO is not applicable in MODE 4 with RNS open and in MODE 5, because LTOP is provided. Overpressure protection is not required in MODE 6 with reactor vessel head detensioned.

The Note allows entry into MODES 3 and 4 with the lift setpoints outside the LCO limits. This permits testing and examination of the safety valves at high pressure and temperature near their normal operating range, but only after the valves have had a preliminary cold setting. The cold setting gives assurance that the valves are OPERABLE near their design condition. Only one valve at a time will be removed from service for testing. The 36 hour exception is based on 18 hour outage time for each of the two valves. The 18 hour period is derived from operating experience that hot testing can be performed in this time frame.

ACTIONS

A.1

With one pressurizer safety valve inoperable, restoration must take place within 15 minutes. The Completion Time of 15 minutes reflects the importance of maintaining the RCS Overpressure Protection System. An inoperable safety valve coincident with an RCS overpressure event could challenge the integrity of the pressure boundary.

B.1 and B.2

If the Required Action of A.1 cannot be met within the required Completion Time or if two pressurizer safety valves are inoperable, the plant must be placed in a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 with the RNS aligned to the RCS and RCS temperature < 275°F within 24 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. With the RNS aligned to the RCS, overpressure protection is provided by the LTOP System. The change from MODE 1, 2, or 3 to MODE 4 reduces the RCS energy (core power and pressure), lowers the potential for large pressurizer insurges, and thereby removes the need for overpressure protection by two pressurizer safety valves.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.6.1

SRs are specified in the Inservice Testing Program. Pressurizer safety valves are to be tested one at a time and in accordance with the requirements of ASME OM Code (Ref. 4), which provides the activities and Frequency necessary to satisfy the SRs. No additional requirements are specified.

The pressurizer safety valve setpoint is ± 1% for OPERABILITY, and the values are reset to remain within ± 1% during the Surveillance to allow for drift.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.7 RCS Operational LEAKAGE

BASES

BACKGROUND

Components that contain or transport the coolant to or from the reactor core comprise the RCS. Component joints are made by welding, bolting, rolling, or pressure loading, and valves isolate connecting systems from the RCS.

During plant life, the joint and valve interfaces can produce varying amounts of reactor coolant LEAKAGE, through either normal operational wear or mechanical deterioration. The purpose of the RCS Operational LEAKAGE LCO is to limit system operation in the presence of LEAKAGE from these sources to amounts that do not compromise safety. This LCO specifies the types and amounts of LEAKAGE.

10 CFR 50, Appendix A, GDC 30 (Ref. 1), requires means for detecting and, to the extent practical, identifying the source of reactor coolant LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting leakage detection systems.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring RCS LEAKAGE into the containment area is necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE is necessary to provide quantitative information to the operators, allowing them to take corrective action should a leak occur that is detrimental to the safety of the facility and the public.

A limited amount of LEAKAGE inside containment is expected from auxiliary systems that cannot be made 100% leaktight. LEAKAGE from these systems should be detected, located, and isolated from the containment atmosphere, if possible, to not interfere with RCS LEAKAGE detection.

This LCO deals with protection of the reactor coolant pressure boundary (RCPB) from degradation and the core from inadequate cooling, in addition to preventing the accident analyses radiation release assumptions from being exceeded. The consequences of violating this LCO include the possibility of a loss of coolant accident (LOCA).

BASES

APPLICABLE SAFETY ANALYSES

Except for primary to secondary LEAKAGE, the safety analyses do not address operational LEAKAGE. However, other operational LEAKAGE is related to the safety analyses for LOCA. The amount of LEAKAGE can affect the probability of such an event. The safety analysis for an event resulting in steam discharge to the atmosphere assumes a 300 gpd primary to secondary LEAKAGE as the initial condition.

Primary to secondary LEAKAGE is a factor in the dose releases outside containment resulting from a steam line break (SLB) accident. To a lesser extent, other accidents or transients involve secondary steam release to the atmosphere, such as a steam generator tube rupture (SGTR). The leak contaminates the secondary fluid.

The Chapter 15 (Ref. 3) analyses for the accidents involving secondary side releases assume 150 gpd primary to secondary LEAKAGE in each generator as an initial condition. The design basis radiological consequences resulting from a postulated SLB accident and SGTR are provided in Sections 15.1.5 and 15.6.3 of Chapter 15, respectively.

The RCS operational LEAKAGE satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS operation LEAKAGE shall be limited to:

a. Pressure Boundary LEAKAGE

No pressure boundary LEAKAGE is allowed, being indicative of material deterioration. LEAKAGE of this type is unacceptable as the leak itself could cause further deterioration, resulting in higher LEAKAGE. Violation of this LCO could result in continued degradation of the RCPB. LEAKAGE past seals and gaskets are not pressure boundary LEAKAGE.

b. Unidentified LEAKAGE

0.5 gpm of unidentified LEAKAGE is allowed as a reasonable minimum detectable amount that the containment air F18 particulate radioactivity monitoring and containment sump level monitoring equipment, can detect within a reasonable time period. This leak rate supports leak before break (LBB) criteria. Violation of this LCO could result in continued degradation of the RCPB, if the LEAKAGE is from the pressure boundary.

BASES

LCO (continued)

c. Identified LEAKAGE

Up to 10 gpm of identified LEAKAGE is considered allowable because LEAKAGE is from known sources that do not interfere with detection of unidentified LEAKAGE and is well within the capability of the RCS Makeup System. Identified LEAKAGE includes LEAKAGE to the containment from specifically known and located sources, but does not include pressure boundary LEAKAGE. Violation of this LCO could result in continued degradation of a component or system.

d. Primary to Secondary LEAKAGE through One SG

The limit of 150 gallons per day per SG is based on the operational LEAKAGE performance criterion in NEI 97-06, Steam Generator Program Guidelines (Ref. 4). The Steam Generator Program operational LEAKAGE performance criterion in NEI 97-06 states, "The RCS operational primary to secondary leakage through any one SG shall be limited to 150 gallons per day." The limit is based on operating experience with SG tube degradation mechanisms that result in tube leakage. The operational leakage rate criterion in conjunction with the implementation of the Steam Generator Program is an effective measure for minimizing the frequency of steam generator tube ruptures.

e. Primary to In-Containment Refueling Water Storage Tank (IRWST) LEAKAGE through the Passive Residual Heat Removal Heat Exchanger (PRHR HX)

The 500 gpd limit from the PRHR HX is based on the assumption that a single crack leaking this amount would not lead to a PRHR HX tube rupture under the stress condition of an RCS pressure increase event. If leaked through many cracks, the cracks are very small, and the above assumption is conservative. This is conservative because the thickness of the PRHR HX tubes is approximately 60% greater than the thickness of the SG tubes. Furthermore, a PRHR HX tube rupture would result in an isolable leak and would not lead to a direct release of radioactivity to the atmosphere.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, the potential for RCPB LEAKAGE is greatest when the RCS is pressurized.

In MODES 5 and 6, LEAKAGE limits are not required because the reactor coolant pressure is far lower, resulting in lower stresses and reduced potentials for LEAKAGE.

ACTIONS

A.1

Unidentified LEAKAGE or identified LEAKAGE in excess of the LCO limits must be reduced to within limits within 4 hours. This Completion Time allows time to verify leakage rates and either identify unidentified LEAKAGE or reduce LEAKAGE to within limits before the reactor must be shut down. This action is necessary to prevent further deterioration of the RCPB.

B.1 and B.2

If any pressure boundary LEAKAGE exists, or primary to secondary LEAKAGE is not within limits, or if unidentified or identified LEAKAGE cannot be reduced to within limits within 4 hours, the reactor must be brought to lower pressure conditions to reduce the severity of the LEAKAGE and its potential consequences. It should be noted that LEAKAGE past seals and gaskets is not pressure boundary LEAKAGE. The reactor must be brought to MODE 3 within 6 hours and to MODE 5 within 36 hours. This action reduces the LEAKAGE and also reduces the factors which tend to degrade the pressure boundary.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without ACTIONS challenging plant systems. In MODE 5, the pressure stresses acting on the RCPB are much lower, and further deterioration is much less likely.

SURVEILLANCE REQUIREMENTS

SR 3.4.7.1

Verifying RCS LEAKAGE within the LCO limits ensures the integrity of the RCPB is maintained. Pressure boundary LEAKAGE would at first appear as unidentified LEAKAGE and can only be positively identified by inspection.

Unidentified LEAKAGE and identified LEAKAGE are determined by performance of a RCS water inventory balance.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The RCS water inventory balance must be met with the reactor at steady state operating conditions. The Surveillance is modified by two Notes. Note 1 states that this SR is not required to be performed until 12 hours after establishing steady state operation. The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.

Steady state operation is required to perform a proper inventory balance since calculations during maneuvering are not useful. For RCS operational LEAKAGE determination by inventory balance, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, and with no makeup or letdown.

An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere F18 particulate radioactivity and the containment sump level. It should be noted that LEAKAGE past seals and gaskets is not pressure boundary LEAKAGE. These LEAKAGE detection systems are specified in LCO 3.4.9, “RCS LEAKAGE Detection Instrumentation.”

Note 2 states that this SR is not applicable to primary to secondary LEAKAGE because LEAKAGE of 150 gallons per day cannot be measured accurately by an RCS water inventory balance.

The containment atmosphere F18 particulate radioactivity LEAKAGE measurement is valid only for plant power > 20% RTP.

The containment atmosphere F18 particulate radioactivity LEAKAGE measurement during MODE 1 is not valid while containment purge occurs or within 2 hours after the end of containment purge.

The containment sump level change method of detecting leaks during MODES 1, 2, 3, and 4 is not valid while containment purge occurs or within 2 hours after the end of containment purge.

The containment sump level change method of detecting leaks during MODES 1, 2, 3, and 4 is not valid during extremely cold outside ambient conditions when frost is forming in the interior of the containment vessel.

The 72-hour Frequency is a reasonable interval to trend LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.7.2

This SR verifies that primary to secondary LEAKAGE is less or equal to 150 gallons per day through any one SG. Satisfying the primary to secondary LEAKAGE limit ensures that the operational LEAKAGE performance criterion in the Steam Generator Program is met. If this SR is not met, compliance with LCO 3.4.18, "Steam Generator Tube Integrity," should be evaluated. The 150 gallons per day limit is measured at room temperature as described in Reference 5. The operational LEAKAGE rate limit applies to LEAKAGE through any one SG. If it is not practical to assign the LEAKAGE to an individual SG, all the primary to secondary LEAKAGE should be conservatively assumed to be from one SG.

The Surveillance is modified by a Note which states that the Surveillance is not required to be performed until 12 hours after establishment of steady state operation. For RCS primary to secondary LEAKAGE determination, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown, and RCP seal injection and return flows.

The Surveillance Frequency of 72 hours is a reasonable interval to trend primary to secondary LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents. The primary to secondary LEAKAGE is determined using continuous process radiation monitors or radiochemical grab sampling in accordance with the EPRI guidelines (Ref. 5).

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.8 Minimum RCS Flow

BASES

BACKGROUND

The AP1000 RCS consists of the reactor vessel and two heat transfer loops, each containing a steam generator (SG), two reactor coolant pumps (RCPs), a single hot leg and two cold legs for circulating reactor coolant. Loop 1 also contains connections to the pressurizer and passive residual heat removal (PRHR).

The primary function of the reactor coolant is removal of decay heat and the transfer of this heat, via the SGs to the secondary plant fluid. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

Within the RCS, coolant loop flow can be provided by the reactor coolant pumps, the Normal Residual Heat Removal System (RNS), and to a lesser degree when in the passive mode of operation, natural circulation.

APPLICABLE SAFETY ANALYSES

An initial condition in the Design Basis Accident (DBA) analysis of a possible Boron Dilution Event (BDE) in MODE 3, 4, or 5 is the assumption of a minimum mixing flow in the RCS. In this scenario, dilute water is inadvertently introduced into the RCS, is uniformly mixed with the primary coolant, and flows to the core. The increase in reactivity is detected by the source range instrumentation which provides a signal to terminate the inadvertent dilution before the available SDM is lost. If there is inadequate mixing in the RCS, the dilute water may stratify in the primary system, and there will be no indication by the source range instrumentation that a dilution event is in progress. When primary flow is finally increased, the dilution event may have progressed to the point that mitigation by the source range instrumentation is too late to prevent the loss of SDM.

Thus, a minimum mixing flow in the RCS is a process variable which is an initial condition in a DBA analysis.

Minimum RCS Flow satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that a minimum RCS flow be maintained provides assurance that in the event of an inadvertent BDE, the diluted water will be properly mixed with the primary system coolant, and the increase in core reactivity will be detected by the source range instrumentation.

BASES

LCO (continued)

Note 1 permits all RCPS to be de-energized for ≤ 1 hour per 8 hour period. The purpose of the Note is to permit tests that are designed to validate various accident analysis values. One of these tests is for the validation of the pump coastdown curve, used as input to a number of accident analyses including a loss of flow accident. This test is generally performed in MODE 3 during the initial startup testing program, and as such should only be performed once. If, however, changes are made to the RCS that would cause a change to the flow characteristics of the RCS, the input values of the coastdown curve may need to be revalidated by conducting the test again.

Another test performed during the startup testing program is the validation of the rod drop times during cold conditions, both with and without flow.

The no-flow tests may be performed in MODE 3, 4, or 5, and require that the pumps be stopped for a short period of time. The Note permits the de-energizing of the pumps in order to perform this test and validate the assumed analysis values. As with the validation of the pump coastdown curve, this test should only be performed once, unless the flow characteristics of the RCS are changed. The 1 hour time period specified is adequate to perform the desired tests and experience has shown that boron stratification is not a problem during this short period with no forced flow.

Utilization of the Note is permitted provided the following conditions are met along with any other conditions imposed by initial startup test procedures:

a. No operations are permitted that would dilute the RCS boron concentration with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1, thereby maintaining the margin to criticality. Boron reduction with coolant at boron concentrations less than required to assure SDM is maintained is prohibited because a uniform concentration distribution throughout the RCS cannot be ensured when in natural circulation and

b. Core outlet temperature is maintained at least 10°F below saturation temperature, so that no vapor bubble may form and possibly cause natural circulation flow obstruction.

Note 2 prohibits startup of an RCP when the RCS temperature is $\geq$ 350°F unless pressurizer level is < 92%. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started.

BASES

LCO (continued)

Note 3 requires that the secondary side water temperature of each SG be ≤ 50°F above each of the RCS cold leg temperatures before the start of an RCP with any RCS cold leg temperature ≤ 350°F, and the RCP must be started at ≤ 25% of RCP speed. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started. This limitation also helps to ensure that the RNS system pressure remains below both the piping design pressure and the acceptable RNS relief valve inlet pressure.

APPLICABILITY

Minimum RCS flow is required in MODES 3, 4, and 5 with the reactor trip breakers (RTBs) open and with unborated water sources not isolated from the RCS because an inadvertent BDE is considered possible in these MODES.

In MODES 1 and 2, and in MODES 3, 4, and 5 with the RTBs closed, LCO 3.4.4 requires all four RCPs to be in operation. Thus, in the event of an inadvertent boron dilution, adequate mixing will occur.

A minimum mixing flow is not required in MODE 6 because LCO 3.9.2 requires that all valves used to isolate unborated water sources shall be secured in the closed position. In this situation, an inadvertent BDE is not considered credible.

ACTIONS

A.1

If no RCP is in operation, all sources of unborated water must be isolated within 1 hour. This action assures that no unborated water will be introduced into the RCS when proper mixing cannot be assured. The allowed Completion Time requires that prompt action be taken, and is based on the low probability of a DBA occurring during this time.

A.2

The Requirement to perform SR 3.1.1.1 (SDM verification) within 1 hour assures that if the boron concentration in the RCS has been reduced and not detected by the source range instrumentation, prompt action may be taken to restore the required SDM. The allowed Completion Time is consistent with that required of Action A.1 because the conditions and consequences are the same.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.8.1

This Surveillance requires verification every 12 hours that a minimum mixing flow is present in the RCS. A Frequency of 12 hours is adequate considering the low probability of an inadvertent BDE during this time, and the ease of verifying the required RCS flow.

REFERENCES None.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.9 RCS Leakage Detection Instrumentation

BASES

BACKGROUND

GDC 30 of Appendix A to 10CFR50 (Ref. 1) requires means for detecting, and, to the extent practical, identifying the source of RCS LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting LEAKAGE detection systems.

LEAKAGE detection systems must have the capability to detect significant reactor coolant pressure boundary (RCPB) degradation as soon after occurrence as practical to minimize the potential for propagation to a gross failure. Thus, an early indication or warning signal is necessary to permit proper evaluation of all unidentified LEAKAGE.

Industry practice has shown that water flow changes of 0.5 gpm can be readily detected in contained volumes by monitoring changes in water level, in flow rate, or in the operating frequency of a pump. The containment sump used to collect unidentified LEAKAGE, is instrumented to alarm for increases of 0.5 gpm in the normal flow rates. This sensitivity is acceptable for detecting increases in unidentified LEAKAGE. Note that the containment sump level instruments are also used to identify leakage from the main steam lines inside containment. Since there is not another method to identify steam line leakage in a short time frame, two sump level sensors are required to be OPERABLE. The containment water level sensors (LCO 3.3.3) provide a diverse backup method that can detect a 0.5 gpm leak within 3.5 days.

The reactor coolant contains radioactivity that, when released to the containment, can be detected by radiation monitoring instrumentation. Reactor coolant radioactivity used for leak detection is the decay of F18. The production of F18 is proportional to the reactor power level. F18 becomes a particulate after leaving the RCS, and it is used for leak detection. Instrument sensitivities for particulate monitoring are practical for these LEAKAGE detection systems. The Radiation Monitoring System includes monitoring F18 particulate activity to provide leak detection.

APPLICABLE SAFETY ANALYSES

The need to evaluate the severity of an alarm or an indication is important to the operators, and the ability to compare and verify with indications from other systems is necessary. The system response times and sensitivities are described in Chapter 15 (Ref. 3).

BASES

APPLICABLE SAFETY ANALYSES (continued)

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring RCS LEAKAGE into the containment area is necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE provides quantitative information to the operators, allowing them to take corrective action should a leak occur.

RCS LEAKAGE detection instrumentation satisfies Criterion 1 of 10 CFR 50.36(c)(2)(ii).

LCO

One method of protecting against large RCS LEAKAGE derives from the ability of instruments to rapidly detect extremely small leaks. This LCO requires instruments of diverse monitoring principles to be OPERABLE to provide a high degree of confidence that small leaks are detected in time to allow actions to place the plant in a safe condition, when RCS LEAKAGE indicates possible RCPB degradation.

The LCO is satisfied when monitors of diverse measurement means are available. Thus, the containment sump level monitor, in combination with an F18 particulate radioactivity monitor, provides an acceptable minimum. Containment sump level monitoring is performed by three redundant, seismically qualified level instruments. The LCO note clarifies that if LEAKAGE is prevented from draining to the sump, its level change measurements made by OPERABLE sump level instruments will not be valid for quantifying the LEAKAGE.

APPLICABILITY

Because of elevated RCS temperature and pressure in MODES 1, 2, 3, and 4, RCS LEAKAGE detection instrumentation is required to be OPERABLE.

In MODE 5 or 6, the temperature is ≤ 200°F and pressure is maintained low or at atmospheric pressure. Since the temperatures and pressures are lower than those for MODES 1, 2, 3, and 4, the likelihood of LEAKAGE and crack propagation are much smaller. Therefore, the requirements of this LCO are not applicable in MODES 5 and 6.

Containment sump level monitoring is a valid method for detecting LEAKAGE in MODES 1, 2, 3, and 4. The containment atmosphere F18 particulate radioactivity LEAKAGE measurement during MODE 1 is valid only for reactor power > 20% RTP. RCS inventory monitoring via the pressurizer level changes is valid in MODES 1, 2, 3, and 4 only when RCS conditions are stable, i.e., temperature is constant, pressure is constant, no makeup and no letdown.

BASES

APPLICABILITY (continued)

The containment sump level change method of detecting leaks during MODES 1, 2, 3, and 4 is not valid while containment purge occurs or within 2 hours after the end of containment purge.

The containment atmosphere F18 particulate radioactivity LEAKAGE measurement during MODE 1 is not valid while containment purge occurs or within 2 hours after the end of containment purge.

The containment sump level change method of detecting leaks during MODES 1, 2, 3, and 4 is not valid during extremely cold outside ambient conditions when frost is forming on the interior of the containment vessel.

ACTIONS

The actions are modified by a Note that indicates that the provisions of LCO 3.0.4 are not applicable. As a result, a MODE change is allowed when leakage detection channels are inoperable. This allowance is provided because in each condition other instrumentation is available to monitor for RCS LEAKAGE.

A.1 and A.2

With one of the two required containment sump level channels inoperable, the one remaining OPERABLE channel is sufficient for RCS leakage monitoring since the containment radiation provides a method to monitor RCS leakage. However, that is not the case for the steam line leakage monitoring. The remaining OPERABLE sump level monitor is adequate as long as it continues to operate properly. Continuing plant operation is expected to result in containment sump level indication increases and in periodic operation of the containment sump pump. Therefore, proper operation of the one remaining sump level sensor is verified by the operators checking the volume input to the sump (as determined by the sump level changes and discharges from the containment) to determine that it does not change significantly. A significant change is considered to be ±10 gallons per day or 33% (whichever is greater) of the volume input for the first 24 hours after this Condition is entered. The containment sump level instruments are capable of detecting a volume change of less than 2 gallons. The containment water level sensors also provide a diverse backup that can detect a 0.5 gpm leak within 3.5 days.

Restoration of two sump channels to OPERABLE status is required to regain the function in a Completion Time of 14 days after the monitor's failure. This time is acceptable, considering the frequency and adequacy of the monitoring of the change in integrated sump discharge required by Action A.1.

BASES

ACTIONS (continued)

B.1 and B.2

With two of the two required containment sump level channels inoperable, no other form of sampling can provide the equivalent information; however, the containment atmosphere F18 particulate radioactivity monitor will provide indications of changes in LEAKAGE. Together with the atmosphere monitor, the periodic surveillance for RCS inventory balance, SR 3.4.7.1, must be performed at an increased frequency of 24 hours to provide information that is adequate to detect LEAKAGE. A Note is added allowing that SR 3.4.7.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.

Restoration of one sump channel to OPERABLE status is required to regain the function in a Completion Time of 72 hours after the monitor's failure. This time is acceptable, considering the frequency and adequacy of the RCS inventory balance required by Action A.1.

C.1.1, C.1.2, and C.2

With the F18 particulate containment atmosphere radioactivity-monitoring instrumentation channel inoperable, alternative action is required. Either grab samples of the containment atmosphere must be taken and analyzed or RCS inventory balanced, in accordance with SR 3.4.7.1, to provide alternate periodic information.

With a sample obtained and analyzed or an RCS inventory balance performed every 24 hours, the reactor may be operated for up to 30 days to allow restoration of the radioactivity monitor.

The 24 hours interval for grab samples or RCS inventory balance provides periodic information that is adequate to detect LEAKAGE. A Note is added allowing that SR 3.4.7.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, and makeup and letdown). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. The 30 day Completion Time recognizes at least one other form of leak detection is available.

BASES

ACTIONS (continued)

D.1 and D.2

If a Required Action of Condition A, B or C cannot be met within the required Completion Time, the reactor must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner without challenging plant systems.

E.1

With all required monitors inoperable, no automatic means of monitoring leakage is available and plant shutdown in accordance with LCO 3.0.3 is required.

SURVEILLANCE REQUIREMENTS

SR 3.4.9.1

SR 3.4.9.1 requires the performance of a CHANNEL CHECK of the containment atmosphere F18 particulate radioactivity monitor. The check gives reasonable confidence that the channel is operating properly. The Frequency of 12 hours is based on instrument reliability and risk and is reasonable for detecting off normal conditions.

SR 3.4.9.2

SR 3.4.9.2 requires the performance of a CHANNEL OPERATIONAL TEST (COT) on the atmosphere F18 particulate radioactivity monitor. The test ensures that the monitor can perform its function in the desired manner. The test verifies the alarm setpoint and relative accuracy of the instrument string. The Frequency of 92 days considers risks and instrument reliability, and operating experience has shown that it is proper for detecting degradation.

SR 3.4.9.3 and SR 3.4.9.4

These SRs require the performance of a CHANNEL CALIBRATION for each of the RCS Leakage detection instrumentation channels. The calibration verifies the accuracy of the instrument string, including the instruments located inside containment. The Frequency of 24 months is a typical refueling cycle and considers channel reliability. Again, operating experience has proven that this Frequency is acceptable.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.10 RCS Specific Activity

BASES

BACKGROUND

The limits on RCS specific activity ensure that the doses due to postulated accidents are within the doses reported in Chapter 15.

The RCS specific activity LCO limits the allowable concentration of iodines and noble gases in the reactor coolant. The LCO limits are established to be consistent with a fuel defect level of 0.25 percent and to ensure that plant operation remains within the conditions assumed for shielding and Design Basis Accident (DBA) release analyses.

The LCO contains specific activity limits for both DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133. The allowable levels are intended to limit the doses due to postulated accidents to within the values calculated in the radiological consequences analyses (as reported in Chapter 15).

APPLICABLE SAFETY ANALYSES

The LCO limits on the reactor coolant specific activity are a factor in accident analyses that assume a release of primary coolant to the environment either directly as in a Steam Generator Tube Rupture (SGTR) or indirectly by way of LEAKAGE to the secondary coolant system and then to the environment (the Steam Line Break).

The events which incorporate the LCO values for primary coolant specific activity in the radiological consequence analysis include the following:

Steam generator tube rupture (SGTR)
Steam line break (SLB)
Locked RCP rotor
Rod ejection
Small line break outside containment
Loss of coolant accident (LOCA) (early stages)

The limiting event for release of primary coolant activity is the SLB. The SLB dose analysis considers the possibility of a pre-existing iodine spike (in which case the maximum LCO of 60 µCi/gm DOSE EQUIVALENT I-131 is assumed) as well as the more likely initiation of an iodine spike due to the reactor trip and depressurization. In the latter case, the LCO of 1.0 µCi/gm DOSE EQUIVALENT I-131 is assumed at the initiation of the accident, but the primary coolant specific activity is assumed to increase with time due to the elevated iodine appearance rate in the coolant. The reactor coolant noble gas specific activity for both cases is

BASES

APPLICABLE SAFETY ANALYSES (continued)

assumed to be the LCO of 280 µCi/gm DOSE EQUIVALENT XE-133. The safety analysis assumes the specific activity of the secondary coolant at its limit of 0.1 µCi/gm DOSE EQUIVALENT I-131 from LCO 3.7.4, "Secondary Specific Activity."

The LCO limits ensure that, in either case, the doses reported in Chapter 15 remain bounding.

The RCS specific activity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The specific iodine activity is limited to 1.0 µCi/gm DOSE EQUIVALENT I-131, and the specific noble gas activity is limited to 280 µCi/gm DOSE EQUIVALENT XE-133. These limits ensure that the doses resulting from a DBA will be within the values reported in Chapter 15. Secondary coolant activities are addressed by LCO 3.7.4, "Secondary Specific Activity."

The SLB and SGTR accident analyses (Refs. 1 and 2) show that the offsite doses are within acceptance limits. Violation of the LCO may result in reactor coolant radioactivity levels that could, in the event of an SLB or SGTR accident, lead to doses that exceed those reported Chapter 15.

APPLICABILITY

In MODES 1 and 2, and in MODE 3 with RCS average temperature ≥ 500°F, operation within the LCO limits for DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133 specific activity are necessary to contain the potential consequences of a SGTR to within the calculated site boundary dose values.

For operation in MODE 3 with RCS average temperature < 500°F and in MODES 4 and 5, the release of radioactivity in the event of a SGTR is unlikely since the saturation pressure of the reactor coolant is below the lift pressure settings of the main steam safety valves.

ACTIONS

A.1 and A.2

With the DOSE EQUIVALENT I-131 greater than the LCO limit, samples at intervals of 4 hours must be taken to verify that DOSE EQUIVALENT I-131 is ≤ 60 µCi/gm. The Completion Time of 4 hours is required to obtain and analyze a sample. Sampling is to continue to provide a trend.

BASES

ACTIONS (continued)

The DOSE EQUIVALENT I-131 must be restored to normal within 48 hours. If the concentration cannot be restored to within the LCO limit in 48 hours, it is assumed that the LCO violation is not the result of normal iodine spiking.

A Note to the Required Action of Condition A excludes the MODE change restriction of LCO 3.0.4. This exception allows entry into the applicable MODE(S) while relying on the ACTIONS even though the ACTIONS may eventually require plant shutdown. This exception is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient specific activity excursions while the plant remains at, or proceeds to power operation.

B.1 and B.2

With DOSE EQUIVALENT XE-133 in excess of the allowed limit, an analysis must be performed within 4 hours to determine DOSE EQUIVALENT I-131. The allowed Completion Time of 4 hours is required to obtain and analyze a sample.

The change to MODE 3 and RCS average temperature < 500°F lowers the saturation pressure of the reactor coolant below the set points of the main steam safety valves, and prevents venting the SG to the environment in a SGTR event. The allowed Completion Time of 6 hours is reasonable, based on operating experience to reach MODE 3 from full power conditions in an orderly manner, without challenging plant systems.

C.1

If a Required Action and the associated Completion Time of Condition A is not met or if the DOSE EQUIVALENT I-131 is > 60 µCi/gm., the reactor must be brought to MODE 3 with RCS average temperature < 500°F within 6 hours. The Completion Time of 6 hours is reasonable, based on operation experience, to reach MODE 3 below 500°F from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.10.1

SR 3.4.10.1 requires performing a measure of the noble gas specific activity of the reactor coolant at least once every 7 days. This is a quantitative measure of radionuclides with half lives longer than

BASES

SURVEILLANCE REQUIREMENTS (continued)

15 minutes. This Surveillance provides an indication of any increase in the release of noble gas activity from fuel rods containing cladding defects.

Trending the results of this Surveillance allows proper remedial action to be taken before reaching the LCO limit under normal operating conditions. The 7 day Frequency considers the unlikelihood of a significant increase in fuel defect level during the time.

SR 3.4.10.2

This Surveillance is performed in MODE 1 only to ensure iodine remains within limit during normal operation and following fast power changes when increased releases of iodine from the fuel (iodine spiking) is apt to occur. The 14 day Frequency is adequate to trend changes in the iodine activity level. The Frequency, between 2 and 6 hours after a power change of ≥ 15% RTP within a 1 hour period, is established because the iodine levels peak during this time following fuel failures; samples at other times would provide inaccurate results.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.11 Automatic Depressurization System (ADS) – Operating

BASES

BACKGROUND

The ADS is designed to assure that core cooling and injection can be achieved for Design Basis Accidents (DBA). The four stages of ADS valves are sequenced in coordination with the passive core cooling system injection performance characteristics.

The ADS consists of 10 flow paths arranged in four different stages that open sequentially (Ref. 1). Stages 1, 2, and 3 each include 2 flow paths. Each of the stage 1, 2, 3 flow paths has a common inlet header connected to the top of the pressurizer. The outlets of the stage 1, 2, 3 flow paths combine into one of the two common discharge lines to the spargers located in the incontainment refueling water storage tank (IRWST). The first stage valves are 4 inch valves with DC motor operators. The second and third stage valves are 8 inch valves with DC motor operators. An OPERABLE stage 1, 2, or 3 automatic depressurization flow path consists of two OPERABLE normally closed motor operated valves, in series.

Stage 4 includes 4 flow paths. The fourth stage ADS valves are 14 inch squib valves. The four fourth stage flow paths connect directly to the top of the reactor coolant hot legs and vent directly into the associated steam generator compartment. An OPERABLE stage 4 flow path consists of an open motor operated valve and an OPERABLE closed squib valve. These motor operated valves are not required to be OPERABLE because they are open.

The automatic depressurization valves are designed to open automatically when actuated, and to remain open for the duration of any automatic depressurization event. The valves are actuated sequentially. The stage 1 valves are actuated on a low core makeup tank (CMT) level. Stages 2 and 3 are actuated on the stage 1 signal plus time delays. Stage 4 is actuated on a Low 2 CMT level signal with a minimum time delay after stage 3. Stage 4 is blocked from actuating at normal RCS pressure.

In order to perform a controlled, manual depressurization of the RCS, the valves are opened starting with the first stage. The first stage valves can also be modulated to perform a partial RCS depressurization if required. ADS stage 1, 2, 3 valves may be manually operated under controlled conditions for testing purposes.

BASES

BACKGROUND (continued)

ADS stages 1, 2 and 3 valves are designed to open relatively slowly, from approximately 40 seconds for the first stage valves, to approximately 100 seconds for the second and third stage valves.

The ADS valves are powered by batteries. In the unlikely event that offsite and onsite AC power is lost for an extended period of time, a timer will actuate ADS within 24 hours of the time at which AC power is lost, before battery power has been degraded to the point where the valves cannot be opened.

The number and capacity of the ADS flow paths are selected so that adequate safety injection is provided from the accumulators, IRWST and containment recirculation for the limiting DBA loss of coolant accident (LOCA). For small break LOCAs the limiting single failure is the loss of one fourth stage flow path (Ref. 2). The PRA (Ref. 3) shows that adequate core cooling can be provided with the failure of up to seven (all ADS stage 1 to 3 and one ADS stage 4) flow paths. The ADS PRA success criteria following a LOCA or non-LOCA with failure of other decay heat removal features is for 3 of 4 ADS stage 4 valves to open. All of the ADS stage 1, 2, 3 valves can fail to open. This ADS capacity is sufficient to support PXS gravity injection and containment recirculation operation.

APPLICABLE SAFETY ANALYSES

For non-LOCA events, use of the ADS is not required and is not anticipated. For these events, injection of borated water into the core from the CMTs may be required for makeup or boration. However, the amount of water necessary will not reduce the level in the CMTs to the point of ADS actuation.

For events which involve a loss of primary coolant inventory, such as a LOCA, the ADS will be actuated, allowing for injection from the accumulators, the IRWST, and the containment recirculation (Ref. 2).

The ADS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that the 16 ADS valves be OPERABLE ensures that upon actuation, the depressurization of the RCS will proceed smoothly and completely, as assumed in the DBA safety analyses.

For the ADS to be considered OPERABLE, the 16 ADS valves must be closed and OPERABLE (capable of opening on an actuation signal). In addition, the stage 4 motor operated isolation valves must be open. These stage 4 motor operated isolation valves are not required to be OPERABLE because they are maintained open per SR 3.4.11.1.

BASES

APPLICABILITY

In MODES 1, 2, 3 and 4 the ADS must be OPERABLE to mitigate the potential consequences of any event which causes a reduction in the RCS inventory, such as a LOCA.

The requirements for the ADS in MODES 5 and 6 are specified in LCO 3.4.12, “Automatic Depressurization System (ADS) – Shutdown, RCS Intact,” and LCO 3.4.13, “Automatic Depressurization System – Shutdown, RCS Open.”

ACTIONS

A.1

If any one ADS stage 1, 2, or 3 flow path is determined to be inoperable, the remaining OPERABLE ADS flow paths are more than adequate to perform the required safety function as long as a single failure involving the other flow path of the same stage does not also occur. A flow path is inoperable if one or two of the ADS valves in the flow path are determined to be inoperable. A Completion Time of 7 days is reasonable based on the capability of the remaining ADS valves to perform the required safety functions assumed in the safety analyses and the low probability of a DBA during this time period.

If more than one ADS stage 1, 2, or 3 flow paths are inoperable, Condition C or D is applicable.

B.1

If any one ADS stage 4 flow path is determined to be inoperable, the remaining OPERABLE stage 4 ADS flow paths are adequate to perform the required safety function as long as a single failure of an additional stage 4 ADS flow path does not also occur. A Completion Time of 72 hours is reasonable based on the capability of the remaining ADS valves to perform the required safety functions assumed in the safety analyses and the low probability of a DBA during this time period. This Completion Time is the same as is used for two train ECCS systems which are capable of performing their safety function without a single failure.

C.1

If two or three flow paths with a combined flow capacity less than or equal to the largest capacity ADS division are determined to be inoperable, the remaining OPERABLE ADS flow paths are adequate to perform the required safety function as long as a single failure does not also occur. Divisions A and B have the largest flow capacity, each consisting of one stage 1 flow path, one stage 2 or 3 flow path, and one stage 4 flow path. This Condition is equivalent to the worst case single failure of an ADS division.

BASES

ACTION (continued)

This Condition is applicable to any combination of two inoperable flow paths, except two stage 4 flow paths. Applicable combinations of three inoperable flow paths include:

One stage 1, one stage 2 or 3, and one stage 4
One stage 1 and two stage 2 or 3
Two stage 1 and one stage 2, 3, or 4
Two stage 2 or 3 and one stage 4
Three stage 2 or 3

A Completion Time of 72 hours is reasonable based on the capability of the remaining ADS valves to perform the required safety functions assumed in the safety analyses and the low probability of a DBA during this time period. This Completion Time is the same as is used for two train ECCS systems which are capable of performing their safety function without a single failure.

Condition D is applicable, if two stage 4 flow paths are inoperable, more than three flow paths are inoperable, or a combination of three flow paths not listed above (i.e., with a combined flow capacity greater than the largest capacity ADS division) is inoperable.

D.1 and D.2

If the Required Actions and associated Completion Times are not met or the requirements of LCO 3.4.11 are not met for reasons other than Condition A, B, or C, the plant must be brought to MODE 5 where the probability and consequences on an event are minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner, without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.11.1

Each stage 4 ADS isolation motor operated valve must be verified to be open every 12 hours. Note that these valves receive confirmatory open signals. The Surveillance Frequency is acceptable considering valve position is manually monitored in the control room.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.11.2

This Surveillance requires verification that each ADS stage 1, 2, 3 valve strokes to its fully open position. Note that this surveillance is performed during shutdown conditions.

The Surveillance Frequency for demonstrating valve OPERABILITY references the Inservice Testing Program.

SR 3.4.11.3

This Surveillance requires verification that each ADS stage 4 squib valve is OPERABLE in accordance with the Inservice Testing Program. The Surveillance Frequency for verifying valve OPERABILITY references the Inservice Testing Program.

The squib valves will be tested in accordance with the ASME OM Code. The applicable ASME OM Code squib valve requirements are specified in paragraph 4.6, Inservice Tests for Category D Explosively Actuated Valves. The requirements include actuation of a sample of the installed valves each 2 years and periodic replacement of charges.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.12 Automatic Depressurization System (ADS) – Shutdown, RCS Intact

BASES

BACKGROUND	A description of the ADS is provided in the Bases for LCO 3.4.11, "Automatic Depressurization System (ADS) – Operating."
APPLICABLE SAFETY ANALYSES	For postulated events in MODE 5 with the RCS pressure boundary intact, the primary protection is the Passive Residual Heat Removal Heat Exchanger (PRHR HX). Use of the ADS is not required and is not anticipated. For these events, injection of borated water into the core from the core makeup tanks (CMTs) may be required for makeup or boration. However, the amount of water necessary will not reduce the level in the CMTs to the point of ADS actuation. No LOCAs are postulated during plant operation in MODE 5, however loss of primary coolant through LEAKAGE or inadvertent draining may occur. For such shutdown events occurring in MODE 5 it is anticipated that the ADS will be actuated, allowing injection from the in-containment refueling water storage tank (IRWST) and the containment recirculation if containment flooding occurs (Ref. 2). The ADS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).
LCO	The requirement that 9 ADS flow paths be OPERABLE assures that upon actuation, the depressurization of the RCS will proceed smoothly and completely, as assumed in the DBA safety analyses. An ADS stage 1, 2, or 3 flow path is considered OPERABLE if both valves in the line are closed and OPERABLE (capable of opening on an actuation signal). In addition, an ADS stage 4 flow path is OPERABLE if the motor operated isolation valve is open and the squib valve is closed and OPERABLE (capable of opening on an actuation signal).
APPLICABILITY	In MODE 5 with the reactor coolant pressure boundary (RCPB) intact, 9 flow paths of the ADS must be OPERABLE to mitigate the potential consequences of any event which causes a reduction in the RCS inventory, such as a LOCA.

BASES

APPLICABILITY (continued)

The requirements for the ADS in MODES 1 through 4 are specified in LCO 3.4.11, “Automatic Depressurization System (ADS) – Operating;” and in MODE 5 with the RCS pressure boundary open and MODE 6 in LCO 3.4.13, “Automatic Depressurization System (ADS) – Shutdown, RCS Open.”

ACTIONS

A.1

If any one ADS stage 1, 2, or 3 flow path is determined to be inoperable, the remaining OPERABLE ADS flow paths are more than adequate to perform the required safety function as long as a single failure involving the other flow path of the same stage does not also occur. A flow path is inoperable if one or two of the ADS valves in the flow path are determined to be inoperable. A Completion Time of 7 days is acceptable since the OPERABLE ADS paths can mitigate shutdown events without a single failure.

If more than one ADS stage 1, 2, or 3 flow paths are inoperable, Condition C or D is applicable.

B.1

If any one ADS stage 4 flow path is determined to be inoperable, the remaining OPERABLE stage 4 ADS flow paths are adequate to perform the required safety function as long as a single failure of an additional stage 4 ADS flow path does not also occur. A Completion Time of 72 hours is reasonable based on the capability of the remaining ADS valves to perform the required safety functions assumed in the safety analyses and the low probability of a shutdown event during this time period. This Completion Time is the same as is used for two train ECCS systems which are capable of performing their safety function without a single failure.

C.1

If two or three flow paths with a combined flow capacity less than or equal to the largest capacity ADS division are determined to be inoperable, the remaining OPERABLE ADS flow paths are adequate to perform the required safety function as long as a single failure does not also occur. Divisions A and B have the largest flow capacity, each consisting of one stage 1 flow path, one stage 2 or 3 flow path, and one stage 4 flow path. This Condition is equivalent to the worst case single failure of an ADS division.

BASES

ACTIONS (continued)

This Condition is applicable to any combination of two inoperable flow paths, except two stage 4 flow paths. Applicable combinations of three inoperable flow paths include:

One stage 1, one stage 2 or 3, and one stage 4
One stage 1 and two stage 2 or 3
Two stage 1 and one stage 2, 3, or 4
Two stage 2 or 3 and one stage 4
Three stage 2 or 3

A Completion Time of 72 hours is reasonable based on the capability of the remaining ADS valves to perform the required safety functions assumed in the safety analyses and the low probability of a shutdown event during this time period. This Completion Time is the same as is used for two train ECCS systems which are capable of performing their safety function without a single failure.

Condition D is applicable, if two stage 4 flow paths are inoperable, more than three flow paths are inoperable, or a combination of three flow paths not listed above (i.e., with a combined flow capacity greater than the largest capacity ADS division) is inoperable.

D.1

If the Required Actions and associated Completion Times are not met or the requirements of LCO 3.4.12 are not met for reasons other than Condition A, B, or C, the plant must be placed in a MODE in which this LCO does not apply. Action must be initiated, immediately, to place the plant in MODE 5 with the RCS pressure boundary open and ≥ 20% pressurizer level.

SURVEILLANCE REQUIREMENTS

SR 3.4.12.1

The LCO 3.4.11 Surveillance Requirements are applicable to the ADS valves required to be OPERABLE. The Frequencies associated with each specified SR are applicable. Refer to the corresponding Bases for LCO 3.4.11 for a discussion of each SR.

REFERENCES

1. AP1000 Probabilistic Risk Assessment, Appendix A.
2. Section 19E.4, “Safety Analyses and Evaluations.”

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.13 Automatic Depressurization System (ADS) – Shutdown, RCS Open

BASES

BACKGROUND

A description of the ADS is provided in the Bases for LCO 3.4.11, "Automatic Depressurization System (ADS) – Operating."

APPLICABLE SAFETY ANALYSES

When the plant is shutdown with the RCS depressurized, the core makeup tanks (CMTs) are isolated to prevent CMT injection. Since the ADS is actuated by low CMT level, automatic actuation of the ADS is not available. The required ADS stage 1, 2, and 3 vent paths are opened and two ADS stage 4 flow paths are OPERABLE to ensure that in-containment refueling water storage tank (IRWST) injection and containment recirculation can occur, if needed to mitigate events requiring RCS makeup, boration or core cooling (Ref. 1).

The ADS vent path must be maintained until the upper internals are removed, providing an adequate vent path for IRWST injection.

The ADS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that ADS stage 1, 2, and 3 flow paths be open, from the pressurizer through the spargers into the IRWST, and that two ADS stage 4 flow paths be OPERABLE assures that sufficient vent area is available to support IRWST injection.

The Note allows closure of the RCS pressure boundary when the pressurizer level is < 20% to facilitate vacuum refill following mid-loop operations to establish a pressurizer water level ≥ 20%. Prior to closure of the ADS valves, compliance with LCO 3.4.12, ADS – Shutdown, RCS Intact, should be verified.

APPLICABILITY

In MODE 5 with the reactor coolant system pressure boundary (RCPB) open or pressurizer level < 20% and in MODE 6 with the upper internals in place, the stage 1, 2, and 3 ADS vent paths must be open and two ADS stage 4 flow paths be OPERABLE.

The requirements for the ADS in MODES 1 through 4 are specified in LCO 3.4.11, "Automatic Depressurization System (ADS) – Operating;" and in MODE 5 with the RCPB intact in LCO 3.4.12, "Automatic Depressurization System (ADS) – Shutdown, RCS Intact."

BASES

ACTIONS

A.1 and A.2

If one required ADS stage 1, 2, or 3 flow path is closed, action must be taken to open the affected path or establish an alternative flow path within 72 hours. In this Condition the remaining open ADS stage 1, 2, and 3 flow paths and the OPERABLE ADS stage 4 flow paths are adequate to perform the required safety function without an additional single failure. The stage 4 valves would have to be opened by the operator in case of an event in this MODE. The required vent area may be restored by opening the affected ADS flow path or an alternate vent path with an equivalent area. Considering that the required function is available in this Condition a Completion Time of 72 hours is acceptable.

B.1 and B.2

If one required ADS stage 4 flow path is closed and inoperable, action must be taken to establish an alternative flow path, or restore at least two stage 4 flow paths to OPERABLE status within 36 hours. In this Condition the remaining open ADS stage 1, 2, and 3 flow paths and the one OPERABLE ADS stage 4 flow path are adequate to perform the required safety function without an additional single failure. The required vent area may be restored by opening an alternate vent path with an equivalent area. Acceptable alternate vent paths exclude the use of the pressurizer manway as pressurizer surge line flooding phenomena can negate the IRWST elevation head necessary for successful gravity injection. Alternatively, two stage 4 flow paths may be restored to OPERABLE status. Therefore a Completion Time of 36 hours is considered acceptable.

C.1 and C.2

If the Required Actions and associated Completion Times are not met or the requirements of LCO 3.4.13 are not met for reasons other than Conditions A or B while in MODE 5, the plant must be placed in a condition which minimizes the potential for requiring ADS venting and IRWST injection. The time to RCS boiling is maximized by increasing RCS inventory to ≥ 20% pressurizer level and maintaining RCS temperature as low as practical.

Additionally, action to suspend positive reactivity additions is required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS.

BASES

ACTIONS (continued)

D.1 and D.2

If the Required Actions and associated Completion Times are not met or the requirements of LCO 3.4.13 are not met for reasons other than Conditions A or B while in MODE 6, the plant must be placed in a condition which precludes the need for the ADS vent paths. Action must be initiated, immediately, to remove the upper internals, providing the required vent path. The time to RCS boiling is maximized by increasing RCS inventory and maintaining RCS temperature as low as practical. Additionally, action to suspend positive reactivity additions is required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS.

SURVEILLANCE REQUIREMENTS

SR 3.4.13.1

Each required ADS flow path is verified to be open by verifying that the stage 1, 2, and 3 valves are in their fully open position every 12 hours, as indicated in the control room. This Surveillance Frequency is acceptable based on administrative controls which preclude repositioning the valves.

SR 3.4.13.2

The LCO 3.4.11 Surveillance Requirements (SR 3.4.11.1 and SR 3.4.11.3) are applicable to the stage 4 ADS valves required to be OPERABLE. The Frequencies associated with each specified SR are applicable. Refer to the corresponding Bases for LCO 3.4.11 for a discussion of each SR.

REFERENCES

1. Section 19E.4, “Safety Analyses and Evaluations.”

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.14 Low Temperature Overpressure Protection (LTOP) System

BASES

BACKGROUND

The LTOP System limits RCS pressure at low temperatures so that the integrity of the reactor coolant pressure boundary (RCPB) is not compromised by violating the pressure and temperature (P/T) limits of 10 CFR 50, Appendix G (Ref. 1). The reactor vessel is the limiting RCPB component for demonstrating such protection. The PTLR provides the limits which set the maximum allowable setpoints for the Normal Residual Heat Removal System (RNS) suction relief valve. LCO 3.4.3 provides the maximum RCS pressure for the existing RCS cold leg temperature during cooldown, shutdown, and heatup to meet the Reference 1 requirements during the LTOP MODES.

The reactor vessel material is less tough at low temperatures than at normal operating temperature. As the vessel neutron exposure accumulates, the material toughness decreases and becomes less resistant to pressure stress at low temperatures (Ref. 2). RCS pressure, therefore, is maintained low at low temperatures and is increased only as temperature is increased.

The potential for vessel overpressurization is most acute when the RCS is water solid, occurring only while shutdown; a pressure fluctuation can occur more quickly than an operator can react to relieve the condition. Exceeding the RCS P/T limits by a significant amount could cause brittle cracking of the reactor vessel. LCO 3.4.3, “RCS Pressure and Temperature (P/T) Limits,” requires administrative control of RCS pressure and temperature during heatup and cooldown to prevent exceeding the PTLR limits.

This LCO provides RCS overpressure protection by having a maximum coolant input capability and having adequate pressure relief capacity. Limiting coolant input capability requires isolating the accumulators. The pressure relief capacity requires the RNS suction relief valve or a depressurized RCS and an RCS vent of sufficient size. The RNS suction relief valve or the open RCS vent is the overpressure protection device that acts to terminate an increasing pressure event.

RNS Suction Relief Valve Requirements

During the LTOP MODES, the RNS system is operated for decay heat removal. Therefore, the RNS suction isolation valves are open in the

BASES

BACKGROUND (continued)

piping from the RCS hot legs to the inlet of the RNS system. While these valves are open, the RNS suction relief valve is exposed to the RCS and able to relieve pressure transients in the RCS.

The RNS suction relief valve is a spring loaded, water relief valve with a pressure tolerance and an accumulation limit established by Section III of the American Society of Mechanical Engineers (ASME) Code (Ref. 3) for Class 2 relief valves.

The RNS suction isolation valves must be open to make the RNS suction relief valves OPERABLE for RCS overpressure mitigation.

RCS Vent Requirements

Once the RCS is depressurized, a vent exposed to the containment atmosphere will maintain the RCS at containment ambient pressure in an RCS overpressure transient, if the relieving requirements of the transient do not exceed the capabilities of the vent. Thus, the vent path must be capable of relieving the flow resulting from the limiting LTOP mass or heat input transient, and maintaining pressure below the P/T limits. The required vent capacity may be provided by one or more vent paths.

For an RCS vent to meet the flow capacity requirement, it may require removing one or more pressurizer safety valves or manually opening one or more Automatic Depressurization System (ADS) valves. The vent path(s) must be above the level of reactor coolant, so as not to drain the RCS when open.

APPLICABLE SAFETY ANALYSES

Safety analyses (Ref. 4) demonstrate that the reactor vessel is adequately protected against exceeding the Reference 1 P/T limits. In MODES 1, 2, and 3, and in MODE 4 with the RCS temperature above 275°F, the pressurizer safety valves will prevent RCS pressure from exceeding the Reference 1 limits. When the RNS is aligned and open to the RCS, overpressure protection is provided by the RNS suction relief valve, or a depressurized RCS and a sufficiently sized open RCS vent.

The actual temperature at which the pressure in the P/T limit curve falls below the suction relief setpoint increases as the reactor vessel material toughness decreases due to neutron embrittlement. Each time the PTLR curves are revised, the LTOP System must be re-evaluated to ensure its functional requirements can still be met using the RNS suction relief valve, or the depressurized and vented RCS condition.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The PTLR contains the acceptance limits that define the LTOP requirements. Any change to the RCS must be evaluated against the Reference 4 analyses to determine the impact of the change on the LTOP acceptance limits.

Transients that are capable of overpressurizing the RCS are categorized as either mass or heat input transients. The events listed below were used in the analysis to size the RNS suction relief valve. Therefore, any events with a mass or heat input greater than the listed events cannot be accommodated and must be prevented.

Mass Input

a. Makeup water flow rate to the RCS assuming both CVS makeup pumps are in operation and letdown is isolated.

Heat Input

a. Restart of one reactor coolant pump (RCP) with water in the steam generator secondary side 50°F hotter than the primary side water, and the RCS water solid.

RNS Suction Relief Valve Performance

Since the RNS suction relief valve does not have a variable P/T lift setpoint, the analysis must show that with chosen setpoint, the relief valve will pass flow greater than that required for the limiting LTOP transient while maintaining RCS pressure less than the minimum of either the P/T limit curve, 110 percent of the design pressure of the normal residual heat removal system, or the acceptable RNS relief valve inlet pressure. The current analysis shows that up to a temperature of 70°F, the mass input transient is limiting, and above this temperature the heat input transient is limiting.

To prevent the possibility of a heat input transient, and thereby limit the required flow rate of the RNS suction relief valve, administrative requirements in the LCO note have been imposed for starting an RCP.

BASES

APPLICABLE SAFETY ANALYSES (continued)

RCS Vent Performance

With the RCS depressurized, a vent size of 4.15 square inches is capable of mitigating a limiting overpressure transient. The area of the vent is equivalent to the area of the inlet pipe to the RNS suction relief valve so the capacity of the vent is greater than the flow possible with either the mass or heat input transient, while maintaining the RCS pressure less than the minimum of either the maximum pressure on the P/T limit curve or 110 percent of the design pressure of the normal residual heat removal system.

The required vent area may be obtained by opening one ADS Stage 2, 3, or 4 flow path.

The RCS vent size will be reevaluated for compliance each time the P/T limit curves are revised based on the results of the vessel material surveillance.

The RCS vent is passive and is not subject to active failure.

The LTOP System satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that the LTOP System is OPERABLE. The LTOP System is OPERABLE when the maximum coolant input and minimum pressure relief capabilities are OPERABLE. Violation of this LCO could lead to the loss of low temperature overpressure mitigation and violation of the Reference 1 limits as a result of an operational transient.

To limit the coolant input capability, the LCO requires all accumulator discharge isolation valves closed and immobilized, when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS temperature allowed in the PTLR.

The elements of the LCO that provide low temperature overpressure mitigation through pressure relief are:

a. One OPERABLE RNS suction relief valve; or

   An RNS suction relief valve is OPERABLE for LTOP when both RNS suction isolation valves in one flow path are open, its setpoint is set within the PTLR (Reference 6) limit, and testing has proven its ability to open at this setpoint.

BASES

LCO (continued)

b. A depressurized RCS and an RCS vent.

An RCS vent is OPERABLE when open with an area of ≥ 4.15 square inches.

Each of these methods of overpressure prevention is capable of mitigating the limiting LTOP transient.

Note 1 prohibits startup of an RCP when the RCS temperature is ≥ 350°F unless pressurizer level is < 92%. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started.

Note 2 requires that the secondary side water temperature of each SG be ≤ 50°F above each of the RCS cold leg temperatures before the start of an RCP with any RCS cold leg temperature ≤ 350°F, and the RCP must be started at ≤ 25% of RCP speed. This restraint is to prevent a low temperature overpressure event due to a thermal transient when an RCP is started. This limitation also helps to ensure that the RNS system pressure remains below both the piping design pressure and the acceptable RNS relief valve inlet pressure.

APPLICABILITY This LCO is applicable in MODE 4 when any cold leg temperature is below 275°F, MODE 5, and in MODE 6 when the reactor vessel head is on. The pressurizer safety valves provide overpressure protection that meets the Reference 1 P/T limits above 275°F. In MODE 6, the reactor vessel head is off, and overpressurization cannot occur.

LCO 3.4.3 provides the operational P/T limits for all MODES. LCO 3.4.6, “Pressurizer Safety Valves,” requires the OPERABILITY of the pressurizer safety valves that provide overpressure protection during MODES 1, 2, and 3, and MODE 4 with the RNS isolated or RCS temperature ≥ 275°F.

Low temperature overpressure prevention is most critical during shutdown when the RCS is water solid, and a mass or heat input transient can cause a very rapid increase in RCS pressure with little or no time for operator action to mitigate the event.

The Applicability is modified by a Note stating that accumulator isolation is only required when the accumulator pressure is more than or at the maximum RCS pressure for the existing temperature, as allowed by the P/T limit curves.

This Note permits the accumulator discharge isolation valve Surveillance to be performed only under these pressure and temperature conditions.

BASES

ACTIONS

A.1, B.1, and B.2

An unisolated accumulator requires isolation within 1 hour. This is only required when the accumulator pressure is at or more than the maximum RCS pressure for the existing temperature allowed by the P/T limit curves.

If isolation is needed and cannot be accomplished in 1 hour, Required Action B.1 and Required Action B.2 provide two options, either of which must be performed in the next 12 hours. By increasing the RCS temperature to > 275°F, the accumulator pressure cannot exceed the LTOP limits if the accumulators are fully injected. Depressurizing the accumulators below the LTOP limit from the PTLR also gives this protection.

The Completion Times are based on operating experience that these activities can be accomplished in these time periods and on engineering evaluations indicating that an event requiring LTOP is not likely in the allowed times.

C.1 and C.2

If the RNS suction relief valve is inoperable and the RCS is not depressurized, there is a potential to overpressurize the RCS and exceed the limits allowed in LCO 3.4.3. The suction relief valve is considered inoperable if the RNS isolation valves have isolated the RNS from the RCS in such a way that the suction relief valve cannot perform its intended safety function, or if the valve itself will not operate to perform its intended safety function.

Under these conditions, Required Actions C.1 or C.2 provide two options, either of which must be accomplished in 12 hours. If the RNS suction relief valve cannot be restored to OPERABLE status, the RCS must be depressurized and vented with a RCS vent which provides a flow area sufficient to mitigate any of the design low temperature overpressure events.

The 12 hour Completion Time represents a reasonable time to repair the relief valve, open the RNS isolation valves or otherwise restore the system to OPERABLE status, or depressurize and vent the RCS, without imposing a lengthy period when the LTOP system is not able to mitigate a low temperature overpressure event.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.14.1

To minimize the potential for a low temperature overpressure event by limiting the mass input capability, the accumulator discharge isolation valves are verified closed and locked out. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the main control room to verify the required status of the equipment.

SR 3.4.14.2

The RNS suction relief valve shall be demonstrated OPERABLE by verifying two RNS suction isolation valves in one flow path are open. This Surveillance is only performed if the RNS suction relief valve is being used to satisfy this LCO.

The RNS suction isolation valves are verified to be opened every 12 hours. The Frequency is considered adequate in view of other administrative controls such as valve status indications available to the operator in the control room that verify the RNS suction isolation valves remain open.

SR 3.4.14.3

The RCS vent of ≥ 4.15 square inches is proven OPERABLE by verifying its open condition either:

a. Once every 12 hours for a valve that is not locked (valves that are sealed or secured in the open position are considered “locked” in this context) or

b. Once every 31 days for other vent path(s) (e.g., a vent valve that is locked, sealed, or secured in position or a removed pressurizer safety valve or open manway also fits this category).

The passive vent arrangement must only be open to be OPERABLE. This Surveillance is required to be performed if the vent is being used to satisfy the pressure relief requirements of the LCO 3.4.14b.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.14.4

The RNS suction relief valve shall be demonstrated OPERABLE by verifying that two RNS suction isolation valves in one flow path are open and by testing it in accordance with the Inservice Testing Program. (Refer to SR 3.4.14.2 for the RNS suction isolation valve Surveillance.) This Surveillance is only required to be performed if the RNS suction relief valve is being used to meet this LCO. The ASME OM Code (Ref. 5) test per Inservice Testing Program verifies OPERABILITY by proving proper relief valve mechanical motion and by measuring and, if required, adjusting the lift setpoint.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.15 RCS Pressure Isolation Valve (PIV) Integrity

BASES

BACKGROUND

10 CFR 50.2, 10 CFR 50.55a(c), and GDC 55 of 10 CFR 50, Appendix A (Refs. 1, 2, and 3), define the RCS pressure boundary as all those pressure containing components such as pressure vessels, piping, pumps, and valves which are connected to the reactor coolant system, up to and including the outermost containment isolation valve in system piping which penetrates primary reactor containment, the second of two valves normally closed during normal reactor operation in system piping which does not penetrate primary reactor containment, and the reactor coolant system safety and relief valves. This includes any two normally closed valves in series within the reactor coolant pressure boundary (RCPB), which separate the high pressure RCS from an attached low pressure system. During their lives, these valves can experience varying amounts of reactor coolant leakage through either normal operational wear or mechanical deterioration. The AP1000 PIVs are listed in Chapter 3, Table 3.9-18. The RCS PIV Leakage LCO allows RCS high pressure operation when PIV leakage has been verified.

The purpose of this specification is to prevent overpressure failure or degradation of low pressure portions of connecting systems. The following criteria was used in identifying PIVs for inclusion in the specification. A valve was included in this specification if its failure may result in:

1. Failure of low pressure portions of connected systems, such as a Loss of Coolant Accident (LOCA) outside of containment, which could place the plant in an unanalyzed condition.

2. Degradation of low pressure portions of connected systems, such as damage to a core cooling system, which could degrade a safety related function that mitigates a DBA.

Valves considered for inclusion in this specification are used to isolate the RCS from the following connected systems:

a. Passive Core Cooling System (PXS) Accumulators;

b. Normal Residual Heat Removal System (RNS); and

c. Chemical and Volume Control System (CVS).

BASES

BACKGROUND (continued)

The RNS pressure boundary isolation valves are considered to meet the first criterion for inclusion in this specification. The PXS accumulator check valves were determined to meet the second PIV criteria for inclusion in this specification. It is determined that the CVS PIVs do not meet either criteria for inclusion in this specification.

The PIVs that are addressed by this specification are listed in Chapter 3, Table 3.9-18.

The CVS pressure isolation valves were not included in this specification based on the defined criteria. The justification for excluding the CVS PIVs is discussed in the following paragraph.

The CVS contains four high pressure/low pressure connections with the RCS. Since the portion of the CVS which is located inside reactor containment is designed to full RCS pressure, the high pressure/low pressure interfaces with the RCS are the lines that penetrate the reactor containment. The CVS lines that penetrate containment include the makeup line, the letdown line to the Liquid Radwaste System, the hydrogen supply line, and the demineralizer resin sluice line used to transfer spent resins from the demineralizers to the Solid Radwaste System. These lines each contain two safety related containment isolation valves which are addressed by the Containment Isolation Specification (LCO 3.6.3). In addition to the containment isolation valves in each of the CVS lines that interface with the RCS, there are additional valves in each line that provide diverse isolation capability. Since more restrictive requirements are imposed by LCO 3.6.3, the CVS isolation valves are not included in this LCO.

Since the purpose of this LCO is to verify that the PIVs have not suffered gross failures, the valve leakage test in conjunction with tests specified in the IST program provide an acceptable method of determining valve integrity. The ability of the valves to transition from open to closed provides assurance that the valve can perform its pressure isolation function as required. A small amount leakage through these valves is allowed, provided that the integrity of the valve was demonstrated.

Violation of this LCO could result in continued degradation of a PIV, which could lead to overpressurization of a low pressure system or the failure of a safety related function to mitigate a DBA.

BASES

APPLICABLE SAFETY ANALYSES

Pressure isolation valve integrity is not considered in any design basis accident analyses. This specification provides for monitoring the condition of the reactor coolant pressure boundary to detect degradation which could lead to accidents or which could impair a connected system's ability to mitigate DBAs.

RCS PIV integrity satisfies, Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS PIV leakage is identified LEAKAGE into closed systems connected to the RCS. Isolation valve leakage is usually small. Leakage that increases significantly suggests that something is operationally wrong and corrective action must be taken.

The LCO PIV leakage limit is 0.5 gpm per inch nominal valve size up to a maximum of 5 gpm per valve. This limit is well within the makeup capability of the CVS makeup pumps. This leak rate will not result in the overpressure of a connected low pressure system. Reference 5 permits leakage testing at a lower pressure differential than between the specified maximum RCS pressure and the normal pressure of the connected system during RCS operation (the maximum pressure differential) in those types of valves in which the higher service pressure will tend to diminish the overall leakage of the valve. In such cases, the observed leakage rate at lower differential pressures can be assumed to be the leakage at the maximum pressure differential. Verification that the valve leakage diminishes with increasing pressure differential is sufficient to verify that the valve characteristics are such that higher service pressure results in a decrease in overall leakage.

APPLICABILITY

In MODES 1, 2, and 3 and MODE 4, with RCS not being cooled by the RNS, this LCO applies when the RCS is pressurized.

In MODE 4, with RNS in operation, and MODES 5 and 6, the RCS pressure is reduced and is not sufficient to overpressurize the connected low pressure systems.

ACTIONS

The ACTIONS are modified by two Notes. Note 1 provides clarification that each flow path allows separate entry into a Condition. This is allowed based upon the functional independence of the flow path. Note 2 requires an evaluation of affected systems if a PIV is inoperable. The pressurization may have affected system OPERABILITY, or isolation of an affected flow path with an alternate valve may have degraded the ability of the interconnected system to perform its safety function.

BASES

ACTIONS (continued)

A.1

With one or more PIVs inoperable, the affected flow path(s) must be isolated. Required Action A.1 is modified by a Note that the valves used for isolation must meet the same integrity requirements as the PIVs and must be within the RCPB or the high pressure portion of the system.

Required Action A.1 requires that the isolation with one valve must be performed within 8 hours. Eight hours provides time to verify IST compliance for the alternate isolation valve and isolate the flow path. The 8 hour Completion Time allows the actions and restricts the operation with inoperable isolation valves.

A.2

Required Action A.2 specifies verification that a second OPERABLE PIV can meet the leakage limits. This valve is required to be a check valve, or a closed valve, if it isolates a line that penetrates containment. For the accumulator valves, the normally open accumulator isolation valve is a suitable replacement PIV, but can remain open because leakage into the accumulator is continuously monitored. If leakage into the accumulators increased to the allowable operational leakage limit, then the valve could be used to isolate the accumulators from the RCS.

The 72 hour Completion Time allows the actions and restricts the operation with inoperable isolation valves.

B.1 and B.2

If PIV integrity cannot be restored, the system isolated, or the other Required Actions accomplished, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. This Action may reduce the leakage and reduces the potential for a LOCA outside containment.

SURVEILLANCE REQUIREMENTS

SR 3.4.15.1

Performance of leakage testing on each RCS PIV or isolation valve used to satisfy Required Action A.1 and Required Action A.2 is required to verify that leakage is below the specified limit and to identify each leaking

BASES

SURVEILLANCE REQUIREMENTS (continued)

valve. The leakage limit of 0.5 gpm per inch nominal valve size up to a minimum of 5 gpm applies to each valve. Leakage testing requires a stable pressure condition.

For the two PIVs in series, the leakage requirement applies to each valve individually and not to the combined leakage across both valves. If the PIVs are not individually leakage tested, one valve may have failed completely and not be detected if the other valve in series meets the leakage requirement. In this situation, the protection provided by redundant valves would be lost.

Testing shall be performed every 24 months, a typical refueling cycle. The 24 month Frequency is consistent with 10 CFR 50.55a(g) (Ref. 4) as contained in the Inservice Testing Program and is within frequency allowed by the American Society of Mechanical Engineers (ASME) OM Code (Ref. 5).

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.16 Reactor Vessel Head Vent (RVHV)

BASES

BACKGROUND

The reactor vessel head vent (RVHV) is designed to assure that long-term operation of the Core Makeup Tanks (CMTs) does not result in overfilling of the pressurizer during Condition II Design Basis Accidents (DBAs). The RVHV can be manually actuated by the operators in the main control room to reduce the pressurizer water level during long-term operation of the CMTs.

The RVHV consists of two parallel flow paths each containing two RVHV isolation valves in series. The RVHV valves are connected to the reactor vessel head via a common line. The outlets of the RVHV flow paths combine into one common discharge line which connects to a single ADS discharge header that discharges to spargers located in the incontainment refueling water storage tank (IRWST). The RVHV valves are 1 inch valves with DC solenoid operators.

The RVHV valves are designed to open when actuated by the operator, and to reclose when actuated by the operator from the main control room.

The number and capacity of the RVHV flow paths are selected so that letdown flow from the RCS is sufficient to prevent pressurizer overfill for events where extended operation of the CMTs causes the pressurizer water level to increase. Although realistic evaluations of the Condition II non-LOCA events does not result in pressurizer overfill, conservative analyses of some of these events can result in pressurizer overfill if no operator actions are assumed.

APPLICABLE SAFETY ANALYSES

For Condition II non-LOCA events, such as inadvertent passive core cooling system operation and chemical and volume control system malfunction, the use of the RVHV may be required to prevent long-term pressurizer overfill (Ref. 1).

For LOCA events, the RVHV is not required.

The RVHV satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that all four RVHV valves be OPERABLE ensures that upon actuation, the RVHV can reduce the pressurizer water level as assumed in the DBA safety analyses.

BASES

LCO (continued)

For the RVHV to be considered OPERABLE, all four valves must be closed and OPERABLE (capable of opening from the main control room).

APPLICABILITY

In MODES 1, 2, 3, and 4 with the RCS not being cooled by the RNS, the RVHV must be OPERABLE to mitigate the potential consequences of any event which causes an increase in the pressurizer water level that could otherwise result in overfilling of the pressurizer.

In MODE 4, with the RCS being cooled by the RNS, and in MODES 5 and 6, operation of the CMTs or CVS will not result in a pressurizer overfill event.

ACTIONS

A.1

If one or two RVHV valves in a single flow path are determined to be inoperable, the flow path is inoperable. The remaining OPERABLE RVHV flow path is adequate to perform the required safety function. A Completion Time of 72 hours is acceptable since the OPERABLE RVHV paths can mitigate DBAs without a single failure.

B.1

If both flow paths are determined to be inoperable, the RVHV is degraded such that the system is not available for some DBA non-LOCA analyses for which it may be required. A Completion Time of 6 hours is permitted to restore at least one flow path. This Completion Time is acceptable considering that the realistic analysis of these non-LOCA events do not result in pressurizer overfill.

C.1 and C.2

If the Required Actions and associated Completion Times are not met or the requirements of LCO 3.4.16 are not met for reasons other than Conditions A or B, the plant must be brought to MODE 4 where the probability and consequences of an event are minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner, without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.16.1

The dedicated component level remote manual valve switches in the main control room shall be used to stroke each RVHV valve to demonstrate OPERABILITY of the controls.

This Surveillance requires verification that each RVHV valve strokes to its fully open position. The Surveillance Frequency for demonstrating valve OPERABILITY references the Inservice Testing Program.

REFERENCES

1. Section 15.5, “Increase in Reactor Coolant System Inventory.”

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.17 Chemical and Volume Control System (CVS) Makeup Isolation Valves

BASES

BACKGROUND

One of the principle functions of the CVS system is to maintain the reactor coolant inventory by providing water makeup for reactor coolant system (RCS) LEAKAGE, shrinkage of the reactor coolant during cooldowns, and RCS boron concentration changes. In the automatic makeup mode of operation, the pressurizer water level starts and stops CVS makeup to the RCS.

Although the CVS is not considered a safety related system, certain isolation functions of the system are considered safety related functions. The appropriate isolation valves have been classified and designed as safety related. One of the safety related functions provided by the CVS is the termination of RCS makeup to prevent overfilling of the pressurizer during non-LOCA transients or to prevent steam generator overfilling during a steam generator tube rupture. The CVS makeup line containment isolation valves provide this RCS makeup isolation function.

APPLICABLE SAFETY ANALYSES

One of the initial assumptions in the analysis of several non-LOCA events and during a steam generator tube rupture accident is that excessive CVS makeup to the RCS may aggravate the consequences of the accident. The need to isolate the CVS makeup to the RCS is detected by the pressurizer level instruments or the steam generator narrow range level instruments. These instruments will supply a signal to the makeup line containment isolation valves in the CVS causing these valves to close and terminate RCS makeup. Thus the CVS makeup isolation valves are components which function to mitigate an accident.

CVS isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The requirement that at least two CVS makeup isolation valves be OPERABLE assures that there will be redundant means available to terminate CVS makeup to the RCS during a non-LOCA event or a steam generator tube rupture accident should that become necessary.

APPLICABILITY

The requirement that at least two CVS makeup isolation valves be OPERABLE is applicable in MODES 1, 2, 3, and 4 with the normal residual heat removal system (RNS) suction to the RCS not open

BASES

APPLICABILITY (continued)

because a pressurizer overfill event or steam generator tube rupture accident is considered possible in these MODES, and the automatic closure of these valves is assumed in the safety analysis.

In the applicable MODES, the need to isolate the CVS makeup to the RCS is detected by the pressurizer level instruments (high 1 setpoint coincident with safeguards actuation or high 2 setpoint) or the steam generator narrow range level instruments (high setpoint coincident with reactor trip (P-4) or high 2 setpoint).

This isolation function is not required in MODE 4 with the RNS suction open to the RCS or in lower MODES. In such MODES, pressurizer or steam generator overfill is prevented by the RNS suction relief valve.

ACTIONS

A.1

If only one CVS makeup isolation valve is OPERABLE, the second valve must be restored to OPERABLE status in 72 hours. The allowed Completion Time assures expeditious action will be taken, and is acceptable because the safety function of automatically isolating RCS makeup can be accomplished by the redundant isolation valve.

B.1

If the Required Actions and associated Completion Time of Condition A are not met, or if both CVS makeup isolation valves are not OPERABLE (i.e., not able to be closed automatically), then the makeup flow path to the RCS must be isolated. Isolation can be accomplished by manually closing the CVS makeup isolation MOVs or alternatively, manual valve(s) in the makeup line between the makeup pumps and the RCS.

The Action is modified by a Note allowing the flow path to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the main control room. In this way, the flow path can be rapidly isolated when a need for isolation is indicated.

SURVEILLANCE REQUIREMENTS

SR 3.4.17.1

Verification that the RCS makeup isolation valves are OPERABLE, by stroking each valve closed, demonstrates that the valves can perform their safety related function. The Frequency is in accordance with the Inservice Testing Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.17.2

Verification that the RCS makeup isolation valves closure times are less than that assumed in the safety analysis, is performed by measuring the time required for each valve to close. The Frequency is in accordance with the Inservice Testing Program.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.18 Steam Generator (SG) Tube Integrity

BASES

BACKGROUND

Steam generator (SG) tubes are small diameter, thin walled tubes that carry primary coolant through the primary to secondary heat exchangers. The SG tubes have a number of important safety functions. Steam generator tubes are an integral part of the reactor coolant pressure boundary (RCPB) and, as such, are relied on to maintain the primary system's pressure and inventory. The SG tubes isolate the radioactive fission products in the primary coolant from the secondary system. In addition, as part of the RCPB, the SG tubes are unique in that they act as the heat transfer surface between the primary and secondary systems to remove heat from the primary system. This Specification addresses only the RCPB integrity function of the SG. The SG heat removal function is addressed by LCO 3.4.4, "RCS Loops."

SG tube integrity means that the tubes are capable of performing their intended RCPB safety function consistent with the licensing basis, including applicable regulatory requirements.

Steam generator tubing is subject to a variety of degradation mechanisms. Steam generator tubes may experience tube degradation related to corrosion phenomena, such as wastage, pitting, intergranular attack, and stress corrosion cracking, along with other mechanically induced phenomena such as denting and wear. These degradation mechanisms can impair tube integrity if they are not managed effectively. The SG performance criteria are used to manage SG tube degradation.

Specification 5.5.4, "Steam Generator (SG) Program," requires that a program be established and implemented to ensure that SG tube integrity is maintained. Pursuant to Specification 5.5.4, tube integrity is maintained when the SG performance criteria are met. There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. The SG performance criteria are described in Specification 5.5.4. Meeting the SG performance criteria provides reasonable assurance of maintaining tube integrity at normal and accident conditions.

The processes used to meet the SG performance criteria are defined by the Steam Generator Program Guidelines (Ref. 1).

BASES

APPLICABLE SAFETY ANALYSES

The steam generator tube rupture (SGTR) accident is the limiting design basis event for SG tubes and avoiding an SGTR is the basis for this Specification. The analysis of a SGTR event assumes a bounding primary to secondary LEAKAGE rate equal to the operational LEAKAGE rate limits in LCO 3.4.7, "RCS Operational LEAKAGE," plus the leakage rate associated with a double-ended rupture of a single tube. The accident analysis for a SGTR assumes the contaminated secondary fluid is only briefly released to the atmosphere via safety valves and the majority is discharged to the main condenser.

The analysis for design basis accidents and transients other than a SGTR assume the SG tubes retain their structural integrity (i.e., they are assumed not to rupture.) In these analyses, the steam discharge to the atmosphere includes primary to secondary SG tube LEAKAGE equivalent to the operational leakage limit of 150 gpd per SG. For accidents that do not involve fuel damage, the primary coolant activity level of DOSE EQUIVALENT I-131 is assumed to be equal to the LCO 3.4.10, "RCS Specific Activity," limits. For accidents that assume fuel damage, the primary coolant activity is a function of the amount of activity released from the damaged fuel. The dose consequences of these events are within the limits of GDC 19 (Ref. 2), 10 CFR 50.34 (Ref. 3) or the NRC approved licensing basis (e.g., a small fraction of these limits).

Steam generator tube integrity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that SG tube integrity be maintained. The LCO also requires that all SG tubes that satisfy the repair criteria be plugged in accordance with the Steam Generator Program.

During an SG inspection, any inspected tube that satisfies the Steam Generator Program repair criteria is removed from service by plugging. If a tube was determined to satisfy the repair criteria but was not plugged, the tube may still have tube integrity.

In the context of this Specification, a SG tube is defined as the entire length of the tube, including the tube wall, between the tube-to-tubesheet weld at the tube inlet and the tube-to-tubesheet weld at the tube outlet. The tube-to-tubesheet weld is not considered part of the tube.

A SG tube has tube integrity when it satisfies the SG performance criteria. The SG performance criteria are defined in Specification 5.5.4, "Steam Generator Program," and describe acceptable SG tube performance. The Steam Generator Program also provides the evaluation process for determining conformance with the SG performance criteria.

BASES

LCO (continued)

There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. Failure to meet any one of these criteria is considered failure to meet the LCO.

The structural integrity performance criterion provides a margin of safety against tube burst or collapse under normal and accident conditions, and ensures structural integrity of the SG tubes under all anticipated transients included in the design specification. Tube burst is defined as, "The gross structural failure of the tube wall. The condition typically corresponds to an unstable opening displacement (e.g., opening area increased in response to constant pressure) accompanied by ductile (plastic) tearing of the tube material at the ends of the degradation." Tube collapse is defined as, "For the load displacement curve for a given structure, collapse occurs at the top of the load versus displacement curve where the slope of the curve becomes zero." The structural integrity performance criterion provides guidance on assessing loads that have a significant effect on burst or collapse. In that context, the term "significant" is defined as "An accident loading condition other than differential pressure is considered significant when the addition of such loads in the assessment of the structural integrity performance criterion could cause a lower structural limit or limiting burst/collapse condition to be established." For tube integrity evaluations, except for circumferential degradation, axial thermal loads are classified as secondary loads. For circumferential degradation, the classification of axial thermal loads as primary or secondary loads will be evaluated on a case-by-case basis. The division between primary and secondary classifications will be based on detailed analysis and/or testing.

Structural integrity requires that the primary membrane stress intensity in a tube not exceed the yield strength for all ASME Code, Section III, Service Level A (normal operating conditions) and Service Level B (upset or abnormal conditions) transients included in the design specification. This includes safety factors and applicable design basis loads based on ASME Code, Section III, Subsection NB (Ref. 4) and Draft Regulatory Guide 1.121 (Ref. 5).

The accident induced leakage performance criterion ensures that the primary to secondary LEAKAGE caused by a design basis accident, other than a SGTR, is within the accident analysis assumptions. The accident analysis assumes that accident induced leakage does not exceed 150 gpd per SG. The accident induced leakage rate includes any primary to secondary LEAKAGE existing prior to the accident in addition to primary to secondary LEAKAGE induced during the accident.

BASES

LCO (continued)

The operational LEAKAGE performance criterion provides an observable indication of SG tube conditions during plant operation. The limit on operational LEAKAGE is contained in LCO 3.4.7, "RCS Operational LEAKAGE," and limits primary to secondary LEAKAGE through any one SG to 150 gallons per day. This limit is based on the assumption that a single crack leaking this amount would not propagate to a SGTR under the stress conditions of a LOCA or a main steam line break. If this amount of LEAKAGE is due to more than one crack, the cracks are very small, and the above assumption is conservative.

APPLICABILITY

Steam generator tube integrity is challenged when the pressure differential across the tubes is large. Large differential pressures across SG tubes can only be experienced in MODE 1, 2, 3, or 4.

RCS conditions are far less challenging in MODES 5 and 6 than during MODES 1, 2, 3, and 4. In MODES 5 and 6, primary to secondary differential pressure is low, resulting in lower stresses and reduced potential for LEAKAGE.

ACTIONS

The ACTIONS are modified by a Note clarifying that the Conditions may be entered independently for each SG tube. This is acceptable because the Required Actions provide appropriate compensatory actions for each affected SG tube. Complying with the Required Actions may allow for continued operation, and subsequent affected SG tubes are governed by subsequent Condition entry and application of associated Required Actions.

A.1 and A.2

Condition A applies if it is discovered that one or more SG tubes examined in an inservice inspection satisfy the tube repair criteria but were not plugged in accordance with the Steam Generator Program as required by SR 3.4.18.2. An evaluation of SG tube integrity of the affected tube(s) must be made. Steam generator tube integrity is based on meeting the SG performance criteria described in the Steam Generator Program. The SG repair criteria define limits on SG tube degradation that allow for flaw growth between inspections while still providing assurance that the SG performance criteria will continue to be met. In order to determine if a SG tube that should have been plugged has tube integrity, an evaluation must be completed that demonstrates that the SG performance criteria will continue to be met until the next refueling outage or SG tube inspection. The tube integrity determination

BASES

ACTIONS (continued)

is based on the estimated condition of the tube at the time the situation is discovered and the estimated growth of the degradation prior to the next SG tube inspection. If it is determined that tube integrity is not being maintained, Condition B applies.

A Completion Time of 7 days is sufficient to complete the evaluation while minimizing the risk of plant operation with a SG tube that may not have tube integrity.

If the evaluation determines that the affected tube(s) have tube integrity, Required Action A.2 allows plant operation to continue until the next refueling outage or SG inspection provided the inspection interval continues to be supported by an operational assessment that reflects the affected tubes. However, the affected tube(s) must be plugged prior to entering MODE 4 following the next refueling outage or SG inspection. This Completion Time is acceptable since operation until the next inspection is supported by the operational assessment.

B.1 and B.2

If the Required Actions and associated Completion Times of Condition A are not met or if SG tube integrity is not being maintained, the reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the desired plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.18.1

During shutdown periods the SGs are inspected as required by this SR and the Steam Generator Program. NEI 97-06, Steam Generator Program Guidelines (Ref. 1), and its referenced EPRI Guidelines, establish the content of the Steam Generator Program. Use of the Steam Generator Program ensures that the inspection is appropriate and consistent with accepted industry practices.

During SG inspections a condition monitoring assessment of the SG tubes is performed. The condition monitoring assessment determines the "as found" condition of the SG tubes. The purpose of the condition monitoring assessment is to ensure that the SG performance criteria have been met for the previous operating period.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Steam Generator Program determines the scope of the inspection and the methods used to determine whether the tubes contain flaws satisfying the tube repair criteria. Inspection scope (i.e., which tubes or areas of tubing within the SG are to be inspected) is a function of existing and potential degradation locations. The Steam Generator Program also specifies the inspection methods to be used to find potential degradation. Inspection methods are a function of degradation morphology, non-destructive examination (NDE) technique capabilities, and inspection locations.

The Steam Generator Program defines the Frequency of SR 3.4.18.1. The Frequency is determined by the operational assessment and other limits in the SG examination guidelines (Ref. 6). The Steam Generator Program uses information on existing degradations and growth rates to determine an inspection Frequency that provides reasonable assurance that the tubing will meet the SG performance criteria at the next scheduled inspection. In addition, Specification 5.5.4 contains prescriptive requirements concerning inspection intervals to provide added assurance that the SG performance criteria will be met between scheduled inspections.

SR 3.4.18.2

During an SG inspection, any inspected tube that satisfies the Steam Generator Program repair criteria is removed from service by plugging. The tube repair criteria delineated in Specification 5.5.4 are intended to ensure that tubes accepted for continued service satisfy the SG performance criteria with allowance for error in the flaw size measurement and for future flaw growth. In addition, the tube repair criteria, in conjunction with other elements of the Steam Generator Program, ensure that the SG performance criteria will continue to be met until the next inspection of the subject tube(s). Reference 1 provides guidance for performing operational assessments to verify that the tubes remaining in service will continue to meet the SG performance criteria.

The Frequency of prior to entering MODE 4 following a SG inspection ensures that the Surveillance has been completed and all tubes meeting the repair criteria are plugged prior to subjecting the SG tubes to significant primary to secondary pressure differential.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.1 Accumulators

BASES

BACKGROUND

Two redundant PXS accumulators provide sufficient water to the reactor vessel during the blowdown phase of a large-break loss-of-coolant accident (LOCA), to provide inventory to help accomplish the refill phase that follows thereafter, to provide Reactor Coolant System (RCS) makeup for a small-break LOCA, and to provide RCS boration for steam line breaks (Ref. 2).

The blowdown phase of a large break LOCA is the initial period of the transient during which the RCS departs from equilibrium conditions, and heat from fission product decay, hot internals, and the vessel continues to be transferred to the reactor coolant. The blowdown phase of the transient ends when the RCS pressure falls to a value approaching that of the containment atmosphere.

In the refill phase of a LOCA, which immediately follows the blowdown phase, reactor coolant inventory has vacated the core through steam flashing and ejection out through the break. The core is essentially in adiabatic heatup. The accumulator inventory is available to help fill voids in the lower plenum and reactor vessel downcomer so as to establish a recovery level at the bottom of the core and ongoing reflood of the core.

The accumulators are pressure vessels, partially filled with borated water and pressurized with nitrogen gas. The accumulators are passive components, since no operator or control actions are required for them to perform their function. Internal accumulator pressure is sufficient to discharge the accumulator contents to the RCS, if RCS pressure decreases below the static accumulator pressure.

Each accumulator is piped into the reactor vessel via an accumulator line and is isolated from the RCS by two check valves in series.

A normally open motor operated valve is arranged in series with the check valves. Upon initiation of a safeguards actuation signal, the normally open valves receive a confirmatory open signal.

Power lockout and position alarms ensure that the valves meet the requirements of the Institute of Electrical and Electronic Engineers (IEEE) Standard 603-1991 (Ref. 1) for “operating bypasses” and that the accumulators will be available for injection without being subject to a single failure.

BASES

BACKGROUND (continued)

The accumulator size, water volume, and nitrogen cover pressure are selected so that both of the accumulators are sufficient to recover the core cooling before significant clad melting or zirconium water reaction can occur following a large break LOCA. One accumulator is adequate during a small break LOCA where the entire contents of one accumulator can possibly be lost via the pipe break. This accumulator performance is based on design basis accident (DBA) assumptions and models (Ref. 3). The Probabilistic Risk Assessment (PRA) (Ref. 4) shows that one of the two accumulators is sufficient for a large break LOCA caused by spurious ADS actuation and that none of the accumulators are required for small break LOCAs, assuming that at least one core makeup tank (CMT) is available. In addition, both accumulators are required for a large break LOCA caused by the break of a cold leg pipe; the probability of this break has been significantly reduced by incorporation of leak-before-break.

APPLICABLE SAFETY ANALYSES

The accumulators are assumed to be OPERABLE in both the large and small break LOCA analyses at full power (Ref. 3) that establish the acceptance limits for the accumulators. Reference to the analyses for these DBAs is used to assess changes in the accumulators as they relate to the acceptance limits.

For a small break LOCA, a large range of break sizes and locations were analyzed to verify the adequacy of the design. The cases analyzed include the rupture of one 8 inch direct vessel injection line and several smaller break sizes. Acceptable PXS performance was demonstrated.

For a larger LOCA, including a double ended RCS piping rupture, the PXS can provide a sufficiently large flow rate, assuming both accumulators are OPERABLE, to quickly fill the reactor vessel lower plenum and downcomer. Both accumulators, in conjunction with the CMTs, ensure rapid reflooding of the core. For a large LOCA, both lines are available since an 8 inch line break would be a small LOCA.

Following a non-LOCA event such as a steam line break, the RCS experiences a decrease in temperature and pressure due to an increase in energy removal by the secondary system. The cooldown results in a reduction of the core SHUTDOWN MARGIN with a potential for return to power. During such an event the accumulators provide injection of borated water to assist the CMT’s boration to mitigate the reactivity transient and ensure the core remains shut down.

The accumulators satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

This LCO establishes the minimum conditions necessary to ensure that sufficient accumulator flow will be available to meet the necessary acceptance criteria established for core cooling by 10 CFR 50.46 (Ref. 5). These conditions are:

a. Maximum fuel element cladding temperature is ≤ 2200°F;

b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation;

c. Maximum hydrogen generation from a zirconium-water reaction is ≤ 0.01 times the hypothetical amount that would be generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react; and

d. The core is maintained in a coolable geometry.

Since the accumulators discharge during the blowdown phase of a LOCA, they do not contribute to the long term cooling requirements of 10 CFR 50.46.

For an accumulator to be OPERABLE, the isolation valve must be fully open with power removed, and the limits established in the Surveillance Requirements for contained water, boron concentration, and nitrogen cover pressure must be met.

APPLICABILITY

In MODES 1 and 2, and in MODES 3 and 4 with RCS pressure > 1000 psig, the accumulator OPERABILITY requirements are based on full power operation. Although cooling requirements decrease as power decreases, the accumulators are still required to provide core cooling as long as elevated RCS pressures and temperatures exist.

This LCO is only applicable at pressures > 1000 psig. At pressures ≤ 1000 psig, the rate of RCS blowdown is such that adequate injection flow from other sources exists to retain peak clad temperatures below the 10 CFR 50.46 limit of 2200°F.

In MODES 3 and 4 with RCS pressure ≤ 1000 psig, and in MODES 5 and 6, the accumulator motor operated isolation valves are closed to isolate the accumulators from the RCS. This allows the RCS cooldown and depressurization without discharging the accumulators into the RCS or requiring depressurization of the accumulators.

BASES

ACTIONS

A.1

If the boron concentration of one accumulator is not within limits, action must be taken to restore the parameter.

Deviations in boron concentration are expected to be slight, considering that the pressure and volume are verified once per 12 hours. For one accumulator, boron concentration not within limits will have an insignificant effect on the ability of the accumulators to perform their safety function. Therefore, a Completion Time of 72 hours is considered to be acceptable.

B.1

If one accumulator is inoperable for a reason other than boron concentration, the accumulator must be returned to OPERABLE status within 8 hours. With one accumulator inoperable, the remaining accumulator is capable of providing the required safety function, except for one low probability event (large cold leg LOCA) discussed in the background section. The effectiveness of one accumulator is demonstrated in analysis performed to justify PRA success criteria (Ref. 4). The analysis contained in this reference shows that for a range of other events including small LOCAs and large hot leg LOCAs that with one accumulator unavailable the core is adequately cooled. The incremental conditional core damage probability with this AOT is more than an order of magnitude less than the value indicated to have a small impact on plant risk (Ref. 7).

The 8 hour Completion Time to open the valve, remove power to the valve, or restore the proper water volume or nitrogen cover pressure ensures that prompt action will be taken to return the inoperable accumulator to OPERABLE status. The Completion Time is reasonable since the CMTs are required to be available to provide small break LOCA mitigation (i.e., entry into Condition C or E of LCO 3.5.2 has not occurred). The effectiveness of backup CMT injection is demonstrated in analysis performed to justify PRA success criteria (Ref. 3). The analysis contained in this reference shows that for a small LOCA, the injection from one CMT without any accumulator injection supports adequate core cooling. This analysis provides a high confidence that with the unavailability of one accumulator, the core can be cooled following design bases accidents.

The 1 hour Completion Time, in the case with simultaneous entry into Condition C or E of LCO 3.5.2, requires very prompt actions to restore either the accumulator or the CMT to OPERABLE status. This Completion Time is considered reasonable because of the low probability of simultaneously entering these multiple PXS Conditions and the very small likelihood of a LOCA occurring at the same time.

BASES

ACTIONS (continued)

C.1 and C.2

If the Required Action and associated Completion Time of Conditions A or B are not met, the plant must be placed in a MODE or condition in which the LCO does not apply. This is done by placing the plant in MODE 3 within 6 hours and with pressurizer pressure to ≤ 1000 psig within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

D.1

If more than one accumulator is inoperable, the plant is in a condition outside the accident analyses; therefore, LCO 3.0.3 must be entered immediately.

SURVEILLANCE REQUIREMENTS

SR 3.5.1.1

Each accumulator valve should be verified to be fully open every 12 hours. This verification ensures each accumulator isolation valve is fully open, as indicated in the control room, and timely discovery if a valve should be less than fully open. If an isolation valve is not fully open, the rate of injection to the RCS would be reduced. Although a motor operated valve position should not change with power removed, a partially closed valve could result in not meeting DBA analyses assumptions (Ref. 3). A 12 hour Frequency is considered reasonable in view of the other administrative controls which ensure that a mispositioned isolation valve is unlikely.

SR 3.5.1.2 and 3.5.1.3

Verification every 12 hours of the borated water volume and nitrogen cover pressure in each accumulator is sufficient to ensure adequate injection during a LOCA. Because of the static design of the accumulator, a 12 hour Frequency usually allows the operator to identify changes before limits are reached. Considering that control room alarms are provided for both parameters these limits are effectively subject to continuous monitoring. The 12 hour Frequency is considered reasonable considering the availability of the control room alarms and the likelihood that, with any deviation which may occur, the accumulators will perform their safety function with slight deviations in these parameters.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.1.4

The boron concentration should be verified to be within required limits for each accumulator every 31 days, since the static design of the accumulators limits the ways in which the concentration can be changed. The 31 day Frequency is adequate to identify changes that could occur from mechanisms such as in-leakage. Sampling the affected accumulator within 6 hours after a 3% volume increase will promptly identify whether the volume change has caused a reduction of boron concentration to below the required limit. It is not necessary to verify boron concentration if the added water inventory is from the in-containment refueling water storage tank (IRWST), because the water contained in the IRWST is within the accumulator boron concentration requirements. This is consistent with the recommendation of NUREG-1366 (Ref. 6).

SR 3.5.1.5

Verification every 31 days that power is removed from each accumulator isolation valve operator when the pressurizer pressure is ≥ 2000 psig ensures that an active failure could not result in the undetected closure of an accumulator motor operated isolation valve. If this were to occur, reduced accumulator capacity might be available for injection following a DBA that required operation of the accumulators. Since power is removed under administrative control, the 31 day Frequency will provide adequate assurance that power is removed.

This SR allows power to be supplied to the motor operated isolation valves when pressurizer pressure is < 2000 psig, thus allowing operational flexibility by avoiding unnecessary delays to manipulate the breakers during unit startup or shutdowns.

Should closure of a valve occur, the safeguard actuation signal provided to the valve would open a closed valve, if required.

SR 3.5.1.6

This SR requires performance of a system performance test of each accumulator to verify flow capabilities. The system performance test demonstrates that the accumulator injection line resistance assumed in accident analyses is maintained. Although the likelihood that system performance would degrade with time is low, it is considered prudent to periodically verify system performance. The System Level Operability Testing Program provides specific test requirements and acceptance criteria.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.2 Core Makeup Tanks (CMTs) – Operating

BASES

BACKGROUND

Two redundant CMTs provide sufficient borated water to assure Reactor Coolant System (RCS) reactivity and inventory control for all design basis accidents (DBAs), including both loss of coolant accident (LOCA) events and non-LOCA events (Ref. 1).

The CMTs are cylindrical tanks with hemispherical upper and lower heads. They are made of carbon steel and clad on the internal surfaces with stainless steel. They are located in containment at an elevation slightly above the reactor coolant loops. Each tank is full of borated water at > 3400 ppm. During normal operation, the CMTs are maintained at RCS pressure through a normally open pressure balance line from the cold leg.

The outlet line from each CMT is connected to one of two direct vessel injection lines, which provides an injection path for the water supplied by the CMT. The outlet line from each CMT is isolated by parallel, normally closed, fail open valves. Upon receipt of a safeguards actuation signal, these four valves open to align the CMTs to the RCS.

The CMTs will inject to the RCS as inventory is lost and steam or reactor coolant is supplied to the CMT to displace the water that is injected. Steam or reactor coolant is provided to the CMT through the cold leg balance line, depending upon the specific event that has occurred. The inlet line from the cold leg is sized for LOCA events, where the cold legs become voided and higher CMT injection flows are required.

The injection line from each CMT contains a flow tuning orifice that is used to provide a mechanism for the field adjustment of the injection line resistance. The orifice is used to establish the required flow rates for the associated plant conditions assumed in the CMT design. The CMT flow is based on providing injection for a minimum of 20 minutes after CMT actuation.

The CMT size and injection capability are selected to provide adequate RCS boration and safety injection for the limiting DBA. One CMT is adequate for this function during a small break LOCA where one CMT completely spills via the pipe break (Ref. 2). The Probabilistic Risk Assessment (PRA) (Ref. 3) shows that none of the CMTs are required for small LOCAs, assuming that at least one accumulator is available.

BASES

APPLICABLE SAFETY ANALYSES

The CMTs are assumed to be OPERABLE to provide emergency boration and core makeup when the Chemical and Volume Control System (CVS) is inoperable, and to mitigate the consequences of any DBA which requires the safety injection of borated water (Ref. 2).

Following a non-LOCA event such as a steam line break, the RCS experiences a decrease in temperature and pressure due to an increase in energy removal by the secondary system. The cooldown results in a reduction of the core SHUTDOWN MARGIN due to the negative moderator temperature coefficient, with a potential for return to power. The actuation of the CMTs following this event provides injection of borated water to mitigate the reactivity transient and ensure the core remains shut down.

In the case of a steam generator tube rupture (SGTR), CMT injection provides borated water to compensate for RCS LEAKAGE.

In the case of an RCS leak of 10 gallons per minute, the CMTs can delay depressurization for at least 10 hours, providing makeup to the RCS and remain able to provide the borated water to compensate for RCS shrinkage and to assure the RCS boration for a safe shutdown.

In the case of a LOCA, the CMTs provide a relatively large makeup flow rate for approximately 20 minutes, in conjunction with the accumulators to provide the initial core cooling.

CMTs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO establishes the minimum conditions necessary to ensure that sufficient CMT flow will be available to meet the initial conditions assumed in the safety analyses. OPERABILITY is not expected to be challenged due to small gas accumulations in the high point, and rapid gas accumulations are not expected during plant operation. However, a relatively small gas volume was incorporated into the design for alerting operators to provide sufficient time to initiate venting operations before the gas volume would be expected to increase to a sufficient volume that might potentially challenge the OPERABILITY of natural circulation flow. Therefore, noncondensible gas accumulation in the inlet line high point that causes the water level to drop below the sensor will require operator action to investigate the cause of the gas accumulation and to vent the associated high point(s).

The volume of each CMT represents 100% of the total injected flow assumed in LOCA analysis. If the injection line from a single CMT to the vessel breaks, no single active failure on the other CMT will prevent the injection of borated water into the vessel. Thus the assumptions of the LOCA analysis will be satisfied.

BASES

LCO (continued)

For non-LOCA analysis, two CMTs are assumed. Note that for non-LOCA analysis, the accident cannot disable a CMT.

APPLICABILITY

In MODES 1, 2, 3, and 4 when the RCS is not being cooled by the Normal Residual Heat Removal System (RNS) the CMTs are required to be OPERABLE to provide borated water for RCS inventory makeup and reactivity control following a design basis event and subsequent cooldown.

The CMT requirements in MODE 5 with the RCS pressure boundary intact are specified in LCO 3.5.3, “Core Makeup Tanks (CMTs) – Shutdown, RCS Intact.”

The CMTs are not required to be OPERABLE while in MODE 5 with the RCS pressure boundary open or in MODE 6 because the RCS is depressurized and borated water can be supplied from the In-containment Refueling Water Storage Tank (IRWST), if needed.

In the unlikely event of a total loss of AC power sources, coupled with an inoperable Passive Residual Heat Removal Heat Exchanger (PRHR HX) (beyond DBA), the CMTs may be used in a feed and bleed sequence to remove heat from the RCS.

ACTIONS

A.1

With one outlet isolation valve inoperable on one CMT, action must be taken to restore the valve. In this Condition, the CMT is capable of performing its safety function, provided a single failure of the remaining parallel isolation valve does not occur. A Completion Time of 72 hours is acceptable for two train ECCS systems which are capable of performing their safety function without a single failure.

B.1

If the water temperature or boron concentration of one CMT is not within limits, it must be returned to within limits within 72 hours. The deviations in these parameters are expected to be slight, considering the frequent surveillances and control room monitors. With the temperature above the limit, the full core cooling capability assumed in the safety analysis may not be available. With the boron concentration not within limits, the ability to maintain subcriticality following a DBA may be degraded. However, because only one of two CMTs is inoperable, and the deviations of these parameters are expected to be slight, it is probable that more than a required amount of boron and cooling capability will be available to meet

BASES

the conditions assumed in the safety analysis.

ACTIONS (continued)

Since the CMTs are redundant, safety class components, the 72 hour Completion Time is consistent with the times normally allowed for this type of component.

C.1

With two CMTs inoperable due to water temperature or boron concentration, at least one CMT must be restored to within limits in 8 hours. The deviations in these parameters are expected to be slight, considering the frequent surveillances and control room monitors. A Completion Time of 8 hours is considered reasonable since the CMTs are expected to be capable of performing their safety function with slight deviations in these parameters and the accumulators are required to be available for LOCA mitigation (i.e., entry into Condition B of LCO 3.5.1 has not occurred). The effectiveness of accumulator injection is demonstrated in analysis performed to justify PRA success criteria (Ref. 3). The analysis contained in this reference shows that for a small LOCA, the injection from one accumulator without any CMT injection supports adequate core cooling. This analysis provides a high confidence that with the unavailability of two CMTs due to water temperature or boron concentration deviations, the core can be cooled following design bases accidents.

The 1 hour Completion Time, in the case with simultaneous entry into Condition B of LCO 3.5.1, requires very prompt actions to restore either the CMT or the accumulator to OPERABLE status. This Completion Time is considered reasonable because of the low probability of simultaneously entering these multiple PXS Conditions and the very small likelihood of a LOCA occurring at the same time.

D.1

Excessive amounts of noncondensible gases in a CMT inlet line may interfere with the natural circulation flow (hot water from the RCS through the balance line into the CMT and cold water from the CMT through the direct vessel injection line into the vessel) assumed in the safety analyses for some transients. For CMT injection following a LOCA (steam will enter the CMT through the balance line, displacing the CMT water), gases in the CMT inlet line are not detrimental to the CMT function. The presence of some noncondensible gases does not mean that the CMT natural circulation capability is immediately inoperable, but that gases are collecting and should be vented.

BASES

The level sensor location has been selected to permit additional gas accumulation prior to significantly affecting the natural circulation flow so that adequate time may be provided to permit containment entry for

ACTIONS (continued)

venting the gas. Anticipated noncondensible gas accumulation in this piping segment is expected to be relatively slow.

The venting of these gases requires containment entry to manually operate the vent valves. A Completion Time of 24 hours is permitted for venting noncondensible gases and is acceptable, since, for the transients, the natural circulation capability of one CMT is adequate to ensure mitigation assuming less conservative analysis assumptions regarding stuck rods and core characteristics.

E.1

With one CMT inoperable for reasons other than Condition A, B, C, D, operation of the CMT may not be available. Action must be taken to restore the inoperable CMT to OPERABLE status within 8 hours. The remaining CMT is sufficient for DBAs except for LOCA in the OPERABLE CMTs DVI line. The 8 hour Completion Time is based on the required availability of injection from the accumulators (provided that entry into Condition B of LCO 3.5.1 has not occurred) to provide SI injection. The effectiveness of accumulator injection is demonstrated in analysis performed to justify PRA success criteria (Ref. 3). The analysis contained in this reference shows that for a small LOCA, the injection from one accumulator without any CMT supports adequate core cooling. This analysis provides a high confidence that with the unavailability of one CMT, the core can be cooled following design bases accidents.

The 1 hour Completion Time, in the case with simultaneous entry into Condition B of LCO 3.5.1, requires very prompt actions to restore either the CMT or the accumulator to OPERABLE status. This Completion Time is considered reasonable because of the low probability of simultaneously entering these multiple PXS Conditions and the very small likelihood of a LOCA occurring at the same time.

F.1 and F.2

If the Required Action or associated Completion Time of Condition A, B, C, D, or E are not met or the LCO is not met for reasons other than Conditions A through E, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power

BASES

conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.5.2.1 and SR 3.5.2.2

Verification every 24 hours and 7 days that the temperature and the volume, respectively, of the borated water in each CMT is within limits ensures that when a CMT is needed to inject water into the RCS, the injected water temperature and volume will be within the limits assumed

in the accident analysis. The 24 hour Frequency is adequate, based on the fact that no mechanism exists to rapidly change the temperature of a large tank of water such as a CMT. These parameters are normally monitored in the control room by indication and alarms. Also, there are provisions for monitoring the temperature of the inlet and outlet lines to detect in-leakage which may affect the CMT water temperature.

SR 3.5.2.3

Each CMT inlet isolation valve must be verified to be fully open each 12 hours. Frequent verification is considered to be important, since a CMT can not perform its safety function, if the valve is closed. Control room instrumentation is normally available for this verification.

SR 3.5.2.4

Verification that excessive amounts of noncondensible gases have not caused the water level to drop below the sensor in the inlet line is required every 24 hours. The inlet line of each CMT has a vertical section of pipe which serves as a high point collection point for noncondensible gases. Control room indication of the water level in the high point collection point is available to verify that noncondensible gases have collected to the extent that the water level is depressed below the allowable level. The thermal dispersion sensor locations on the vertical pipe sections have been selected to permit additional gas accumulation before injection flow is significantly affected so that adequate time may be provided to permit containment entry for venting the gas.

The 24 hour Frequency is based on the expected low rate of gas accumulation and the availability of control room indication.

SR 3.5.2.5

Verification every 7 days that the boron concentration in each CMT is within the required limits ensures that the reactivity control from each CMT, assumed in the safety analysis, will be available as required. The 7 day Frequency is adequate to promptly identify changes which could occur from mechanisms such as in-leakage.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.6

Verification that the redundant outlet isolation valves are OPERABLE by stroking the valves open ensures that each CMT will function as designed when these valves are actuated. Prior to opening the outlet isolation valves, the inlet isolation valve should be closed temporarily. Closing the inlet isolation valve ensures that the CMT contents will not be diluted or heated by flow from the RCS. Upon completion of the test, the inlet isolation valves must be opened. The Surveillance Frequency references the inservice testing requirements.

SR 3.5.2.7

This SR requires performance of a system performance test of each CMT to verify flow capabilities. The system performance test demonstrates that the CMT injection line resistance assumed in DBA analyses is maintained. Although the likelihood that system performance would degrade with time is low, it is considered prudent to periodically verify system performance. The System Level Operability Testing Program provides specific test requirements and acceptance criteria.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.3 Core Makeup Tanks (CMTs) – Shutdown, RCS Intact

BASES

BACKGROUND

A description of the CMTs is provided in the Bases for LCO 3.5.2, “Core Makeup Tanks – Operating.”

APPLICABLE SAFETY ANALYSES

When the plant is shutdown with the Reactor Coolant System (RCS) pressure boundary intact, the CMT and Passive Residual Heat Removal (PRHR) are the preferred methods for mitigation of postulated events such as loss of normal decay heat removal capability (either loss of Startup Feedwater or loss of normal residual heat removal system). The CMT and PRHR are preferred because the RCS pressure boundary can remain intact, thus preserving one of the barriers to fission product release. For these events, the PRHR provides the safety related heat removal path. And the CMT maintains RCS inventory control. These events can also be mitigated by In-containment Refueling Water Storage Tank (IRWST) injection; however, the RCS must be depressurized (vented) in order to facilitate IRWST injection.

Since no loss of coolant accidents (LOCAs) are postulated during MODES 5 and 6, the possibility of a break in the direct vessel injection line is not considered. As a result, only one CMT is required to be available to provide core cooling in response to postulated events. The two parallel CMT outlet isolation valves ensure that injection from one CMT occurs in the event of a single active failure.

CMTs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO establishes the minimum conditions necessary to ensure that one CMT will be available for RCS inventory control in the event of the loss of normal decay heat removal capability. The two CMT outlet isolation valves must be OPERABLE to ensure that at least one valve will operate, assuming that the other valve is disabled by a single active failure.

APPLICABILITY

In MODE 4 without steam generator heat removal and in MODE 5 with the RCS pressure boundary intact, one CMT is required to provide borated water to the RCS in the event the nonsafety related chemical and volume control system makeup pumps are not available to provide RCS inventory control.

BASES

APPLICABILITY (continued)

The CMT requirements in MODES 1, 2, 3, and 4 are specified in LCO 3.5.2, “Core Makeup Tanks (CMTs) – Operating.”

The CMTs are not required to be OPERABLE while in MODE 5 with the RCS open or in MODE 6 because the RCS is depressurized and borated water can be supplied from the IRWST, if needed.

ACTIONS

A.1

With one outlet isolation valve inoperable action must be taken to restore the valve. In this Condition the CMT is capable of performing its safety function, provided a single failure of the remaining parallel isolation valve does not occur. A Completion Time of 72 hours is consistent with times normally applied to an ECCS system which is capable of performing its safety function without a single failure.

B.1

If the water temperature or boron concentration in the CMT is not within limits, it must be returned to within limits within 72 hours. With the temperature above the limit the makeup capability assumed in the safety analysis may not be available. With the boron concentration not within limits, the ability to maintain subcriticality may be degraded.

Because the mechanisms for significantly altering these parameters in the CMT are limited, it is probable that more than the required amount of boron and cooling capacity will be available to meet the conditions assumed in the safety analysis. Therefore, the 72 hour Completion Time is acceptable.

C.1

With the required CMT inoperable for reasons other than Condition A or B operation of the CMT may not be available. Action must be taken to restore the inoperable CMT to OPERABLE status within 8 hours. LOCAs are not postulated during the MODEs when this LCO is applicable. The only safety function is to provide LEAKAGE makeup in case normal RCS makeup is unavailable. The 8 hour Completion Time is based on the availability of injection from the IRWST to provide RCS makeup. The ability of the IRWST to provide RCS injection is demonstrated by analysis performed to show that IRWST injection together with ADS venting provides adequate core cooling. Such analysis was performed for the loss of RNS cooling during midloop operations. The analysis was performed in support of the AP1000 PRA (Ref. 2).

BASES

ACTIONS (continued)

D.1

If the Required Action or associated Completion Time of Conditions A, B, or C are not met or the LCO is not met for reasons other than Conditions A through C, action must be initiated, immediately, to place the plant in a MODE where this LCO does not apply. Action must be initiated, immediately, to place the plant in MODE 5 with RCS pressure boundary open and ≥ 20% pressurizer level. In this condition, core cooling and RCS makeup are provided by IRWST injection and sump recirculation. Opening of the ADS valves ensures that IRWST injection can occur.

SURVEILLANCE REQUIREMENTS

SR 3.5.3.1

The LCO 3.5.2 Surveillance Requirements (SR 3.5.2.1 through 3.5.2.7) are applicable to the CMT required to be OPERABLE. The Frequencies associated with each specified SR are applicable. Refer to the corresponding Bases for LCO 3.5.2 for a discussion of each SR.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.4 Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Operating

BASES

BACKGROUND

The normal heat removal mechanism is the steam generators, which are supplied by the startup feedwater system. However, this path utilizes non-safety related components and systems, so its failure must be considered. In the event the steam generators are not available to remove decay heat for any reason, including loss of startup feedwater, the heat removal path is the PRHR HX (Ref. 1).

The principle component of the PRHR HX is a 100% capacity heat exchanger mounted in the In-containment Refueling Water Storage Tank (IRWST). The heat exchanger is connected to the Reactor Coolant System (RCS) by a inlet line from one RCS hot leg, and an outlet line to the associated steam generator cold leg channel head. The inlet line to the passive heat exchanger contains a normally open, motor operated isolation valve. The outlet line is isolated by two parallel, normally closed air operated valves, which fail open on loss of air pressure or control signal. There is a vertical collection point at the top of the common inlet piping high point which serves as a gas collector. It is provided with level detectors that indicate when noncondensible gases have collected in this area. There are provisions to manually vent these gases to the IRWST.

In order to preserve the IRWST water for long term PRHR HX operation, a gutter is provided to collect and return water to the IRWST that has condensed on the inside surface of the containment shell. During normal plant operation any water collected by the gutter is directed to the normal containment sump. During PRHR HX operation, redundant series air operated valves are actuated to block the draining of condensate to the normal sump and to force the condensate into the IRWST. These valves fail closed on loss of air pressure or control signal.

The PRHR HX size and heat removal capability is selected to provide adequate core cooling for the limiting non-LOCA heatup Design Basis Accidents (DBAs) (Ref. 2). The Probability Risk Assessment (PRA) (Ref. 3) shows that PRHR HX is not required assuming that passive feed and bleed is available. Passive feed and bleed uses the Automatic Depressurization System (ADS) for bleed and the CMTs/accumulators/ IRWST for feed.

BASES

APPLICABLE SAFETY ANALYSES

In the event of a non-LOCA DBA during normal operation, the PRHR HX is automatically actuated to provide decay heat removal path in the event the normal path through the steam generators is not available (Ref. 2).

The non-LOCA events which establish the PRHR HX parameters are those involving a decrease in heat removal by the secondary system, such as loss of main feedwater or other failure in the feedwater system. Since the PRHR HX is passive, it will mitigate the consequences of these events with a complete loss of all AC power sources. The PRHR HX actuates when the CMTs are actuated during LOCA events.

The PRHR HX satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that the PRHR HX be OPERABLE so that it can respond appropriately to the DBAs which may require its operation. Since this is a passive component, it does not require the actuation of active components such as pumps for its OPERABILITY and will be OPERABLE if the inlet valves are in their normally open position, and the normally closed, fail open outlet valves open on receipt of an actuation signal.

In addition to the appropriate valve configuration, OPERABILITY may be impaired by noncondensible gases collecting in the system. OPERABILITY is not expected to be challenged due to small gas accumulations in the high point, and rapid gas accumulations are not expected during plant operation. However, a relatively small gas volume was incorporated into the design for alerting operators to provide sufficient time to initiate venting operations before the gas volume would be expected to increase to a sufficient volume that might potentially challenge the OPERABILITY of natural circulation flow. Therefore, noncondensible gas accumulation in the inlet line high point that causes the water level to drop below the sensor will require operator action to investigate the cause of the gas accumulation and to vent the associated high point(s).

The note requires a reactor coolant pump (RCP) to be operating in the loop with the PRHR HX, Loop 1, if any RCPs are operating. If RCPs are only operating in Loop 2 and no RCPs are operating in Loop 1, there is a possibility there may be reverse flow in the PRHR HX.

APPLICABILITY

The PRHR HX must be OPERABLE in MODES 1, 2, 3, and 4 with the RCS not cooled by the Normal Residual Heat Removal System (RNS) if a plant cooldown is required and the normal cooldown path is not available. Under these conditions, the PRHR HX may be actuated to provide core cooling and to mitigate the consequences of a DBA.

BASES

APPLICABILITY (continued)

The PRHR HX requirements in MODE 4 with RCS cooling provided by the RNS and in MODE 5 with the RCS pressure boundary intact are specified in LCO 3.5.5, “Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Shutdown, RCS Intact.”

The PRHR HX is not capable of natural circulation cooling of the RCS in MODE 5 with the RCS pressure boundary open or in MODE 6.

ACTIONS

A.1

The outlet line from the PRHR HX is controlled by a pair of normally closed, fail open, air operated valves, arranged in parallel. Thus they are redundant and, if either valve is OPERABLE, the system can function at 100% capacity, assuming other OPERABILITY conditions are met.

If one valve is inoperable, a Completion Time of 72 hours has been allowed to restore the inoperable valve(s) to OPERABLE status. This Completion Time is consistent with the Completion Times specified for other parallel redundant safety related systems.

B.1

With one air operated IRWST gutter isolation valve inoperable, the remaining isolation valve can function to drain the gutter to the IRWST. Action must be taken to restore the inoperable gutter isolation valve to OPERABLE status within 72 hours. The 72 hour Completion Time is acceptable based on the capability of the remaining valve to perform 100% of the required safety function assumed in the safety analyses.

C.1

Excessive amounts of noncondensible gases in the PRHR HX inlet line may interfere with the natural circulation flow of reactor coolant through the PRHR HX. The presence of some noncondensible gases does not mean that the PRHR HX is immediately inoperable, but that gases are collecting and should be vented.

The level sensor location has been selected to permit additional gas accumulation before natural circulation flow is significantly affected so that sufficient time may be provided to permit containment entry for venting the gas. Anticipated noncondensible gas accumulation in this piping segment is expected to be relatively slow.

BASES

ACTIONS (continued)

The venting of these gases requires containment entry to manually operate the appropriate vent valves. A Completion Time of 24 hours is acceptable considering that passive feed and bleed cooling is available to remove heat from the RCS.

D.1 and D.2

If any of the above Required Actions have not been accomplished in the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4, with the RCS cooled by the RNS, within 24 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

E.1

With the LCO not met for reasons other than Condition A, B, or C, the PRHR HX must be restored within 8 hours. The 8 hour Completion Time is based on the availability of passive feed and bleed cooling to provide RCS heat removal. The effectiveness of feed and bleed cooling has been demonstrated in analysis and evaluations performed to justify PRA success criteria (Ref. 3). The analysis contained in this reference shows that for a range of events including loss of main feedwater, SGTR, and small LOCA (as small as 1/2") that feed and bleed cooling provides adequate core cooling.

These analyses and evaluations provide a high confidence that with the unavailability of the PRHR HX the core can be cooled following design bases accidents.

F.1 and F.2

If the PRHR HX is not restored in accordance with Action E.1 within 8 hours, the plant must be placed in a MODE in which the LCO does not apply. This is accomplished by placing the plant in MODE 3 within 6 hours and in MODE 5 within 36 hours.

Action F.1 is modified by a Note which requires that prior to initiating cooldown of the plant to MODE 3, redundant means of providing SG feedwater be verified as OPERABLE. Possible means include main feedwater and startup feedwater pumps. With the PRHR HX and redundant means of feeding the SGs INOPERABLE, the unit is in a seriously degraded condition with no means for conducting a controlled cooldown. In such a condition, the unit should not be perturbed by any

BASES

ACTIONS (continued)

action, including a power change, that might result in a trip. If redundant means of feeding the SGs are not available, the plant should be maintained in the current MODE until redundant means are restored. LCO 3.0.3 and all other Required Actions shall be suspended until the redundant means are restored, because they could force the unit into a less safe condition.

Action F.2 is modified by a Note which requires that prior to stopping SG feedwater, redundant means of cooling the RCS to cold shutdown conditions must be verified as OPERABLE. One redundant means of cooling the RCS to cold shutdown includes the normal residual heat removal system (RNS) and its necessary support system (both component cooling system pumps and heat exchangers, and both service water system pumps and fans). Without availability of these redundant cooling means, the unit is in a seriously degraded condition with no means for continuing the controlled cooldown. Until the redundant cooling means are restored, heat removal using SG feedwater should be maintained. LCO 3.0.3 and all other Required Actions shall be suspended until the systems and equipment required for further cooldown are restored, because they could force the unit into a less safe condition.

SURVEILLANCE REQUIREMENTS

SR 3.5.4.1

Verification, using remote indication, that the common outlet manual isolation valve is fully open ensures that the flow path from the heat exchangers to the RCS is available. Misalignment of this valve could render the heat exchanger inoperable. A 12 hour Frequency is reasonable considering that the valve is manually positioned and has control room position indication and alarm.

SR 3.5.4.2

Verification that the motor operated inlet valve is fully open, as indicated in the main control room, ensures timely discovery if the valve is not fully open. The 12 hour Frequency is consistent with the ease of verification, confirmatory open signals, and redundant series valve controls that prevent spurious closure.

SR 3.5.4.3

Verification that excessive amounts of noncondensible gases have not caused the water level to drop below the sensor in the inlet line is required every 24 hours. The inlet line of the PRHR HX has a vertical section of pipe which serves as a high point collection point for noncondensible gases. The thermal dispersion sensor location on the

SURVEILLANCE REQUIREMENTS (continued)

vertical pipe section has have been selected to permit additional gas accumulation before natural circulation flow is significantly affected so that sufficient time may be provided to permit containment entry for venting the gas.

Control room indication of the water level in this high point collection point is available to verify that noncondensible gases have not collected to the extent that the water level is depressed below the allowable level. The 24 hour Frequency is based on the expected low rate of gas accumulation and the availability of control room indication.

SR 3.5.4.4

Verification is required to confirm that power is removed from the motor operated inlet isolation valve every 31 days. Removal of power from this valve reduces the likelihood that the valve will be inadvertently closed as a result of a fire. The 31 day Frequency is acceptable considering the frequent surveillance of valve position and that the valve has a confirmatory open signal.

SR 3.5.4.5

Verification that both air operated outlet valves and both IRWST gutter isolation valves are OPERABLE ensures that the PRHR HX will actuate on command, with return flow from the gutter to the IRWST, since all other components of the system are normally in the OPERABLE configuration. Since these valves are redundant, if one valve is inoperable, the system can function at 100% capacity. Verification requires the actual operation of each valve through a full cycle to demonstrate OPERABILITY. The Surveillance Frequency is provided in the Inservice Testing Program.

SR 3.5.4.6

This SR requires performance of a system performance test of the PRHR HX to verify system heat transfer capabilities. The system performance test demonstrates that the PRHR HX heat transfer assumed in accident analyses is maintained. Although the likelihood that system performance would degrade with time is low, it is considered prudent to periodically verify system performance. The System Level Operability Testing Program provides specific test requirements and acceptance criteria.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.4.7

This surveillance requires visual inspection of the IRWST gutters to verify that the return flow to the IRWST will not be restricted by debris. A Frequency of 24 months is adequate, since there are no known sources of debris with which the gutters could become restricted.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.5 Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Shutdown, RCS Intact

BASES

BACKGROUND	A description of the PRHR HX is provided in the Bases for LCO 3.5.4, "Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Operating."
APPLICABLE SAFETY ANALYSES	In the event of a loss of normal decay heat removal capability during shutdown with the Reactor Coolant System (RCS) pressure boundary intact, the PRHR HX provides the preferred safety related heat removal path. When required, the PRHR HX is manually actuated and can maintain the RCS < 420°F. Alternatively, the heat removal function can be provided by depressurizing the RCS with the Automatic Depressurization System (ADS) and injection of the In-containment Refueling Water Storage Tank (IRWST) with containment closure capability provided. The PRHR HX is preferred because the RCS pressure boundary remains intact, thus preserving a barrier to fission product release. The PRHR HX satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).
LCO	This LCO requires the PRHR HX to be OPERABLE so that it can be placed in service in the event normal decay heat removal capability is lost. Since this a passive component, it does not require the actuation of active components such as pumps for its OPERABILITY and will be OPERABLE if the inlet valves are in their normally open position, and the normally closed, fail open outlet valves open on receipt of an actuation signal. In addition to the appropriate valve configuration, OPERABILITY may be impaired by flow blockage caused by noncondensible gases collecting in the system. Thus the absence of non-condensible gases in the high point is necessary for system OPERABILITY. The note requires a reactor coolant pump (RCP) to be operating in the loop with the PRHR HX, Loop 1, if any RCPs are operating. If RCPs are only operating in loop 2 and no RCPs are operating in loop 1, there is a possibility there may be reverse flow in the PRHR HX.

BASES

APPLICABILITY

The PRHR HX must be OPERABLE in MODE 4 with RCS cooling provided by the Normal Residual Heat Removal System (RNS) and in MODE 5 with the RCS pressure boundary intact and pressurizer level ≥ 20% to provide decay heat removal in the event the normal residual heat removal system is not available.

The PRHR HX requirements in MODES 1, 2, 3, and 4 with RCS cooling not provided by the RNS are specified in LCO 3.5.4, “Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Operating.”

The PRHR HX is not capable of natural circulation cooling of the RCS in MODE 5 with either the RCS pressure boundary open or with the RCS intact when pressurizer level ≤ 20%, or in MODE 6.

ACTIONS

A.1

The outlet line from the PRHR HX is isolated by a pair of normally closed, fail open, air operated valves, arranged in parallel. They are redundant, and if either valve is OPERABLE the system can function at 100% capacity, assuming other OPERABILITY conditions are met.

Since these valves are redundant, if one valve is inoperable, a Completion Time of 72 hours has been allowed to restore the inoperable valve to OPERABLE status. This Completion Time is consistent with the Completion Times specified for other parallel redundant safety related systems.

B.1

With one air operated IRWST gutter isolation valve inoperable, the remaining isolation valve can function to drain the gutter to the IRWST. Action must be taken to restore the inoperable gutter isolation valve to OPERABLE status within 72 hours. The 72 hour Completion Time is acceptable based on the capability of the remaining valve to perform 100% of the required safety function assumed in the safety analyses.

C.1

At the inlet piping high point there is a vertical chamber which serves as a collection point for noncondensible gases. This collection point is provided with detectors which alarm to indicate when gases have collected in this area. The presence of an alarm does not mean that PRHR HX is immediately inoperable, but that gases are collecting and should be vented. A Completion Time of 24 hours is acceptable, considering that passive feed and bleed cooling is available to revise heat from the RCS.

BASES

ACTIONS (continued)

D.1

With the LCO not met for reasons other than Condition A, B, or C, the PRHR HX must be restored within 8 hours. The 8 hour Completion Time is acceptable based on the availability of passive feed and bleed cooling to provide RCS heat removal. The effectiveness of feed and bleed cooling is discussed in the bases for LCO 3.5.4, Action E.1.

E.1

If any of the above Required Actions have not been accomplished in the required Completion Time, or the LCO is not met for reasons other than Conditions A, B, C, or D, action must be initiated, immediately, to be in MODE 5 with the RCS pressure boundary open and pressurizer level ≥ 20%. The time to RCS boiling is maximized in the event of loss of normal decay heat removal capability, by maintaining a visible level in the pressurizer. Additionally, in this MODE the RCS must be opened, such that safety related decay heat removal can be immediately initiated by actuation of the IRWST injection valve(s).

SURVEILLANCE REQUIREMENTS

SR 3.5.5.1

The LCO 3.5.4 Surveillance Requirements are applicable to the PRHR HX required to be OPERABLE. The Frequencies associated with each specified SR are applicable. Refer to the corresponding Bases for LCO 3.5.4 for a discussion of each SR.

REFERENCES None.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.6 In-containment Refueling Water Storage Tank (IRWST) – Operating

BASES

BACKGROUND

The IRWST is a large stainless steel lined tank filled with borated water (Ref. 1). It is located below the operating deck in containment. The tank is designed to meet seismic Category 1 requirements. The floor of the IRWST is elevated above the reactor coolant loop so that borated water can drain by gravity into the Reactor Coolant System (RCS). The IRWST is maintained at ambient containment pressure.

The IRWST has two injection flow paths. The injection paths are connected to the reactor vessel through two direct vessel injection lines which are also used by the accumulators and the core makeup tanks. Each path includes an injection flow path and a containment recirculation flow path. Each injection path includes a normally open motor operated isolation valve and two parallel actuation lines each isolated by one check valve and one squib valve in series.

The IRWST has two containment recirculation flow paths. Each containment recirculation path contains two parallel actuation flow paths, one path is isolated by a normally open motor operated valve in series with a squib valve and one path is isolated by a check valve in series with a squib valve.

During refueling operations, the IRWST is used to flood the refueling cavity. During abnormal events, the IRWST serves as a heat sink for the passive residual heat removal heat exchangers, as a heat sink for the depressurization spargers, and as a source of low head (ambient containment pressure) safety injection during loss of coolant accidents (LOCAs) and loss of decay heat removal in MODE 5 (loops not filled). The IRWST can be cooled by the Normal Residual Heat Removal System (RNS) system.

The IRWST size and injection capability is selected to provide adequate core cooling for the limiting Design Basis Accidents (DBAs) (Ref. 2).

APPLICABLE SAFETY ANALYSES

During non-LOCA events, the IRWST serves as the initial heat sink for the PRHR Heat Exchanger (PRHR HX) if used during reactor cooldown to MODE 4. If RNS is available, it will be actuated in MODE 4 and used to continue the plant cooldown to MODE 5. If RNS is not available, cooldown can continue on PRHR. Continued PRHR HX operation will result in the water in the IRWST heating up to saturation conditions and boiling. The steam generated in the IRWST enters the containment

BASES

APPLICABLE SAFETY ANALYSES (continued)

through the IRWST vents. Most of the steam generated in the IRWST condenses on the inside of the containment vessel and drains back to the IRWST.

For events which involve a loss of primary coolant inventory, such as a large break LOCA, or other events involving automatic depressurization, the IRWST provides low pressure safety injection (Ref. 2). The IRWST drain down time is dependent on several factors, including break size, location, and the return of steam condensate from the passive containment cooling system. During drain down, when the water in the IRWST reaches the Low 5 level, the containment sump will be sufficiently flooded, to initiate containment sump recirculation. This permits continued cooling of the core by recirculation of the spilled water in the containment sumps via the sump recirculation flow paths. In this situation, core cooling can continue indefinitely.

When the plant is in midloop operation, the pressurizer Automatic Depressurization System (ADS) valves are open, and the RNS is used to cool the RCS. The RNS is not a safety related system, so its failure must be considered. In this situation, with the RCS drained and the pressure boundary open, the PRHR HX cannot be used. In such a case, core cooling is provided by gravity injection from the IRWST, venting the RCS through the ADS. Injection from the IRWST provides core cooling until the tank empties and gravity recirculation from the containment starts. With the containment closed, the recirculation can continue indefinitely, with the decay heat generated steam condensing on the containment vessel and draining back into the IRWST.

The IRWST satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The IRWST requirements ensure that an adequate supply of borated water is available to act as a heat sink for PRHR and to supply the required volume of borated water as safety injection for core cooling and reactivity control.

To be considered OPERABLE, the IRWST must meet the water volume, boron concentration, and temperature limits defined in the surveillance requirements. The motor operated injection isolation valves must be open with power removed, and the motor operated sump recirculation isolation valves must be open. OPERABILITY is not expected to be challenged due to small gas accumulations in the high point, and rapid gas accumulations are not expected during plant operation. However, a relatively small gas volume was incorporated into the design for alerting operators to provide sufficient time to initiate venting operations before the gas volume would be expected to increase to a sufficient volume that

BASES

LCO (continued) might potentially challenge the OPERABILITY of passive safety injection flow. Therefore, noncondensible gas accumulation in the injection line high point that causes the water level to drop below the sensor will require operator action to investigate the cause of the gas accumulation and to vent the associated high point(s).

APPLICABILITY In MODES 1, 2, 3, and 4, a safety related function of the IRWST is to provide a heat sink for PRHR. In MODES 1, 2, 3, and 4, a second safety related function is the low head safety injection of borated water following a LOCA for core cooling and reactivity control. Both of these functions must be available to meet the initial assumptions of the safety analyses. These assumptions require the specified boron concentration, the minimum water volume, and the maximum water temperature.

The requirements for the IRWST in MODES 5 and 6 are specified in LCO 3.5.7, In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 5 and LCO 3.5.8, In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 6.

ACTIONS A.1

If an IRWST injection line actuation valve flow path or a containment recirculation line actuation valve flow path is inoperable, then the valve actuation flow path must be restored to OPERABLE status within 72 hours. In this condition, three other IRWST injection or containment sump recirculation flow paths are available and can provide 100% of the required flow assuming a break in the direct vessel injection line associated with the other injection train, but with no single failure of the actuation valve flow path in the same injection or sump recirculation flow path. The 72 hour Completion Time is consistent with times normally applied to degraded two train ECCS systems which can provide 100% of the required flow without a single failure.

B.1

Excessive amounts of noncondensible gases in one of the high point vents in one IRWST injection line may interfere with the passive injection of IRWST water into the reactor vessel from the associated parallel flow path in the affected injection line. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection through the affected flow path could be delayed. However, the presence of some noncondensible gases does not mean that the IRWST injection capability is immediately inoperable, but that gases are collecting and should be vented. The venting of these gases requires containment entry to

ACTIONS (continued)

manually operate the vent valves. In this Condition, the parallel flow path in the affected injection line is capable of providing 100% of the required injection flow and the other IRWST injection line remains fully OPERABLE. These IRWST flow paths can provide the credited flow in the event of a direct vessel injection (DVI) line break downstream of the fully OPERABLE injection line, provided a single failure of the remaining parallel isolation valve does not occur. A Completion Time of 72 hours is acceptable for two train ECCS systems, which are capable of performing their safety function without a single failure.

C.1

Excessive amounts of noncondensible gases in both of the high point vents in one IRWST injection line may affect the passive injection of IRWST water into the reactor vessel from the affected injection line. Sufficient gas accumulation could potentially challenge IRWST injection capability. However, the presence of some noncondensible gases does not immediately render the IRWST injection capability inoperable, but that gases are collecting and should be vented.

The level sensor location has been selected to permit additional gas accumulation before injection flow is significantly affected so that adequate time may be provided to permit containment entry for venting the gas. Anticipated noncondensible gas accumulation in this piping segment is expected to be relatively slow.

In this Condition, the remaining OPERABLE IRWST injection line is capable of performing the safety function for all plant events except for one, DVI line break. For this one event, the line with gas accumulation in both high point vents will be capable of performing the safety function with a small amount of voiding that is not expected to significantly challenge the required injection flow.

The venting of these gases requires containment entry to manually operate the vent valves. Considering the relatively slow rate of gas accumulation, venting within 8 hours should normally prevent accumulation of amounts of noncondensible gases that could significantly challenge IRWST injection capability. A Completion Time of 8 hours is permitted for venting noncondensible gases and is acceptable since the injection capability of the other IRWST injection line is sufficient to ensure event mitigation, or in the event of a break in the DVI line connected to the OPERABLE injection line, the injection line with gas accumulation will be capable of providing the required injection flow with some voiding. If only one of the affected high point vents is vented, then Condition B will apply to the remaining high point vent with noncondensible gas accumulation.

BASES

ACTIONS (continued)

D.1

If the IRWST water volume, boron concentration, or temperature are not within limits, the core cooling capability from injection or PRHR HX heat transfer and the reactivity benefit of injection assumed in safety analyses may not be available. Due to the large volume of the IRWST, online monitoring of volume and temperature, and frequent surveillances, the deviation of these parameters is expected to be minor. The allowable deviation of the water volume is limited to 3%. This limit prevents a significant change in boron concentration and is consistent with the long-term cooling analysis performed to justify PRA success criteria (Ref. 3), which assumed multiple failures with as many as 3 CMTs/Accum not injecting. This analysis shows that there is significant margin with respect to the water supplies that support containment recirculation operation. The 8-hour Completion Time is acceptable, considering that the IRWST will be fully capable of performing its assumed safety function in response to DBAs with slight deviations in these parameters.

E.1

If the motor operated IRWST isolation valves are not fully open or valve power is not removed, injection flow from the IRWST may be less than assumed in the safety analysis. In this situation, the valves must be restored to fully open with valve power removed in 1 hour. This Completion Time is acceptable based on risk considerations.

F.1 and F.2

If the IRWST cannot be returned to OPERABLE status within the associated Completion Times or the LCO is not met for reasons other than Conditions A, B, C, D, or E, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.5.6.1

The IRWST borated water temperature must be verified every 24 hours to ensure that the temperature is within the limit assumed in the accident analysis. This Frequency is sufficient to identify a temperature change that would approach the limit and has been shown to be acceptable through operating experience.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.6.2

Verification every 24 hours that the IRWST borated water volume is above the required minimum level will ensure that a sufficient initial supply is available for safety injection and floodup volume for recirculation and as the heat sink for PRHR. During shutdown with the refueling cavity flooded with water from the IRWST, this Surveillance requires that the combined volume of borated water in the IRWST and refueling cavity meet the specified limit. Since the IRWST volume is normally stable, and is monitored by redundant main control indication and alarm, a 24 hour Frequency is appropriate.

SR 3.5.6.3

Verification that excessive amounts of noncondensible gases have not caused the water level to drop below the sensor in the four IRWST injection line squib valve lines is required every 24 hours. The 8x8x8 inch tee after the outlet of the IRWST injection line squib valve lines has a vertical section of pipe which serves as a high point collection point for noncondensible gases. The thermal dispersion sensor locations on the vertical pipe sections have been selected to permit additional gas accumulation prior to significantly affecting the injection flow so that adequate time may be provided to permit containment entry for venting the gas.

Control room indication of the water level in this high point collection point is available to verify that noncondensible gases have not collected to the extent that the water level is depressed below the allowable level. The 24 hour Frequency is based on the expected low rate of gas accumulation and the availability of control room indication.

SR 3.5.6.4

Verification every 31 days that the boron concentration of the IRWST is greater than the required limit, ensures that the reactor will remain subcritical following a LOCA. Since the IRWST volume is large and normally stable, the 31 day Frequency is acceptable, considering additional verifications are required within 6 hours after each solution volume increase of 15,000 gal. In addition, the relatively frequent surveillance of the IRWST water volume provides assurance that the IRWST boron concentration is not changed.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.6.5

This surveillance requires verification that each motor operated isolation valve is fully open. This surveillance may be performed with available remote position indication instrumentation. The 12 hour Frequency is acceptable, considering the redundant remote indication and alarms and that power is removed from the valve operator.

SR 3.5.6.6

Verification is required to confirm that power is removed from each motor operated IRWST isolation valve each 31 days. Removal of power from these valves reduces the likelihood that the valves will be inadvertently closed. The 31 day Frequency is acceptable considering frequent surveillance of valve position and that the valve has a confirmatory open signal.

SR 3.5.6.7

Each motor operated containment recirculation isolation valve must be verified to be fully open. This valve is required to be open to improve containment recirculation reliability. The 31 day Frequency is acceptable considering the valve has a confirmatory open signal. This surveillance may be performed with available remote position indication instrumentation.

SR 3.5.6.8

This Surveillance requires verification that each IRWST injection and each containment recirculation squib valve is OPERABLE in accordance with the Inservice Testing Program. The Surveillance Frequency for verifying valve OPERABILITY references the Inservice Testing Program.

The squib valves will be tested in accordance with the ASME OM Code. The applicable ASME OM Code squib valve requirements are specified in paragraph 4.6, Inservice Tests for Category D Explosively Actuated Valves. The requirements include actuation of a sample of the installed valves each 2 years and periodic replacement of charges.

SR 3.5.6.9

Visual inspection is required each 24 months to verify that the IRWST screens and the containment recirculation screens are not restricted by debris. A Frequency of 24 months is adequate, since there are no known sources of debris with which the gutters could become restricted.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.6.10

This SR requires performance of a system inspection and performance test of the IRWST injection and recirculation flow paths to verify system flow capabilities. The system inspection and performance test demonstrates that the IRWST injection and recirculation capabilities assumed in accident analyses is maintained. Although the likelihood that system performance would degrade with time is low, it is considered prudent to periodically verify system performance. The System Level Operability Testing Program provides specific test requirements and acceptance criteria.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.7 In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 5

BASES

BACKGROUND	A description of the IRWST is provided in LCO 3.5.6, “In-containment Refueling Water Storage Tank – Operating.”
APPLICABLE SAFETY ANALYSES	For postulated shutdown events in MODE 5 with the Reactor Coolant System (RCS) pressure boundary intact, the primary protection is Passive Residual Heat Removal (PRHR), where the IRWST serves as the initial heat sink for the PRHR heat exchanger (PRHR HX). For events in MODE 5 with the RCS pressure boundary open, PRHR is not available and RCS heat removal is provided by IRWST injection and containment sump recirculation. IRWST injection could be required to mitigate some events by providing RCS inventory makeup. No loss of coolant accidents (LOCAs) are postulated during plant operation in MODE 5; therefore, the rupture of the direct vessel injection line (DVI) is not assumed. Since the DVI rupture is not assumed, only one train of IRWST injection and recirculation flow paths is required to mitigation postulated events, assuming a single failure. The IRWST satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).
LCO	The IRWST requirements ensure that an adequate supply of borated water is available to act as a heat sink for PRHR and to supply the required volume of borated water as safety injection for core cooling and reactivity control. To be considered OPERABLE, the IRWST must meet the water volume, boron concentration, and temperature limits defined in the Surveillance Requirements, and one path of injection and recirculation must be OPERABLE (the motor operated injection isolation valve must be open with power removed, and the motor operated sump recirculation isolation valves must be open). The absence of noncondensible gases in the high point vents is necessary for system OPERABILITY.
APPLICABILITY	In MODE 5 with the RCS pressure boundary intact or with the RCS open with pressurizer level ≥ 20%, the IRWST is an RCS injection source of borated water for core cooling and reactivity control. Additionally, in MODE 5 with the RCS pressure boundary intact, the IRWST provides the heat sink for PRHR.

BASES

APPLICABILITY (continued)

The requirements for the IRWST in MODES 1, 2, 3, and 4 are specified in LCO 3.5.6, In-containment Refueling Water Storage Tank (IRWST) – Operating. The requirements for the IRWST in MODE 6 are specified in LCO 3.5.8, In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 6.

ACTIONS

A.1

If a motor operated containment sump isolation valve in the required sump recirculation flow path is not fully open, the valve must be fully opened within 72 hours. The 72 hour Completion Time is consistent with times normally applied to degraded two train ECCS systems which can provide 100% of the required flow without a single failure.

B.1

Excessive amounts of noncondensible gases in one of the high point vents in the required IRWST injection line may interfere with the passive injection of IRWST water into the reactor vessel from the associated parallel flow path in the affected injection line. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection through the affected flow path could be delayed. However, the presence of some noncondensible gases does not mean that the IRWST injection capability is immediately inoperable, but that gases are collecting and should be vented. Venting of these gases requires containment entry to manually operate the vent valves. In this Condition the parallel flow path in the affected injection line is capable of providing 100% of the required injection. A DVI line break is not postulated in MODE 5. A Completion Time of 72 hours is acceptable since the IRWST is capable of performing the safety function without a single failure of the remaining parallel isolation valve. In addition, the 72-hour Completion Time is consistent with the time normally applicable to one inoperable train in a two train ECCS system.

C.1

Excessive amounts of noncondensible gases in both of the high point vents in the required IRWST injection line may interfere with the passive injection of IRWST water into the reactor vessel from the affected injection line. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection could be delayed long enough to cause core uncover. However, the presence of some noncondensible gases does not mean that the IRWST injection capability is immediately inoperable, but that gases are collecting and should be vented. Venting of these gases requires containment entry to manually operate the vent valves. Considering the slow rate of gas accumulation, venting within

BASES

ACTIONS (continued)

8 hours should normally prevent accumulation of amounts of noncondensible gases that could interfere with IRWST injection. A Completion Time of 8 hours is permitted for venting noncondensible gases and is acceptable since the injection capability is not significantly affected. If only one of the affected high point vents is vented, then Condition B will apply to the remaining high point vent with noncondensible gas accumulation.

D.1

If the IRWST water volume, boron concentration, or temperature are not within limits, the core cooling capability from injection or PRHR heat transfer and the reactivity benefit of injection assumed in safety analyses may not be available. Due to the large volume of the IRWST, online monitoring of volume and temperature, and frequent surveillances, the deviation of these parameters is expected to be minor. The allowable deviation of the water volume is limited to 3%. This limit prevents a significant change in boron concentration and is consistent with the long-term cooling analysis performed to justify PRA success criteria (Ref. 3), which assumed multiple failures with as many as 3 CMTs/Accum not injecting. This analysis shows that there is significant margin with respect to the water supplies that support containment recirculation operation. The 8-hour Completion Time is acceptable, considering that the IRWST will be fully capable of performing its assumed safety function in response to DBAs with slight deviations in these parameters.

E.1

If the required motor operated IRWST isolation valve is not fully open or valve power is not removed, injection flow from the IRWST may be less than assumed in the safety analysis. In this situation, the valve must be restored to fully open with valve power removed in 1 hour. This Completion Time is acceptable based on risk considerations.

F.1 and F.2

If the IRWST cannot be returned to OPERABLE status within the associated Completion Times or the LCO is not met for reasons other than Conditions A, B, C, D, or E, the plant must be placed in a condition in which the probability and consequences of an event are minimized to the extent possible. This is done by immediately initiating action to place the plant in MODE 5 with the RCS intact with ≥ 20% pressurizer level. The time to RCS boiling is maximized by maintaining RCS inventory at ≥ 20% pressurizer level and maintaining RCS temperature as low as practical. With the RCS intact, the availability of the PRHR HX is maintained. Additionally, action to suspend positive reactivity additions is

BASES

ACTIONS (continued)

required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS.

SURVEILLANCE REQUIREMENTS

SR 3.5.7.1

The LCO 3.5.6 Surveillance Requirements and Frequencies (SR 3.5.6.1 through 3.5.6.10) are applicable to the IRWST and the flow paths required to be OPERABLE. Refer to the corresponding Bases for LCO 3.5.6 for a discussion of each SR.

B 3.5 PASSIVE CORE COOLING SYSTEM (PXS)

B 3.5.8 In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 6

BASES

BACKGROUND	A description of the IRWST is provided in LCO 3.5.6, “In-containment Refueling Water Storage Tank (IRWST) – Operating.”
APPLICABLE SAFETY ANALYSES	For MODE 6, heat removal is provided by IRWST injection and containment sump recirculation. IRWST injection could be required to mitigate some events by providing RCS inventory makeup. One line with redundant, parallel valves is required to accommodate a single failure (to open) of an isolation valve. The IRWST satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).
LCO	The IRWST requirements ensure that an adequate supply of borated water is available to supply the required volume of borated water as safety injection for core cooling and reactivity control. To be considered OPERABLE, the IRWST in combination with the refueling cavity must meet the water volume, boron concentration, and temperature limits defined in the Surveillance Requirements, and one path of injection and recirculation must be OPERABLE. The motor operated injection isolation valve must be open and power removed, and the motor operated sump recirculation isolation valves must be open and OPERABLE. Any cavity leakage should be estimated and made up with borated water such that the volume in the IRWST plus the refueling cavity will meet the IRWST volume requirement. The absence of noncondensible gases in the high point vents is necessary for system OPERABILITY.
APPLICABILITY	In MODE 6, the IRWST is an Reactor Coolant System (RCS) injection source of borated water for core cooling and reactivity control. The requirements for the IRWST in MODES 1, 2, 3, and 4 are specified in LCO 3.5.6, In-containment Refueling Water Storage Tank (IRWST) – Operating. The requirements for the IRWST in MODE 5 are specified in LCO 3.5.7, In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 5.

BASES

ACTIONS

A.1

With the required motor operated containment sump isolation valve not fully open, the valve must be fully opened within 72 hours. The 72 hour Completion Time is consistent with times normally applied to degraded two train ECCS systems which can provide 100% of the required flow without a single failure.

B.1

Excessive amounts of noncondensible gases in one of the high point vents in the required IRWST injection line may interfere with the passive injection of IRWST water into the reactor vessel from the associated parallel flow path in the affected injection line. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection through the affected flow path could be delayed. However, the presence of some noncondensible gases does not mean that the IRWST injection capability is immediately inoperable, but that gases are collecting and should be vented. Venting of these gases requires containment entry to manually operate the vent valves. In this Condition, the parallel flow path in the affected injection line is capable of providing 100% of the required injection. A DVI line break is not postulated in MODE 6. A Completion Time of 72 hours is acceptable since the IRWST is capable of performing the safety function without a single failure of the remaining parallel isolation valve. In addition, the 72-hour Completion Time is consistent with the time normally applicable to one inoperable train in a two train ECCS system.

C.1

Excessive amounts of noncondensible gases in both of the high point vents in the required IRWST injection line may interfere with the passive injection of IRWST water into the reactor vessel from the affected injection line. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection could be delayed long enough to cause core uncover. However, the presence of some noncondensible gases does not mean that the IRWST injection capability is immediately inoperable, but that gases are collecting and should be vented. Venting of these gases requires containment entry to manually operate the vent valves. Considering the slow rate of gas accumulation, venting within 8 hours should normally prevent accumulation of amounts of noncondensible gases that could interfere with IRWST injection. A Completion Time of 8 hours is permitted for venting noncondensible gases and is acceptable since the injection capability is not significantly affected. If only one of the affected high point vents is vented, then Condition B will apply to the remaining high point vent with noncondensible gas accumulation.

BASES

ACTIONS (continued)

D.1

If the IRWST and refueling cavity water volume, boron concentration, or temperature are not within limits, the core cooling capability from injection or PRHR HX heat transfer and the reactivity benefit of injection assumed in safety analyses may not be available. Due to the large volume of the IRWST, online monitoring of volume and temperature, and frequent surveillances, the deviation of these parameters is expected to be minor. The allowable deviation of the water volume is limited to 3%. This limit prevents a significant change in boron concentration and is consistent with the long-term cooling analysis performed to justify PRA success criteria (Ref. 3), which assumed multiple failures with as many as 3 CMTs/Accum not injecting. This analysis shows that there is significant margin with respect to the water supplies that support containment recirculation operation. The 8-hour Completion Time is acceptable, considering that the IRWST will be fully capable of performing its assumed safety function in response to DBAs with slight deviations in these parameters.

E.1

If the required motor operated IRWST isolation valve is not fully open or valve power is not removed, injection flow from the IRWST may be less than assumed in the safety analysis. In this situation, the valve must be restored to fully open with valve power removed in 1 hour. This Completion Time is acceptable based on risk considerations.

F.1 and F.2

If the IRWST cannot be returned to OPERABLE status within the associated Completion Times or the LCO is not met for reasons other than Conditions A, B, C, D, or E, the plant must be placed in a Condition in which the probability and consequences of an event are minimized to the extent possible. In MODE 6, action must be immediately initiated to be in MODE 6 with the cavity water level ≥ 23 feet above the top of the reactor vessel flange.

The time to RCS boiling is maximized by maximizing the RCS inventory and maintaining RCS temperature as low as practical. With the RCS intact, another means of removing decay heat is available (the PRHR HX). Additionally, action to suspend positive reactivity additions is required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS. These Actions place the plant in a condition which maximizes the time to IRWST injection, thus providing time for repairs or application of alternative cooling capabilities.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.5.8.1

The IRWST and refueling cavity borated water temperature must be verified every 24 hours to ensure that the temperature is within the limit assumed in accident analysis. This Frequency is sufficient to identify a temperature change that would approach the limit and has been shown to be acceptable through operating experience.

SR 3.5.8.2

Verification every 24 hours that the IRWST and refueling cavity borated water volume is above the required minimum level will ensure that a sufficient intitial supply is available for safety injection and floodup volume for recirculation and as the heat sink for PRHR. During shutdown with the refueling cavity flooded with water from the IRWST, the Surveillance requires that the combined volume of borated water in the IRWST and refueling cavity meets the specified limit. Since the IRWST volume is normally stable, and is monitored by redundant main control indication and alarm, a 24 hour Frequency is appropriate.

SR 3.5.8.3

Verification every 31 days that the boron concentration of the IRWST and refueling cavity is greater than the required limit ensures that the reactor will remain subcritical following shutdown events. Since the IRWST volume is large and normally stable, the 31 day Frequency is acceptable, considering additional verifications are required within 6 hours after each solution volume increase of 15,000 gal.

SR 3.5.8.4

LCO 3.5.6 Surveillance Requirements and Frequencies SR 3.5.6.3 and 3.5.6.5 through 3.5.6.10 are applicable to the IRWST and the flow paths required to be OPERABLE. Refer to the corresponding Bases for LCO 3.5.6 for a discussion of each SR.

REFERENCES None.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.1 Containment

BASES

BACKGROUND

The containment is a free standing steel pressure vessel surrounded by a reinforced concrete shield building. The containment vessel, including all its penetrations, is a low-leakage steel vessel designed to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA) such that offsite radiation exposures are maintained within limits. The containment and shield building provide shielding from the fission products that may be present in the containment atmosphere following accident conditions.

The containment vessel is a vertical cylindrical steel pressure vessel with elliptical upper and lower heads, completely enclosed by a seismic Category I reinforced concrete shield building. A 4.5 foot wide annular space exists between the walls and domes of the steel containment vessel and the concrete shield building to permit inservice inspection and air flow over the steel dome for containment cooling. The containment utilizes the outer concrete building for shielding and a missile barrier, and the inner steel containment for leak tightness and passive containment cooling.

Containment piping penetration assemblies provide for the passage of process, service and sampling pipelines into the containment vessel while maintaining containment integrity. The shield building provides biological shielding and environmental missile protection for the containment vessel and the Nuclear Steam Supply System.

The inner steel containment and its penetrations establish the leakage limiting boundary of the containment. Maintaining the containment OPERABLE limits the leakage of fission product radioactivity from the containment to the environment. SR 3.6.1.1 leakage rate Surveillance Requirements conform with 10 CFR 50, Appendix J (Ref. 1), as modified by approved exemptions.

The isolation devices for the penetrations in the containment boundary are a part of the containment leak tight barrier. To maintain this leak tight barrier:

a. All penetrations required to be closed during accident conditions are either:

    1. capable of being closed by an OPERABLE automatic containment isolation system, or

BASES

BACKGROUND (continued)

2. closed by manual valves, blind flanges, or de-activated automatic valves secured in their closed positions, except as provided in LCO 3.6.3, “Containment Isolation Valves”;

b. Each air lock is OPERABLE, except as provided in LCO 3.6.2, “Containment Air Locks”; and

c. All equipment hatches are closed.

APPLICABLE SAFETY ANALYSES

The safety design basis for the containment is that the containment must withstand the pressures and temperatures of the limiting DBA without exceeding the design leakage rates.

The DBAs that result in a challenge to containment OPERABILITY from high pressures and temperatures are a loss of coolant accident (LOCA), a steam line break, and a rod ejection accident (REA) (Ref. 2). In addition, release of significant fission product radioactivity within containment can occur from a LOCA or REA. The DBA analyses assume that the containment is OPERABLE such that, for the DBAs involving release of fission product radioactivity, release to the environment is controlled by the rate of containment leakage. The containment is designed with an allowable leakage rate of 0.10% of containment air weight of the original content of containment air after a DBA per day (Ref. 3). This leakage rate, used in the evaluation of offsite doses resulting from accidents, is defined in 10 CFR 50, Appendix J (Ref. 1), as L_a: the maximum allowable containment leakage rate at the calculated peak containment internal pressure (P_a) resulting from the limiting DBA. The allowable leakage rate represented by L_a forms the basis for the acceptance criteria imposed on containment leakage rate testing. L_a is assumed to be 0.10% per day in the safety analysis.

Satisfactory leakage rate test results is a requirement for the establishment of containment OPERABILITY.

The containment satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Containment OPERABILITY is maintained by limiting leakage to ≤ 1.0 L_a, except prior to the first startup after performing a required Containment Leakage Rate Testing Program Leakage Test. At this time, the applicable leakage limits must be met.

BASES

LCO (continued)

Compliance with this LCO will ensure a containment configuration, including equipment hatches, that is structurally sound and that will limit leakage to those leakage rates assumed in the safety analysis.

Individual leakage rates specified for the containment air lock (LCO 3.6.2) are not specifically part of the acceptance criteria of 10 CFR 50, Appendix J, Option B. Therefore, leakage rates exceeding these individual limits only result in the containment being inoperable when the leakage results in exceeding the overall acceptance criteria of 1.0 L_a.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material into containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. The MODES 5 and 6 requirements are specified in LCO 3.6.8, “Containment Penetrations”.

ACTIONS

A.1

In the event containment is inoperable, containment must be restored to OPERABLE status within 1 hour. The 1 hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining containment OPERABLE during MODES 1, 2, 3, and 4. This time period also ensures that the probability of an accident (requiring containment OPERABILITY) occurring during periods when containment is inoperable is minimal.

B.1 and B.2

If containment cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.1.1

Maintaining the containment OPERABLE requires compliance with the visual examinations and leakage rate test requirements of the Containment Leakage Rate Testing Program. Failure to meet air lock leakage limits specified in LCO 3.6.2 does not invalidate the acceptability of these overall leakage determinations unless their contribution to overall Type A, B, and C leakage causes that to exceed limits. As left leakage prior to the first startup after performing a required leakage test is required to be $< 0.6\ L_a$ for combined Type B and C leakage, and $< 0.75\ L_a$ for overall Type A leakage. At all other times between required leakage rate tests, the acceptance criteria is based on an overall Type A leakage limit of $\leq 1.0\ L_a$. At $\leq 1.0\ L_a$ the offsite dose consequences are bounded by the assumptions of the safety analysis. SR Frequencies are as required by the Containment Leakage Rate Testing Program. These periodic testing requirements verify that the containment leakage rate does not exceed the leakage rate assumed in the safety analysis.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.2 Containment Air Locks

BASES

BACKGROUND

Containment air locks form part of the containment pressure boundary and provide a means for personnel access during all MODES of operation.

Each air lock is nominally a right circular cylinder, 10 feet in diameter, with a door at each end. The doors are interlocked to prevent simultaneous opening. During periods when containment is not required to be OPERABLE, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. Each air lock door has been designed and tested to certify its ability to withstand a pressure in excess of the maximum expected pressure following a Design Basis Accident (DBA) in containment. As such, closure of a single door supports containment OPERABILITY. Each of the doors contains double gasketed seals and local leakage rate testing capability to ensure pressure integrity. To effect a leak tight seal, the air lock design uses pressure seated doors (i.e., an increase in containment internal pressure results in increased sealing force on each door).

The containment air locks form part of the containment pressure boundary. As such, air lock integrity and leak tightness are essential for maintaining the containment leakage rate within limit in the event of a DBA. Not maintaining air lock integrity or leak tightness may result in a leakage rate in excess of that assumed in the unit safety analyses.

APPLICABLE SAFETY ANALYSES

The DBA that results in the largest release of radioactive material within containment is a loss of coolant accident (LOCA) (Ref. 3). In the analyses of DBAs, it is assumed that containment is OPERABLE, such that release of fission products to the environment is controlled by the rate of containment leakage. The containment is designed with an allowable leakage rate of 0.10% of containment air weight of the original content of containment air per day after a DBA (Ref. 2). This leakage rate is defined in 10 CFR 50, Appendix J (Ref. 1), as L_a, the maximum allowable containment leakage rate at the calculated peak containment internal pressure P_a following a DBA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air locks.

The containment air locks satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

Each containment air lock forms part of the containment pressure boundary. As part of containment, the air lock safety function is related to control of offsite radiation exposures resulting from a DBA. Thus, each air lock's structural integrity and leak tightness are essential to the successful mitigation of such an event.

Each air lock is required to be OPERABLE. For the air lock to be considered OPERABLE, the air lock interlock mechanism must be OPERABLE, the air lock must be in compliance with the Type B air lock leakage test, and both air lock doors must be OPERABLE. The interlock allows only one air lock door of an air lock to be opened at one time. This provision ensures that a gross breach of containment does not exist when containment is required to be OPERABLE. Closure of a single door in each air lock is necessary to support containment OPERABILITY following postulated events. Nevertheless, both doors are kept closed when the air lock is not being used for normal entry and exit from containment.

APPLICABILITY

In MODES 1, 2, 3, and 4 a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES and large inventory of coolant. Therefore, containment air locks are not required to be OPERABLE in MODES 5 and 6 to prevent leakage of radioactive material from containment. However, containment closure capability is required within MODES 5 and 6 as specified in LCO 3.6.8.

ACTIONS

The ACTIONS are modified by a Note that allows entry and exit to perform repairs on the affected air lock component. If the outer door is inoperable, then it may be easily accessed to repair without interrupting containment integrity. If containment entry is required, it is preferred that the air lock be accessed from inside primary containment by entering through the other OPERABLE air lock. However, if this is not practicable, or if repairs on either door must be performed from the barrel side of the door then it is permissible to enter the air lock through the OPERABLE door, which means there is a short time during which the containment boundary is not intact (during access through the OPERABLE door). The ability to open the OPERABLE door, even if it means the containment boundary is temporarily not intact, is acceptable due to the low probability of an event that could pressurize the containment during the short time in which the OPERABLE door is expected to be open. After each entry and exit, the OPERABLE door must be immediately closed. If ALARA conditions permit, entry and exit should be via an OPERABLE air lock.

BASES

ACTIONS (continued)

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each air lock. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable air lock. Complying with the Required Actions may allow for continued operation, and a subsequent inoperable air lock is governed by subsequent Condition entry and application of associated Required Actions.

In the event that air lock leakage results in exceeding the overall containment leakage rate, Note 3 directs entry into the applicable Conditions and Required Actions of LCO 3.6.1, “Containment.”

A.1, A.2, and A.3

With one air lock door in one or more containment air locks inoperable, the OPERABLE door must be verified closed (Required Action A.1) in each affected containment air lock. This ensures a leak tight containment barrier is maintained by the use of an OPERABLE air lock door. This action must be completed within 1 hour. This specified time period is consistent with the ACTIONS of LCO 3.6.1, “Containment,” which requires containment be restored to OPERABLE status within 1 hour.

In addition, the affected air lock penetration must be isolated by locking closed the OPERABLE air lock door within the 24 hour Completion Time. The 24 hour Completion Time is reasonable for locking the OPERABLE air lock door, considering the OPERABLE door of the affected air lock is being maintained closed.

Required Action A.3 verifies that an air lock with an inoperable door has been isolated by the use of a locked and closed OPERABLE air lock door. This ensures that an acceptable containment leakage boundary is maintained. The Completion Time of once per 31 days is reasonable based on engineering judgement and is considered adequate in view of the low likelihood of a locked door being mispositioned and other administrative controls. Required Action A.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified to be locked closed by administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

BASES

ACTIONS (continued)

The Required Actions are modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the airlock are inoperable. With both doors in the same airlock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. The exception of Note 1 does not affect tracking the Completion Time from the initial entry into Condition A; only the requirement to comply with the Required Actions. Note 2 allows use of an airlock for entry and exit for 7 days, under administrative controls if both airlocks have an inoperable door. This 7 day restriction begins when the second air lock is discovered inoperable. Containment entry may be required on a periodic basis to perform Technical Specification (TS) Surveillances and Required Actions, as well as other activities on equipment inside containment that are required by TS or activities on equipment that support TS-required equipment. This Note is not intended to preclude performing other activities (non-TS-related activities) if the containment is entered, using the inoperable airlock, to perform an allowed activity listed above. This allowance is acceptable due to the low probability of an event that could pressurize the containment during the short time in which the OPERABLE door is expected to be open.

B.1, B.2, and B.3

With an air lock door interlock mechanism inoperable in one or more air locks, the Required Actions and associated Completion Times are consistent with Condition A.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same airlock are inoperable. With both doors in the same airlock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. Note 2 allows entry into and exit from containment under the control of a dedicated individual stationed at the airlock to ensure that only one door is opened at a time (the individual performs the function of the interlock).

Required Action B.3 is modified by a Note that applies to airlock doors located in high radiation areas that allows these doors to be verified locked closed by administrative means. Allowing verification by administrative means is considered acceptable since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position is small.

BASES

ACTIONS (continued)

C.1, C.2, and C.3

With one or more air locks inoperable for reasons other than those described in Condition A or B, Required Action C.1 requires action to be initiated immediately to evaluate previous combined leakage rates using current air lock test results. An evaluation is acceptable, since it is overly conservative to immediately declare the containment inoperable if both doors in an air lock have failed a seal test or if the overall air lock leakage is not within limits. In many instances (e.g., only one seal per door has failed), containment remains OPERABLE, yet only 1 hour (per LCO 3.6.1) would be provided to restore the air lock door to OPERABLE status prior to requiring a plant shutdown. In addition, even with both doors failing the seal test, the overall containment leakage rate can still be within limits.

Required Action C.2 requires that one door in the affected containment air lock must be verified to be closed within the 1 hour Completion Time. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires that containment be restored to OPERABLE status within 1 hour.

Additionally, the affected air lock(s) must be restored to OPERABLE status within the 24 hour Completion Time. The specified time period is considered reasonable for restoring an inoperable air lock to OPERABLE status, assuming that at least one door is maintained closed in each affected air lock.

D.1 and D.2

If the inoperable containment air lock cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.2.1

Maintaining containment air locks OPERABLE requires compliance with the leakage rate test requirements of the Containment Leakage Rate Testing Program. This SR reflects the leakage rate testing requirements with respect to air lock leakage (Type B leakage tests). The acceptance

BASES

SURVEILLANCE REQUIREMENTS (continued)

criteria were established during initial air lock and containment OPERABILITY testing. The periodic testing requirements verify that the air lock leakage does not exceed the allowed fraction of the overall containment leakage rate. The Frequency is as required by the Containment Leakage Rate Testing Program.

The SR has been modified by two Notes. Note 1 states that an inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test. This is considered reasonable since either air lock door is capable of providing a fission product barrier in the event of a DBA. Note 2 has been added to this SR requiring the results to be evaluated against the acceptance criteria applicable to SR 3.6.1.1. This ensures that air lock leakage is properly accounted for in determining the combined Type B and C containment leakage rate.

SR 3.6.2.2

The air lock door interlock is designed to prevent simultaneous opening of both doors in a single air lock. Since both the inner and outer doors of an air lock are designed to withstand the maximum expected post accident containment pressure, closure of either door will support containment OPERABILITY. Thus, the door interlock feature supports containment OPERABILITY while the air lock is being used for personnel transit in and out of the containment. Periodic testing of this interlock demonstrates that the interlock will function as designed and that simultaneous inner and outer door opening will not inadvertently occur. Due to the purely mechanical nature of this interlock, and given that the interlock mechanism is not normally challenged when the containment air lock door is used for entry and exit (procedures require strict adherence to single door opening), this test is only required to be performed every 24 months. The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage, and the potential for loss of containment OPERABILITY if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at 24 month Frequency. The 24 month Frequency is based on engineering judgment and is considered adequate given that the interlock is not challenged during the use of the airlock.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.3 Containment Isolation Valves

BASES

BACKGROUND

The containment isolation valves form part of the containment pressure boundary and provide a means for fluid penetrations not serving accident consequence limiting systems to be provided with two isolation barriers. These isolation devices are either passive or active (automatic). Manual valves, de-activated automatic valves secured in their closed position (including check valves with flow through the valve secured), blind flanges, and closed systems are considered passive devices. Check valves, or other automatic valves designed to close without operator action following an accident, are considered active devices. Two barriers in series are provided for each penetration so that no single credible failure or malfunction of an active component can result in a loss of isolation or leakage that exceeds limits assumed in the safety analyses. One of these barriers may be a closed system. These barriers (typically containment isolation valves) make up the Containment Isolation System.

Automatic isolation signals are produced during accident conditions. Section 6.2 (Ref. 1) identifies parameters which initiate isolation signal generation for containment isolation valves. The containment isolation valves (and blind flanges) help ensure that the containment atmosphere will be isolated from the environment in the event of a release of fission product radioactivity to the containment atmosphere as a result of a Design Basis Accident (DBA).

The OPERABILITY requirements for containment isolation valves help ensure that containment is isolated within the time limits assumed in the safety analysis. Therefore, the OPERABILITY requirements provide assurance that containment function assumed in the safety analysis will be maintained.

<u>Containment Air Filtration System 16-inch purge valves</u>

The Containment Air Filtration System operates to:

a. Supply outside air into the containment for ventilation and cooling or heating,

b. Reduce the concentration of noble gases within containment prior to and during personnel access, and

c. Equalize internal and external pressures.

BASES

BACKGROUND (continued)

Since the valves used in the Containment Air Filtration System are designed to meet the requirements for automatic containment isolation valves, these valves may be opened as needed in MODES 1, 2, 3 and 4.

APPLICABLE SAFETY ANALYSES

The containment isolation valve LCO was derived from the assumptions related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during major accidents. As part of the containment boundary, containment isolation valve OPERABILITY supports leak tightness of the containment. Therefore, the safety analysis of any event requiring isolation of containment is applicable to this LCO.

The DBAs that result in a release of radioactive material within containment are a loss of coolant accident (LOCA) and a rod ejection accident (Ref. 2). In the analyses for each of the accidents, it is assumed that containment isolation valves are either closed or function to close within the required isolation time following event initiation. This ensures that potential paths to the environment through containment isolation valves (including containment purge valves) are minimized.

The DBA dose analysis assumes that, following containment isolation signal generation, the containment purge isolation valves are closed within 10 seconds. The remainder of the automatic isolation valves are assumed closed and the containment leakage is terminated except for the design leakage rate, L_a. Since the containment isolation valves are powered from the 1E division batteries no diesel generator startup time is applied.

The single failure criterion required to be imposed in the conduct of plant safety analyses was considered in the design of the containment purge isolation valves. Two valves in series on each purge line provide assurance that both the supply and exhaust lines could be isolated even if a single failure occurred. The inboard and outboard isolation valves on each line are pneumatically operated, spring closed valves that fail in the closed position and are provided with power via independent sources.

The containment isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Containment isolation valves form a part of the containment boundary. The containment isolation valves' safety function is related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during a DBA.

BASES

LCO (continued)

The automatic power operated isolation valves are required to have isolation times within limits and to actuate on an automatic isolation signal. The valves covered by this LCO are listed along with their associated stroke times in the Section 6.2 (Ref. 1).

The normally closed isolation valves are considered OPERABLE when manual valves are closed, automatic valves are de-activated and secured in their closed position, or blind flanges are in place and closed systems are intact. These passive isolation valves/devices are those listed in Reference 1.

This LCO provides assurance that the containment isolation valves and purge valves will perform their designed safety functions to minimize the loss of reactor coolant inventory and establish the containment boundary during accidents.

APPLICABILITY

In MODES 1, 2, 3, and 4 a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, containment isolation valves are not required to be OPERABLE in MODES 5 and 6 to prevent leakage of radioactive material from containment. However, containment closure capability is required in MODES 5 and 6. The requirements for containment isolation valves during MODES 5 and 6 are addressed in LCO 3.6.8, “Containment Penetrations.”

ACTIONS

The ACTIONS are modified by a Note allowing containment penetration flow paths to be unisolated intermittently under administrative control. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the penetration can be rapidly isolated when a need for containment isolation is indicated.

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each penetration flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable containment isolation valve. Complying with the Required Actions may allow for continued operation, and subsequent inoperable containment isolation valves are governed by subsequent Condition entry and application of associated Required Actions.

BASES

ACTIONS (continued)

The ACTIONS are further modified by a third Note, which ensures appropriate remedial actions are taken, if necessary, if the affected systems are rendered inoperable by an inoperable containment isolation valve.

In the event that the containment isolation valve leakage results in exceeding the overall containment leakage rate, Note 4 directs entry into the applicable Conditions and Required Actions of LCO 3.6.1.

A.1 and A.2

In the event one containment isolation valve in one or more penetration flow paths is inoperable the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve, a blind flange, or a check valve with flow through the valve secured. For a penetration flow path isolated in accordance with Required Action A.1, the device used to isolate the penetration should be the closest available one to containment. Required Action A.1 must be completed within 4 hours. The 4 hour Completion Time is reasonable considering the time required to isolate the penetration, the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4, and the availability of a second barrier.

For affected penetrations that cannot be restored to OPERABLE status within the 4 hour Completion Time and have been isolated in accordance with Required Action A.1, the affected penetrations must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations that are required to be isolated following an accident and that are no longer capable of being automatically isolated, will be in the isolation position should an event occur. This Required Action does not require any testing or valve manipulation. Rather, it involves verification, through a system walkdown, that those isolation devices outside containment and capable of potentially being mispositioned are in the correct position. The Completion Time of “once per 31 days for isolation devices outside containment” is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as “prior to entering MODE 4 from MODE 5, if not performed within the previous 92 days,” is based on engineering judgment and is considered reasonable in view of

BASES

ACTIONS (continued)

the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

Condition A has been modified by a Note indicating that this Condition is only applicable to those penetration flow paths with two containment isolation valves. For penetration flow paths with one containment isolation valve and a closed system, Condition C provides the appropriate actions.

Required Action A.2 is modified by two Notes. Note 1 applies to isolation devices located in high-radiation areas, and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these valves once they have been verified to be in the proper position, is small.

B.1

With two containment isolation valves in one or more penetration flow paths inoperable, the affected penetration flow path must be isolated within 1 hour. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and deactivated automatic valve, a closed manual valve and a blind flange. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1. In the event the affected penetration is isolated in accordance with Required Action B.1, the affected penetration must be verified to be isolated on a periodic basis per Required Action A.2 which remains in effect. This periodic verification is necessary to ensure leak tightness of containment and that penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying each affected penetration flow path is isolated is appropriate considering the fact that the valves are operated under administrative control and the probability of their misalignment is low.

BASES

ACTIONS (continued)

Condition B is modified by a Note indicating this Condition is only applicable to penetration flow paths with two isolation valves. Condition A of this LCO addresses the condition of one containment isolation valve inoperable in this type of penetration flow path.

C.1 and C.2

With one or more penetration flow paths with one containment isolation valve inoperable, the inoperable valve flow path must be restored to OPERABLE status or the affected penetration must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and deactivated automatic valve, a closed manual valve, and a blind flange. A check valve may not be used to isolate the affected penetration flow path. Required Action C.1 must be completed within the 72 hour Completion Time. The specified time period is reasonable considering the relative stability of the closed system (hence, reliability) to act as a penetration isolation boundary and the relative importance of maintaining containment integrity during MODES 1, 2, 3, and 4. In the event that the affected penetration is isolated in accordance with Required Action C.1, the affected penetration must be verified to be isolated on a periodic basis. This periodic verification is necessary to assure leak tightness of containment and that containment penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying that each affected penetration flow path is isolated is appropriate because the valves are operated under administrative controls and the probability of their misalignment is low.

Condition C is modified by a Note indicating that this Condition is only applicable to penetration flow paths with only one containment isolation valve and a closed system. The closed system must meet the requirements of Ref. 4. This Note is necessary since this Condition is written to specifically address those penetration flow paths in a closed system.

Required Action C.2 is modified by two Notes. Note 1 applies to valves and blind flanges located in high radiation areas, and allows these devices to be verified closed by use of administrative controls. Allowing verification by administrative controls is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered

BASES

ACTIONS (continued)

acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these valves, once they have been verified to be in the proper position, is small.

D.1 and D.2

If the Required Actions and associated Completion Times are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.3.1

This SR ensures that the 16 inch purge valves are closed as required or, if open, open for an allowable reason. If a purge valve is open in violation of this SR, the valve is considered inoperable. If the inoperable valve is not otherwise known to have excessive leakage when closed, it is not considered to have leakage outside of limits. The SR is not required to be met when the 16 inch purge valves are open for the reasons stated. The valves may be opened for pressure control, ALARA or air quality considerations for personnel entry, or for Surveillances that require the valves to be open. The 16 inch purge valves are capable of closing in the environment following a LOCA. Therefore, these valves are allowed to be open for limited periods of time. The 31 day Frequency is consistent with other containment isolation valve requirements discussed in SR 3.6.3.2.

SR 3.6.3.2

This SR requires verification that each containment isolation manual valve and blind flange located outside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside of the containment boundary is within design limits. This SR does not require any testing or valve manipulation. Rather, it involves verification, through a system walkdown, that those valves outside containment and capable of being mispositioned are in the correct position. Since verification of valve position for valves outside containment is relatively easy, the 31 day Frequency is based on

BASES

SURVEILLANCE REQUIREMENTS (continued)

engineering judgment and was chosen to provide added assurance of the correct positions. The SR specifies that containment isolation valves that are open under administrative controls are not required to meet the SR during the time the valves are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

The Note applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3, and 4 for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in the proper position, is small.

SR 3.6.3.3

This SR requires verification that each containment isolation manual valve and blind flange located inside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside of the containment boundary is within design limits. For containment isolation valves inside containment, the Frequency specified as “prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days” is appropriate since these containment isolation valves are operated under administrative control and the probability of their misalignment is low. The SR specifies that containment isolation valves that are open under administrative controls are not required to meet the SR during the time they are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

This Note allows valves and blind flanges located in high radiation areas to be verified closed by use of administrative controls. Allowing verification by administrative controls is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3, and 4 for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in the proper position, is small.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.3.4

Verifying that the isolation time of each automatic power operated containment isolation valve is within limits is required to demonstrate OPERABILITY. The isolation time test ensures that the valve will isolate in a time period less than or equal to that assumed in the safety analysis. The isolation times are specified in Section 6.2.3 (Ref. 1) and Frequency of this SR is in accordance with the Inservice Testing Program.

SR 3.6.3.5

Automatic containment isolation valves close on isolation signal to prevent leakage of radioactive material from containment following a DBA. This SR ensures that each automatic containment isolation valve will actuate to its isolation position on a containment isolation signal. This surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass this Surveillance when performed at the 24 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.4 Containment Pressure

BASES

BACKGROUND

The containment pressure is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or steam line break (SLB). These limits also prevent the containment pressure from exceeding the containment design negative pressure differential with respect to the outside atmosphere in the event of transients which result in a negative pressure.

Containment pressure is a process variable that is monitored and controlled. The containment pressure limits are derived from the operating band of conditions used in the containment pressure analyses for the Design Basis Events which result in internal or external pressure loads on the containment vessel. Should operation occur outside these limits, the initial containment pressure would be outside the range used for containment pressure analyses.

APPLICABLE SAFETY ANALYSES

Containment internal pressure is an initial condition used in the DBA analyses to establish the maximum peak containment internal pressure. The limiting DBAs considered, relative to containment pressure, are the LOCA and SLB, which are analyzed using computer pressure transients. The worst case LOCA generates larger mass and energy release than the worst cast SLB. Thus, the LOCA event bounds the SLB event from the containment peak pressure standpoint (Ref. 1).

The initial pressure condition used in the containment analysis was 15.7 psia (1.0 psig). This resulted in a maximum peak pressure from a LOCA, P_a, of 58.3 psig. The containment analysis (Ref. 1) shows that the maximum peak calculated containment pressure results from the limiting LOCA. The maximum containment pressure resulting from the worst case LOCA, P_a, does not exceed the containment design pressure, 59 psig.

The containment was also designed for an external pressure load equivalent to 1.7 psid. The limiting negative pressure transient is a loss of all AC power sources coincident with extreme cold weather conditions which cool the external surface of the containment vessel. The initial pressure condition used in this analysis was -0.2 psig. This resulted in a minimum pressure inside containment, as illustrated in Reference 1,

BASES

APPLICABLE SAFETY ANALYSES (continued)

which is less than the design load. Other external pressure load events evaluated include:

Failed fan cooler control

Malfunction of containment purge system

Inadvertent Passive Containment Cooling System (PCS) actuation

Containment pressure satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

Maintaining containment pressure at less than or equal to the LCO upper pressure limit ensures that, in the event of a DBA, the resultant peak containment accident pressure will remain below the containment design pressure.

Maintaining containment pressure at greater than or equal to the LCO lower pressure limit ensures that the containment will not exceed the design negative differential pressure following negative pressure transients. If the containment pressure does not meet the low pressure limit, the containment vacuum relief capacity of one flow path may not be adequate to ensure the containment pressure meets the negative pressure design limit.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. Since maintaining containment pressure within the high pressure limit is essential to ensure initial conditions assumed in the accident analyses are maintained, the LCO is applicable in MODES 1, 2, 3, and 4.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment pressure within the high pressure limit of the LCO is not required in MODE 5 or 6.

In MODES 1 through 6, the potential exists for excessive containment cooling events to produce a negative containment pressure below the design limit. However, in MODES 5 and 6, a containment air flow path may be opened (LCO 3.6.8, Containment Penetrations), providing a vacuum relief path that is sufficient to preclude a negative containment pressure below the design limit.

BASES

APPLICABILITY (continued)

Therefore, maintaining containment pressure within the low pressure limit is essential to ensure initial conditions assumed in the cooling events in MODES 1 through 4 and in MODES 5 and 6 without an open containment air flow path ≥ 6 inches in diameter. With a 6 inch diameter or equivalent containment air flow path, the vacuum relief function is not needed to mitigate a low pressure event.

ACTIONS

A.1

When containment pressure is not within the limits of the LCO, it must be restored within 1 hour. The Required Action is necessary to return operation to within the bounds of the containment analysis. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1, "Containment," which requires that containment be restored to OPERABLE status within 1 hour.

B.1, B.2, and B.3

If the containment pressure cannot be restored to within its limits within the required Completion Time, the plant must be placed in a condition in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

If the containment high pressure limit is not met, entry into MODE 5 is sufficient to exit the Applicability. If the containment low pressure limit is not met, Required Action B.3 applies.

If in MODE 5 or 6 the containment low pressure limit is not met, a containment air flow path ≥ 6 inches in diameter shall be opened within 44 hours from condition entry. Any flow path (or paths) with an area equivalent to 6 inches in diameter is adequate to provide the necessary air flow.

BASES

ACTIONS (continued)

The primary means of opening a containment air flow path is by establishing a containment air filtration system (VFS) air flow path into containment. Manual actuation and maintenance as necessary to open a purge supply, purge exhaust, or vacuum relief flow path are available means to open a containment air flow path. In addition, opening of a spare penetration is an acceptable means to provide the necessary flow path. Opening of an equipment hatch or a containment airlock is acceptable, but may not be possible due to the differential pressure condition. Containment air flow paths opened must comply with LCO 3.6.8, Containment Penetrations.

The 44 hour Completion Time is reasonable for opening a containment air flow path in an orderly manner.

SURVEILLANCE REQUIREMENTS

SR 3.6.4.1

Verifying that containment pressure is within limits ensures that unit operation remains within the limits assumed in the containment analysis. The 12 hour Frequency of this SR was developed based on operating experience related to trending of both containment pressure variations during the applicable MODES. Furthermore, the 12 hour Frequency is considered adequate in view of other indications available in the main control room, including alarms, to alert the operator to an abnormal containment pressure condition.

REFERENCES

1. Section 6.2, “Containment Systems.”

B 3.6 CONTAINMENT SYSTEMS

B 3.6.5 Containment Air Temperature

BASES

BACKGROUND

The containment structure serves to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA). The containment average air temperature is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or steam line break (SLB).

The containment average air temperature limit is derived from the input conditions used in the containment functional analyses and the containment structure external pressure analyses. This LCO ensures that initial conditions assumed in the analysis of containment response to a DBA are not violated during plant operations. The total amount of energy to be removed from containment by the passive containment cooling system during post accident conditions is dependent upon the energy released to the containment due to the event, as well as the initial containment temperature and pressure. The higher the initial temperature, the more energy that must be removed, resulting in higher peak containment pressure and temperature. Exceeding containment design pressure may result in leakage greater than that assumed in the accident analysis. Operation with containment temperature in excess of the LCO limit violates an initial condition assumed in the accident analysis.

APPLICABLE SAFETY ANALYSES

Containment average air temperature is an initial condition used in the DBA analyses that establishes the containment environmental qualification operating envelope for both pressure and temperature. The limit for containment average air temperature ensures that operation is maintained within the assumptions used in the DBA analyses for containment (Ref. 1).

The limiting DBAs considered relative to containment OPERABILITY are the LOCA and SLB. The DBA LOCA and SLB are analyzed using computer codes designed to predict the resultant containment pressure transients. No two DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to containment Engineered Safety Feature (ESF) systems, assuming the loss of one Class 1E Engineered Safety Features Actuation Cabinet (ESFAC) Division, which is the worst case single active failure, resulting in one Passive Containment Cooling System flow path being rendered inoperable.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The limiting DBA for the maximum peak containment air temperature is a LOCA or SLB. The initial containment average air temperature assumed in the design basis analyses (Ref. 1) is 120°F.

The DBA temperature transients are used to establish the environmental qualification operating envelope for containment. The basis of the containment environmental qualification temperature envelope is to ensure the performance of safety related equipment inside containment (Ref. 2). The containment vessel design temperature is 300°F. The containment vessel temperature remains below 300°F for DBAs. Therefore, it is concluded that the calculated transient containment air temperature is acceptable for the DBAs.

The temperature limit is also used in the depressurization analyses to ensure that the minimum pressure limit is maintained following an inadvertent actuation of the Passive Containment Cooling System (Ref. 1).

The containment is designed for an external pressure load equivalent to 1.7 psid. The limiting negative pressure transient is a loss of all ac power sources coincident with extreme cold weather conditions, which cool the external surface of the containment vessel. The initial containment average air temperature condition used in this analysis is 120°F. This resulted in a minimum pressure inside containment, as illustrated in Reference 1, which is less than the design load.

The containment pressure transient is sensitive to the initial air mass in containment and, therefore, to the initial containment air temperature. The limiting DBA for establishing the maximum peak containment internal pressure is an SLB or LOCA. The temperature limit is used in the DBA analyses to ensure that in the event of an accident the maximum containment internal pressure will not be exceeded.

Containment average air temperature satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, with an initial containment average air temperature less than or equal to the LCO temperature limit, the resultant peak accident temperature is computed to remain within acceptable limits. As a result, the ability of containment to perform its design function is ensured.

BASES

LCO (continued)

The LCO establishes the maximum containment average air temperature initial condition required for the excessive cooling analysis. If the containment average air temperature exceeds the limit, the containment vacuum relief capacity of one flow path may not be adequate to ensure the containment pressure meets the negative pressure design limit.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment average air temperature within the limit is not required in MODE 5 or 6 for a DBA LOCA or SLB.

In MODES 1 through 6, the potential exists for excessive containment cooling events to produce a negative containment pressure below the design limit. However, in MODES 5 and 6, a containment equipment hatch or airlock may be opened (LCO 3.6.8, Containment Penetrations), providing a vacuum relief path that is sufficient to preclude a negative containment pressure below the design limit.

Therefore, maintaining containment average air temperature within the limit is essential to ensure initial conditions assumed in the cooling events in MODES 1 through 4 and in MODES 5 and 6 with both containment equipment hatches and both containment airlocks closed.

ACTIONS

A.1

When containment average air temperature is not within the limit of the LCO, it must be restored to within its limit within 8 hours. This Required Action is necessary to return operation to within the bounds of the containment analysis. The 8 hour Completion Time is acceptable considering the sensitivity of the conservative analysis to variations in this parameter, and provides sufficient time to correct minor problems.

BASES

ACTIONS (continued)

B.1, B.2, and B.3

If the containment average air temperature cannot be restored to within its limit within the required Completion Time, the plant must be placed in a condition in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

In MODE 5 or 6, a containment equipment hatch or a containment airlock shall be opened within 44 hours from Condition entry. Opening of a hatch or an airlock is necessary to provide the required vacuum relief path in the event of a low pressure event if the average air temperature initial condition is not met. The allowed Completion Time is reasonable for opening a hatch or an airlock in an orderly manner.

SURVEILLANCE REQUIREMENTS

SR 3.6.5.1

Verifying that the containment average air temperature is within the LCO limit ensures that containment operation remains within the limits assumed for the containment analyses. In order to determine the containment average air temperature, a weighted average is calculated using measurements taken at locations within the containment selected to provide a representative sample of the associated containment atmosphere. The 24 hour Frequency of this Surveillance Requirement is considered acceptable based on observed slow rates of temperature increase within containment as a result of environmental heat sources (due to the large volume of containment). Furthermore, the 24 hour Frequency is considered adequate in view of other indications available in the main control room, including alarms, to alert the operator to an abnormal containment temperature condition.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.6 Passive Containment Cooling System (PCS) – Operating

BASES

BACKGROUND

The PCS provides containment cooling to limit post accident pressure and temperature in containment to less than the design values. Reduction of containment pressure reduces the release of fission product radioactivity from containment to the environment, in the event of a Design Basis Accident (DBA). The Passive Containment Cooling System is designed to meet the requirements of 10 CFR 50 Appendix A GDC 38 “Containment Heat Removal” and GDC 40 “Testing of Containment Heat Removal Systems” (Ref. 1).

The PCS consists of a 800,000 gal (nominal) cooling water tank, four headered tank discharge lines with flow restricting orifices, and two separate full capacity discharge flow paths to the containment vessel with 3 sets of isolation valves, each capable of meeting the design bases. Algae growth is not expected within the Passive Containment Cooling Water Storage Tank (PCCWST); however, to assure water clarity is maintained, a prevailing concentration of hydrogen peroxide is maintained at 50 ppm. The recirculation pumps and heater provide freeze protection for the passive containment cooling water storage tank. However, OPERABILITY of the tank is assured by compliance with the temperature limits specified in SR 3.6.6.1 and not by the recirculation pumps and heater. In addition to the recirculation pumps and heater, the PCS water storage tank temperature can be maintained within limits by the ambient temperature, the large thermal inertia of the tank, or heat from other sources. The PCS valve room temperature must not be below freezing for an extended period to assure the water flow path to the containment shell is available. The isolation valves on each flow path are powered from a separate Division.

Upon actuation of the isolation valves, gravity flow of water from the cooling water tank (contained in the shield building structure above the containment) onto the upper portion of the containment shell reduces the containment pressure and temperature following a DBA. The flow of water to the containment shell surface is initially established to assure that the required short term containment cooling requirements following the postulated worst case LOCA are achieved. As the decay heat from the core becomes less with time, the water flow to the containment shell is reduced in three steps. The change in flow rate is attained without active components in the system and is dependent only on the decreasing water level in the elevated storage tank. In order to ensure the containment surface is adequately and effectively wetted, the water is introduced at the center of the containment dome and flows outward. Weirs are placed on the dome surface to distribute the water and ensure

BASES

BACKGROUND (continued)

effective wetting of the dome and vertical sides of the containment shell. The monitoring of the containment surface through the Reliability Assurance Program (RAP) and the Inservice Testing Program assures containment surface does not unacceptably degrade containment heat removal performance. During the initial test program, the containment coverage will be measured at the base of the upper annulus in addition to the coverage at the spring line for the full flow case and a lower flow case with PCS recirculation pumps delivering to the containment shell. These benchmark values at the base of the upper annulus will be used to develop acceptance criteria for technical specifications. Contamination can be removed by PCS actuation and by using coating vendor cleaning procedures.

The path for the natural circulation of air is from the air intakes in the shield building, down the outside of the baffle, up along the containment shell to the top, center exit in the shield building and is always open. The drains in the upper annulus region must be clear to prevent water from blocking the air flow path. Heat is removed from within the containment utilizing the steel containment shell as the heat transfer surface combining conductive heat transfer to the water film, convective heat transfer from the water film to the air, radiative heat transfer from the film to the air baffle, and mass transfer (evaporation) of the water film into the air. As the air heats up and water evaporates into the air, it becomes less dense than the cooler air in the air inlet annulus. This differential causes an increase in the natural circulation of the air upward along the containment surface, with heated air/water vapor exiting the top/center of the shield building. Additional system design details are provided in Reference 3.

The PCS is actuated either automatically, by a containment High-2 pressure signal, or manually. Automatic actuation opens the cooling water tank discharge valves, allowing gravity flow of the cooling water onto the containment shell. The manual containment cooling actuation consists of four momentary controls, if two associated controls are operated simultaneously, actuation will occur in all divisions. The discharge continues for at least three days.

The PCS is designed to limit post-accident pressure and temperature in containment to less than the design values. Reduction of containment pressure reduces the release of fission product radioactivity from containment to the environment, in the event of a DBA.

The PCS is an ESF system and is designed to ensure that the heat removal capability required during the post accident period can be attained.

BASES

APPLICABLE SAFETY ANALYSES

The Passive Containment Cooling System limits the temperature and pressure that could be experienced following a DBA. The limiting DBAs considered are the loss of coolant accident (LOCA) and the steam line break (SLB). The LOCA and SLB are analyzed using computer codes designed to predict the resultant containment pressure and temperature transients. No DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to containment ESF system, assuming the loss of one Class 1E Engineered Safety Features Actuation Cabinet (ESFAC) Division, which is the worst case single active failure and results in one PCS flow path being inoperable.

The analyses and evaluations assume a unit specific power level of 3400 MWt, one passive containment cooling train operating, and initial (pre-accident) containment conditions of 120°F and 1.0 psig. The analyses also assume a response time delayed initiation to provide conservative peak calculated containment pressure and temperature responses.

For certain aspects of transient accident analyses, maximizing the calculated containment pressure is not conservative. In particular, the effectiveness of the Passive Core Cooling System during the core reflood phase of a LOCA analysis increases with increasing containment backpressure. For these calculations, the containment backpressure is calculated in a manner designed to conservatively minimize, rather than maximize, the calculated transient containment pressures in accordance with 10 CFR 50, Appendix K (Ref. 2).

Containment cooling system performance for post accident conditions is given in Reference 3. The result of the analysis is that each train can provide 100% of the required peak cooling capacity during the post accident condition.

The modeled Passive Containment Cooling System actuation response time from the containment analysis is based upon a response time associated with exceeding the containment High-2 pressure setpoint to opening of isolation valves.

The Passive Containment Cooling System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, one passive containment cooling water flow path is required to maintain the containment peak pressure and temperature below the design limits (Ref. 3). To ensure that this requirement is met, two passive containment cooling water flow paths are provided.

BASES

LCO (continued)

Therefore, in the event of an accident, at least one flow path operates, assuming the worst case single active failure occurs. A third PCS flow path is provided for protection against multiple failure scenarios modeled in the PRA. To ensure that these requirements are met, three PCS water flow paths must be OPERABLE.

The PCS includes a cooling water tank, valves, piping, instruments and controls to ensure an OPERABLE flow path capable of delivering water from the cooling water tank upon an actuation signal. An OPERABLE flow path consists of a normally closed valve capable of automatically opening in series with a normally open valve. For the two flow paths containing air-operated valves, it is preferred because of PRA insights that these valves be normally closed.

The PCS cooling water storage tank ensures that an adequate supply of water is available to cool and depressurize the containment in the event of a Design Basis Accident (DBA). To be considered OPERABLE, the PCS cooling water storage tank must meet the water volume and temperature limits established in the SRs. To be considered OPERABLE, the air flow path from the shield building annulus inlet to the exit must be unobstructed, with unobstructed upper annulus safety-related drains providing a path for containment cooling water runoff to preclude blockage of the air flow path.

APPLICABILITY In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment and an increase in containment pressure and temperature requiring the operation of the PCS.

During shutdown the PCS may be required to remove heat from containment. The requirements in MODES 5 and 6 are specified in LCO 3.6.7, Passive Containment Cooling System (PCS) – Shutdown.

ACTIONS A.1

With one passive containment cooling water flow path inoperable, the affected flow path must be restored within 7 days. In this degraded condition, the remaining flow paths are capable of providing greater than 100% of the heat removal needs after an accident, even considering the worst single failure. The 7 day Completion Time was chosen in light of the remaining heat removal capability and the low probability of a DBA occurring during this period.

BASES

ACTIONS (continued)

B.1

With two passive containment cooling water flow paths inoperable, at least one affected flow path must be restored to OPERABLE status within 72 hours. In this degraded condition, the remaining flow path is capable of providing greater than 100% of the heat removal needs after an accident. The 72 hour Completion Time was chosen in light of the remaining heat removal capability and the low probability of DBA occurring during this period.

C.1

If the cooling water tank is inoperable, it must be restored to OPERABLE status within 8 hours. The tank may be declared inoperable due to low water level or temperature out of limits. The 8 hour Completion Time is reasonable based on the remaining heat removal capability of the system and the availability of cooling water from alternate sources.

D.1 and D.2

If any of the Required Actions and associated Completion Times are not met, or if the LCO is not met for reasons other than Condition A, B, or C, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 84 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. The extended interval to reach MODE 5 allows additional time and is reasonable when considering that the driving force for a release of radioactive material from the Reactor Coolant System is reduced in MODE 3.

SURVEILLANCE REQUIREMENTS

SR 3.6.6.1

This surveillance requires verification that the cooling water temperature is within the limits assumed in the accident analyses. The 7-day Frequency is adequate to identify a temperature change that would approach the temperature limits since the tank is large and temperature variations are slow.

The surveillance Frequency is increased to 24 hours in the event that the tank temperature approaches its limits; i.e., once temperature increases

BASES

SURVEILLANCE REQUIREMENTS (continued)

either to ≥ 100°F, or decreases to ≤ 50°F. Since the maximum tank temperature variation during the normal surveillance Frequency of 7 days is only about 1°F, the tank temperature cannot exceed its limits before the increased surveillance Frequency takes effect.

SR 3.6.6.2

Verification that the cooling water volume is above the required minimum ensures that a sufficient supply is available for containment cooling. Since the cooling water volume is normally stable and low level is indicated by a main control room alarm, a 7 day Frequency is appropriate and has been shown to be acceptable in similar applications.

SR 3.6.6.3

Verifying the correct alignment of power operated, and automatic valves, excluding check valves, in the Passive Containment Cooling System provides assurance that the proper flow paths exist for system operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position since these were verified to be in the correct positions prior to being secured. This SR does not require any testing or valve manipulation. Rather, it involves verification, through control room instrumentation or a system walkdown, that valves capable of potentially being mispositioned are in the correct position. The 31 day Frequency is appropriate because the valves are operated under administrative control, and an improper valve position would only affect a single flow path. This Frequency has been shown to be acceptable through operating experience.

SR 3.6.6.4

This SR requires verification that each automatic isolation valve actuates to its correct position upon receipt of an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillances were performed with the reactor at power. The 24 month Frequency is also acceptable based on consideration of the design reliability (and confirmed by operating experience) of the equipment. Operating experience has shown that these components usually pass the Surveillances when performed at the 24 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.6.5

Periodic inspections of the PCS air flow path from the shield building annulus inlet to the exit ensure that it is unobstructed, the baffle plates are properly installed, and the upper annulus safety-related drains are unobstructed. Although there are no anticipated mechanisms which would cause air flow path or annulus drain obstruction and the effect of a missing air baffle section is small, it is considered prudent to verify this capability every 24 months. Additionally, the 24 month Frequency is based on the desire to perform this Surveillance under conditions that apply during a plant outage, on the need to have access to the locations, and because of the potential for an unplanned transient if the Surveillance were performed with the reactor at power. This Frequency has been found to be sufficient to detect abnormal degradation in similar situations.

SR 3.6.6.6

This SR requires performance of a Passive Containment Cooling System test to verify system flow and water coverage capabilities. The system performance test demonstrates that the containment cooling capability assumed in accident analyses is maintained by verifying the flow rates via each standpipe and measurement of containment wetting coverage. The System Level Operability Testing Program provides specific test requirements and acceptance criteria. Although the likelihood that system performance would degrade with time is low, it is considered prudent to periodically verify system performance. The first refueling and 10 year Frequency is based on the ability of the more frequent surveillances to verify the OPERABILITY of the active components and features which could degrade with time.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.7 Passive Containment Cooling System (PCS) – Shutdown

BASES

BACKGROUND

A description of the PCS is provided in the Bases for LCO 3.6.6, “Passive Containment Cooling System – Operating.”

APPLICABLE SAFETY ANALYSES

The PCS limits the temperature and pressure that could be experienced during shutdown following a loss of decay heat removal.

For shutdown events, the Reactor Coolant System (RCS) sensible and decay heat removal requirements are reduced as compared to heat removal requirements for MODE 1, 2, 3, or 4 events. Therefore, the shutdown containment heat removal requirements are bounded by analyses of MODES 1, 2, 3, and 4 events. A discussion of MODES 1, 2, 3, and 4 DBAs is provided in the Bases for LCO 3.6.6, “Passive Containment Cooling System (PCS) – Operating.”

The PCS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

For postulated shutdown events, one passive containment cooling water flow path is required to provide the required containment heat removal capability (Ref. 1). To ensure that this requirement is met, two passive containment cooling water flow paths are provided. Therefore, in the event of an accident, at least one flow path operates, assuming the worst case single active failure occurs. A third PCS flow path is provided for protection against multiple failure scenarios modeled in the PRA. To ensure that these requirements are met, three PCS water flow paths must be OPERABLE.

The PCS includes a cooling water tank, valves, piping, instruments and controls to ensure an OPERABLE flow path capable of delivering water from the cooling water tank upon an actuation signal.

The PCS cooling water storage tank ensures that an adequate supply of water is available to cool and depressurize the containment in the event of a loss of decay heat removal. To be considered OPERABLE, the PCS cooling water storage tank must meet the water volume and temperature limits established in the SRs. To be considered OPERABLE, the air flow path from the shield building annulus inlet to the exit must be unobstructed, with unobstructed upper annulus safety-related drains providing a path for containment cooling water runoff to preclude blockage of the air flow path.

BASES

APPLICABILITY

OPERABILITY of the PCS is required in either MODE 5 or 6 with the calculated reactor decay heat greater than 6 MWt for heat removal in the event of a loss of nonsafety decay heat removal capabilities.

With the decay heat at or below 6.0 MWt, the decay heat can be removed from containment with air cooling alone. Confirmation of decay heat levels may be determined consistent with the assumptions and analysis basis of ANS 1979 plus 2 sigma or via an energy balance of the reactor coolant system.

The PCS requirements in MODES 1, 2, 3, and 4 are specified in LCO 3.6.6, “Passive Containment Cooling System (PCS) – Operating.”

ACTIONS

A.1

With one passive containment cooling water flow path inoperable, the affected flow path must be restored within 7 days. In this degraded condition, the remaining flow paths are capable of providing greater than 100% of the heat removal needs after an accident, even considering the worst single failure. The 7 day Completion Time was chosen in light of the remaining heat removal capability and the low probability of a DBA occurring during this period.

B.1

With two passive containment cooling water flow paths inoperable, at least one affected flow path must be restored to OPERABLE status within 72 hours. In this degraded condition, the remaining flow path is capable of providing greater than 100% of the heat removal needs after an accident. The 72 hour Completion Time was chosen in light of the remaining heat removal capability and the low probability of an event occurring during this period.

C.1

If the cooling water tank is inoperable, it must be restored to OPERABLE status within 8 hours. The tank may be declared inoperable due to low water volume or temperature out of limits. The 8 hour Completion Time is reasonable based on the remaining heat removal capability of the system and the availability of cooling water from alternate sources.

D.1.1, D.1.2, and D.2

Action must be initiated if any of the Required Actions and associated Completion Times are not met, or if the LCO is not met for reasons other than Condition A, B, or C. If in MODE 5 with the RCS pressure boundary

BASES

ACTIONS (continued)

open and/or pressurizer level < 20%, action must be initiated, immediately, to increase the RCS level to a pressurizer level ≥ 20% and to close the RCS so that the Passive Residual Heat Removal Heat Exchanger (PRHR HX) operation is available. If in MODE 6, action must be initiated, immediately, to increase the refueling cavity water level ≥ 23 feet above the top of the reactor vessel flange. In both cases, the time to RCS boiling is maximized by maximizing the RCS inventory and maintaining RCS temperature as low as practical. Additionally, action to suspend positive reactivity additions is required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS.

These Actions place the plant in a condition which maximize the time to actuation of the Passive Containment Cooling System, thus providing time for repairs or application of alternative cooling capabilities.

SURVEILLANCE REQUIREMENTS

SR 3.6.7.1

The LCO 3.6.6 Surveillance Requirements (SR 3.6.6.1 through 3.6.6.6) are applicable. The Frequencies associated with each specified SR are applicable. Refer to the corresponding Bases for LCO 3.6.6 for a discussion of each SR.

REFERENCES

1. Section 6.2, “Containment Systems.”

B 3.6 CONTAINMENT SYSTEMS

B 3.6.8 Containment Penetrations

BASES

BACKGROUND

Containment closure capability is required during shutdown operations when there is fuel inside containment. Containment closure is required to maintain within containment the cooling water inventory. Due to the large volume of the In-Containment Refueling Water Storage Tank (IRWST) and the reduced sensible heat during shutdown, the loss of some of the water inventory can be accepted. Further, accident analyses have shown that containment closure capability is not required to meet offsite dose requirements. Therefore, containment does not need to be leak tight as required for MODES 1 through 4.

In MODES 5 and 6, the LCO requirements are referred to as "containment closure" rather than "containment OPERABILITY." Containment closure means that all potential escape paths are closed or capable of being closed. Since there is no requirement for containment leak tightness, compliance with the Appendix J leakage criteria and tests are not required.

In MODES 5 and 6, there is no potential for steam release into the containment immediately following an accident. Pressurization of the containment could only occur after heatup of the IRWST due to Passive Residual Heat Removal Heat Exchanger (PRHR HX) operation (MODE 5 with RCS intact) or after heatup of the RCS with direct venting to the containment (MODE 5 with reduced RCS inventory or MODE 6 with the refueling cavity not fully flooded) or after heatup of the RCS and refueling cavity (MODE 6 with refueling cavity fully flooded). The time from loss of normal cooling until steam release to the containment for four representative sets of plant conditions is shown in Figure B 3.6.8-1 as a function of time after shutdown. Because local manual action may be required to achieve containment closure it is assumed that the containment hatches, air locks and penetrations must be closed prior to steaming into containment.

Figure B 3.6.8-1 provides allowable closure times for four representative sets of plant conditions. The time to steaming is dependent on various plant parameters (RCS temperature, IRWST temperature, etc.) and plant configuration (RCS Pressure Boundary Intact, RCS Open, etc.). Therefore, the actual representation of the time to steaming may be different than that provided in Figure B 3.6.8-1. In determining the minimum time to steaming, conservative assumptions regarding core decay heat, RCS configuration, and initial RCS inventory are used to minimize the calculated time to steaming. The curves are based on the

BASES

BACKGROUND (continued)

core decay heat prior to refueling so that closure times are longer following the core reload.

As presented in Tables 54-1 and 54-4 of Reference 2, the most risk significant events during shutdown are events that lead to a loss of Normal Residual Heat Removal System (RNS) cooling. Of these, the limiting events that lead to steaming to containment are the loss of shutdown cooling events, specifically:

- Loss of decay heat removal during drained conditions due to a failure of component cooling water or service water system;
- Loss-of-offsite power during drained conditions; and
- Loss of decay heat removal during drained conditions due to failure of the normal residual heat removal system.

These events are further discussed in Section 19.59.5 of Reference 1. Time to steaming is dependent on the postulated RCS configuration (intact versus open), and is based on the response of the plant considering features such as the operation of the 4th stage Automatic Depressurization System (ADS) valves if necessary, status of the upper internals, status of refueling cavity, etc. Conservative assumptions regarding these features are made in the determination of the minimum time to steaming. The time assumed in the PRA to close the penetrations before steaming to containment included 15 minutes for the diagnosis and decision-making time, in addition to the time required to physically complete the closure action.

The risk of overdraining the RCS has been significantly reduced in the AP1000 due to the automatic protection features associated with the hot leg level instruments which isolate letdown on low hot leg water level. Overdraining the RCS is no longer a significant contributor to core damage, as shown in Table 54-4 of Reference 2.

The assumptions used in determining the required closure time for the various containment openings should be conservative, and should be consistent with the plant operating procedures, staffing levels, and status of the containment openings. The evaluation should consider the ability to close the containment for the limiting loss of shutdown cooling event, and considering the possibility of a station blackout. In determining if containment can be closed within the time permitted to containment closure specified in Figure B 3.6.8-1, the time to close containment penetrations must include both the diagnosis and decision-making time and the time required to physically complete the closure action.

BASES

BACKGROUND (continued)

Containment should be closed during the initial mid-loop period for a refueling since the time permitted to containment closure is shorter than the time to diagnose and make a decision that closure is needed following an event. The need to close containment for the mid-loop period following a refueling must be evaluated since decay heat varies with the time after shutdown and the impact of the partial core replacement with new fuel. It is expected that containment will be closed for activities where drain-down is planned, such as the RCS drain-down from no-load pressurizer level for the initial mid-loop period during a refueling. Containment is not expected to be closed for minor, unplanned RCS volume transients, such as a short-term inventory where the pressurizer level may be reduced, but not emptied, and where recovery actions are within the time to containment closure.

The containment equipment hatches, which are part of the containment pressure boundary, provide a means for moving large equipment and components into and out of containment. If closed, the equipment hatch must be held in place by at least four bolts. Good engineering practice dictates that bolts required by this LCO be approximately equally spaced. Alternatively, if open, each equipment hatch can be installed using a dedicated set of hardware, tools and equipment. A self-contained power source is provided to drive each hoist while lowering the hatch into position. Large equipment and components may be moved through the hatches as long as they can be removed and the hatch closed prior to steaming into the containment.

The design of the equipment hatch is such that the four bolts would only be needed to support the hatch in place and provide adequate strength to support the hatch dead weight and associated loads. The hatch is installed on the inside containment and is held in place against a matching flange surface with mating bolt pattern by the bolts. Once the dead weight is supported, any pressure (greater than atmospheric) within containment will serve to exert closure force on the hatch toward the mating flange surface serving to reduce stresses on bolts. Therefore the determination of the number of bolts is limited to the quantity required to support the hatch itself and not related to any potential containment pressure.

The containment air locks, which are also part of the containment pressure boundary, provide a means for personnel access during MODES 1, 2, 3, and 4 unit operation in accordance with LCO 3.6.2, “Containment Air Locks.” Each air lock has a door at both ends. The doors are normally interlocked to prevent simultaneous opening when containment OPERABILITY is required. During periods of unit shutdown when containment closure is required, the door interlock mechanism may

BASES

BACKGROUND (continued)

be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. Temporary equipment connections (e.g., power or communications cables) are permitted as long as they can be removed to allow containment closure prior to steaming into the containment.

Containment spare penetrations which also provide a part of the containment boundary provide for temporary support services (electrical, I&C, air, and water supplies) during MODES 5 and 6. Each penetration is flanged and normally closed. During periods of plant shutdown, temporary support systems may be routed through the penetrations; temporary equipment connections (e.g., power or communications cables) are permitted as long as they can be removed to allow containment closure prior to steaming into the containment. The spare penetrations must be closed or, if open, capable of closure prior to steaming to containment.

Containment penetrations, including purge system flow paths, that provide direct access from containment atmosphere to outside atmosphere must be isolated or capable of being isolated on at least one side. Isolation may be achieved by an OPERABLE automatic isolation valve, or by a manual isolation valve, blind flange, or equivalent. Equivalent isolation methods must be approved and may include use of a material that can provide a temporary barrier for the containment penetrations. The equivalent isolation barrier must be capable of maintaining containment isolation at the containment design pressure of 59 psig (Ref. 1).

APPLICABLE SAFETY ANALYSES

For postulated shutdown events in MODES 5 and 6, RCS heat removal is provided by either passive residual heat removal (PRHR) or IRWST injection and containment sump recirculation. To support RCS heat removal, containment closure is required to limit the loss of the cooling water inventory from containment (Ref. 1).

Containment penetrations satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO limits the loss of cooling water inventory in containment to assure continued coolant inventory by limiting the potential escape paths for water released within containment. Penetrations closed in accordance with these requirements are not required to be leak tight.

BASES

LCO (continued)

The LCO requires any penetration providing direct access from the containment atmosphere to the outside atmosphere to be closed or capable of being closed prior to steaming into the containment. The equipment hatches may be open; however, the hatches shall be clear of obstructions such that capability to close the hatch within the indicated time period is maintained. The hardware, tools, equipment and power sources necessary to install the hatches shall be available when the hatch is open. Both doors in each containment air lock may be open; however, the air locks shall be clear of obstructions such that the capability to close at least one door within the indicated time period is maintained. Alternatively, one door in an air lock may be closed. Containment spare penetrations may be open; however, the penetrations shall be capable of being closed within the indicated time period. Direct access penetrations shall be closed by at least one manual or automatic isolation valve, blind flange or equivalent, or capable of being closed by at least one valve actuated by a containment isolation signal. If direct access penetrations are open, OPERABILITY of the containment isolation instrumentation is required for the open penetrations by LCO 3.3.2, Function 3.a, Containment Isolation, Manual Initiation. An OPERABLE Containment Isolation Function includes LCO 3.3.2, Function 19.b, Containment Air Filtration System Isolation, Containment Isolation. Figure B 3.6.8-1 provides the acceptable required closure times for various representative MODES and conditions.

APPLICABILITY

The containment penetration requirements are applicable during conditions for which the primary safety related core cooling and boration capabilities are provided by IRWST or injection or PRHR – MODES 5 and 6. The capability to close containment is required to ensure that the cooling water inventory is not lost in the event of an accident.

In MODES 1, 2, 3, and 4, containment penetration requirements are addressed by LCO 3.6.1.

ACTIONS

A.1

If the containment equipment hatches, air locks, or any containment penetration that provides direct access from the containment atmosphere to the outside atmosphere is not in the required status, including the containment isolation function not capable of actuation when automatic isolation valves are open, the penetration(s) must be restored to the required status within 1 hour.

BASES

ACTIONS (continued)

B.1.1, B.1.2, and B.2

If Required Action A.1 is not completed within 1 hour or the LCO is not met for reasons other than Condition A, action must be taken to minimize the probability and consequences of an accident.

In MODE 5, action must be initiated, immediately, to be in MODE 5 with a pressurizer level ≥ 20% and to close the RCS so that the PRHR HX operation is available. In MODE 6, action must be initiated, immediately, to be in MODE 6 with the refueling cavity water level ≥ 23 feet above the top of the reactor vessel flange. The time to RCS steaming to containment is maximized by maximizing RCS inventory, and allowing PRHR HX operation. Additionally, action to suspend positive reactivity additions is required to ensure that the SDM is maintained. Sources of positive reactivity addition include boron dilution, withdrawal of reactivity control assemblies, and excessive cooling of the RCS.

SURVEILLANCE REQUIREMENTS

SR 3.6.8.1

This Surveillance demonstrates that each of the containment penetrations required to be in its closed position is in that position. The Surveillance on the open purge and exhaust valves will demonstrate that the valves are not blocked from closing. Also the Surveillance will demonstrate that each valve operator has motive power, which will ensure that each valve is capable of being closed by an OPERABLE automatic containment purge and exhaust isolation signal. Open containment spare penetrations shall be verified capable of being closed prior to steaming to containment by removal of obstructions and installation of the flange or by other closure means which will limit loss of the cooling water inventory from containment.

The Surveillance is performed every 7 days. The Surveillance interval is selected to ensure that the required penetration status is maintained during shutdown inspections, testing, and maintenance.

SR 3.6.8.2

Each of the two equipment hatches is provided with a set of hardware, tools, equipment, and self-contained power source for moving the hatch from its storage location and installing it in the opening. The required set of hardware and tools shall be visually inspected to ensure that they can perform the required functions. The equipment and power source shall

BASES

SURVEILLANCE REQUIREMENTS (continued)

be inspected and/or operated as necessary to verify that the hatch can be installed. The power source shall be verified as containing sufficient energy to install the hatch from the storage location.

The 7 day Frequency is adequate considering that the hardware, tools, equipment, and power sources are dedicated to the associated equipment hatch and not used for any other functions.

The SR is modified by a Note which only requires that the surveillance be met for an open equipment hatch. If the equipment hatch is installed in position, then the availability of the means to install the hatch is not required.

SR 3.6.8.3

This Surveillance demonstrates that at least one valve in each open penetration actuates to its isolation position on manual initiation or on an actual or simulated containment isolation signal. The 24 month Frequency maintains consistency with other similar valve testing requirements. The OPERABILITY requirements for the Containment Isolation function are specified in LCO 3.3.2.

The SR is modified by a Note stating that this Surveillance is not required to be met for valves in isolated penetrations. The LCO provides the option to close penetrations in lieu of requiring automatic actuation capability.

Time Prior to Coolant Inventory Boiling

B 3.6 CONTAINMENT SYSTEMS

B 3.6.9 pH Adjustment

BASES

BACKGROUND

The Passive Core Cooling System (PXS) includes four pH adjustment baskets which provide adjustment of the pH of the water in the containment following an accident where the containment floods.

Following an accident with a large release of radioactivity, the containment pH is automatically adjusted to greater than or equal to 7.0, to enhance iodine retention in the containment water. Chemical addition is necessary to counter the affects of the boric acid contained in the safety injection supplies and acids produced in the post-LOCA environment (nitric acid from the irradiation of water and air and hydrochloric acid from irradiation and pyrolysis of electric cable insulation). The desired pH values significantly reduce formation of elemental iodine in the containment water, which reduces the production of organic iodine and the total airborne iodine in the containment. This pH adjustment is also provided to prevent stress corrosion cracking of safety related containment components during long-term cooling.

Dodecahydrate trisodium phosphate (TSP) contained in baskets provides a passive means of pH control for such accidents. The baskets are made of stainless steel with a mesh front that readily permits contact with water. These baskets are located inside containment at an elevation that is below the minimum floodup level. The baskets are placed at least a foot above the floor to reduce the chance that water spills will dissolve the TSP. Natural recirculation of water inside the containment, following a LOCA, is driven by the core decay heat and provides mixing to achieve a uniform pH. The dodecahydrate form of TSP ($Na_3PO_4 \cdot 12H_2O$) is initially loaded into the baskets because it is hydrated and will undergo less physical and chemical change than would anhydrous TSP as a result of the humidity inside containment. (Refs. 1 and 2)

APPLICABLE SAFETY ANALYSES

In the event of a Design Basis Accident (DBA), iodine may be released from the fuel to containment. To limit this iodine release from containment, the pH of the water in the containment sump is adjusted by the addition of TSP. Adjusting the sump water to neutral or alkaline pH (pH ≥ 7.0) will augment the retention of the iodine, and thus reduce the iodine available to leak to the environment.

pH adjustment satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The requirement to maintain the pH adjustment baskets with ≥ 560 ft^3 of TSP assures that for DBA releases of iodine into containment, the pH of the containment sump will be adjusted to enhance the retention of the iodine.

A required volume is specified instead of mass because it is not feasible to weigh the TSP in the containment. The minimum required volume is based on the manufactured density of TSP. This is conservative because the density of TSP may increase after installation due to compaction.

APPLICABILITY

In MODES 1, 2, 3, and 4 a DBA could cause release of radioactive iodine to containment requiring pH adjustment. The pH adjustment baskets assist in reducing the airborne iodine fission product inventory available for release to the environment.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Thus, pH adjustment is not required to be OPERABLE in MODES 5 and 6.

ACTIONS

A.1

If the TSP volume in the baskets is not within limits, the iodine retention may be less than that assumed in the accident analysis for the limiting DBA. Due to the very low probability that the volume of TSP may change, the variations are expected to be minor such that the required capability is substantially available. The 72 hour Completion Time for restoration to within limits is consistent with times applied to minor degradations of ECCS parameters.

B.1 and B.2

If the Required Actions and associated Completion Times are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 84 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.9.1

The minimum amount of TSP is 560 ft^3. A volume is specified since it is not feasible to weigh the TSP contained in the pH adjustment baskets. This volume is based on providing sufficient TSP to buffer the post accident containment water to a minimum pH of 7.0. Additionally, the TSP volume is based on treating the maximum volume of post accident water (908,000 gallons) containing the maximum amount of boron (2990 ppm) as well as other sources of acid. The minimum required mass of TSP is 26,460 pounds at an assumed assay of 100%.

The minimum required volume of TSP is based on this minimum required mass of TSP, the minimum density of TSP plus margin to account for degradation of TSP during plant operation. The minimum TSP density is based on the manufactured density (54 lbm/ft^3), since the density may increase and the volume decrease, during plant operation, due to agglomeration from humidity inside the containment. The minimum required TSP volume also has about 10% margin to account for degradation of TSP during plant operation.

The periodic verification is required every 24 months, since access to the TSP baskets is only feasible during outages, and normal fuel cycles are scheduled for 24 months. Operating experience has shown this Surveillance Frequency acceptable due to the margin in the volume of TSP placed in the containment building.

SR 3.6.9.2

Testing must be performed to ensure the solubility and buffering ability of the TSP after exposure to the containment environment. A representative sample of 2.39 grams of TSP from one of the baskets in containment is submerged in ≥ 1 liter of water at a boron concentration of 2990 ppm and at the standard temperature of 25 ± 5°C. Without agitation, the solution pH should be raised to ≥ 7.0 within 4 hours.

The minimum required amount of TSP is sufficient to buffer the maximum amount of boron 2990 ppm, the maximum amount of other acids, and the maximum amount of water 908,000 gallons that can exist in the containment following an accident and achieve a minimum pH of 7.0.

Agitation of the test solution is prohibited, since an adequate standard for the agitation intensity cannot be specified. The test time of 4 hours is necessary to allow time for the dissolved TSP to naturally diffuse through the sample solution. In the post LOCA sump area, rapid mixing would occur due to liquid flow, significantly decreasing the actual amount of time

BASES

SURVEILLANCE REQUIREMENTS (continued)

before the required pH is achieved. This would ensure compliance with the Standard Review Plan requirement of a pH ≥ 7.0 by the onset of recirculation after a LOCA.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.10 Vacuum Relief Valves

BASES

BACKGROUND

The purpose of the vacuum relief lines is to protect the containment vessel from damage due to a negative pressure (that is, a lower pressure inside than outside). Excessive negative pressure inside containment can occur, if there is a loss of ac power (containment recirculation cooling system (VCS) containment heating not available, reactor trip decay heating only) with a differential (inside to outside) ambient temperature > 90°F. In this case, the relative low outside ambient temperature may cool containment faster than the available heat sources (primarily, reactor decay heat) can heat containment, resulting in a reduction of the containment temperature and pressure below the negative pressure design limit since normal non-safety-related pressure control means are not available due to loss of ac power. In addition, excessive negative pressure inside containment can occur, in the event of malfunction of the Containment Fan Coolers (containment air filtration system (VFS)) control, in combination with low outside ambient temperature, which reduces containment temperature.

The containment pressure vessel contains two 100-percent capacity vacuum relief flow paths with a shared containment penetration that protect the containment from excessive external pressure loading. Each flow path outside containment contains a normally closed, motor-operated valve (MOV). The MOVs receive an ESF “open” signal on Containment Pressure–Low 2. The MOVs close on an ESF containment isolation signal, as well as on High-1 containment radioactivity. Each flow path inside containment contains a normally closed, self-actuated check valve inside containment that opens on a negative differential pressure of 0.2 psi. A vacuum relief flow path consists of one MOV and one check valve, and the shared containment penetration.

The parallel vacuum relief MOVs are interlocked with the 16 inch containment purge discharge isolation valve inside containment, VFS-PL-V009, which shares the containment penetration. The vacuum relief MOVs are blocked from opening if VFS-PL-V009 is not closed. If the VFS-PL-V009 is not closed, then the vacuum relief MOVs will automatically close to direct VFS purge exhaust through the normal VFS discharge flow path. However, if vacuum relief actuation is required, the vacuum relief MOV actuation signal overrides the closing interlock with VFS-PL-V009 to allow the vacuum relief MOVs to open ensuring that the vacuum relief protection actuates. (Ref. 3)

BASES

APPLICABLE SAFETY ANALYSES

Design of the vacuum relief system involves calculating the effect of loss of ac power and an ambient air temperature in combination with limited containment heating that reduces the atmospheric temperature (and hence pressure) inside containment (Ref. 1). Conservative assumptions are used for relevant parameters in the calculation; for example, maximum inside containment temperature, minimum outside air temperature, maximum humidity, and maximum heat transfer coefficients (Ref. 1). The resulting containment pressure versus time is calculated, including the effect of the opening of the vacuum relief valves when their negative pressure setpoint is reached. It is also assumed that one valve fails to open.

The containment was designed for an external pressure load equivalent to 1.7 psid. The excessive containment cooling events were analyzed to determine the resulting reduction in containment pressure. The initial pressure condition used in this analysis was -0.2 psig. This resulted in a minimum pressure inside the containment less than the design load.

The applicable safety analyses results for the loss of ac power event bounds the analyses for the other external pressure load events described in the Bases for LCO 3.6.4, “Containment Pressure.”

The vacuum relief valves must also perform the containment isolation function during a containment high pressure event. For this reason, the system is designed to take the full containment positive design pressure and the environmental conditions (temperature, pressure, humidity, radiation, chemical attack, and the like) associated with the containment DBA.

The vacuum relief valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO establishes the maximum containment temperature initial condition and the minimum equipment required to accomplish the vacuum relief function following excessive containment cooling events (Ref. 1). Two 100-percent vacuum relief flow paths are required to be OPERABLE to ensure that at least one is available, assuming one or both valves in the other flow path fail to open. A vacuum relief flow path is OPERABLE if the MOV opens on an ESF open signal and the self-actuated check valves open on a negative differential pressure of 0.2 psi.

The containment inside to outside differential air temperature limit of ≤ 90°F ensures that the initial condition for the excessive cooling analysis is met. If the differential air temperature exceeds the limit, the containment vacuum relief capacity of one flow path may not be adequate to ensure the containment pressure meets the negative pressure design limit.

BASES

APPLICABILITY

In MODES 1 through 6, the potential exists for excessive containment cooling events to produce a negative containment pressure below the design limit. However, in MODE 5 or 6, a containment air flow path may be opened (LCO 3.6.8, Containment Penetrations), providing a vacuum relief path that is sufficient to preclude a negative containment pressure below the design limit.

Therefore, the vacuum relief flow paths are required to be OPERABLE in MODES 1 through 4 and in MODES 5 and 6 without an open containment air flow path ≥ 6 inches in diameter. With a 6 inch diameter or equivalent containment air flow path, the vacuum relief function is not needed to mitigate a low pressure event.

ACTIONS

A.1

When one of the required vacuum relief flow paths is inoperable, the inoperable flow path must be restored to OPERABLE status within 72 hours. The specified time period is consistent with other LCOs for the loss of one train of a system required to mitigate the consequences of a LOCA or other DBA.

B.1 and B.2

If the containment inside to outside differential air temperature is > 90°F, then the differential air temperature shall be restored to within the limit within 8 hours. The 8-hour Completion Time is reasonable, considering that limit is based on a worst case condition and the time needed to reduce the containment temperature while controlling pressure within limits of LCO 3.6.4, Containment Pressure.

If the differential temperature cannot be restored, Required Action B.2 provides an alternate requirement. Reduction of the containment average temperature to ≤ 80°F provides an initial condition for excessive cooling events that ensures the vacuum relief system capacity is sufficient (Ref. 1).

C.1, C.2, and C3

If the Required Action and associated Completion Time of Conditions A or B are not met or both vacuum relief flow paths are inoperable, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

In MODE 5 or 6, a containment air flow path ≥ 6 inches in diameter shall be opened within 44 hours from Condition entry. Any flow path (or paths) with an area equivalent to 6 inches in diameter is adequate to provide the necessary air flow.

The primary means of opening a containment air flow path is by establishing a VFS air flow path into containment. Manual actuation and maintenance as necessary to open a purge supply, purge exhaust, or vacuum relief flow path are available means to open a containment air flow path. In addition, opening of a spare penetration is an acceptable means to provide the necessary flow path. Opening of an equipment hatch or a containment airlock is acceptable. Containment air flow paths opened must comply with LCO 3.6.8, Containment Penetrations.

The 44 hour Completion Time is reasonable for opening a containment air flow path in an orderly manner.

SURVEILLANCE REQUIREMENTS

SR 3.6.10.1

Verification that the containment inside to outside differential air temperature is ≤ 90°F is required every 12 hours. The containment inside to outside differential air temperature is the difference between the outside ambient air temperature (measured by the site meteorological instrumentation or equivalent) and the inside containment average air temperature (measured using the same instrumentation as used for SR 3.6.5.1).

The Frequency is based on the normally stable containment average air temperature and the relatively small outside ambient air temperature changes within this time.

SR 3.6.10.2

This SR cites the Inservice Testing Program, which establishes the requirement that inservice testing of the ASME Code Class 1, 2, and 3 valves shall be performed in accordance with the ASME OM Code (Ref. 2). Therefore, SR Frequency is governed by the Inservice Testing Program.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

BASES

BACKGROUND

The primary purpose of the MSSVs is to provide overpressure protection for the secondary system. The MSSVs also provide protection against overpressurizing the reactor coolant pressure boundary (RCPB) by providing a heat sink for the removal of energy from the Reactor Coolant System (RCS) if the preferred heat sink, provided by the Condenser and Circulating Water System, is not available.

Six MSSVs are located on each main steam header, outside containment, upstream of the main steam isolation valves, as described in Reference 1. The MSSVs must have sufficient capacity to limit the secondary system pressure to ≤ 110% of the steam generator design pressure in order to meet the requirements of the ASME Code, Section III (Ref. 2). The MSSV design includes staggered setpoints, as shown in Table 3.7.1-2 of the specification, so that only the needed valves actuate. Staggered setpoints reduce the potential for valve chattering that is due to steam pressure insufficient to fully open the valves following a turbine-reactor trip.

APPLICABLE SAFETY ANALYSES

The design basis for the MSSVs comes from Reference 2 and its purpose is to limit the secondary system pressure to ≤ 110% of design pressure for any anticipated operating occurrence (AOO) or accident considered in the Design Basis Accident (DBA) and transient analysis.

The events that challenge the relieving capacity of the MSSVs, are those characterized as decreased heat removal events, which are presented in Section 15.2 (Ref. 3). Of these, the full power turbine trip without turbine bypass is the limiting AOO. This event also terminates normal feedwater flow to the steam generators.

The safety analysis demonstrates that the transient response for turbine trip without a direct reactor trip presents no hazard to the integrity of the RCS or the Main Steam System. One turbine trip analysis is performed assuming primary system pressure control via operation of the pressurizer spray. This analysis demonstrates that the DNB design basis is met. Another analysis is performed assuming no primary system pressure control, but crediting reactor trip on high pressurizer pressure and operation of the pressurizer safety valves. This analysis demonstrates that RCS integrity is maintained by showing that the maximum RCS pressure does not exceed 110% of the design pressure.

BASES

APPLICABLE SAFETY ANALYSES (continued)

All cases analyzed demonstrate that the MSSVs maintain Main Steam System integrity by limiting the maximum steam pressure to less than 110% of the steam generator design pressure.

In addition to the decreased heat removal events, reactivity insertion events may also challenge the relieving capacity of the MSSVs. The uncontrolled rod cluster control assembly (RCCA) bank withdrawal at power event is characterized by an increase in core power and steam generation rate until reactor trip occurs when either the Overtemperature ΔT or Power Range Neutron Flux-High setpoint is reached. Steam flow to the turbine will not increase from its initial value for this event. The increased heat transfer to the secondary side causes an increase in steam pressure and may result in opening of the MSSVs prior to reactor trip, assuming no credit for operation of the atmospheric or condenser steam dump valves. The DCD Section 15.4.2 safety analysis of the RCCA bank withdrawal at power event for a range of initial core power levels demonstrates that the MSSVs are capable of preventing secondary side overpressurization for this AOO.

The DCD safety analyses discussed above assume that all of the MSSVs for each steam generator are OPERABLE. If there are inoperable MSSV(s), it is necessary to limit the primary system power during steady-state operation and AOOs to a value that does not result in exceeding the combined steam flow capacity of the turbine (if available) and the remaining OPERABLE MSSVs. The required limitation on primary system power necessary to prevent secondary system overpressurization may be determined by system transient analyses or conservatively arrived at by a simple heat balance calculation. In some circumstances it is necessary to limit the primary side heat generation that can be achieved during an AOO by reducing the setpoint of the Power Range Neutron Flux-High reactor trip function. For example, if more than one MSSV on a single steam generator is inoperable, an uncontrolled RCCA bank withdrawal at power event occurring from a partial power level may result in an increase in reactor power that exceeds the combined steam flow capacity of the turbine and the remaining OPERABLE MSSVs. Thus, for multiple inoperable MSSVs on the same steam generator it is necessary to prevent this power increase by lowering the Power Range Neutron Flux-High setpoint to an appropriate value.

The MSSVs are assumed to have two active and one passive failure modes. The active failure modes are spurious opening, and failure to reclose once opened. The passive failure mode is failure to open upon demand.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The MSSVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The accident analysis requires six MSSVs per steam generator to provide overpressure protection for design basis transients occurring at 102% of RTP. A MSSV will be considered inoperable if it fails to open in the event of a pressure excursion in excess of the setpoint. The LCO requires that six MSSVs be OPERABLE in compliance with Reference 2. Operation with less than the full number of MSSVs requires limitations on allowable THERMAL POWER (to meet ASME Code requirements). These limitations are according to Table 3.7.1-1 of the specification and Required Action A.1.

The OPERABILITY of the MSSVs is defined as the ability to open within the setpoint tolerances, relieve steam generator overpressure, and reseat when pressure has been reduced. The OPERABILITY of the MSSVs is determined by periodic surveillance testing in accordance with the Inservice Testing Program.

The lift settings specified in Table 3.7.1-2 in the accompanying LCO, correspond to ambient conditions of the valve at nominal operating temperature and pressure.

This LCO provides assurance that the MSSVs will perform their designed safety functions to mitigate the consequences of accidents that could result in a challenge to the RCPB or Main Steam System integrity.

APPLICABILITY

In MODE 1, 2, 3, or 4 (without the normal residual heat removal system in service), six MSSVs per steam generator are required to be OPERABLE.

In MODES 4 (with the normal residual heat removal system in service) and 5, there are no credible transients requiring the MSSVs. The steam generators are not normally used for heat removal in MODES 5 and 6, and thus cannot be overpressurized. There is no requirement for the MSSVs to be OPERABLE in these MODES.

BASES

ACTIONS

The ACTIONS table is modified by a Note indicating that separate Condition entry is allowed for each MSSV.

A.1 and A.2

With one or more MSSVs inoperable, reduce power so that the available MSSV relieving capacity meets Reference 2 requirements for the applicable THERMAL POWER.

Operation with less than all six MSSVs OPERABLE for each steam generator is permissible, if THERMAL POWER is proportionally limited to the relief capacity of the remaining MSSVs. This is accomplished by restricting THERMAL POWER so that the energy transfer to the most limiting steam generator is not greater than the available relief capacity in that steam generator. The maximum THERMAL POWER corresponding to the heat removal capacity of the remaining OPERABLE MSSVs is determined via a conservative heat balance calculation as described in the attachment to Reference 6, with an appropriate allowance for calorimetric power uncertainty.

To determine the maximum THERMAL POWER corresponding to the heat removal capacity of the remaining OPERABLE MSSVs, the governing heat transfer relationship is the equation $q = \dot{m}\,\Delta h$, where q is the heat input from the primary side, $\dot{m}$ is the mass flow rate of the steam, and Δh is the increase in enthalpy that occurs in converting the secondary side water to steam. If it is conservatively assumed that the secondary side water is all saturated liquid (i.e., no subcooled feedwater), then the Δh is the heat of vaporization (h_{fg}) at the steam relief pressure. The following equation is used to determine the maximum allowable power level for continued operation with inoperable MSSVs.

$$\text{Maximum NSSS Power} \leq (100/Q)\,(W_s\, h_{fg}\, N) / K$$

where:

Q = Nominal NSSS power rating of the plant (including reactor coolant pump heat), MWt

K = Conversion factor, 947.82 (Btu/sec)/MWt

w_s = Minimum total steam flow rate capability of the OPERABLE MSSVs on any one steam generator at the highest OPERABLE MSSV opening pressure, including tolerance and accumulation as appropriate, lbm/sec

BASES

ACTIONS (continued)

h_{fg} = Heat of vaporization at the highest MSSV opening pressure, including tolerance and accumulation as appropriate, Btu/lbm

N = Number of steam generators in the plant

To determine the Table 3.7.1-1 Maximum Allowable Power, the Maximum NSSS Power calculated using the equation above is reduced by 9% RTP to account for Nuclear Instrument System trip channel uncertainties.

The allowed Completion Times are reasonable based on operating experience to accomplish the Required Actions in an orderly manner without challenging unit systems.

B.1 and B.2

If the MSSVs cannot be restored to OPERABLE status within the associated Completion Time, or if one or more steam generators have less than two MSSVs OPERABLE, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the plant must be placed in at least MODE 3 within 6 hours, and in MODE 4, with RCS cooling provided by the Normal Residual Heat Removal System (RNS), within 24 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.1.1

This SR verifies the OPERABILITY of the MSSVs by the verification of each MSSV lift setpoint in accordance with the Inservice Testing Program. The safety and relief valve tests are required to be performed in accordance with ASME OM Code (Ref. 5). According to Reference 5, the following tests are required:

a. Visual examination;

b. Seat tightness determination;

c. Set pressure determination (lift setting);

d. Compliance with owner's seat tightness criteria; and

e. Verification of the balancing device integrity on balanced valves.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The ANSI/ASME standard requires that all valves be tested every 5 years and a minimum of 20% of the valves be tested every 24 months. The ASME Code specifies the activities and frequencies necessary to satisfy the requirements. Table 3.7.1-2 allows a ±1% setpoint tolerance for OPERABILITY, and the valves are reset to remain within ±1% during the Surveillance to allow for drift. The lift settings, according to Table 3.7.1-2, correspond to ambient conditions of the valve at nominal operating temperature and pressure.

This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. The MSSVs may be either bench tested or tested in situ at hot conditions using an assist device to simulate lift pressure. If the MSSVs are not tested at hot conditions, the lift setting pressure shall be corrected to ambient conditions of the valve at operating temperature and pressure.

B 3.7 PLANT SYSTEMS

B 3.7.2 Main Steam Isolation Valves (MSIVs)

BASES

BACKGROUND

Each main steam line has one safety related MSIV to isolate steam flow from the secondary side of the steam generators following a high energy line break. MSIV closure terminates flow from the unaffected (intact) steam generator.

One MSIV is located in each main steam line outside containment. The MSIVs are downstream from the main steam safety valves (MSSVs). Downstream from the MSIVs, main steam enters the high pressure turbine through four stop valves and four governing control valves. Closing the MSIVs isolates each steam generator from the other and isolates the turbine bypass system, and other steam supplies from the steam generator.

The MSIVs, turbine stop and control valves, turbine bypass valves, and moisture separator reheater 2nd stage steam isolation valves close on a main steam isolation signal generated by either low steam line pressure, high containment pressure, Low T_{cold}, or high negative steam pressure rate. The MSIVs fail closed on loss of control air or actuation signal from either of two 1E power divisions.

Each MSIV has an MSIV bypass valve. Although these bypass valves are normally closed, they receive the same emergency closure signal as do their associated MSIVs. The MSIVs may also be actuated manually.

A description of the MSIVs is found in the Section 10.3 (Ref. 1). Descriptions for the turbine bypass valves, and moisture separator reheater 2nd stage steam isolation valves are found in the Section 10.4 (Ref. 6).

APPLICABLE SAFETY ANALYSES

The design basis of the MSIVs is established by the containment analysis for the large steam line break (SLB) inside containment, discussed in the Section 6.2 (Ref. 2). It is also affected by the accident analysis of the SLB events presented in the Section 15.1 (Ref. 3). The design precludes the blowdown of more than one steam generator, assuming a single active component failure (e.g., the failure of one MSIV to close on demand).

Design basis events of concern for containment analysis are SLB inside containment with the failure of the associated MSIV to close, or a main feedline break with the associated failure of a feedline isolation or control

BASES

APPLICABLE SAFETY ANALYSES (continued)

valve to close. At lower powers, the steam generator inventory and temperature are at their maximum, maximizing the analyzed mass and energy release to the containment. Due to reverse flow and failure of the MSIV to close, the additional mass and energy in the steam headers, downstream from the other MSIV, contribute to the total release. With the most reactive rod cluster control assembly assumed stuck in the fully withdrawn position, there is an increased possibility that the core will become critical and return to power. The core is ultimately shut down by the boric acid injection delivered by the Core Makeup Tanks (CMTs).

The accident analysis compares several different SLB events against different acceptance criteria. The large SLB outside containment upstream of the MSIV is limiting for offsite dose, although a break in this short section of main steam header has a very low probability. The large SLB inside containment at hot zero power is the limiting case for a post trip return to power. The analysis includes consideration of scenarios with offsite power available, and with a loss of offsite power. With offsite power available, the reactor coolant pumps continue to circulate coolant for a longer period through the steam generators, maximizing the Reactor Coolant System cooldown. The reactor protection system includes a safety related signal that initiates the coastdown of the reactor coolant pumps early in the large SLB transient. Therefore, there is very little difference in the predicted departure from nucleate boiling ratio between cases with and without offsite power. Significant single failures considered include failure of an MSIV to close.

The non-safety related turbine stop or control valves, in combination with the turbine bypass, and moisture separator reheater 2nd stage steam isolation valves, are assumed as a backup to isolate the steam flow path given a single failure of an MSIV. The safety analyses do not differentiate between the availability of the turbine stop valve or its series control valve. Either the turbine stop valves or its associated turbine control valve are required by this LCO to be OPERABLE. These valves, along with the turbine bypass, and moisture separator reheater 2nd stage steam isolation valves are considered as alternate downstream valves.

The MSIVs serve a safety related function and remain open during power operation. These valves operate under the following situations:

a. High energy line break inside containment. In order to maximize the mass and energy release into containment, the analysis assumes that the MSIV in the affected steam generator remains open. For this accident scenario, steam is discharged into containment from both steam generators until the unaffected loop MSIV closes. After

BASES

APPLICABLE SAFETY ANALYSES (continued)

MSIV closure, steam is discharged into containment only from the affected steam generator and from the residual steam in the main steam header downstream of the closed MSIV in the unaffected loop. Closure of the MSIV isolates the break from the unaffected steam generator.

b. A break outside of containment, and upstream or downstream from the MSIVs, is not a containment pressurization concern. The uncontrolled blowdown of more than one steam generator must be prevented to limit the potential for uncontrolled Reactor Coolant System (RCS) cooldown and positive reactivity addition. Closure of the MSIVs or alternate downstream valves isolates the break, and limits the blowdown to a single steam generator.

c. Following a steam generator tube rupture, closure of the MSIVs isolates the ruptured steam generator to minimize radiological releases.

d. The MSIVs are also utilized during other events such as a feedwater line break; however, these events are less limiting so far as MSIV OPERABILITY is concerned.

The MSIVs and the alternate downstream valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

Following an SLB and main steam isolation signal, the analyses assume continued steam loss through the steam line condensate drain lines, turbine gland seal system, and the main steam to auxiliary steam header which supplies the auxiliary steam line to the deaerator. Since these valves are not assumed for steam isolation, they do not satisfy the 10 CFR 50.36(c)(2)(ii) criteria.

LCO

This LCO requires that one MSIV in each of the two steam lines be OPERABLE. The MSIVs are considered OPERABLE when their isolation times are within limits, and they close on an isolation actuation signal.

This LCO requires that four turbine stop valves or their associated turbine control valve, six turbine bypass valves, and two moisture separator reheater 2nd stage steam isolation valves be OPERABLE. A valve is considered OPERABLE when its isolation time is within the safety analysis isolation time limit of 5 seconds and it closes on an MSIV

BASES

LCO (continued)

actuation signal. The turbine bypass valves are alternatively considered OPERABLE when closed and administratively maintained closed with automatic actuation blocked as appropriate.

This LCO provides assurance that the MSIVs will perform their design safety function to mitigate the consequences of accidents that could result in offsite exposures comparable to the 10 CFR 50.34 limits or the NRC staff approved licensing basis.

This LCO provides assurance that the design and performance of the alternate downstream valves are compatible with the accident conditions for which they are called upon to function (Ref. 5).

APPLICABILITY

The MSIVs, turbine stop or associated turbine control valves, turbine bypass valves, and moisture separator reheater 2nd stage steam isolation valves must be OPERABLE in MODE 1 and MODES 2, 3, and 4, except when steam flow is isolated when there is significant mass and energy in the RCS and steam generators. Therefore, these valves must be OPERABLE or closed. When these valves are closed, they are already performing their required function.

In MODE 5 or 6, the steam generators do not contain much energy because their temperature is below the boiling point of water; therefore, the MSIVs and alternate downstream valves are not required for isolation of potential high energy secondary system pipe breaks in these MODES.

ACTIONS

A.1

With one MSIV inoperable in MODE 1, action must be taken to restore OPERABLE status within 8 hours. Some repairs to the valves can be made with the plant hot. The 8 hour Completion Time is reasonable considering the low probability of an accident occurring during this time period that would require a closure of these valves. With a single MSIV inoperable, the safety function, isolation of the steam flow path, is provided by the OPERABLE alternate downstream valves, but cannot accommodate a single failure. The assumptions and criteria of the accident analyses are preserved by the ability to automatically isolate the steam flow path.

The 8 hour Completion Time is greater than that normally allowed for containment isolation valves because the MSIVs are valves that isolate a

BASES

ACTIONS (continued)

closed system penetrating containment. These valves differ from other containment isolation valves in that the closed system provides a positive means for containment isolation.

B.1

With any number of the turbine stop valves and the associated turbine control valve, turbine bypass, or moisture separator reheater 2nd stage steam isolation valves inoperable in MODE 1, action must be taken to restore OPERABLE status within 72 hours. Some repairs to the valves can be made with the plant hot. The 72 hour Completion Time is reasonable considering the low probability of an accident occurring during this time period that would require a closure of these valves. With the backup isolation valves inoperable, the safety function, isolation of the steam flow path, is provided by the remaining OPERABLE valves, but cannot accommodate a single failure. The assumptions and criteria of the accident analyses are preserved by the ability to automatically isolate the steam flow path.

C.1

With two MSIVs inoperable in MODE 1 or one MSIV and an alternate downstream valve inoperable or if the valves cannot be restored to OPERABLE status in accordance with Required Action A.1 or B.1, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 2 within 6 hours and Condition D would be entered. The Completion Time is reasonable, based on operating experience, to reach MODE 2 in an orderly manner and without challenging unit systems.

D.1 and D.2

Condition D is modified by a Note indicating that a separate Condition entry is allowed for each MSIV.

Since the MSIVs are required to be OPERABLE in MODES 2, 3, and 4, the inoperable MSIVs may either be restored to OPERABLE status or closed. When closed, the MSIVs are already in the position required by the assumptions in the safety analysis.

The 8 hour Completion Time is consistent with that allowed in Condition A, and conservative considering the reduced energy in the steam generators in MODES 2, 3, and 4.

BASES

ACTIONS (continued)

For inoperable MSIVs that cannot be restored to OPERABLE status within the specified Completion Time but were closed, these inoperable valves must be verified to be continually closed on a periodic basis. This is necessary to ensure that the assumptions in the safety analyses remain valid. The 7 day Completion Time is based on engineering judgment, and is considered reasonable in view of MSIV status indications available in the control room and other administrative controls which ensure that these valves will continue to be closed.

E.1 and E.2

If the MSIVs cannot be restored to OPERABLE status or closed within the associated Completion Times of Condition D, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the plant must be placed in at least MODE 3 within 6 hours, and in MODE 4 with normal residual heat removal system in service within 24 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from MODE 2 conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.2.1

This SR verifies that MSIV closure time is ≤ 5.0 seconds, on an actual or simulated actuation signal. The MSIV isolation time is assumed in the accident and containment analyses. This Surveillance is normally performed upon returning the unit to operation following a refueling outage. The MSIVs should not be tested at power, since even a part stroke exercise increases the risk of a valve closure when the unit is generating power. As the MSIVs are not tested at power, they are exempt from the ASME OM Code (Ref. 7) requirements during operation in MODE 1 or 2.

The Frequency is in accordance with the Inservice Testing Program.

This test is conducted in MODE 3 with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, to establish conditions consistent with those under which the acceptance criterion was generated.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.2.2

This SR verifies that the turbine stop, turbine control, turbine bypass, and moisture separator reheater 2nd stage steam isolation valves' closure time is ≤ 5.0 seconds, on an actual or simulated actuation signal. These alternate downstream isolation valves must meet the MSIV isolation time assumed in the accident and containment analyses. This Surveillance is normally performed upon returning the unit to operation following a refueling outage. The alternate downstream valves should not be tested at power, since even a part stroke exercise increases the risk of a valve closure when the unit is generating power. As the alternate downstream valves are not tested at power, they are exempt from the ASME OM Code (Ref. 7) requirements during operation in MODE 1 or 2.

The Frequency is in accordance with the Inservice Testing Program.

This test is conducted in MODE 3 with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, to establish conditions consistent with those under which the acceptance criterion was generated.

B 3.7 PLANT SYSTEMS

B 3.7.3 Main Feedwater Isolation and Control Valves (MFIVs and MFCVs)

BASES

BACKGROUND

The MFIVs isolate main feedwater (MFW) flow to the secondary side of the steam generators following a high energy line break. The safety related function of the MFCVs is to provide the second isolation of MFW flow to the secondary side of the steam generators following a high energy line break. Closure of the MFIVs or MFCVs terminates flow to the steam generators, terminating the event for feedwater line breaks occurring upstream of the MFIVs or MFCVs. The consequences of events occurring in the main steam lines or in the MFW lines downstream from the MFIVs will be mitigated by their closure. Closure of the MFIVs or MFCVs, effectively terminates the addition of main feedwater to an affected steam generator, limiting the mass and energy release for steam or feedwater line breaks inside containment, and reducing the cooldown effects for steam line breaks (SLBs).

The MFIVs or MFCVs isolate the nonsafety related portions from the safety related portions of the system. In the event of a secondary side pipe rupture inside containment, the valves limit the quantity of high energy fluid that enters containment through the break, and provide a pressure boundary for the controlled addition of startup feedwater (SFW) to the intact loops of the steam generator.

One MFIV and one MFCV are located on each MFW line, outside but close to containment. The MFIVs and MFCVs are located in the MFW line and are independent of the delivery of the MFW or SFW via the SFW line which is separately connected and isolated from the steam generator. This configuration permits MFW or SFW to be supplied to the steam generators following MFIV or MFCV closure. The piping volume from these valves to the steam generators must be accounted for in calculating mass and energy releases following either an SLB or FWLB.

The MFIVs and MFCVs close on receipt of engineered safeguards feedwater isolation signal generated from any of the following conditions:

- Automatic or manual safeguards actuation “S” signal
- High steam generator level
- Low-2 T_{avg} signal coincident with reactor trip (P-4)
- Manual actuation

BASES

BACKGROUND (continued)

Additionally, the MFIVs close automatically on a Low-1 T_{avg} coincident with reactor trip (P-4). Each valve may be actuated manually. In addition to the MFIVs and the MFCVs, a check valve is available outside containment to isolate the feedwater line penetrating containment. In the event of feedwater line depressurization due to pump trip on line break, the check valve provides rapid backup isolation of the steam generators limiting the inventory loss. A description of the MFIVs and MFCVs is found in Reference 1.

APPLICABLE SAFETY ANALYSES

The design basis of the MFIVs and MFCVs is established by the analyses for the large SLB. It is also influenced by the accident analysis for the large Feedwater Line Break (FWLB). Closure of the MFIVs (or MFCVs) may also be relied on to mitigate an SLB for core response analysis and excess feedwater event upon the receipt of a steam generator water level – High 2 signal.

Failure of an MFIV (or MFCV), to close following an SLB or FWLB, can result in additional mass and energy being delivered to the steam generators, contributing to cooldown. This failure also results in additional mass and energy releases following an SLB or FWLB event.

The MFIVs and MFCVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO ensures that the MFIVs and the MFCVs will isolate the main feedwater system.

This LCO requires that the one isolation valve and one control valve on each feedwater line be OPERABLE. These valves are considered OPERABLE when their isolation times are within limits and they close on an isolation actuation signal.

Failure to meet the LCO requirements can result in additional mass and energy being released to containment following an SLB or FWLB inside containment. A main feedwater isolation signal on high steam generator level is relied on to terminate an excess feedwater flow event, and therefore failure to meet the LCO may result in the introduction of water into the main steam lines.

APPLICABILITY

The MFIVs and MFCVs must be OPERABLE whenever there is significant mass and energy in the Reactor Coolant System and the steam generators. This ensures that, in the event of a high energy line

BASES

APPLICABILITY (continued)

break, a single failure cannot result in the blowdown of more than one steam generator. In MODE 1, 2, 3, or 4, these valves are required to be OPERABLE to limit the amount of available fluid that could be added to the containment in the case of a secondary system pipe break inside containment. When the valves are closed and deactivated or isolated by a closed manual valve, they are already performing their safety function.

In MODES 5 and 6 steam generator energy is low. Therefore, the MFIVs and the MFCVs are normally closed since MFW is not required.

ACTIONS

The ACTIONS table is modified by a Note indicating that separate condition entry is allowed for each valve.

A.1, A.2, B.1, and B.2

With one or two MFIVs, or one or two MFCVs inoperable, close or isolate inoperable affected flow path in 72 hours. When these flow paths are isolated, they are performing their required safety function.

The 72 hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves, and the low probability of an event that would require isolation of the main feedwater flow paths occurring during this period.

For inoperable MFIVs and MFCVs valves that cannot be restored to OPERABLE status within the specified Completion Time but are closed or isolated, the flow paths must be verified on a periodic basis to be closed or isolated. This is necessary to ensure that the assumptions in the safety analyses remain valid. The 7 day Completion Time is reasonable based on engineering judgment, in view of valve status indications available in the control room, and other administrative controls, to ensure that these valves are closed or isolated.

C.1

With two inoperable valves in the same flow path there may be no redundant system to operate automatically and perform the required safety function. Under these conditions, one valve in the affected flow path must be restored to OPERABLE status, or the affected flow path isolated within 8 hours. This action returns the system to the situation in which at least one valve in the affected flow path is performing the required safety function. The 8 hour Completion Time is a reasonable amount of time to complete the actions required to close the MFIV, or

BASES

ACTIONS (continued)

MFCV, which includes performing a controlled plant shutdown. The Completion Time is reasonable based on operating experience to reach MODE 2 with the MFIV or MFCV closed, from full-power conditions in an orderly manner and without challenging plant systems.

D.1, D.2, and D.3

If the MFIVs and MFCVs cannot be restored to OPERABLE status, or closed, or isolated within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the plant must be placed in at least MODE 3 within 6 hours, in MODE 4 with the normal residual heat removal system in service within 24 hours, and the affected flow path isolated within 36 hours or in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.3.1

This SR verifies that the closure time of each MFIV and MFCV is ≤ 5.0 seconds, on an actual or simulated actuation signal. The MFIV and MFCV isolation times are assumed in the accident and containment analyses. This Surveillance is normally performed upon returning the unit to operation following a refueling outage. These valves should not be tested at power, since even a part stroke exercise increases the risk of a valve closure when the unit is generating power. This is consistent with the ASME OM Code (Ref. 2) quarterly stroke requirements during operation in MODE 1 or 2.

The Frequency is in accordance with the Inservice Testing Program.

The test is conducted in MODE 3 with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, to establish conditions consistent with those under which the acceptance criterion was generated.

B 3.7 PLANT SYSTEMS

B 3.7.4 Secondary Specific Activity

BASES

BACKGROUND

Activity in the secondary coolant results from steam generator tube LEAKAGE from the Reactor Coolant System (RCS). Other fission product isotopes, as well as activated corrosion products in lesser amounts, may also be found in the secondary coolant. While fission products present in the primary coolant, as well as activated corrosion products, enter the secondary coolant system due to the primary to secondary LEAKAGE, only the iodines are of a significant concern relative to airborne release of activity in the event of an accident or abnormal occurrence (radioactive noble gases that enter the secondary side are not retained in the coolant but are released to the environment via the condenser air removal system throughout normal operation).

The limit on secondary coolant radioactive iodines minimizes releases to the environment due to anticipated operational occurrences or postulated accidents.

APPLICABLE SAFETY ANALYSES

The accident analysis of the main steam line break (SLB) as discussed in Chapter 15 (Ref. 1) assumes the initial secondary coolant specific activity to have a radioactive isotope concentration of 0.1 µCi/gm DOSE EQUIVALENT I-131. This assumption is used in the analysis for determining the radiological consequences of the postulated accident. The accident analysis, based on this and other assumptions, shows that the radiological consequences of a postulated SLB are within the acceptance criteria in SRP Section 15.0.1, and within the exposure guideline values of 10 CFR Part 50.34.

Secondary specific activity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

As indicated in the Applicable Safety Analyses, the specific activity limit of the secondary coolant is required to be ≤ 0.1 µCi/gm DOSE EQUIVALENT I-131 to maintain the validity of the analyses reported in Chapter 15 (Ref. 1).

Monitoring the specific activity of the secondary coolant ensures that when secondary specific activity limits are exceeded, appropriate actions are taken in a timely manner to place the unit in an operational MODE that would minimize the radiological consequences of a DBA.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4 the limits on secondary specific activity apply due to the potential for secondary steam releases to the atmosphere.

In MODES 5 and 6, the steam generators are not being used for heat removal. Both the RCS and steam generators are depressurized, and primary to secondary LEAKAGE is minimal. Therefore, monitoring of secondary specific activity is not required.

ACTIONS

A.1 and A.2

DOSE EQUIVALENT I-131 exceeding the allowable value in the secondary coolant, is an indication of a problem in the RCS and contributes to increased post accident doses. If the secondary specific activity cannot be restored to within limits within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.4.1

This SR verifies that the secondary specific activity is within the limits of the accident analysis. A gamma isotopic analysis of the secondary coolant, which determines DOSE EQUIVALENT I-131, confirms the validity of the safety analysis assumptions as to the source terms in post accident releases. It also serves to identify and trend any unusual isotopic concentrations that might indicate changes in reactor coolant activity or leakage. The 31 day Frequency is based on the detection of increasing trends of the level of DOSE EQUIVALENT I-131, and allows for appropriate action to be taken to maintain levels below the LCO limit.

B 3.7 PLANT SYSTEMS

B 3.7.5 Spent Fuel Pool Water Level

BASES

BACKGROUND

The minimum water level in the spent fuel pool meets the assumptions of iodine decontamination factors following a fuel handling accident. The specified water level shields and minimizes the general area dose when the storage racks are at their maximum capacity. The water also provides shielding during the movement of spent fuel, and a large capacity heat sink in the event the spent fuel pool cooling system is inoperable.

A general description of the spent fuel pool design is given in Section 9.1.2 (Ref. 1). A description of the Spent Fuel Pool Cooling System is given in Section 9.1.3 (Ref. 2). The assumptions of the fuel handling accident are given in Section 15.7.4 (Ref. 3).

APPLICABLE SAFETY ANALYSES

The minimum water level in the spent fuel pool meets the assumptions of the fuel handling accident described in Regulatory Guide 1.183 (Ref. 4). The design basis radiological consequences resulting from a postulated fuel handling accident are within the dose values provided in Section 15.7.4 (Ref. 3).

According to Reference 3 there is 23 ft of water between the damaged fuel bundle and the fuel pool surface during a fuel handling accident. In the case of a single bundle dropped and lying horizontally on top of the spent fuel racks, however, there may be < 23 ft of water above the top of the fuel bundle and the surface, indicated by the width of the bundle. This slight reduction in water depth does not adversely affect the margin of conservatism associated with the assumed pool scrubbing factor of 500 for elemental iodine.

In addition to mitigation of the effects of a fuel handling accident, the required minimum water level in the spent fuel pool provides a large capacity heat sink for spent fuel pool cooling in the event the spent fuel pool cooling system is inoperable.

The Spent Fuel Pool Water Level satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The spent fuel pool water level is required to be ≥ 23 ft over the top of irradiated fuel assemblies seated in the storage racks. The specified water level preserves the assumptions of the fuel handling accident

BASES

LCO (continued)

analysis (Ref. 3) and loss of spent fuel pool cooling. As such, it is the minimum required for fuel storage and movement within the spent fuel pool.

APPLICABILITY This LCO applies at all times since the loss of spent fuel pool cooling is not MODE dependent.

ACTIONS LCO 3.0.3 is applicable while in MODE 1, 2, 3, or 4. Since spent fuel pool cooling requirements apply at all times, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. Spent fuel pool cooling requirements are independent of reactor operations. Entering LCO 3.0.3 while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

LCO 3.0.8 is applicable while in MODE 5 or 6. Since spent fuel pool cooling requirements apply at all times, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. Spent fuel pool cooling requirements are independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

When the initial conditions for prevention of an accident cannot be met, steps should be taken to preclude the accident from occurring. When the spent fuel pool water level is lower than the required level, the movement of irradiated fuel assemblies shall be suspended. This action effectively precludes the occurrence of a fuel handling accident. This does not preclude movement of a fuel assembly to a safe position.

If moving irradiated fuel assemblies while in MODE 4, 5, or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2 and 3, the fuel movement is independent of reactor operations. Therefore, inability to suspend movement of irradiated fuel assemblies is not a sufficient reason to require a reactor shutdown.

A.2

If the water level in the spent fuel pool is < 23 ft, the heat capacity of the spent fuel pool will be less than that assumed in the event of a loss of spent fuel pool cooling. In this case, action must be initiated within 1 hour

BASES

ACTIONS (continued)

to restore the water level in the spent fuel pool to ≥ 23 ft above the top of the irradiated fuel assemblies. Initiation of this action requires that the action be continued until a water level of ≥ 23 ft is attained.

The Completion Time of 1 hour assures prompt action to compensate for a degraded condition.

SURVEILLANCE REQUIREMENTS

SR 3.7.5.1

This SR verifies sufficient spent fuel pool water is available in the event of a fuel handling accident or loss of spent fuel pool cooling. The water level in the spent fuel pool must be checked periodically. The 7 day Frequency is appropriate because the volume in the pool is normally stable. Water level changes are controlled by plant procedures and are acceptable based on operating experience.

During refueling operations, the level in the spent fuel pool is in equilibrium with the refueling canal, and the level in the refueling canal is checked daily in accordance with SR 3.9.4.1.

B 3.7 PLANT SYSTEMS

B 3.7.6 Main Control Room Emergency Habitability System (VES)

BASES

BACKGROUND

The Main Control Room Emergency Habitability System (VES) provides a protected environment from which operators can control the plant following an uncontrolled release of radioactivity, hazardous chemicals, or smoke. The system is designed to operate following a Design Basis Accident (DBA) which requires protection from the release of radioactivity. In these events, the Nuclear Island Non-Radioactive Ventilation System (VBS) would continue to function if AC power is available. If AC power is lost or a High-2 Main Control Room Envelope (MCRE) radiation signal is received, the VES is actuated. The major functions of the VES are: 1) to provide forced ventilation to deliver an adequate supply of breathable air (Ref. 4) for the MCRE occupants; 2) to provide forced ventilation to maintain the MCRE at a 1/8 inch water gauge positive pressure with respect to the surrounding areas; 3) provide passive filtration to filter contaminated air in the MCRE; and 4) to limit the temperature increase of the MCRE equipment and facilities that must remain functional during an accident, via the heat absorption of passive heat sinks.

The VES consists of compressed air storage tanks, two air delivery flow paths, an eductor, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), associated valves or dampers, piping, and instrumentation. The tanks contain enough breathable air to supply the required air flow to the MCRE for at least 72 hours. The VES system is designed to maintain CO_2 concentration less than 0.5% for up to 11 MCRE occupants.

The MCRE is the area within the confines of the MCRE boundary that contains the spaces that control room operators inhabit to control the unit during normal and accident conditions. This area encompasses the main control area, operations work area, operational break room, shift supervisor’s office, kitchen, and toilet facilities (Ref. 1). The MCRE is protected during normal operation, natural events, and accident conditions. The MCRE boundary is the combination of walls, floor, roof, electrical and mechanical penetrations, and access doors. The OPERABILITY of the MCRE boundary must be maintained to ensure that the inleakage of unfiltered air into the MCRE will not exceed the inleakage assumed in the licensing basis analysis of design basis accident (DBA) consequences to MCRE occupants. The MCRE and its boundary are defined in the Main Control Room Envelope Habitability Program.

BASES

BACKGROUND (continued)

Sufficient thermal mass exists in the surrounding concrete structure (including walls, ceiling and floors) to absorb the heat generated inside the MCRE, which is initially at or below 75°F. Heat sources inside the MCRE include operator workstations, emergency lighting and occupants. Sufficient insulation is provided surrounding the MCRE pressure boundary to preserve the minimum required thermal capacity of the heat sink. The insulation also limits the heat gain from the adjoining areas following the loss of VBS cooling.

In the unlikely event that power to the VBS is unavailable for more than 72 hours, MCRE habitability is maintained by operating one of the two MCRE ancillary fans to supply outside air to the MCRE.

The compressed air storage tanks are initially filled to contain greater than 327,574 scf of compressed air. The compressed air storage tanks, the tank pressure, and the room temperature are monitored to confirm that the required volume of breathable air is stored. During operation of the VES, a self contained pressure regulating valve maintains a constant downstream pressure regardless of the upstream pressure. An orifice downstream of the regulating valve is used to control the air flow rate into the MCRE. The MCRE is maintained at a 1/8 inch water gauge positive pressure to minimize the infiltration of airborne contaminants from the surrounding areas. The VES operation in maintaining the MCRE habitable is discussed in Reference 1.

APPLICABLE SAFETY ANALYSES

The compressed air storage tanks are sized such that the set of tanks has a combined capacity that provides at least 72 hours of VES operation.

Operation of the VES is automatically initiated by the following safety related signal: high-2 particulate or iodine radioactivity.

In the event of a loss of all AC power, the VES functions to provide ventilation, pressurization, and cooling of the MCRE pressure boundary. In the event of a high level of gaseous radioactivity outside of the MCRE, the VBS continues to operate to provide pressurization and filtration functions. The MCRE air supply downstream of the filtration units is monitored by a safety related radiation detector. Upon high-2 particulate or iodine radioactivity setpoint, a safety related signal is generated to isolate the MCRE and to initiate air flow from the VES storage tanks. Isolation of the MCRE consists of closing safety related valves in the lines that penetrate the MCRE pressure boundary. Valves in the VBS supply and exhaust ducts, and the Sanitary Drainage System (SDS) vent lines are automatically isolated. VES air flow is initiated by a safety related signal which opens the isolation valves in the VES supply lines.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The VES provides protection from smoke and hazardous chemicals to the MCRE occupants. The analysis of hazardous chemical releases demonstrates that the toxicity limits are not exceeded in the MCRE following a hazardous chemical release (Ref. 1). The evaluation of a smoke challenge demonstrates that it will not result in the inability of the MCRE occupants to control the reactor either from the control room or from the remote shutdown room (Ref. 2).

The VES functions to mitigate a DBA or transient that either assumes the failure of or challenges the integrity of the fission product barrier.

The VES satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The VES limits the MCRE temperature rise and maintains the MCRE at a positive pressure relative to the surrounding environment.

Two air delivery flow paths are required to be OPERABLE to ensure that at least one is available, assuming a single failure.

The VES is considered OPERABLE when the individual components necessary to deliver a supply of breathable air to the MCRE are OPERABLE. This includes components listed in SR 3.7.6.3 through 3.7.6.10. In addition, the MCRE pressure boundary must be maintained, including the integrity of the walls, floors, ceilings, electrical and mechanical penetrations, and access doors. The MCRE pressure boundary includes the Potable Water System (PWS) and SDS running (piping drain) traps, which retain a fluid level sufficient to maintain a seal preventing gas flow through the piping. The MCRE pressure boundary also includes the Waste Water System (WWS) drain line, which is isolated by a normally closed isolation valve.
In order for the VES to be considered OPERABLE, the MCRE boundary must be maintained such that the MCRE occupant dose from a large radioactive release does not exceed the calculated dose in the licensing basis consequence analysis for DBAs, and that MCRE occupants are protected from hazardous chemicals and smoke.

The LCO is modified by a Note allowing the MCRE boundary to be opened intermittently under administrative controls. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these

BASES

LCO (continued)

controls should be proceduralized and consist of stationing a dedicated individual at the opening who is in continuous communication with the operators in the MCRE. This individual will have a method to rapidly close the opening and to restore the MCRE boundary to a condition equivalent to the design condition when a need for MCRE isolation is indicated.

APPLICABILITY

In MODES 1, 2, 3, and 4 and during movement of irradiated fuel assemblies, the VES must be OPERABLE to ensure that the MCRE will remain habitable during and following a DBA.

The VES is not required to be OPERABLE in MODES 5 and 6 when irradiated fuel is not being moved because accidents resulting in fission product release are not postulated.

ACTIONS

LCO 3.0.8 is applicable while in MODE 5 or 6. Since irradiated fuel assembly movement can occur in MODE 5 or 6, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, the fuel movement is independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

When a VES valve, a VES damper, or a main control room boundary isolation valve is inoperable, action is required to restore the component to OPERABLE status. A Completion Time of 7 days is permitted to restore the valve or damper to OPERABLE status before action must be taken to reduce power. The Completion Time of 7 days is based on engineering judgment, considering the low probability of an accident that would result in a significant radiation release from the fuel, the low probability of not containing the radiation, and that the remaining components can provide the required capability.

B.1

When the MCRE air temperature is outside the acceptable range during VBS operation, action is required to restore it to an acceptable range. A Completion Time of 24 hours is permitted based upon the availability of temperature indication in the MCRE. It is judged to be a sufficient amount of time allotted to correct the deficiency in the nonsafety ventilation system before shutting down.

BASES

ACTIONS (continued)

C.1, C.2, and C.3

If the unfiltered inleakage of potentially contaminated air past the MCRE boundary and into the MCRE can result in MCRE occupant radiological dose greater than the calculated dose of the licensing basis analyses of DBA consequences (allowed to be up to 5 rem TEDE), or inadequate protection of MCRE occupants from hazardous chemicals or smoke, the MCRE boundary is inoperable. Actions must be taken to restore an OPERABLE MCRE boundary within 90 days.

During the period that the MCRE boundary is considered inoperable, action must be initiated to implement mitigating actions to lessen the effect on MCRE occupants from the potential hazards of a radiological or chemical event or a challenge from smoke. Actions must be taken within 24 hours to verify that in the event of a DBA, the mitigating actions will ensure that MCRE occupant radiological exposures will not exceed the calculated dose of the licensing basis analyses of DBA consequences, and that MCRE occupants are protected from hazardous chemicals and smoke. These mitigating actions (i.e., actions that are taken to offset the consequences of the inoperable MCRE boundary) should be preplanned for implementation upon entry into the condition, regardless of whether entry is intentional or unintentional. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of mitigating actions. The 90 day Completion Time is reasonable based on the determination that the mitigating actions will ensure protection of MCRE occupants within analyzed limits while limiting the probability that MCRE occupants will have to implement protective measures that may adversely affect their ability to control the reactor and maintain it in a safe shutdown condition in the event of a DBA. In addition, the 90 day Completion Time is a reasonable time to diagnose, plan and possibly repair, and test most problems with the MCRE boundary.

D.1, D.2, and D.3

If one bank of VES air tanks (8 tanks out of 32 total) is inoperable, then the VES is able to supply air to the MCRE for 54 hours (75% of the required 72 hours). If the VES is actuated, the operator must take actions to maintain habitability of the MCRE once the air in the tanks has been exhausted. The VBS supplemental filtration mode or MCRE ancillary fans are both capable of maintaining the habitability of the MCRE after 54 hours.

BASES

ACTIONS (continued)

With one bank of VES air tanks inoperable, action must be taken to restore OPERABLE status within 7 days. In this Condition, the stored amount of compressed air in the remaining OPERABLE VES air tanks must be verified within 2 hours and every 12 hours thereafter to be at least 245,680 scf. The 245,680 scf value is 75 percent of the minimum amount of stored compressed air that must be available in the compressed air storage tanks. The standard volume is determined using the compressed air storage tank room temperature (VAS-TE-080A/B), compressed air storage tanks pressure (VES-PT-001A/B), and Figure B 3.7.6-2, Compressed Air Storage Tanks Minimum Volume – One Bank of VES Air Tanks (8 Tanks) Inoperable. Values above the 245,680 scf line in the figure meet the Required Action criteria. Verification that the minimum volume of compressed air is contained in the OPERABLE compressed air storage tanks ensures a 54 hour air supply will be available if needed. Additionally, within 24 hours, the VBS ancillary fans are verified to be OPERABLE so that, if needed, can be put into use once the OPERABLE compressed air storage tanks have been exhausted. The Completion Times associated with these actions and the 7 day Completion Time to restore VES to OPERABLE are based on engineering judgment, considering the low probability of an accident that would result in a significant radiation release from the reactor core, the low probability of radioactivity release, and that the remaining components and compensatory systems can provide the required capability. The 54 hours of air in the remaining OPERABLE compressed air storage tanks, along with compensatory operator actions, are adequate to protect the main control room envelope habitability. Dose calculations verify that the MCRE dose limits will remain within the requirements of GDC 19 with the compensatory actions taken at 54 hours.

E.1 and E.2

In MODE 1, 2, 3, or 4 if the Required Actions and Completion Times of Conditions A, B, C, or D are not met, or the VES is inoperable for reasons other than Conditions A, B, C, or D, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours.

BASES

ACTIONS (continued)

F.1

During movement of irradiated fuel assemblies, if the Required Actions and Completion Times of Conditions A, B, C, or D are not met, or the VES is inoperable for reasons other than Conditions A, B, C, or D, or the VES is inoperable due to an inoperable MCRE boundary, action must be taken immediately to suspend the movement of fuel. This does not preclude the movement of fuel to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.7.6.1

The MCRE air temperature is checked at a frequency of 24 hours to verify that the VBS is performing as required to maintain the initial condition temperature assumed in the safety analysis, and to ensure that the MCRE temperature will not exceed the required conditions after loss of VBS cooling. The surveillance limit of 75°F is the initial heat sink temperature assumed in the VES thermal analysis. The 24 hour Frequency is acceptable based on the availability of temperature indication in the MCRE.

SR 3.7.6.2

Verification every 24 hours that compressed air storage tanks contain greater than 327,574 scf of breathable air.

The standard volume is determined using the compressed air storage tank room temperature (VAS-TE-080A/B), compressed air storage tanks pressure (VES-PT-001A/B), and Figure B 3.7.6-1, Compressed Air Storage Tanks Minimum Volume. Values above the 327,574 scf line in the figure meet the surveillance criteria. Verification that the minimum volume of compressed air is contained in the compressed air storage tanks ensures that there will be an adequate supply of breathable air to maintain MCRE habitability for a period of 72 hours. The Frequency of 24 hours is based on the availability of pressure indication in the MCRE.

SR 3.7.6.3

VES air delivery isolation valves are required to be verified as OPERABLE. The Frequency required is in accordance with the Inservice Testing Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.6.4

Standby systems should be checked periodically to ensure that they function properly. As the environment and normal operating conditions on this system are not too severe, testing VES once every month provides an adequate check of the system. The 31 day Frequency is based on the reliability of the equipment and the availability of system redundancy.

SR 3.7.6.5

VES air header isolation valves are required to be verified open at 31 day intervals. This SR is designed to ensure that the pathways for supplying breathable air to the MCRE are available should loss of VBS occur. These valves should be closed only during required testing or maintenance of downstream components, or to preclude complete depressurization of the system should the VES isolation valves in the air delivery line open inadvertently or begin to leak.

SR 3.7.6.6

Verification that the air quality of the air storage tanks meets the requirements of Appendix C, Table C-1 of ASHRAE Standard 62 is required every 92 days. If air has not been added to the air storage tanks since the previous verification, verification may be accomplished by confirmation of the acceptability of the previous surveillance results along with examination of the documented record of air makeup. The purpose of ASHRAE Standard 62 states: “This standard specifies minimum ventilation rates and indoor air quality that will be acceptable to human occupants and are intended to minimize the potential for adverse health effects.” Verification of the initial air quality (in combination with the other surveillances) ensures that breathable air is available for 11 MCRE occupants for at least 72 hours.

SR 3.7.6.7

Verification that the VBS isolation valves and the Sanitary Drainage System (SDS) isolation valves are OPERABLE and will actuate upon demand is required every 24 months to ensure that the MCRE can be isolated upon loss of VBS operation.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.6.8

Verification that each VES pressure relief isolation valve within the MCRE pressure boundary is OPERABLE is required in accordance with the Inservice Testing Program. The SR is used in combination with SR 3.7.6.9 to ensure that adequate vent area is available to mitigate MCRE overpressurization.

SR 3.7.6.9

Verification that the VES pressure relief damper is OPERABLE is required at 24 month intervals. The SR is used in combination with SR 3.7.6.8 to ensure that adequate vent area is available to mitigate MCRE overpressurization.

SR 3.7.6.10

Verification of the OPERABILITY of the self-contained pressure regulating valve in each VES air delivery flow path is required in accordance with the Inservice Testing Program. This is done to ensure that a sufficient supply of air is provided as required, and that uncontrolled air flow into the MCRE will not occur.

SR 3.7.6.11

This SR verifies the OPERABILITY of the MCRE boundary by testing for unfiltered air inleakage past the MCRE boundary and into the MCRE. The details of the testing are specified in the Main Control Room Envelope Habitability Program.

The MCRE is considered habitable when the radiological dose to MCRE occupants calculated in the licensing basis analyses of DBA consequences is no more than 5 rem TEDE and the MCRE occupants are protected from hazardous chemicals and smoke. This SR verifies that the unfiltered air inleakage into the MCRE is no greater than the flow rate assumed in the licensing basis analyses of DBA consequences. When unfiltered air inleakage is greater than the assumed flow rate, Condition C must be entered. Required Action C.3 allows time to restore the MCRE boundary to OPERABLE status provided mitigating actions can ensure that the MCRE remains within the licensing basis habitability limits for the occupants following an accident. Compensatory measures are discussed in Regulatory Guide 1.196, Section C.2.7.3 (Ref. 3) which endorses, with exceptions, NEI 99-03, Section 8.4 and Appendix F (Ref. 5). These compensatory measures may also be used as mitigating

BASES

SURVEILLANCE REQUIREMENTS (continued)

actions as required by Required Action C.2. Temporary analytical methods may also be used as compensatory measures to restore OPERABILITY (Ref. 6). Options for restoring the MCRE boundary to OPERABLE status include changing the licensing basis DBA consequence analysis, repairing the MCRE boundary, or a combination of these actions. Depending upon the nature of the problem and the corrective action, a full scope inleakage test may not be necessary to establish that the MCRE boundary has been restored to OPERABLE status.

SR 3.7.6.12

This SR verifies that the required VES testing is performed in accordance with the Ventilation Filter Testing Program (VFTP). The VES filter tests are in accordance with Regulatory Guide 1.52 (Ref. 7). The VFTP includes testing the performance of the HEPA filter, charcoal adsorber efficiency, minimum flow rate, and physical properties of the activated charcoal. Specific test frequencies and additional information are discussed in detail in the VFTP.

Compressed Air Storage Tanks Minimum Volume – One Bank of VES Air Tanks (8 Tanks) Inoperable

B 3.7 PLANT SYSTEMS

B 3.7.7 Startup Feedwater Isolation and Control Valves

BASES

BACKGROUND

The startup feedwater system supplies feedwater to the steam generators during plant startup, hot standby and cooldown, and in the event of main feedwater unavailability.

The startup feedwater system serves no safety related function and has no safety related design basis, except to isolate feedwater in the event of a feedwater, steam line break, a steam generator tube rupture or other secondary side event.

The startup feedwater system consists of a flow path to each of the steam generators. Each flow path consists of two series startup feedwater valves to provide feedwater control for low feedwater demand conditions. Feedwater can be supplied to the startup feedwater line via either the main or startup feedwater pumps. The feedwater is delivered directly to the SG independent of the main feedwater line. Each startup feedwater line contains one control valve and one isolation valve (Ref. 1).

APPLICABLE SAFETY ANALYSES

The basis for the requirement to isolate the startup feedwater system is established by the analysis for large Steam Line Break (SLB) inside containment. It is also based on the analysis for a large Feedline Break (FLB) and a steam generator tube rupture.

Failure to isolate the startup feedwater system following a SLB or FLB can lead to additional mass and energy being delivered to the steam generators, resulting in excessive cooldown and additional mass and energy release in containment. Failure to isolate the startup feedwater following a steam generator tube rupture may result in overfilling the steam generator.

Low T_{cold} or high steam generator level signals close the startup feedwater control and isolation valves and trips the startup feedwater pumps.

The startup feedwater isolation and control valves are components which actuate to mitigate a Design Basis Accident, and as such meet Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

This LCO ensures that the startup feedwater isolation and control valves will actuate on command, following a SLB, FLB or SGTR, and isolate startup feedwater flow to the steam generators.

The startup feedwater isolation and control valves are considered OPERABLE when they automatically close on an isolation actuation signal, and their isolation times are within the required limits.

APPLICABILITY

The startup feedwater isolation and control valves must be OPERABLE whenever there is significant mass and energy in the Reactor Coolant System and the steam generators. In MODES 1, 2, 3 and 4, the startup feedwater isolation and control valves are required to be OPERABLE in order to limit the amount of mass and energy that could be added to containment in the event of a SLB or FLB and prevent steam generator overfill in the event of an SGTR. When the valves are closed, they are already performing their safety function.

In MODES 5 and 6, the energy in the steam generators is low, and isolation of the startup feedwater system is not required.

ACTIONS

The ACTIONS are modified by a Note allowing flow paths to be unisolated intermittently under administrative controls. These controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the flow paths can be rapidly isolated.

The second Note allows separate Condition entry for each flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable flow path.

A.1 and A.2

With only one isolation or control valve OPERABLE in one or more flow paths, there is no redundant capability to isolate the flow paths. In this case, both an isolation and a control valve in each flow path must be restored to OPERABLE status with 72 hours, or the flow path must be isolated. A Completion Time of 72 hours is acceptable since, with one valve in a flow path inoperable, there is a second valve available in the flow path to isolate the line.

BASES

ACTIONS (continued)

If the inoperable valve in the flow path can not be restored to OPERABLE status, then the flow path must be isolated within a Completion Time of 72 hours. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure.

For flow paths isolated in accordance with Required Action A.2.1, the affected flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that flow paths required to be isolated following an accident will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification, through a system walkdown, that the isolation devices are in the correct position. The Completion Time of “once per 7 days” is appropriate considering the fact that the devices are operated under administrative controls, valve status indications in the main control room and the probability of their misalignment is low.

B.1

With both the isolation and control valves inoperable in one flow path, the affected flow path must be restored to OPERABLE status or isolated within a Completion Time of 8 hours. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure.

C.1, C.2, and C.3

If the isolation and control valves cannot be restored to OPERABLE status, closed, or isolated within the associated Completion Times, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the plant must be placed in least MODE 3 within 6 hours, and in MODE 4 with RCS cooling provided by the normal residual heat removal system within 24 hours, and the affected flow path isolated within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.7.7.1

This surveillance requires verification in accordance with the Inservice Testing Program to assure that both startup feedwater isolation and control valves are OPERABLE. The Surveillance Frequency is provided in the Inservice Testing Program.

1. Section 10.4.9, “Startup Feedwater System.”

B 3.7 PLANT SYSTEMS

B 3.7.8 Main Steam Line Leakage

BASES

BACKGROUND

A limit on leakage from the main steam line inside containment is required to limit system operation in the presence of excessive leakage. Leakage is limited to an amount which would not compromise safety consistent with the Leak-Before-Break (LBB) analysis discussed in Chapter 3 (Ref. 1). This leakage limit ensures appropriate action can be taken before the integrity of the lines is impaired.

LBB is an argument which allows elimination of design for dynamic load effects of postulated pipe breaks. The fundamental premise of LBB is that the materials used in nuclear plant piping are strong enough that even a large throughwall crack leaking well in excess of rates detectable by present leak detection systems would remain stable, and would not result in a double-ended guillotine break under maximum loading conditions. The benefit of LBB is the elimination of pipe whip restraints, jet impingement effects, subcompartment pressurization, and internal system blowdown loads.

As described in Section 3.6 (Ref. 1), LBB has been applied to the main steam line pipe runs inside containment. Hence, the potential safety significance of secondary side leaks inside containment requires detection and monitoring of leakage inside containment. This LCO protects the main steam lines inside containment against degradation, and helps assure that serious leaks will not develop. The consequences of violating this LCO include the possibility of further degradation of the main steam lines, which may lead to pipe break.

APPLICABLE SAFETY ANALYSES

The safety significance of plant leakage inside containment varies depending on its source, rate, and duration. Therefore, detection and monitoring of plant leakage inside containment are necessary. This is accomplished via the instrumentation required by LCO 3.4.9, “RCS Leakage Detection Instrumentation,” and the Reactor Coolant System (RCS) water inventory balance (SR 3.4.7.1). Subtracting RCS leakage as well as any other identified non-RCS leakage into the containment area from the total plant leakage inside containment provides qualitative information to the operators regarding possible main steam line leakage. This allows the operators to take corrective action should leakage occur which is detrimental to the safety of the facility and/or the public.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Although the main steam line leakage limit is not required by the 10 CFR 50.36(c)(2)(ii) criteria, this specification has been included in Technical Specifications in accordance with NRC direction (Ref. 2).

LCO

Main steam line leakage is defined as leakage inside containment in any portion of the two (2) main steam line pipe walls. Up to 0.5 gpm of leakage is allowable because it is below the leak rate for LBB analyzed cases of a main steam line crack twice as long as a crack leaking at ten (10) times the detectable leak rate under normal operating load conditions. Violation of this LCO could result in continued degradation of the main steam line.

APPLICABILITY

Because of elevated main steam system temperatures and pressures, the potential for main steam line leakage is greatest in MODES 1, 2, 3, and 4.

In MODES 5 and 6, a main steam line leakage limit is not provided because the main steam system pressure is far lower, resulting in lower stresses and a reduced potential for leakage. In addition, the steam generators are not the primary method of RCS heat removal in MODES 5 and 6.

ACTIONS

A.1 and A.2

With main steam line leakage in excess of the LCO limit, the unit must be brought to lower pressure conditions to reduce the severity of the leakage and its potential consequences. The reactor must be placed in MODE 3 with 6 hours and MODE 5 within 36 hours. This action reduces the main steam line pressure and leakage, and also reduces the factors which tend to degrade the main steam lines. The Completion Time of 6 hours to reach MODE 3 from full power without challenging plant systems is reasonable based on operating experience. Similarly, the Completion Time of 36 hours to reach MODE 5 without challenging plant systems is also reasonable based on operating experience. In MODE 5, the pressure stresses acting on the main steam line are much lower, and further deterioration of the main steam line is less likely.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.7.8.1

Verifying that main steam line leakage is within the LCO limit assures the integrity of those lines inside containment is maintained. An early warning of main steam line leakage is provided by the automatic system which monitor the containment sump level. Main steam line leakage would appear as unidentified leakage inside containment via this system, and can only be positively identified by inspection. However, by performance of an RCS water inventory balance (SR 3.4.7.1) and evaluation of the cooling and chilled water systems inside containment, determination of whether the main steam line is a potential source of unidentified leakage inside containment is possible.

B 3.7 PLANT SYSTEMS

B 3.7.9 Fuel Storage Pool Makeup Water Sources

BASES

BACKGROUND

The spent fuel storage pool is normally cooled by the nonsafety spent fuel pool cooling system. In the event the normal cooling system is unavailable, the spent fuel storage pool can be cooled by the normal residual heat removal system. Alternatively, the spent fuel storage pool contains sufficient water inventory for decay heat removal by boiling. To support extended periods of loss of normal pool cooling, makeup water is required to provide additional cooling by boiling. Both safety and non-safety makeup water sources are available on-site.

Three safety-related, gravity fed sources of makeup water are provided to the spent fuel storage pool. These makeup water sources contain sufficient water to maintain spent fuel storage pool cooling for 72 hours. When the spent fuel storage pool decay heat is > 4.7 MWt and ≤ 7.2 MWt, the cask washdown pit must be available to provide makeup to the spent fuel storage pool. When the spent fuel storage pool decay heat is > 5.6 MWt and ≤ 7.2 MWt both the cask washdown pit and the cask loading pit must be available to provide makeup to the spent fuel storage pool. When the spent fuel storage pool decay heat is > 7.2 MWt and the reactor decay heat is ≤ 6.0 MWt, the Passive Containment Cooling Water Storage Tank (PCCWST) must be available to provide makeup water to the spent fuel storage pool (when the tank is no longer required for containment cooling purposes). Additional on-site makeup water sources are available to provide spent fuel storage pool cooling between 3 and 7 days.

The PCCWST is isolated by two normally closed valves. The normally closed valves will be opened only to provide emergency makeup to the spent fuel storage pool. A third downstream valve permits the operator to regulate addition of water to the spent fuel storage pool as required to maintain the cooling water inventory.

Once decay heat in the spent fuel storage pool is reduced to at or below 4.7 MWt, the spent fuel storage pool water inventory is sufficient, without makeup, to maintain the spent fuel storage pool for 72 hours. When the spent fuel storage pool decay heat load is ≤ 5.6 MWt for the cask loading pit and ≤ 4.7 MWt for the cask washdown pit, the pits are no longer required to be OPERABLE for spent fuel storage pool makeup.

A general description of the spent fuel storage pool design is given in Section 9.1.2 (Ref. 1). A description of the Spent Fuel Pool Cooling and Cleanup System is given in Section 9.1.3 (Ref. 2).

BASES

APPLICABLE SAFETY ANALYSES

In the event the normal spent fuel storage pool cooling system is unavailable, the spent fuel cooling is provided by the heat capacity of the water in the pool. The worst case decay heat load (decay heat > 7.2 MWt) is produced by an emergency full core off-load following a refueling plus ten years of spent fuel. For this case the spent fuel storage pool inventory provided by the water over the stored fuel and below the pump suction connection is capable of cooling the spent fuel storage pool without boiling for at least 2.5 hours, following a loss of normal spent fuel storage pool cooling. After boiling starts, makeup water may be required to replace water lost by boiling and is available, without offsite support, via the PCCWST.

The requirements of LCO 3.6.6, “Passive Containment Cooling System – Operating,” are applicable in MODES 1, 2, 3, and 4 and LCO 3.6.7, “Passive Containment Cooling System – Shutdown,” are applicable in MODES 5 and 6 with reactor decay heat > 6.0 MWt. LCOs 3.6.6 and 3.6.7 require availability of the containment cooling water tank for containment heat removal. At or below 6.0 MWt reactor decay heat, containment air cooling is adequate.

Since none of the Chapter 15 Design Basis Accident analyses assume availability of the PCCWST, the cask washdown pit, or the cask loading pit for spent fuel storage pool makeup, the spent fuel storage pool makeup water sources specification does not satisfy any of the 10 CFR 50.36(c)(2)(ii) criteria. This LCO is included in accordance with NRC guidance provided in an NRC letter (Reference 3).

LCO

The spent fuel storage pool makeup water sources are required to contain the following amount of water to be considered OPERABLE:

- Cask washdown pit water level must be ≥ 13.75 ft.
- Cask loading pit water level must be ≥ 43.9 ft.
- PCCWST is required to contain 756,700 gallons of water.

An OPERABLE flow path from the required makeup source assures spent fuel cooling for at least 72 hours. Several additional makeup sources are available, including the ground level PCCAWST. These makeup sources assure spent fuel cooling for at least 7 days.

Note 1 specifies that the cask washdown pit is required to be OPERABLE when the spent fuel storage pool decay heat is > 4.7 MWt and ≤ 7.2 MWt.

BASES

LCO (continued)

Note 2 specifies that the cask loading pit is required to be OPERABLE when the spent fuel storage pool decay heat is > 5.6 MWt and ≤ 7.2 MWt.

Note 3 specifies that the PCCWST is required to be OPERABLE when the spent fuel storage pool decay heat is > 7.2 MWt, which is normal following a full core off load. The larger makeup source is necessary for the higher decay heat load. In MODE 5 and 6, with the calculated reactor decay heat > 6.0 MWt, the PCCWST is reserved for containment cooling in accordance with LCO 3.6.7, Passive Containment Cooling System (PCS) – Shutdown. Thus, fuel movement from the reactor to the spent fuel storage pool must be suspended until reactor decay heat is ≤ 6.0 MWt if the fuel movement will increase the spent fuel storage pool decay heat to > 7.2 MWt.

When a portion of the fuel is returned to the reactor vessel in preparation for startup, the pool decay heat is reduced to ≤ 5.6 MWt and makeup from the cask washdown pit is sufficient.

APPLICABILITY

This LCO applies during storage of fuel in the spent fuel storage pool with a calculated decay heat > 4.7 MWt. With decay heat ≤ 4.7 MWt, the assumed spent fuel storage pool water inventory (i.e., level below the pump suction connection to the pool) provides for 3 days of cooling without makeup.

ACTIONS

LCO 3.0.3 is applicable while in MODE 1, 2, 3, or 4. Since spent fuel pool cooling requirements apply at all times, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. Spent fuel pool cooling requirements are independent of reactor operations. Entering LCO 3.0.3 while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

LCO 3.0.8 is applicable while in MODE 5 or 6. Since spent fuel pool cooling requirements apply at all times, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. Spent fuel pool cooling requirements are independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

If the cask washdown pit (with spent fuel storage pool decay heat > 4.7 and ≤ 7.2 MWt), the cask loading pit (with spent fuel storage pool decay heat > 5.6 MWt and ≤ 7.2 MWt) or the PCCWST (with spent fuel storage

BASES

ACTIONS (continued)

pool decay heat > 7.2 MWt) is inoperable, Action must be initiated immediately to restore the makeup source or its associated flow path to OPERABLE status.

Additionally, in order to provide the maximum cooling capability, the spent fuel pool should be filled to its maximum level. Nonsafety related makeup sources can be used to fill the pool. This action is not specified in the specification, since the benefit of adding approximately 6 inches of water to the pool is less than a 5% improvement in cooling capability.

SURVEILLANCE REQUIREMENTS

SR 3.7.9.1

This SR verifies that the three flow paths from the PCCWST to the containment vessel are isolated and secured to prevent inadvertent opening and loss of required tank volume. The verification is required to be performed prior to declaring the PCCWST OPERABLE for spent fuel storage pool usage.

The 7 day Frequency is appropriate because the valves in the passive containment cooling system are controlled by plant procedures.

SR 3.7.9.2

This SR verifies sufficient PCCWST volume is available in the event of a loss of spent fuel cooling prior to declaring the tank OPERABLE for spent fuel storage pool usage.

The 7 day Frequency is appropriate because the volume in the PCCWST is normally stable and water level changes are controlled by plant procedures.

SR 3.7.9.3

This SR verifies sufficient cask washdown pit water volume is available in the event of a loss of spent fuel cooling. The 13.75 ft level specified provides makeup water for stored fuel with decay heat > 4.7 and ≤ 7.2 MWt. The cask washdown pit is no longer required when the PCCWST is OPERABLE for spent fuel storage pool usage.

The 31 day Frequency is appropriate because the cask washdown pit has only one drain line which is isolated by series manual valves which are only operated in accordance with plant procedures, thus providing assurance that inadvertent level reduction is not likely.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.9.4

This SR verifies sufficient cask loading pit water volume is available and connected to the spent fuel pool such that no action is required in the fuel handling area, in the event of a loss of spent fuel cooling. The 43.9 foot level specified provides makeup water for stored fuel with decay heat > 5.6 and ≤ 7.2 MWt. The cask loading pit is no longer required when the PCCWST is OPERABLE for spent fuel storage pool usage.

The 31 day Frequency is appropriate because the cask loading pit has only one drain line, which is isolated by series manual valves, which are operated only in accordance with plant procedures. This provides assurance that inadvertent level reduction is not likely.

SR 3.7.9.5

This SR requires verification of the OPERABILITY of the manual makeup water source isolation valves in accordance with the requirements and Frequency specified in the Inservice Testing Program. Manual valves PCS-PL-V009, PCS-PL-V045, PCS-PL-V051, isolate the makeup flow path from the PCCWST. Manual valves SFS-PL-V042, SFS-PL-V045, SFS-PL-V049, SFS-PL-V066, and SFS-PL-V068 isolate the makeup flow path from the cask washdown pit.

B 3.7 PLANT SYSTEMS

B 3.7.10 Steam Generator Isolation Valves

BASES

BACKGROUND

The steam generator isolation valves consist of the power operated relief valve (PORV) block valves (SGS-PL-V027A & B), PORVs (SGS-PL-V233A & B), and blowdown isolation valves (SGS-PL-V074A & B and SGS-PL-V075A & B). The PORV flow paths must be isolated following a Steam Generator Tube Rupture (SGTR) to minimize radiological releases. The blowdown flow path must be isolated following Loss of Feedwater and Feedwater Line Break events to retain the steam generator water inventory for Reactor Coolant System (RCS) heat removal.

A PORV is installed in a 6 inch branch line off of the main steam line piping from each steam generator, to provide for controlled removal of reactor decay heat during normal reactor cooldown when the main steam isolation valves are closed or the turbine bypass system is not available. A normally-open block valve is provided in each PORV line to provide backup isolation capability. Both the PORV and the block valve receive a Protection and Safety Monitoring System (PMS) isolation signal on low steam line pressure. The block valve is also a containment isolation valve.

The blowdown line from each steam generator is provided with two series isolation valves, both located outside, but close to, containment. The blowdown valves receive a PMS isolation signal on low SG level and on Passive Residual Heat Removal (PRHR) actuation. The first blowdown isolation valve outside of containment is also a containment isolation valve.

The steam generator PORVs and the blowdown isolation valves fail closed on loss of control or actuation power. The steam generator PORV block valves fail as-is on loss of control or actuation power. The steam generator isolation valves may also be actuated manually.

Descriptions of the PORVs and SG blowdown isolation are found in Section 10.3.2.2.3 and Section 10.4.8 (Refs. 1 & 2).

APPLICABLE SAFETY ANALYSES

The PORV flow paths must be isolated following an SGTR to minimize radiological releases from the ruptured steam generator into the atmosphere. The PORV flow path is assumed to open due to high secondary side pressure, during the SGTR. Dose analyses take credit for subsequent isolation of the PORV flow path by the PORV and/or the block valve which receive a close signal on low steam line pressure.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The blowdown flow path on each SG must be isolated following Loss of Feedwater and Feedwater Line Break events to retain the steam generator water inventory for use in Reactor Coolant System (RCS) heat removal via the SGs. RCS heat removal for these events is, primarily, provided by the Passive Residual Heat Removal Heat Exchanger (PRHR HX); however, the SG heat removal is assumed. The SG blowdown isolation valves receive an isolation signal on low SG level or PRHR actuation. These events take credit for steam generator heat removal using the water inventory retained after blowdown isolation. If the blowdown line were not isolated, much of the inventory would drain from the SG rather than cool the RCS.

The steam generator isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that the steam generator isolation valves consisting of the PORV, PORV block valve, and blowdown isolation valves on each steam generator to be OPERABLE. These isolation valves are considered OPERABLE when the valves are capable of closing on a PMS actuation signal.

This LCO provides assurance that the PORV and PORV block valve will perform their design safety function to mitigate the consequences of an SGTR that could result in offsite exposures.

Additionally, this LCO provides assurance that the steam generator blowdown isolation valves will perform their design safety function to mitigate the consequences of Loss of Feedwater and Feedwater Line Break events by retaining the steam generator water inventory for Reactor Coolant System (RCS) heat removal.

APPLICABILITY

The steam generator isolation valves must be OPERABLE in MODES 1, 2, and 3, and in MODE 4 with the RCS cooling not being provided by the Normal Residual Heat Removal System (RNS).

In MODE 4 with the RCS cooling being provided by the RNS and in MODES 5 and 6, the steam generators are not needed for RCS cooling and the potential for an SGTR or Loss of Feedwater and Feedwater Line Break events is minimized due to the reduced mass and energy in the RCS and steam generators.

BASES

ACTIONS

The ACTIONS are modified by a Note allowing the blowdown isolation flow paths to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the flow path can be rapidly isolated when a need for blowdown isolation is indicated.

The second Note allows separate Condition entry for each steam generator isolation flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable flow path.

A.1

With one valve in one or more PORV flow paths inoperable, action must be taken to isolate the flow path with a closed and deactivated valve. The valve must be deactivated to assure that the flow path will not be opened by a high pressure signal during the course of an SGTR event. This action places the flow path in a condition which assures the safety function is performed. A Completion Time of 72 hours is based on the availability of one OPERABLE PORV flow path isolation valve which is fully capable of performing the required isolation function.

B.1 and B.2

With one valve in one or more blowdown flow paths inoperable, action must be taken to isolate the flow path with a closed valve. This action places the flow path in a condition which assures the safety function is performed. A Completion Time of 72 hours to isolate the flow path is based on the availability of one OPERABLE blowdown flow path isolation valve which is fully capable of performing the required isolation function.

Since the blowdown isolation valve is not deactivated, periodic verification is required to assure that the flow path remains isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of status indications available in the control room, and other administrative controls, to ensure that the valve remains in the closed position.

C.1

With both valves in one or more PORV flow paths inoperable, action must be taken to isolate the flow path with a closed and deactivated valve. The valve must be deactivated to assure that the flow path will not be opened by a high pressure signal during the course of an SGTR event. This

ACTIONS (continued)

action places the flow path in a condition which assures the safety function is performed. The 8 hour Completion Time is reasonable, considering the low probability of an accident occurring during this time period that would require a closure of the SG isolation valves. The incremental conditional core damage probability with this AOT is more than an order of magnitude less than the value indicated to have a small impact on plant risk in Reference 3.

D.1 and D.2

With two valves in one or more blowdown flow paths inoperable, action must be taken to isolate the flow path with a closed valve. This action places the flow path in a condition which assures the safety function is performed. The 8 hour Completion Time is reasonable, considering the low probability of an accident occurring during this time period that would require a closure of the SG isolation valves. The incremental conditional core damage probability with this AOT is more than an order of magnitude less than the value indicated to have a small impact on plant risk in Reference 3.

Since the blowdown isolation valve is not deactivated, periodic verification is required to assure that the flow path remains isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of status indications available in the control room, and other administrative controls, to ensure that the valve remains in the closed position.

E.1 and E.2

If the SG isolation valves cannot be restored to OPERABLE status or are not closed within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed at least in MODE 3 within 6 hours, and in MODE 4 with the RCS cooling provided by the RNS within 24 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions in an orderly manner and without challenging unit systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.7.10.1

The function of the SG isolation valves (PORV block valves (SGS-PL-V027A & B), PORVs (SGS-PL-V233A & B) and blowdown isolation valves (SGS-PL-V074A & B and SGS-PL-V075A & B)) is to isolate the steam generators in the event of SGTR, Loss of Feedwater or Feedwater Line Break. Stroking the valves closed demonstrates their capability to perform the isolation function. The Frequency for this SR is in accordance with the Inservice Testing Program.

B 3.7 PLANT SYSTEMS

B 3.7.11 Fuel Storage Pool Boron Concentration

BASES

BACKGROUND

The water in the spent fuel storage pool normally contains soluble boron, which would result in large subcriticality margins under actual operating conditions. For storage of fuel in the spent fuel racks, the design basis for preventing criticality outside the reactor is that there is a 95 percent probability at a 95 percent confidence level, without soluble boron, that the effective multiplication factor (k_{eff}) of the fuel assembly array will be less than 0.997, including uncertainties and tolerances. The NRC guidelines specify a limiting k_{eff} of 1.0 for normal storage in the absence of soluble boron. Therefore, the design is based on the use of unborated water, which maintains a subcritical condition (Ref. 1). The double contingency principle discussed in ANSI N-16.1-1975 and the April 1978 NRC letter (Ref. 2) allows credit for soluble boron under other abnormal or accident conditions, since only a single independent accident need be considered at one time. For example, the only accident scenario that has a potential for more than negligible positive reactivity effect is an inadvertent misplacement of a new fuel assembly. This accident has the potential for exceeding the limiting reactivity, should there be a concurrent and independent accident condition resulting in the loss of all soluble poison. To mitigate these postulated criticality related accidents, boron is dissolved in the pool water. Safe operation with unborated water and no movement of assemblies may, therefore, be achieved by controlling the location of each assembly in accordance with LCO 3.7.12, “Spent Fuel Pool Storage.” Prior to movement of an assembly, it is necessary to perform SR 3.7.12.1.

APPLICABLE SAFETY ANALYSES

Although credit for the soluble boron normally present in the spent fuel pool water is permitted under abnormal or accident conditions, most abnormal or accident conditions will not result in exceeding the limiting reactivity even in the absence of soluble boron. The effects on reactivity of credible abnormal and accident conditions due to temperature increase, assembly dropped on top of a rack, and misplacement/misloading of a fuel assembly have been analyzed. The reactivity effects of bulk spent fuel pool temperature increase (>140°F) and steaming from the pool water surface or intramodule water gap reductions between the firmly interconnected cell and module arrays due to a seismic event are bounded by the fuel mishandling/misloading reactivity increases and therefore assessed as negligible. The spent fuel pool k_{eff} storage limit of 0.95 is maintained during these events by a minimum boron concentration of greater than or equal to 800 ppm

BASES

APPLICABLE SAFETY ANALYSES (continued)

established by criticality analysis (Ref. 3). Compliance with the LCO minimum boron concentration limit of 2300 ppm ensures that the credited concentration is always available.

The concentration of dissolved boron in the fuel storage pool satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The fuel storage pool boron concentration is required to be ≥ 2300 ppm. The specified concentration of dissolved boron in the fuel storage pool preserves the assumptions used in the analyses of the potential critical accident scenarios as described in References 1 and 3. This concentration of dissolved boron is the minimum required concentration for fuel assembly storage and movement within the fuel storage pool.

APPLICABILITY

This LCO applies whenever fuel assemblies are stored in the spent fuel storage pool and a fuel storage pool verification has not been performed since the last movement of fuel assemblies in the fuel storage pool.

ACTIONS

LCO 3.0.3 is applicable while in MODE 1, 2, 3, or 4. Since spent fuel pool cooling requirements apply in all MODES when fuel is stored in the spent fuel storage pool, the ACTIONS have been modified by the Note stating that LCO 3.0.3 is not applicable. Spent fuel pool boron concentration requirements are independent of reactor operations. Entering LCO 3.0.3 while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

LCO 3.0.8 is applicable while in MODE 5 or 6. Since spent fuel pool cooling requirements apply in all MODES when fuel is stored in the spent fuel storage pool, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. Spent fuel pool boron concentration requirements are independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

BASES

ACTIONS (continued)

A.1, A.2.1, and A.2.2

When the concentration of boron in the fuel storage pool is less than required, immediate action must be taken to preclude the occurrence of an accident or to mitigate the consequences of an accident in progress. This is most efficiently achieved by immediately suspending the movement of fuel assemblies. The concentration of boron is restored simultaneously with suspending movement of fuel assemblies. An acceptable alternative is to verify by administrative means that the fuel storage pool verification has been performed since the last movement of fuel assemblies in the fuel storage pool. However, prior to resuming movement of fuel assemblies, the concentration of boron must be restored. This does not preclude movement of a fuel assembly to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.7.11.1

This SR verifies that the concentration of boron in the fuel storage pool is within the required limit. As long as this SR is met, the analyzed accidents are fully addressed. The 7 day Frequency is appropriate because no major replenishment of pool water is expected to take place over such a short period of time.

B 3.7 PLANT SYSTEMS

B 3.7.12 Spent Fuel Pool Storage

BASES

BACKGROUND

The high density spent fuel storage racks are divided into two separate and distinct regions and include locations for storage of defective fuel as shown in Figure 4.3-1. Region 1, with a maximum of 243 storage locations and the Defective Fuel Cells, with 5 storage locations are designed to accommodate new fuel assemblies with a maximum enrichment of 4.95 weight percent U-235, or spent fuel assemblies regardless of the combination of initial enrichment and burnup. Region 2, with a maximum of 641 storage locations is designed to accommodate spent fuel assemblies in all locations which comply with the combination of initial enrichment and burnup specified in LCO Figure 3.7.12-1, Minimum Fuel Assembly Burnup Versus Initial Enrichment for Region 2 Spent Fuel Cells. Use of the IFE fuel rod storage canister is subject to the same storage requirements as the fuel assemblies.

The water in the spent fuel storage pool normally contains soluble boron, which would result in large subcriticality margins under actual operating conditions. For storage of fuel in the spent fuel racks, the design basis for preventing criticality outside the reactor is that there is a 95 percent probability at a 95 percent confidence level, without soluble boron, that the effective multiplication faction (k_{eff}) of the fuel assembly array will be less than 0.997, including uncertainties and tolerances. The NRC guidelines specify a limiting k_{eff} of 1.0 for normal storage in the absence of soluble boron. Hence, the design is based on the use of unborated water, which maintains a subcritical condition for the allowed loading patterns.

The double contingency principle discussed in ANSI N-16.1-1975 and the April 1978 NRC letter (Ref. 1) allows credit for soluble boron under other abnormal and accident conditions, since only a single independent accident need be considered at one time. For example, the only accident scenario that has the potential for more than negligible positive reactivity effect is an inadvertent misplacement of a new fuel assembly. This accident has the potential for exceeding the limiting reactivity, should there be a concurrent and independent accident condition resulting in the loss of all soluble poison. To mitigate these postulated criticality related accidents, boron is dissolved in the pool water. Safe operation with unborated water and no movement of assemblies may, therefore, be achieved by controlling the combination of initial enrichment and burnup in accordance with the accompanying LCO. Prior to movement of an assembly, it is necessary to perform SR 3.7.12.1.

BASES

APPLICABLE SAFETY ANALYSES

The hypothetical accidents can only take place during or as a result of the movement of an assembly (Refs. 2 and 3). For these accident occurrences, the presence of soluble boron in the spent fuel storage pool (controlled by LCO 3.7.11, “Fuel Storage Pool Boron Concentration”) prevents criticality. By closely controlling the movement of each assembly and by checking the location of each assembly after movement, the time period for potential accidents may be limited to a small fraction of the total operating time. During the remaining time period with no potential for accidents, the operation may be under the auspices of the accompanying LCO.

The configuration of fuel assemblies in the fuel storage pool satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The restrictions on the placement of fuel assemblies within Region 2 of the spent fuel pool in the accompanying LCO, ensure the k_{eff} of the spent fuel storage pool will always remain < 0.997, assuming the pool to be flooded with unborated water and ≤ 0.95, with a boron concentration of greater than or equal to 800 ppm.

Region 2 permits storage of spent fuel assemblies in any cell location provided the assembly meets the combination of initial enrichment and burnup shown in LCO Figure 3.7.12-1, Minimum Fuel Assembly Burnup Versus Initial Enrichment for Region 2 Spent Fuel Cells.

APPLICABILITY

This LCO applies whenever any fuel assembly is stored in Region 2 of this fuel storage pool.

ACTIONS

LCO 3.0.3 is applicable while in MODE 1, 2, 3, or 4. Since spent fuel pool storage requirements apply in all MODES when fuel is stored in Region 2, the ACTIONS have been modified by a Note stating the LCO 3.0.3 is not applicable. Spent fuel pool storage requirements are independent of reactor operations. Entering LCO 3.0.3 while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

LCO 3.0.8 is applicable while in MODE 5 or 6. Since spent fuel pool storage requirements apply in all MODES when fuel is stored in Region 2, the ACTIONS have been modified by a Note stating the LCO 3.0.8 is not applicable. Spent fuel pool storage requirements are independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

BASES

ACTIONS (continued)

A.1

The LCO is not met if spent fuel assemblies stored in Region 2 spent fuel assembly storage locations do not meet the applicable initial enrichment and burnup limits in accordance with Figure 3.7.12-1.

When the LCO is not met, action must be initiated immediately to make the necessary fuel assembly movement(s) in Region 2 to bring the storage configuration into compliance with Figure 3.7.12-1 by moving the affected fuel assemblies to Region 1 or the Defective Fuel Cells.

SURVEILLANCE REQUIREMENTS

SR 3.7.12.1

This SR verifies by administrative means that the initial enrichment and burnup of the fuel assembly is in accordance with Figure 3.7.12-1. Fuel assemblies stored in Region 2 that do not meet the Figure 3.7.12-1 enrichment and burnup limits shall be stored in Region 1–or Defective Fuel Cells.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.1 DC Sources – Operating

BASES

BACKGROUND

The Class 1E DC and UPS System (IDS) provides electrical power for safety related and vital control instrumentation loads, including monitoring and main control room emergency lighting. It also provides power for safe shutdown when all the onsite and offsite AC power sources are lost and cannot be recovered for 72 hours. As required by 10 CFR 50, Appendix A, GDC 17 (Ref. 1), the Class 1E DC electrical power system is designed to have sufficient independence, redundancy, and testability to perform its safety functions, assuming a single failure. The Class 1E DC electrical power system also conforms to the requirements of Regulatory Guide 1.6 (Ref. 2) and IEEE-308 (Ref. 3).

The 250 VDC electrical power system consists of four independent safety related Class 1E DC electrical power subsystems (Division A, B, C, and D). Divisions A and D each consist of one 24 hour battery bank, one battery charger, and the associated control equipment and interconnecting cable. Divisions B and C each consist of two battery banks (one 24 hour and one 72 hour), two battery chargers, and the associated control equipment and interconnecting cabling. The loads on the battery banks (including those on the associated inverters) are grouped according to their role in response to a Design Basis Accident (DBA). Loads which are a one time or limited duration load (engineered safeguards features (ESF) actuation cabinets and reactor trip function) required within the first 24 hours following an accident are connected to the “24 hour” battery bank. Loads which are continuous or required beyond the first 24 hours following an accident (emergency lighting, post accident monitoring, and Qualified Data Processing System) are connected to the “72 hour” battery bank. There are a total of six battery banks. A battery bank consists of two battery strings connected in series. Each battery string consists of 60 cells connected in series. Divisions A and D each have one 2400 ampere hour battery bank and Divisions B and C each have two 2400 ampere hour battery banks.

Additionally, there is one installed spare battery bank and one installed spare battery charger, which provide backup service in the event that one of the battery banks and/or one of the preferred battery chargers is out of service. The spare battery bank and charger are Class 1E and have the same rating as the primary components. If the spare battery bank with the charger is substituted for one of the preferred battery banks or chargers, then the requirements of independence and redundancy between subsystems are maintained and the division is OPERABLE.

BASES

BACKGROUND (continued)

During normal operation, the 250 VDC load is powered from the battery chargers with the batteries floating on the system. In case of loss of normal power to the battery charger, the DC load is automatically powered from the station batteries.

Each battery bank provides power to an inverter, which in turn powers an AC instrumentation and control bus. The AC instrumentation and control bus loads are connected to inverters according to the battery bank type, 24 hour or 72 hour.

The Class 1E DC power distribution system is described in more detail in Bases for LCO 3.8.5, “Distribution System – Operating,” and LCO 3.8.6, “Distribution System – Shutdown.”

Each battery has adequate storage capacity to carry the required load for the required duration as discussed in Reference 4.

Each 250 VDC battery bank, including the spare battery bank, is separately housed in a ventilated room apart from its charger and distribution centers. Each subsystem is located in an area separated physically and electrically from the other subsystems to ensure that a single failure in one subsystem does not cause a failure in a separate subsystem. There is no sharing between separate Class 1E subsystems such as batteries, battery chargers, or distribution panels.

The batteries for each Class 1E electrical power subsystem are based on 125% of required capacity. The voltage limit is 2.13 V per cell, which corresponds to a total minimum voltage output of 256 V per battery discussed in Reference 4. The criteria for sizing large lead storage batteries are defined in IEEE-485 (Ref. 5).

Each electrical power subsystem has ample power output capacity for the steady state operation of connected loads required during normal operation, while at the same time maintaining its battery bank fully charged. Each battery charger has sufficient capacity to restore the battery bank from the design minimum charge to its fully charged state within 24 hours while supplying normal steady state loads (Ref. 4).

APPLICABLE SAFETY ANALYSES

The initial conditions of DBA and transient analyses in the Chapter 6 (Ref. 6) and Chapter 15, (Ref. 7), assume that engineered safety features are OPERABLE. The Class 1E DC electrical power system provides 250 volts power for safety related and vital control instrumentation loads

BASES

APPLICABLE SAFETY ANALYSES (continued)

including monitoring and main control room emergency lighting during all MODES of operation. It also provides power for safe shutdown when all the onsite and offsite AC power sources are lost.

The OPERABILITY of the Class 1E DC sources is consistent with the initial assumptions of the accident analyses. This includes maintaining at least three of the four divisions of DC sources OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite and onsite AC power sources; and

b. A worst case single failure.

The DC Sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Class 1E DC electrical power subsystems are required to be OPERABLE to ensure the availability of the required power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. Loss of Class 1E DC electrical power from one division does not prevent the minimum safety function from being performed (Ref. 4).

An OPERABLE Class 1E DC electrical power subsystem requires all required batteries and respective chargers to be operating and connected to the associated DC bus(es). The spare battery and/or charger may be used by one subsystem for OPERABILITY.

APPLICABILITY

The Class 1E DC electrical power sources are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure safe unit operation and to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients; and

b. Adequate core cooling is provided, and containment integrity and other vital functions are maintained in the event of a postulated DBA.

Class 1E DC electrical power requirements for MODES 5 and 6 are addressed in the Bases for LCO 3.8.2, “DC Sources – Shutdown.”

BASES

ACTIONS

A.1, A.2, and A.3

Condition A represents one division with one or two battery chargers inoperable (e.g., the voltage limit of SR 3.8.1.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action A.1 requires that the battery terminal voltage be restored to greater than or equal to the minimum established float voltage within 6 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within 24 hours, the battery will be restored to its fully charged condition (Required Action A.2) from any discharge that might have occurred due to the charger inoperability.

Because of the passive system design and the use of fail-safe components, the remaining Class 1E DC electrical power subsystems have the capacity to support a safe shutdown and to mitigate most DBAs following a subsequent worst case single failure. The 6 hour Completion Time is reasonable based on engineering judgement balancing the risks of operation without one DC subsystem against the risks of a forced shutdown. Additionally, the Completion Time reflects a reasonable time to assess plant status; attempt to repair or replace, thus avoiding an unnecessary shutdown; and, if necessary, prepare and effect an orderly and safe shutdown.

A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within 24 hours, avoiding a premature shutdown with its own attendant risk.

If established battery terminal float voltage cannot be restored to greater than or equal to the minimum established float voltage within 6 hours, and the charger is not operating in the current-limiting mode, a faulty charger is indicated. A faulty charger that is incapable of maintaining established battery terminal float voltage does not provide assurance that it can revert to and operate properly in the current limit mode that is necessary during the recovery period following a battery discharge event that the DC system is designed for.

BASES

ACTIONS (continued)

If the charger is operating in the current limit mode after 6 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within 24 hours (Required Action A.2).

Required Action A.2 requires that the battery float current be verified as less than or equal to 2 amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it has now been fully recharged. If at the expiration of the initial 24 hour period the battery float current is not less than or equal to 2 amps this indicates there may be additional battery problems and the battery must be declared inoperable.

Required Action A.3 limits the restoration time for the inoperable battery charger to 7 days. This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used (e.g., balance of plant non-Class 1E battery charger). The 7 day Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.

B.1, B.2, and B.3

Condition B represents two divisions with one or more battery chargers inoperable (e.g., the voltage limit of SR 3.8.1.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action B.1 requires that the battery terminal voltage be restored to greater than or equal to the minimum established float voltage within 2 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within 24 hours, the battery will be restored to its fully charged condition (Required Action B.2) from any discharge that might have occurred due to the charger inoperability.

BASES

ACTIONS (continued)

A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within 24 hours, avoiding a premature shutdown with its own attendant risk.

If the charger is operating in the current limit mode after 2 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within 24 hours (Required Action B.2).

Required Action B.2 requires that the battery float current be verified as less than or equal to 2 amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it has now been fully recharged. If at the expiration of the initial 24 hour period the battery float current is not less than or equal to 2 amps this indicates there may be additional battery problems and the battery must be declared inoperable.

Required Action B.3 limits the restoration time for the inoperable battery charger to 7 days. This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used (e.g., balance of plant non-Class 1E battery charger). The 7 day Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.

C.1

Condition C represents one division with one or more batteries inoperable. With one or more batteries inoperable, the DC bus is being supplied by the OPERABLE battery chargers. Any event that results in a loss of the AC bus supporting the battery chargers will also result in loss of DC to that train.

BASES

ACTIONS (continued)

Because of the passive system design and the use of fail-safe components, the remaining Class 1E DC electrical power subsystems have the capacity to support a safe shutdown and to mitigate most DBAs following a subsequent worst case single failure. The 6 hour Completion Time is reasonable based on engineering judgement balancing the risks of operation without one DC subsystem against the risks of a forced shutdown. Additionally, the Completion Time reflects a reasonable time to assess plant status; attempt to repair or replace, thus avoiding an unnecessary shutdown; and, if necessary, prepare and effect an orderly and safe shutdown.

The installed spare battery bank and charger may be used to restore an inoperable Class 1E DC electrical power subsystem; however, all applicable Surveillances must be met by the spare equipment used, prior to declaring the subsystem OPERABLE.

D.1

Condition D represents two divisions with one or more batteries inoperable. With one or more batteries inoperable, the DC bus is being supplied by the OPERABLE battery charger. Any event that results in a loss of the AC bus supporting the battery charger will also result in loss of DC to that train. The 2 hour limit allows sufficient time to effect restoration of an inoperable battery given that the majority of the conditions that lead to battery inoperability (e.g., loss of battery charger, battery cell voltage less than 2.07 V, etc.) are identified in Specifications 3.8.1, 3.8.2, and 3.8.7 together with additional specific completion times.

The installed spare battery bank and charger may be used to restore an inoperable Class 1E DC electrical power subsystem; however, all applicable Surveillances must be met by the spare equipment used, prior to declaring the subsystem OPERABLE.

E.1

If one of the Class 1E DC electrical power subsystems is inoperable, the remaining Class 1E DC electrical power subsystems have the capacity to support a safe shutdown and to mitigate all design basis accidents, based on conservative analysis.

Because of the passive system design and the use of fail-safe components, the remaining Class 1E DC electrical power subsystems have the capacity to support a safe shutdown and to mitigate most DBAs

ACTIONS (continued)

following a subsequent worst case single failure. The 6 hour Completion Time is reasonable based on engineering judgement balancing the risks of operation without one DC subsystem against the risks of a forced shutdown. Additionally, the Completion Time reflects a reasonable time to assess plant status; attempt to repair or replace, thus avoiding an unnecessary shutdown; and, if necessary, prepare and effect an orderly and safe shutdown.

The 6 hour Completion Time is also consistent with the time specified for restoration of one (of four) Protection and Safety Monitoring System (PMS) (LCO 3.3.2, ESFAS Instrumentation). Depending on the nature of the DC electrical power subsystem inoperability, one supported division of instrumentation could be considered inoperable. Inoperability of a PMS Division is similar to loss of one DC electrical power subsystem. In both cases, actuation of the safety functions associated with one of the four subsystems/divisions may no longer be available.

F.1

Condition F represents two subsystems with a loss of ability to completely respond to an event, and a potential loss of ability to remain energized during normal operation. It is, therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for complete loss of DC power to the affected distribution subsystems. The 2 hour limit is consistent with the allowed time for two inoperable DC distribution subsystems.

If two of the required DC electrical power subsystems are inoperable (e.g., inoperable battery, inoperable battery charger(s), or inoperable battery charger and associated inoperable battery), the two remaining DC electrical power subsystems have the capacity to support a safe shutdown and to mitigate all but the very worst case events. Since a subsequent worst case single failure would, however, result in the loss of the third subsystem, leaving only one subsystem with limited capacity to mitigate events, continued power operation should not exceed 2 hours. The 2 hour Completion Time is based on Regulatory Guide 1.93 (Ref. 11) and reflects a reasonable time to assess unit status as a function of the inoperable DC electrical power subsystem and, if the DC electrical power subsystem is not restored to OPERABLE status, to prepare to effect an orderly and safe unit shutdown.

BASES

ACTIONS (continued)

G.1 and G.2

If the inoperable DC electrical power subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.8.1.1

Verifying battery terminal voltage while on float charge for the batteries helps to ensure the effectiveness of the battery chargers which support ability of the batteries to perform their intended function. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a fully charged state while supplying the continuous steady state loads of the associated DC subsystem. On float charge, battery cells will receive adequate current to optimally charge the battery. The voltage requirements are based on the nominal design voltage of the battery and are consistent with the initial voltages assumed in the battery sizing calculations. This voltage maintains the battery plates in a condition that supports maintaining the grid life (expected to be approximately 20 years). The 7 day Frequency is consistent with manufacturer recommendations and IEEE-450 (Ref. 8).

SR 3.8.1.2

This SR verifies the design capacity of the battery chargers. According to Regulatory Guide 1.32 (Ref. 9), the battery charger supply is recommended to be based on the largest combined demands of the various steady state loads and the charging capacity to restore the battery from the design minimum charge state to the fully charged state, irrespective of the status of the unit during these demand occurrences. The minimum required amperes and duration ensure that these requirements can be satisfied.

This SR provides two options. One option requires that each battery charger be capable of supplying 200 amps at the minimum established float voltage for 8 hours. The ampere requirements are based on the output rating of the chargers. The voltage requirements are based on the

BASES

SURVEILLANCE REQUIREMENTS (continued)

charger voltage level after a response to a loss of AC power. The time period is sufficient for the charger temperature to have stabilized and to have been maintained for at least 2 hours.

The other option requires that each battery charger be capable of recharging the battery after a service test coincident with supplying the largest coincident demands of the various continuous steady state loads (irrespective of the status of the plant during which these demands occur). This level of loading may not normally be available following the battery service test and will need to be supplemented with additional loads. The duration for this test may be longer than the charger sizing criteria since the battery recharge is affected by float voltage, temperature, an the exponential decay in charging current. The battery is recharged when the measured charging current is ≤ 2 amps.

The Surveillance Frequency is acceptable, given the unit conditions required to perform the test and the other administrative controls existing to ensure adequate charger performance during these 24 month intervals. In addition, this Frequency is intended to be consistent with expected fuel cycle lengths.

SR 3.8.1.3

A battery service test is a special test of battery capability, as found, to satisfy the design requirements (battery duty cycle) of the Class 1E DC electrical power system. The discharge rate and test length corresponds to the design duty cycle requirements as specified in Reference 4.

The Surveillance Frequency of 24 months is consistent with the recommendations of Regulatory Guide 1.32 (Ref. 9) and Regulatory Guide 1.129 (Ref. 10), which state that the battery service test should be performed with intervals between tests not to exceed 24 months. This Surveillance may be performed during any plant condition with the spare battery and charger providing power to the bus.

This SR is modified by two Notes. Note 1 allows the performance of a modified performance discharge test in lieu of a service test.

The modified performance discharge test is a simulated duty cycle consisting of just two rates; the one minute rate published for the battery or the largest current load of the duty cycle, followed by the test rate employed for the performance test, both of which envelope the duty cycle of the service test. Since the ampere-hours removed by a rated one minute discharge represents a very small portion of the battery capacity,

BASES

SURVEILLANCE REQUIREMENTS (continued)

the test rate can be changed to that for the performance test without compromising the results of the performance discharge test. The battery terminal voltage for the modified performance discharge test should remain above the minimum battery terminal voltage specified in the battery service test for the duration of time equal to that of the service test.

A modified discharge test is a test of the battery capacity and its ability to provide a high rate, short duration load (usually the highest rate of the duty cycle). This will often confirm the battery's ability to meet the critical period of the load duty cycle, in addition to determining its percentage of rated capacity. Initial conditions for the modified performance discharge test should be identical to those specified for a service test.

The reason for Note 2 is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems if the spare battery is not connected. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 or 2. Risk insights or deterministic methods may be used for the assessment.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.2 DC Sources – Shutdown

BASES

BACKGROUND

A description of the Class 1E DC power sources is provided in the Bases for LCO 3.8.1, “DC Sources – Operating.”

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the Chapter 6 (Ref. 1) and Chapter 15 (Ref. 2), assume engineered safety features are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the emergency auxiliaries and control and switching during all MODES of operation.

The OPERABILITY of the DC subsystem is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems’ OPERABILITY.

The OPERABILITY of the minimum Class 1E DC power sources during MODES 5 and 6 and during movement of irradiated fuel assemblies ensures that:

a. The unit can be maintained in the shutdown or refueling condition for extended periods;

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status; and

c. Adequate Class 1E DC power sources are provided to mitigate events postulated during shutdown, such as an inadvertent draindown of the vessel or a fuel handling accident.

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6 because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal

BASES

APPLICABLE SAFETY ANALYSES (continued)

consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems.

The shutdown Technical Specification requirements are designed to ensure that the unit has the capability to mitigate the consequences of certain postulated accidents. Worst case Design Basis Accidents which are analyzed for operating MODES are generally viewed not to be a significant concern during shutdown MODES due to the lower energies involved. The Technical specifications therefore require a lesser complement of electrical equipment to be available during shutdown than is required during operating MODES. More recent work completed on the potential risks associated with shutdown, however, have found significant risk associated with certain shutdown evolutions. As a result, in addition to the requirements established in the Technical Specifications, the industry has adopted NUMARC 91-06, “Guidelines for Industry Actions to Assess Shutdown Management,” as an Industry initiative to manage shutdown tasks and associated electrical support to maintain risk at an acceptable low level. This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The Class 1E DC Sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Class 1E DC electrical power subsystems are required to be OPERABLE to support required trains of Class 1E Distribution System divisions required to be OPERABLE by LCO 3.8.6. This ensures the availability of sufficient Class 1E DC power sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents, inadvertent reactor vessel draindown).

As described in the previous section, “Applicable Safety Analyses,” in the event of an accident during shutdown, the Technical Specifications are designed to maintain the plant in such a condition that, even with a single failure, the plant will not be in immediate difficulty.

BASES

APPLICABILITY

The Class 1E DC power sources required to be OPERABLE in MODES 5 and 6 and during movement of irradiated fuel assemblies provide assurance that:

a. Required features to provide adequate coolant inventory makeup are available for the irradiated fuel assemblies in the core in case of an inadvertent draindown of the reactor vessel;

b. Required features needed to mitigate a fuel-handling accident are available;

c. Required features necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

The Class 1E DC electrical power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.1, “DC Sources – Operating.”

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

A.1 and A.2

With one or more of the required (per LCO 3.8.6, “Distribution Systems – Shutdown”) Class 1E DC power subsystems inoperable, the remaining subsystems may be capable of supporting sufficient systems to allow continuation of CORE ALTERATIONS, fuel movement, and/or operations with a potential for draining the reactor vessel. By allowing the option to declare required features inoperable with the associated DC power source(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCO ACTIONS. In many instances this option would likely involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend CORE ALTERATIONS, movement of irradiated fuel assemblies, any activities that could potentially result in inadvertent draining of the reactor vessel, and operations involving positive reactivity

BASES

ACTIONS (continued)

additions that could result in failure to meet the minimum SDM or boron concentration limit) to assure continued safe operation. The Required Action to suspend positive reactivity additions does not preclude actions to maintain or increase reactor vessel inventory, provided the required SDM is maintained.

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required DC electrical power subsystems and to continue this action until restoration is accomplished in order to provide the necessary Class 1E DC electrical power to the unit safety systems.

The installed spare battery bank and charger may be used to restore an inoperable Class 1E DC power subsystem; however, all applicable surveillances must be met by the spare equipment used, prior to declaring the subsystem OPERABLE.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required Class 1E DC electrical power subsystems should be completed as quickly as possible in order to minimize the time during which the unit safety systems may be without sufficient power.

SURVEILLANCE REQUIREMENTS

SR 3.8.2.1

SR 3.8.2.1 requires performance of all Surveillances required by SR 3.8.1.1 through SR 3.8.1.3. Therefore, see the corresponding Bases for LCO 3.8.1 for a discussion of each SR.

This SR is modified by a Note. The reason for the Note is to preclude requiring the OPERABLE DC sources from being discharged below their capability to provide the required power supply or otherwise rendered inoperable during the performance of SRs. It is the intent that these SRs must still be capable of being met, but actual performance is not required.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.3 Inverters – Operating

BASES

BACKGROUND

The inverters are the preferred source of power for the Class 1E AC instrument and control buses because of the stability and reliability they achieve. Divisions A and D, each consist of one Class 1E inverter. Divisions B and C, each consist of two inverters. The function of the inverter is to convert Class 1E DC electrical power to AC electrical power, thus providing an uninterruptible power source for the instrumentation and controls for the Protection and Safety Monitoring System (PMS). The inverters are powered from the Class 1E 250 V battery sources (Ref. 1).

Under normal operation, a Class 1E inverter supplies power to the Class 1E AC instrument and control bus. If the inverter is inoperable or the Class 1E 250 VDC input to the inverter is unavailable, the Class 1E AC instrument and control bus is powered from the backup source associated with the same division via a static transfer switch featuring a make-before-break contact arrangement. In addition, a manual mechanical bypass switch is used to provide a backup power source to the Class 1E AC instrument and control bus when the inverter is removed from service. The backup source is a Class 1E regulating 480-208/120 volt transformer providing a regulated output to the Class 1E AC instrument and control bus through a static transfer switch and a manual bypass switch.

In addition to powering safety loads, the Class 1E AC power sources are used for emergency lighting in the main control room and remote shutdown workstation. When a normal AC power source for emergency lighting is lost, the loads are automatically transferred to a Class 1E AC power source. Specific details on inverters and their operating characteristics are found in Chapter 8 (Ref. 1).

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) transient analyses in Chapter 6 (Ref. 2) and Chapter 15 (Ref. 3), assume engineered safety features are OPERABLE. The inverters are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the PMS instrumentation and controls so that the fuel, Reactor Coolant System (RCS), and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Technical Specifications 3.2 (Power Distribution Limits), 3.4 (Reactor Coolant System), and 3.6 (Containment Systems).

BASES

APPLICABLE SAFETY ANALYSES (continued)

The OPERABILITY of the inverters is consistent with the initial assumptions of the accident analyses and is based on meeting the design basis of the unit. This includes maintaining at least three of the four Divisions of AC instrument and control buses OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite and onsite AC power source; and

b. A worst case single failure.

Inverters are a part of distribution systems, and as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The inverters ensure the availability of AC electrical power for the systems instrumentation required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA.

Maintaining the required inverters OPERABLE ensures that the redundancy incorporated into the design of the PMS instrumentation and controls is maintained. The six inverters ensure an uninterruptible supply of AC electrical power to the six Class 1E AC instrument and control buses even if all AC power sources are de-energized.

OPERABLE inverters require that the Class 1E AC instrument and control bus be powered by the inverter with output voltage and frequency within tolerances, and the power input to the inverter from a 250 VDC station battery.

This LCO is modified by a Note that allows one inverter to be disconnected from its associated Class 1E DC bus for ≤ 72 hours, if the associated Class 1E AC instrument and control bus is powered from its Class 1E regulating transformer during the period and all other inverters are OPERABLE. This allows an equalizing charge to be placed on one battery bank. If the inverter was not disconnected, the resulting voltage condition might damage the inverter. These provisions minimize the loss of equipment that would occur in the event of a loss of offsite power. The 72 hour time period for the allowance minimizes the time during which a loss of offsite power could result in the loss of equipment energized from the affected Class 1E AC instrument and control bus while taking into consideration the time required to perform an equalizing charge on the battery bank.

BASES

LCO (continued)

The intent of this Note is to limit the number of inverters that may be disconnected. Only the inverter associated with the single battery bank undergoing an equalizing charge may be disconnected. All other inverters must be aligned to their associated batteries.

APPLICABILITY

The inverters are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients; and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

Inverter requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.4, “Inverters – Shutdown.”

ACTIONS

A.1

With a required inverter inoperable, its associated Class 1E AC instrument and control bus is automatically energized from its regulating transformer. A manual switch is also provided which can be used if the static transfer switch does not properly function.

For this reason a Note has been included in Condition A requiring the entry into the Conditions and Required Actions of LCO 3.8.5, “Distribution System – Operating.” This ensures that the vital bus is re-energized within 12 hours.

Required Action A.1 allows 24 hours to fix the inoperable inverter and return it to service. The 24 hour time limit is based upon engineering judgment, taking into consideration the time required to repair an inverter and the additional risk to which the unit is exposed because of the inverter inoperability. This has to be balanced against the risk of an immediate shutdown, along with the potential challenges to safety systems such a shutdown might entail. When the AC instrument and control bus is powered from its regulating transformer, it is relying upon interruptible AC electrical power sources (offsite and onsite). The uninterruptible inverter source to the AC instrument and control buses is the preferred source for powering instrumentation trip setpoint devices.

BASES

ACTIONS (continued)

B.1 and B.2

If the inoperable DC electrical power subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to MODE 5 where the probability and consequences on an event are minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.8.3.1

This Surveillance verifies that the inverters are functioning properly with all required switches and circuit breakers closed and Class 1E AC instrument and control buses energized from the inverter. The verification of proper voltage and frequency output ensures that the required power is readily available for the PMS instrumentation connected to the Class 1E AC instrument and control buses. The 7 day Frequency takes into account the effectiveness of the voltage and frequency instruments, the redundant capability of the inverters, and other indications available in the control room that alert the operator to inverter malfunctions.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.4 Inverters – Shutdown

BASES

BACKGROUND

A description of the inverters is provided in the Bases for Specification 3.8.3, “Inverters – Operating.”

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in Chapter 6 (Ref. 1) and Chapter 15 (Ref. 2), assume engineered safety features are OPERABLE. The DC to AC inverters are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the Protection and Monitoring System Engineered Safety Feature Actuation System instrumentation and controls so that the fuel, Reactor Coolant System, and containment design limits are not exceeded.

The OPERABILITY of the inverters is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems’ OPERABILITY.

The OPERABILITY of the minimum inverters to each Class 1E AC instrument and control bus during MODES 5 and 6, ensures that (Refs. 1 and 2):

a. The unit can be maintained in the shutdown or refueling condition for extended periods;

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status; and

c. Adequate power is available to mitigate events postulated during shutdown, such as an inadvertent draindown of the vessel or a fuel handling accident.

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6 because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal

BASES

APPLICABLE SAFETY ANALYSES (continued)

consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems.

The shutdown Technical Specification requirements are designed to ensure that the unit has the capability to mitigate the consequences of certain postulated accidents. Worst case Design Basis Accidents which are analyzed for operating MODES are generally viewed not to be a significant concern during shutdown MODES due to the lower energies involved. The Technical specifications therefore require a lesser complement of electrical equipment to be available during shutdown than is required during operating MODES. More recent work completed on the potential risks associated with shutdown, however, have found significant risk associated with certain shutdown evolutions. As a result, in addition to the requirements established in the Technical Specifications, the industry has adopted NUMARC 91-06, “Guidelines for Industry Actions to Assess Shutdown Management,” as an Industry initiative to manage shutdown tasks and associated electrical support to maintain risk at an acceptable low level. This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The Class 1E UPS inverters are part of the distribution system and, as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The inverters ensure the availability of electrical power for the instrumentation for systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or postulated DBA. The battery powered inverters provide an uninterruptible supply of AC electrical power to the Class 1E AC instrument and control buses, even if the normal power supply from the 480 VAC is deenergized. OPERABILITY of the inverters requires that the Class 1E instrument and control buses be powered by the inverter with output voltage and frequency within tolerances, and the power input to the inverter from a 250 VDC station battery. This ensures the availability of sufficient inverter power sources to operate the plant in a safe manner and to mitigate the consequences of postulated events during shutdown (fuel handling accidents, inadvertent reactor vessel draindown).

BASES

APPLICABILITY

The inverters required to be OPERABLE in MODES 5 and 6 and during movement of irradiated fuel assemblies provide assurance that:

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel in the core in case of an inadvertent draindown of the reactor vessel;

b. Systems needed to mitigate a fuel handling accident are available;

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

Class 1E UPS inverter requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.3, “Inverters – Operating.”

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

A.1 and A.2

If one or more required (per LCO 3.8.6, Distribution Systems – Shutdown) inverters are inoperable, the remaining OPERABLE inverters may be capable of supporting required features to allow continuation of CORE ALTERATIONS, fuel movement, and operations with a potential for draining the reactor vessel. By allowance of the option to declare required features inoperable with associated inverter(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCOs’ Required Actions. In many instances, this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., suspend CORE ALTERATIONS, movement of irradiated fuel assemblies, any activities that could potentially result in inadvertent draining of the reactor vessel, and operations involving positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6)). Suspending positive reactivity additions that could result in

BASES

ACTIONS (continued)

failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive MTC must also be evaluated to ensure they do not result in a loss of required SDM.

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required inverters and to continue this action until restoration is accomplished in order to provide the necessary inverter power to the unit safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required inverters should be completed as quickly as possible in order to minimize the time the unit safety systems may be without power or powered from a regulating transformer.

SURVEILLANCE REQUIREMENTS

SR 3.8.4.1

This Surveillance verifies that the inverters are functioning properly with all required circuit breakers closed and Class 1E AC instrument and control buses energized from the inverter. The verification of proper voltage and frequency output ensures that the required power is readily available for the instrumentation connected to the Class 1E AC instrument and control buses. The 7 day Frequency takes into account the effectiveness of the voltage and frequency instruments, the redundant capability of the inverters, and other indications available in the control room that alert the operator to inverter malfunctions.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.5 Distribution Systems – Operating

BASES

BACKGROUND

The onsite Class 1E and DC and UPS electrical power distribution system is divided by division into four independent AC and DC electrical power distribution subsystems (Divisions A, B, C, and D).

The Class 1E AC distribution Divisions A and D each consists of one 208/120 V bus. The Class 1E AC distribution Divisions B and C each consists of two 208/120 V buses. The buses are normally powered from separate inverters which are connected to the respective Division Class 1E battery banks. The backup source provided for each Division for the Class 1E AC instrument and control buses is a Class 1E regulating transformer providing regulated output to the Class 1E AC instrument and control buses through a static transfer switch and a manual bypass switch. Power to the transformer is provided by the nonsafety related Main AC Power System. Additional description of this system may be found in the Bases for Specification 3.8.3, “Inverters – Operating.”

The Class 1E DC distribution Divisions A and D each consists of one 250 VDC bus. The Class 1E DC distribution Divisions B and C each consists of two 250 VDC buses. The buses for the four Divisions are normally powered from their associated Division battery chargers. The backup source for each Class 1E DC bus is its associated Class 1E battery bank. Additionally, there is one installed spare Class 1E battery bank and one installed spare Class 1E battery charger, which can provide backup power to a Class 1E DC bus in the event that one of the battery banks or one of the chargers is out of service. Additional description of this system may be found in the Bases for Specification 3.8.1, “DC Sources Operating.”

The list of all required distribution buses is presented in Table B 3.8.5-1 and shown in Section 8.3.2 (Ref. 1).

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in Chapter 6 (Ref. 2) and Chapter 15 (Ref. 3), assume engineered safety features (ESFs) are OPERABLE. The Class 1E AC and DC electrical power distribution systems are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the ESFs so that the fuel, Reactor Coolant System (RCS) and containment design limits are not exceeded.

BASES

APPLICABLE SAFETY ANALYSES (continued)

These limits are discussed in more detail in the Bases for Technical Specifications 3.2 (Power Distribution Limits), 3.4 (Reactor Coolant System), and 3.6 (Containment Systems).

The OPERABILITY of the Class 1E AC and DC electrical power distribution systems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining at least three of the four Divisions of Class 1E AC and DC power distribution systems OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite and onsite AC power sources; and

b. A worst case single failure.

The Class 1E AC and DC electrical power distribution system satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The required power distribution subsystems listed in Table B 3.8.5-1 ensure the availability of Class 1E AC and DC electrical power for the systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. The Division A, B, C, and D Class 1E AC and DC electrical power distribution subsystems are required to be OPERABLE.

Maintaining the Division A, B, C, and D AC and DC electrical power distribution subsystems OPERABLE ensures that the redundancy incorporated into the design of the ESFs is not defeated. Three of the four Class 1E AC and DC power distribution subsystems are capable of providing the necessary electrical power to the associated ESF components. Therefore, a single failure within any subsystem or within the electrical power distribution subsystems will not prevent safe shutdown of the reactor.

OPERABLE Class 1E DC electric power distribution subsystems require the associated buses, motor control centers, and electrical circuits to be energized to their proper voltage from either the associated battery bank or charger. The spare battery bank and/or chargers may be used by one subsystem for OPERABILITY. OPERABLE Class 1E AC electrical power distribution subsystems require the associated buses to be energized to their proper voltages and frequencies from the associated inverter or regulating transformer.

BASES

APPLICABILITY

The Class 1E AC and DC electrical power distribution subsystems are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients; and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

The Class 1E AC and DC electrical power distribution subsystem requirements for MODES 5 and 6 are covered in the Bases for Specification 3.8.6, “Class 1E Distribution Systems – Shutdown.”

ACTIONS

A.1

With one division of the Class 1E AC instrument and control bus inoperable the remaining Class 1E AC instrument and control buses have the capacity to support a safe shutdown and to mitigate all DBAs, based on conservative analysis.

Because of the passive system design and the use of fail-safe components, the remaining Class 1E AC instrument and control buses have the capacity to support a safe shutdown and to mitigate most design basis accidents following a subsequent worst case single failure. The 6 hour Completion Time is reasonable based on engineering judgement balancing the risks of operation without one AC instrument and control bus against the risks of a forced shutdown. Additionally, the Completion Time reflects a reasonable time to assess plant status; attempt to repair or replace, thus avoiding an unnecessary shutdown; and, if necessary, prepare and effect an orderly and safe shutdown.

This 6 hour limit is shorter than Completion Times allowed for most supported systems which would be without power. Taking exception to LCO 3.0.2 for components without adequate DC Power, which would have Required Action Completion Times shorter than 6 hours, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) while allowing stable operations to continue;

BASES

ACTIONS (continued)

b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected division; and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 6 hour Completion Time takes into account the importance to safety of restoring the Class 1E AC instrument and control bus to OPERABLE status, the passive design of the ESF systems, the redundant capability afforded by the other OPERABLE Class 1E AC instrument and control buses, and the low probability of a DBA occurring during this period which requires more than two OPERABLE AC instrument and control buses.

The 6 hour Completion Time is also consistent with the time specified for restoration of one (of four) Protection and Safety Monitoring System division (LCO 3.3.2, ESFAS Instrumentation). Depending on the nature of the AC instrument and control inoperability, one supported division of instrumentation could be considered inoperable. Inoperability of a PMS division is similar to loss of one division AC instrument and control bus. In both cases, actuation of the safety functions associated with one of the four subsystems/divisions may no longer be available.

The second Completion Time for Required Action A.1 establishes a limit on the maximum time allowed for any combination of required distribution subsystems to be inoperable during any single contiguous occurrence of failing to meet the LCO. If Condition A is entered while, for instance, a DC bus is inoperable and subsequently restored OPERABLE, the LCO may already have been not met for up to 6 hours. This could lead to a total of 12 hours, since initial failure of the LCO, to restore the AC instrument and control distribution system. At this time, a DC circuit could again become inoperable, and AC instrument and control distribution restored OPERABLE. This could continue indefinitely.

The Completion Time allows for an exception to the normal “time zero” for beginning the allowed outage time “clock.” This will result in establishing the “time zero” at the time the LCO was initially not met, instead of the time Condition A was entered. The 12 hour Completion Time is an acceptable limitation on this potential to fail to meet the LCO indefinitely.

BASES

ACTIONS (continued)

B.1

With one Division of the Class 1E DC electrical power distribution subsystem inoperable, the remaining Divisions have the capacity to support a safe shutdown and to mitigate all DBAs, based on conservative analysis.

Because of the passive system design and the use of fail-safe components, the remaining Divisions have the capacity to support a safe shutdown and to mitigate most design basis accidents following a subsequent worst case single failure. The 6 hour Completion Time is reasonable based on engineering judgement balancing the risks of operation without one Division against the risks of a forced shutdown. Additionally, the completion time reflects a reasonable time to assess plant status; attempt to repair or replace, thus avoiding an unnecessary shutdown; and, if necessary, prepare and effect an orderly and safe shutdown.

The 6 hour Completion Time is also consistent with the time specified for restoration of one (of four) Protection and Safety Monitoring System division (LCO 3.3.2, ESFAS Instrumentation). Depending on the nature of the DC electrical power distribution subsystem inoperability, one supported division of instrumentation could be considered inoperable. Inoperability of a PMS division is similar to loss of one DC electrical power distribution subsystem. In both cases, actuation of the safety functions associated with one of the four subsystems/divisions may no longer be available.

This 6 hour limit is shorter than Completion Times allowed for most supported systems which would be without power. Taking exception to LCO 3.0.2 for components without adequate DC power, which would have Required Action Completion Times shorter than 6 hours, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) while allowing stable operations to continue;

b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions to restore power to the affected division; and

BASES

ACTIONS (continued)

c. The potential for an event in conjunction with a single failure of a redundant component.

The second Completion Time for Required Action B.1 establishes a limit on the maximum time allowed for any combination of required distribution subsystems to be inoperable during any single contiguous occurrence of failing to meet the LCO. If Condition B is entered while, for instance, an AC instrument and control bus is inoperable and subsequently returned OPERABLE, the LCO may already have been not met for up to 6 hours. This could lead to a total of 6 hours, since initial failure of the LCO, to restore the DC distribution system. At this time, an AC train could again become inoperable, and DC distribution restored OPERABLE. This could continue indefinitely.

This Completion Time allows for an exception to the normal “time zero” for beginning the allowed outage time “clock.” This will result in establishing the “time zero” at the time the LCO was initially not met, instead of the time Condition B was entered. The 12 hour Completion Time is an acceptable limitation on this potential to fail to meet the LCO indefinitely.

C.1

With two divisions of AC instrument and control buses inoperable, the remaining OPERABLE buses are capable of supporting the minimum safety functions necessary to shut down the unit and maintain it in the safe shutdown condition. Overall reliability is reduced, however, since an additional single failure could result in the minimum required ESF functions not being supported. Therefore, the required divisions of AC instrument and control buses must be restored to OPERABLE status within 2 hours by powering the bus from the associated inverter via inverted DC, inverter using internal AC source, or Class 1E constant voltage transformer.

Condition C represents two divisions of AC instrument and control vital buses without power; potentially both the DC source and the associated AC source are nonfunctioning. In this situation, the unit is significantly more vulnerable to a complete loss of all noninterruptable power. It is, therefore, imperative that the operator’s attention focus on stabilizing the unit, minimizing the potential for loss of power to the remaining buses and restoring power to the affected buses.

BASES

ACTIONS (continued)

This 2 hour time limit is more conservative than Completion Times allowed for the vast majority of components that are without adequate AC instrument and control power. Taking exception to LCO 3.0.2 for components without adequate vital AC power, which would have the Required Action Completion Times shorter than 2 hours if declared inoperable, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) and not allowing stable operations to continue);

b. The potential for decreased safety by requiring entry into numerous Applicable Conditions and Required Actions for components without adequate AC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train; and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 2 hour Completion Time takes into account the importance to safety of restoring the AC instrument and control buses to OPERABLE status, the redundant capability afforded by the other OPERABLE buses, and the low probability of a DBA occurring during this period.

The second Completion Time for Required Action C.1 establishes a limit on the maximum allowed for any combination of required distribution subsystems to be inoperable during any single contiguous occurrence of failing to meet the LCO. If Condition C is entered while, for instance, a DC bus is inoperable and subsequently returned to OPERABLE, the LCO may already have been not met for up to 12 hours. This could lead to a total of 14 hours, since initial failure of the LCO, to restore the bus distribution system. At this time, a DC train could again become inoperable, and AC bus distribution restored to OPERABLE. This could continue indefinitely.

This Completion Time allows for an exception to the normal “time zero” for beginning the allowed outage time “clock.” This will result in establishing the “time zero” at the time the LCO was initially not met, instead of the time Condition B was entered. The 16 hour Completion Time is an acceptable limitation on this potential to fail to meet the LCO indefinitely.

BASES

ACTIONS (continued)

D.1

With two divisions of DC electrical power distribution subsystems inoperable, the remaining DC electrical power distribution subsystems are capable of supporting the minimum safety functions necessary to shut down the reactor and maintain it in a safe shutdown condition, assuming no single failure. The overall reliability is reduced, however, because a single failure in the remaining DC electrical power distribution subsystem could result in the minimum required ESF functions not being supported. Therefore, the required DC buses must be restored to OPERABLE status within 2 hours by powering the bus from the associated battery or charger.

Condition D represents two subsystems without adequate DC power; potentially both with the battery significantly degraded and the associated charger nonfunctioning. In this situation, the unit is significantly more vulnerable to a complete loss of all DC power. It is, therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for loss of power to the remaining divisions and restoring power to the affected divisions.

This 2 hour limit is more conservative than Completion Times allowed for the vast majority of components that would be without power. Taking exception to LCO 3.0.2 for components without adequate DC power, which would have Required Action Completion Times shorter than 2 hours, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) while allowing stable operations to continue;

b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected divisions; and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 2 hour Completion Time for DC buses is consistent with Regulatory Guide 1.93 (Ref. 4).

BASES

ACTIONS (continued)

The second Completion Time for Required Action D.1 establishes a limit on the maximum time allowed for any combination of required distribution subsystems to be inoperable during any single contiguous occurrence of failing to meet the LCO. If Condition D is entered while, for instance, an AC instrument and control bus is inoperable and subsequently returned OPERABLE, the LCO may already have been not met for up to 12 hours. This could lead to a total of 14 hours, since initial failure of the LCO, to restore the DC distribution system. At this time, an AC train could again become inoperable, and DC distribution restored to OPERABLE. This could continue indefinitely.

This Completion Time allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." This will result in establishing the "time zero" at the time the LCO was initially not met, instead of the time Condition C was entered. The 16 hour Completion Time is an acceptable limitation on this potential to fail to meet the LCO indefinitely.

E.1 and E.2

If the inoperable distribution subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to MODE 5 where the probability and consequences on an event are minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

F.1

With two Divisions with inoperable distribution subsystems that result in a loss of safety function, adequate core cooling, containment OPERABILITY and other vital functions for DBA mitigation would be compromised, and immediate plant shutdown in accordance with LCO 3.0.3 is required.

SURVEILLANCE REQUIREMENTS

SR 3.8.5.1

This Surveillance verifies that the Class 1E AC and DC electrical power distribution subsystems are functioning properly, with the required circuit breakers and switches properly aligned. The verification of proper voltage availability on the buses ensures that the required voltage is

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.6 Distribution Systems – Shutdown

BASES

BACKGROUND

A description of the Class 1E AC instrument and control bus and Class 1E DC electrical power distribution system is provided in the Bases for Specification 3.8.5, “Distribution System – Operating.”

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in Chapter 6 (Ref. 1) and Chapter 15 (Ref. 2), assume engineered safety features are OPERABLE. The Class 1E AC and DC electrical power sources and associated power distribution systems are designed to provide sufficient capacity, redundancy, and reliability to ensure the availability of necessary power to the ESF systems so that the fuel, Reactor Coolant System, and containment design limits are not exceeded.

The OPERABILITY of the minimum Class 1E AC and DC electrical power sources and associated power distribution subsystems during MODES 5 and 6, and during movement of irradiated fuel assemblies ensures that:

a. The unit can be maintained in the shutdown or refueling condition for extended periods;

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status; and

c. Adequate power is provided to mitigate events postulated during shutdown, such as an inadvertent draindown of the vessel or a fuel handling accident.

The Class 1E AC and DC electrical power distribution systems satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Various combinations of subsystems, equipment, and components are required OPERABLE by other LCOs, depending on the specific plant condition. Implicit in those requirements is the required OPERABILITY of necessary support required features. This LCO explicitly requires energization of the portions of the electrical distribution system necessary to support OPERABILITY of required systems, equipment, and components—all specifically addressed in each LCO and implicitly required via the definition of OPERABILITY.

BASES

LCO (continued)

Maintaining these portions of the distribution system energized ensures the availability of sufficient power to operate the unit in a safe manner to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents).

APPLICABILITY

The Class 1E AC and DC electrical power distribution subsystems are required to be OPERABLE in MODES 5 and 6 and during movement of irradiated fuel assemblies provide assurance that:

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel assemblies in the core in case of an inadvertent draindown of the reactor vessel;

b. Systems needed to mitigate a fuel handling accident are available;

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition and refueling condition.

The Class 1E AC and DC electrical power distribution subsystem requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.5, “Distribution Systems – Operating.”

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

A.1 and A.2

If one or more required Class 1E DC or Class 1E AC instrument and control bus electrical power distribution subsystems are inoperable, the remaining OPERABLE divisions may be capable of supporting required features to allow continuation of CORE ALTERATIONS, fuel movement, and/or operations with a potential for draining the reactor vessel. By

BASES

ACTIONS (continued)

allowing the option to declare required features associated with an inoperable distribution subsystem inoperable, appropriate restrictions will be implemented in accordance with the affected equipment LCO Required Actions. In many instances this would likely involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend CORE ALTERATIONS, movement of irradiated fuel assemblies, any activities that could potentially result in inadvertent draining of the reactor vessel, and operations involving positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6)). Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive MTC must also be evaluated to ensure they do not result in a loss of required SDM.

Suspension of these activities does not preclude completion of actions to establish a safe conservative condition. These actions will minimize the probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required AC and DC electrical power distribution subsystems and to continue this action until restoration is accomplished in order to provide the necessary power to the unit safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required distribution subsystems should be completed as quickly as possible in order to minimize the time the unit safety systems may be without power.

SURVEILLANCE REQUIREMENTS

SR 3.8.6.1

This Surveillance verifies that the Class 1E AC and DC electrical power distribution subsystems are functioning properly, with the required circuit breakers and switches properly aligned. The verification of proper voltage availability on the buses ensures that the required power is readily available for motive as well as control functions for critical system

BASES

SURVEILLANCE REQUIREMENTS (continued)

loads connected to these buses. The 7 day Frequency takes into account the redundant capability of the electrical power distribution subsystems and other indications available in the control room that alert the operator to subsystem malfunctions.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.7 Battery Parameters

BASES

BACKGROUND

LCO 3.8.7, Battery Parameters, delineates the limits on electrolyte temperature, level, float voltage and specific gravity for the DC power source batteries. A discussion of these batteries and their OPERABILITY requirements is provided in the Bases for LCO 3.8.1, "DC Sources – Operating," and LCO 3.8.2, "DC Sources – Shutdown." In addition to the limitations of this Specification, the licensee controlled program also implements a program specified in Specification 5.5.11 for monitoring various battery parameters that is based on the recommendations of IEEE Standard 450-1995, "IEEE Recommended Practice For Maintenance, Testing, And Replacement Of Vented Lead-Acid Batteries For Stationary Applications" (Ref. 3).

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in Chapter 6 (Ref. 1), and Chapter 15 (Ref. 2), assume engineered safety features are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for safety related and vital control instrumentation loads including monitoring and main control room emergency lighting during all MODES of operation. It also provides power for safe shutdown when all the onsite and offsite AC power sources are lost.

The OPERABILITY of the DC subsystems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining at least three of the four Divisions of DC sources OPERABLE during accident conditions, in the event of:

a. An assumed loss of all offsite and onsite AC power sources; and

b. A worst case single failure.

Battery parameters satisfy the Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Battery parameters must remain within acceptable limits to ensure availability of the required DC power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. Battery parameter limits are conservatively established, allowing continued DC electrical system function even with

BASES

LCO (continued)

limits not met. Additional preventative maintenance, testing, and monitoring performed in accordance with the licensee controlled program is conducted as specified in Specification 5.5.11.

APPLICABILITY The battery parameters are required solely for the support of the associated DC electrical power subsystems. Therefore, battery parameter limits are only required when the DC power source is required to be OPERABLE. Refer to the Applicability discussion in Bases for LCO 3.8.1, and LCO 3.8.2.

ACTIONS A.1, A.2, and A.3

With one or more cells in one or more batteries in one Division < 2.07 V, the battery cell is degraded. Within 2 hours verification of the required battery charger, OPERABILITY is made by monitoring the battery terminal voltage (SR 3.8.1.1) and of the overall battery state of charge by monitoring the battery float charge current (SR 3.8.7.1). This assures that there is still sufficient battery capacity to perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of one or more cells in one or more batteries < 2.07 V, and continued operation is permitted for a limited period up to 24 hours.

Since the Required Actions only specify “perform,” a failure of SR 3.8.1.1 or SR 3.8.7.1 acceptance criteria does not result in this Required Action not met. However, if one of the SRs is failed the appropriate Condition(s), depending on the cause of the failures, is entered. If SR 3.8.7.1 is failed then there is not assurance that there is still sufficient battery capacity to perform the intended function and the battery must be declared inoperable immediately.

B.1 and B.2

One or more batteries in one Division with float > 2 amps indicate that a partial discharge of the battery capacity has occurred. This may be due to a temporary loss of a battery charger or possibly due to one or more battery cells in a low voltage condition reflecting some loss of capacity. Within 2 hours verification of the required battery charger OPERABILITY is made by monitoring the battery terminal voltage. If the terminal voltage is found to be less than the minimum established float voltage there are two possibilities, the battery charger is inoperable or is operating in the current limit mode. Condition A addresses charger inoperability. If the

BASES

ACTIONS (continued)

charger is operating in the current limit mode after 2 hours that is an indication that the battery has been substantially discharged and likely cannot perform its required design functions. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within 24 hours (Required Action B.2). The battery must therefore be declared inoperable.

If the float voltage is found to be satisfactory but there are one or more battery cells with float voltage less than 2.07 V, the associated "OR" statement in Condition F is applicable and the battery must be declared inoperable immediately. If float voltage is satisfactory and there are no cells less than 2.07 V there is good assurance that, within 24 hours, the battery will be restored to its fully charged condition (Required Action B.2) from any discharge that might have occurred due to a temporary loss of the battery charger.

A discharged battery with float voltage (the charger setpoint) across its terminals indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within 24 hours, avoiding a premature shutdown with its own attendant risk.

If the condition is due to one or more cells in a low voltage condition but still greater than 2.07 V and float voltage is found to be satisfactory, this is not indication of a substantially discharged battery and 24 hours is a reasonable time prior to declaring the battery inoperable.

Since Required Action B.1 only specifies "perform," a failure of SR 3.8.1.1 acceptance criteria does not result in the Required Action not met. However, if SR 3.8.1.1 is failed, the appropriate Condition(s), depending on the cause of the failure, is entered.

C.1, C.2, and C.3

With one or more batteries in one Division with one or more cells electrolyte level above the top of the plates, but below the minimum established design limits, the battery still retains sufficient capacity to

BASES

ACTIONS (continued)

perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of electrolyte level not met. Within 31 days the minimum established design limits for electrolyte level must be re-established.

With electrolyte level below the top of the plates there is a potential for dryout and plate degradation. Required Actions C.1 and C.2 address this potential (as well as provisions in Specification 5.5.11, Battery Monitoring and Maintenance Program). They are modified by a note that indicates they are only applicable if electrolyte level is below the top of the plates. Within 8 hours level is required to be restored to above the top of the plates. The Required Action C.2 requirement to verify that there is no leakage by visual inspection and the Specification 5.5.11.b item to initiate action to equalize and test in accordance with manufacturer's recommendation are taken from Annex D of IEEE Standard 450-1995. They are performed following the restoration of the electrolyte level to above the top of the plates. Based on the results of the manufacturer's recommended testing the batteries may have to be declared inoperable and the affected cells replaced.

D.1

With one or more batteries in one Division with pilot cell temperature less than the minimum established design limits, 12 hours is allowed to restore the temperature to within limits. A low electrolyte temperature limits the current and power available. Since the battery is sized with margin, while battery capacity is degraded, sufficient capacity exists to perform the intended function and the affected battery is not required to be considered inoperable solely as a result of the pilot cell temperature not met.

E.1

With one or more batteries in two or more Divisions with battery parameters not within limits there is not sufficient assurance that battery capacity has not been affected to the degree that the batteries can still perform their required function, given that redundant batteries are involved. With redundant batteries involved this potential could result in a total loss of function on multiple systems that rely upon the batteries. The longer Completion Times specified for battery parameters on non-redundant batteries not within limits are therefore not appropriate, and the parameters must be restored to within limits in three Divisions within 2 hours.

BASES

ACTIONS (continued)

F.1

With one or more batteries with any battery parameter outside the allowances of the Required Actions for Condition A, B, C, D, or E, sufficient capacity to supply the maximum expected load requirement is not assured and the corresponding battery must be declared inoperable. Additionally, discovering one or more batteries in one Division with one or more battery cells float voltage less than 2.07 V and float current greater than 2 amps indicates that the battery capacity may not be sufficient to perform the intended functions. The battery must therefore be declared inoperable immediately.

SURVEILLANCE REQUIREMENTS

SR 3.8.7.1

Verifying battery float current while on float charge is used to determine the state of charge of the battery. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a charged state. The float current requirements are based on the float current indicative of a charged battery. Use of float current to determine the state of charge of the battery is consistent with IEEE-450 (Ref. 3). The 7 day Frequency is consistent with IEEE-450 (Ref. 3).

This SR is modified by a Note that states the float current requirement is not required to be met when battery terminal voltage is less than the minimum established float voltage of SR 3.8.1.1. When this float voltage is not maintained the Required Actions of LCO 3.8.1 ACTION A are being taken, which provide the necessary and appropriate verifications of the battery condition. Furthermore, the float current limit of 2 amps is established based on the nominal float voltage value and is not directly applicable when this voltage is not maintained.

SR 3.8.7.2 and SR 3.8.7.5

Optimal long term battery performance is obtained by maintaining a float voltage greater than or equal to the minimum established design limits provided by the battery manufacturer, which corresponds to 264.0 V at the battery terminals, or 2.20 Volts per cell. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge, which could eventually render the battery inoperable. Float voltages in this range or less, but greater than 2.07 Volts per cell, are addressed in Specification 5.5.11. SRs 3.8.7.2 and 3.8.7.5 require verification that the cell float voltages are equal to or greater than the short term absolute

BASES

SURVEILLANCE REQUIREMENTS (continued)

minimum voltage of 2.07 V. The Frequency for cell voltage verification every 31 days for pilot cell and 92 days for each connected cell is consistent with IEEE-450 (Ref. 3).

SR 3.8.7.3

The limit specified for electrolyte level ensures that the plates suffer no physical damage and maintains adequate electron transfer capability. The Frequency is consistent with IEEE-450 (Ref. 3).

SR 3.8.7.4

This Surveillance verifies that the pilot cell temperature is greater than or equal to the minimum established design limit (i.e., 60°F). Pilot cell electrolyte temperature is maintained above this temperature to assure the battery can provided the required current and voltage to meet the design requirements. Temperatures lower than assumed in battery sizing calculations act to inhibit or reduce battery capacity. The Frequency is consistent with IEEE-450 (Ref. 3).

SR 3.8.7.6

A battery performance discharge test is a test of constant current capacity of a battery, normally done in the as found condition, after having been in service, to detect any change in the capacity determined by the acceptance test. The test is intended to determine overall battery degradation due to age and usage.

Either the battery performance discharge test or the modified performance discharge test is acceptable for satisfying SR 3.8.7.6; however, only the modified performance discharge test may be used to satisfy the battery service test requirements of SR 3.8.1.3.

A modified discharge test is a test of the battery capacity and its ability to provide a high rate, short duration load (usually the highest rate of the duty cycle). This will often confirm the battery's ability to meet the critical period of the load duty cycle, in addition to determining its percentage of rated capacity. Initial conditions for the modified performance discharge test should be identical to those specified for a service test.

It may consist of just two rates; for instance the one minute rate for the battery or the largest current load of the duty cycle, followed by the test rate employed for the performance test, both of which envelope the duty cycle of the service test. Since the ampere-hours removed by a

BASES

SURVEILLANCE REQUIREMENTS (continued)

one minute discharge represents a very small portion of the battery capacity, the test rate can be changed to that for the performance test without compromising the results of the performance discharge test. The battery terminal voltage for the modified performance discharge test must remain above the minimum battery terminal voltage specified in the battery service test for the duration of time equal to that of the service test.

The acceptance criteria for this Surveillance are consistent with IEEE-450 (Ref. 3) and IEEE-485 (Ref. 4). These references recommend that the battery be replaced if its capacity is below 80% of the manufacturer's rating. A capacity of 80% shows that the battery rate of deterioration is increasing, even if there is ample capacity to meet the load requirements. Furthermore, the battery is sized to meet the assumed duty cycle loads when the battery design capacity reaches this 80% limit.

The Surveillance Frequency for this test is normally 60 months. If the battery shows degradation, or if the battery has reached 85% of its expected life and capacity is < 100% of the manufacturer's rating, the Surveillance Frequency is reduced to 12 months. However, if the battery shows no degradation but has reached 85% of its expected life, the Surveillance Frequency is only reduced to 24 months for batteries that retain capacity ≥ 100% of the manufacturer's ratings. Degradation is indicated, according to IEEE-450 (Ref. 3), when the battery capacity drops by more than 10% relative to its capacity on the previous performance test or when it is ≥ 10% below the manufacturer's rating. These Frequencies are consistent with the recommendations in IEEE-450 (Ref. 3).

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown

BASES

SURVEILLANCE REQUIREMENTS (continued)

and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 or 2. Risk insights or deterministic methods may be used for the assessment.

B 3.9 REFUELING OPERATIONS

B 3.9.1 Boron Concentration

BASES

BACKGROUND

The limit on the boron concentration of the Reactor Coolant System (RCS), the refueling cavity, and the transfer tube during refueling ensures that the reactor remains subcritical during MODE 6. Refueling boron concentration is the soluble boron concentration in the coolant in each of these volumes having direct access to the reactor core during refueling.

The soluble boron concentration offsets the core reactivity and is measured by chemical analysis of a representative sample of the coolant in each of the volumes. The refueling boron concentration limit is specified in the COLR. Plant procedures ensure the specified boron concentration in order to maintain an overall core reactivity of $k_{eff} \leq 0.95$ during fuel handling with control rods and fuel assemblies assumed to be in the most adverse configuration (least negative reactivity) allowed by procedures.

GDC 26 of 10 CFR 50, Appendix A requires that two independent reactivity control systems of different design principles be provided (Ref. 3). One of these systems, the Passive Core Cooling System (PXS), is capable of holding the core subcritical under safe shutdown conditions as described in Section 7.4.

The reactor is brought to shutdown conditions before beginning operations to open the reactor vessel for refueling. After the RCS is cooled down and depressurized, the vessel head is unbolted and slowly removed. The refueling cavity and the fuel transfer canal are then flooded with borated water from the In-containment Refueling Water Storage Tank (IRWST) by the use of the Spent Fuel Pool Cooling System (SFS).

During refueling, the water volumes in the RCS, the fuel transfer canal and the refueling cavity are contiguous. However, the soluble boron concentration is not necessarily the same in each volume. If additions of boron are required during refueling, the Chemical and Volume Control System (CVS) provides the borated makeup.

BASES

BACKGROUND (continued)

The pumping action of the Normal Residual Heat Removal System (RNS) in the RCS, the SFS pumps in the spent fuel pool and refueling cavity, and the natural circulation due to thermal driving heads in the reactor vessel and refueling cavity mix the added concentrated boric acid with the water in the fuel transfer canal. The RNS is in operation during refueling to provide forced circulation in the RCS, while the SFS is in operation to cool and purify the spent fuel pool and refueling cavity. Their operation assists in maintaining the boron concentration in the RCS, the refueling cavity, and fuel transfer canal above the COLR limit.

APPLICABLE SAFETY ANALYSES

The boron concentration limit, specified in the COLR, is based on the core reactivity at the beginning of each fuel cycle (the end of refueling) and includes an uncertainty allowance.

The required boron concentration and the plant refueling procedures that verify the correct fuel loading plan (including full core mapping) ensure that the k_{eff} of the core will remain ≤ 0.95 during the refueling operation. Hence, at least a 5% Δk/k margin of safety is established during refueling.

The RCS boron concentration satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that a minimum boron concentration be maintained in the RCS, the refueling cavity and the transfer tube while in MODE 6. The boron concentration limit specified in the COLR ensures that a core k_{eff} ≤ 0.95 is maintained during fuel handling operations. Violation of the LCO could lead to an inadvertent criticality during MODE 6.

APPLICABILITY

This LCO is applicable in MODE 6 to ensure that the fuel in the reactor vessel will remain subcritical. The required boron concentration ensures a k_{eff} of ≤ 0.95. Above MODE 6, LCO 3.1.1, “SHUTDOWN MARGIN (SDM)” ensures that an adequate amount of negative reactivity is available to shut down the reactor and maintain it subcritical.

BASES

ACTIONS

A.1 and A.2

Continuation of CORE ALTERATIONS or positive reactivity additions (including actions to reduce boron concentration) is contingent upon maintaining the plant in compliance with the LCO. If the boron concentration of any coolant volume in the RCS, the refueling cavity, or the fuel transfer canal is less than its limit, all operations involving CORE ALTERATIONS or positive reactivity additions must be suspended immediately.

Suspension of CORE ALTERATIONS and positive reactivity additions shall not preclude completion of actions to establish a safe condition, including moving a component to a safe position.

A.3

In addition to immediately suspending CORE ALTERATIONS or positive reactivity additions, boration to restore the concentration must be initiated immediately.

In determining the required combination of boration flow rate and concentration, no unique design basis accident (DBA) must be satisfied. The only requirement is to restore the boron concentration to its required value as soon as possible. In order to raise the boron concentration as soon as possible, the operator shall begin boration with the best source available for plant operations.

Once boration is initiated, it must be continued until the boron concentration is restored. The restoration time depends on the amount of boron that must be injected to reach the required concentration.

SURVEILLANCE REQUIREMENTS

SR 3.9.1.1

This SR verifies that the coolant boron concentration in the RCS, the refueling cavity and the fuel transfer canal is within the COLR limit. The boron concentration of the coolant in each volume is determined periodically by chemical analysis.

A minimum Frequency of once every 72 hours is a sufficient interval to verify the boron concentration. The surveillance interval is based on operating experience, isolation of unborated water sources in accordance with LCO 3.9.2, and the availability of the source range neutron flux monitors required by LCO 3.9.3.

3. 10 CFR 50, Appendix A, GDC 26.

B 3.9 REFUELING OPERATIONS

B 3.9.2 Unborated Water Source Flow Paths

BASES

BACKGROUND

During MODE 6 operation, all flow paths for reactor makeup water sources containing unborated water which are connected to the Reactor Coolant System (RCS) must be closed to prevent an unplanned dilution of the reactor coolant. At least one isolation valve in each flow path must be secured in the closed position.

The Chemical and Volume Control System is capable of supplying borated and unborated water to the RCS through various flow paths. Since a positive reactivity addition, made by reducing the boron concentration, is inappropriate during MODE 6, isolation of all unborated water sources prevents an unplanned boron dilution event.

APPLICABLE SAFETY ANALYSES

The possibility of an unplanned boron dilution event (Ref. 1) in MODE 6 is precluded by adherence to this LCO which requires that potential dilution sources be isolated. Closing the required valves during refueling operations prevents the flow of unborated water to the filled portions of the RCS. The valves are used to isolate unborated water sources. These valves have the potential to indirectly allow dilution of the RCS boron concentration in MODE 6. By isolating unborated water sources, a safety analysis for an uncontrolled boron dilution accident in accordance with the Standard Review Plan (Ref. 2) is not required in MODE 6.

The RCS boron concentration satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that flow paths to the RCS from unborated water sources be isolated to prevent unplanned boron dilution during MODE 6 and, thus, avoid a reduction in SHUTDOWN MARGIN.

APPLICABILITY

In MODE 6, this LCO is applicable to prevent an unplanned boron dilution event by ensuring isolation of all sources of unborated water to the RCS.

In MODES 1 through 5, the requirements of LCO 3.1.9, “Chemical and Volume Control System (CVS) Demineralized Water Isolation Valves and Makeup Line Isolation Valves,” apply.

BASES

ACTIONS

The ACTIONS Table has been modified by a Note which allows separate Condition entry for each unborated water source flow path.

A.1

Continuation of CORE ALTERATIONS is contingent upon maintaining the plant in compliance with this LCO. With any valve used to isolate unborated water sources not secured in the closed position, all operations involving CORE ALTERATIONS must be suspended immediately. The Completion Time of “Immediately” shall not preclude completion of actions to establish a safe condition, including movement of a component to a safe location.

Condition A has been modified by a Note to require that Required Action A.3 must be completed whenever Condition A is entered.

A.2

Preventing unplanned dilution of the reactor coolant boron concentration is dependent on maintaining the unborated water isolation valves secured closed. Securing the valves in the closed position verifies that the valves cannot be inadvertently opened. The Completion Time of “Immediately” requires an operator to initiate actions to close an open valve and secure the isolation valve in the closed position immediately. Once actions are initiated, they must be continued until the valves are secured in the closed position.

A.3

Due to the potential of having diluted the boron concentration of the reactor coolant, SR 3.9.1.1 (verification of boron concentration) must be performed whenever Condition A is entered to verify that the required boron concentration exists. The Completion Time of 4 hours is sufficient to obtain and analyze a reactor coolant sample for boron concentration.

SURVEILLANCE REQUIREMENTS

SR 3.9.2.1

These valves are to be secured closed to isolate possible dilution flow paths. The likelihood of a significant reduction in the boron concentration during MODE 6 operations is remote due to the large mass of borated water in the refueling cavity and the fact that all unborated water source flow paths are isolated, precluding a dilution. The boron concentration is checked every 72 hours during MODE 6 under SR 3.9.1.1. This surveillance demonstrates that the valves are closed through a system

BASES

SURVEILLANCE REQUIREMENTS (continued)

walkdown. The 31 day Frequency is based on engineering judgement and is considered reasonable in view of other administrative controls that will verify that the valve opening is an unlikely possibility.

REFERENCES

1. Chapter 15, “Accident Analyses.”
2. NUREG-0800, Standard Review Plan, Section 15.4.6, “Chemical and Volume Control System Malfunction that Results in a Decrease in Boron Concentration in the RCS.”

B 3.9 REFUELING OPERATIONS

B 3.9.3 Nuclear Instrumentation

BASES

BACKGROUND

The source range neutron flux monitors are used to monitor the core reactivity during refueling operations. The source range neutron flux monitors are part of the Protection and Safety Monitoring System (PMS). These detectors are located external to the reactor vessel and detect neutrons leaking from the core.

The source range neutron flux monitors are BF3 detectors operating in the proportional region of the gas filled detector characteristic curve. The detectors monitor the neutron flux in counts per second. The instrument range covers six decades of neutron flux ($1x10^{+6}$ cps) with a 5% instrument accuracy. The detectors also provide continuous visual and audible indication in the main control room and an audible alarm in the main control room and containment building.

APPLICABLE SAFETY ANALYSES

Two OPERABLE source range neutron flux monitors are required to provide a signal to alert the operator to unexpected changes in core reactivity such as those associated with an improperly loaded fuel assembly. During initial fuel loading, or when otherwise required, temporary neutron detectors may be used to provide additional reactivity monitoring (Ref. 2). The potential for an uncontrolled boron dilution accident is eliminated by isolating all unborated water sources as required by LCO 3.9.2 (Ref. 1).

The source range neutron flux monitors satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires two source range neutron flux monitors to be OPERABLE to ensure that redundant monitoring capability is available to detect changes in core reactivity.

APPLICABILITY

In MODE 6, the source range neutron flux monitors are required to be OPERABLE to determine possible changes in core reactivity. There are no other direct means available to monitor the core reactivity conditions. In MODES 2, 3, 4, and 5, the source range detectors and associated circuitry are also required to be OPERABLE by LCO 3.3.1, “Reactor Trip System Instrumentation.”

BASES

ACTIONS

A.1 and A.2

Redundancy has been lost if only one source range neutron flux monitor is OPERABLE. Since these instruments are the only direct means of monitoring core reactivity conditions, CORE ALTERATIONS and positive reactivity additions must be suspended immediately. Performance of Required Action A.1 shall not preclude completion of actions to establish a safe condition.

B.1

If no source range neutron flux monitors are OPERABLE, actions to restore a monitor to OPERABLE status shall be initiated immediately. Once initiated, actions shall be continued until a source range neutron flux monitor is restored to OPERABLE status.

B.2

If no source range neutron flux monitors are OPERABLE, there is no direct means of detecting changes in core reactivity. However, since CORE ALTERATIONS and positive reactivity additions are discontinued, the core reactivity condition is stabilized and no changes are permitted until the source range neutron flux monitors are restored to OPERABLE status. This stable condition is confirmed by performing SR 3.9.1.1 to verify that the required boron concentration exists.

The Completion Time of 4 hours is sufficient to obtain and analyze a reactor coolant sample for boron concentration. The Frequency of once per 12 hours ensures that unplanned changes in boron concentration would be identified. The 12 hour Frequency is reasonable considering the low probability of a change in core reactivity during this time period.

SURVEILLANCE REQUIREMENTS

SR 3.9.3.1

SR 3.9.3.1 is the performance of a CHANNEL CHECK, which is the comparison of the indicated parameter values monitored by each of these instruments. It is based on the assumption that the two indication channels should be consistent for the existing core conditions. Changes in core geometry due to fuel loading can result in significant differences between the source range channels, however each channel should be consistent with its local conditions.

The Frequency of 12 hours is consistent with the CHANNEL CHECK Frequency specified for these same instruments in LCO 3.3.1, “Reactor Trip System Instrumentation.”

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.3.2

SR 3.9.3.2 is the performance of a CHANNEL CALIBRATION every 24 months. This SR is modified by a Note stating that neutron detectors are excluded from the CHANNEL CALIBRATION. The CHANNEL CALIBRATION for the source range neutron flux monitors consisting of obtaining the detector plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to the manufacturer's data. The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage. Operating experience has shown these components usually pass the Surveillance when performed during the refueling outage.

REFERENCES

1. Chapter 15, "Accident Analysis."
2. Section 14.2.6.1, "Initial Fuel Loading."

B 3.9 REFUELING OPERATIONS

B 3.9.4 Refueling Cavity Water Level

BASES

BACKGROUND

The movement of irradiated fuel assemblies within containment requires a minimum water level of 23 ft above the top of the reactor vessel flange. During refueling, this maintains sufficient water level in containment, refueling cavity, refueling canal, fuel transfer canal, and spent fuel pool to retain iodine fission product activity in the event of a fuel handling accident (Refs. 1 and 2). Sufficient iodine activity would be retained to limit offsite doses from the accident to within the values reported in Chapter 15.

APPLICABLE SAFETY ANALYSES

During movement of irradiated fuel assemblies, the water level in the refueling cavity and the refueling canal is an initial condition design parameter in the analysis of a fuel-handling accident in containment, as postulated by Regulatory Guide 1.183 (Ref. 1).

The fuel handling accident analysis inside containment is described in Reference 2. This analysis assumes a minimum water level of 23 feet.

Refueling Cavity Water Level satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

A minimum refueling cavity water level of 23 ft above the reactor vessel flange is required to ensure that the radiological consequences of a postulated fuel handling accident inside containment are within the values calculated in Reference 2.

APPLICABILITY

Refueling Cavity Water Level is applicable when moving irradiated fuel assemblies in containment. The LCO minimizes the possibility of radioactive release due to a fuel handling accident in containment that is beyond the assumptions of the safety analysis. If irradiated fuel assemblies are not being moved in containment, there can be no significant radioactivity release as a result of a postulated fuel handling accident. Requirements for fuel handling accidents in the spent fuel pool are covered by LCO 3.7.5, “Spent Fuel Pool Water Level.”

BASES

ACTIONS

LCO 3.0.8 is applicable while in MODE 5 or 6. Since irradiated fuel assembly movement can occur in MODE 5 or 6, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, the fuel movement is independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

With a water level of < 23 ft above the top of the reactor vessel flange, all operations involving movement of irradiated fuel assemblies within containment shall be suspended immediately to ensure that a fuel handling accident cannot occur.

The suspension of fuel movement shall not preclude completion of movement to safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.4 1

Verification of a minimum water level of 23 ft above the top of the reactor vessel flange ensures that the design basis for the analysis of the postulated fuel handling accident during refueling operations is met. Water at the required level above the top of the reactor vessel flange limits the consequences of damaged fuel rods that are postulated to result from a fuel handling accident inside containment (Ref. 2).

The Frequency of 24 hours is based on engineering judgement and is considered adequate in view of the large volume of water and the normal procedural controls of valve positions which make significant unplanned level changes unlikely.

REFERENCES

1. Regulatory Guide 1.183, “Alternate Radiological Source Terms for Evaluating Design Basis Accidents at Nuclear Power Reactors.”

2. Section 15.7.4, “Fuel Handling Accident.”

B 3.9 REFUELING OPERATIONS

B 3.9.5 Containment Penetrations

BASES

BACKGROUND

During movement of irradiated fuel assemblies within containment, potential releases of fission product radioactivity within containment are monitored and filtered or are restricted from escaping to the environment when the LCO requirements are met. Monitoring of potential releases of radiation is performed in accordance with Administrative Controls Section 5.5.2, “Radioactive Effluent Control Program.” In MODES 1, 2, 3, and 4, containment OPERABILITY is addressed in LCO 3.6.1, “Containment.” In MODES 5 and 6, closure capability of containment penetrations is addressed in LCO 3.6.8, “Containment Penetrations.” Since there is no potential for containment pressurization due to a fuel handling accident, the Appendix J leakage criteria and tests are not required in MODES 5 and 6.

The containment serves to contain fission product radioactivity that may be released from the reactor core following an accident, such that offsite radiation exposures are maintained within the requirements of 10 CFR 50.34. For a fuel handling accident, the AP1000 dose analysis does not rely on containment closure to meet the offsite radiation exposure limits. This LCO is provided as an additional level of defense against the possibility of a fission product release from a fuel handling accident.

The containment equipment hatches, which are part of the containment pressure boundary, provide a means for moving large equipment and components into and out of containment. During movement of irradiated fuel assemblies within containment, an equipment hatch is considered closed if the hatch cover is held in place by at least four bolts. Good engineering practice dictates that the bolts required by this LCO be approximately equally spaced.

If the equipment hatch is open, an alternative barrier between the containment atmosphere and the outside atmosphere shall be in place. Each containment equipment hatch opens into a staging area in the auxiliary building. These staging areas contain doors that open to the radiologically controlled areas of the annex building. The annex building contains a door that opens to the outside atmosphere. The alternate barrier may consist of the staging area in the auxiliary building, or may consist of the staging areas in the auxiliary building and the radiologically controlled areas in the annex building provided the doors from the annex building to the outside atmosphere are closed. The alternate barrier may

BASES

BACKGROUND (continued)

also consist of a temporary equipment hatch cover that provides equivalent isolation capability. The alternate boundary prevents the airborne fission products from being readily released to the atmosphere if the equipment hatches were open during a fuel handling accident.

If an equipment hatch is open during movement of irradiated fuel assemblies within containment, the containment air filtration system (VFS) shall be OPERABLE, and at least one exhaust fan shall be operating to provide for monitoring of air-borne radioactivity. This system services the containment, and upon detection of high radiation, also services the fuel handling area, the auxiliary building (including the staging areas), and the annex building. If high airborne radioactivity is detected in the area enclosed by the alternate barrier, the radiologically controlled area ventilation system (VAS) supply and exhaust duct isolation dampers automatically close to isolate the affected area from the outside environment, and the VAS exhaust is automatically aligned to the VFS exhaust subsystem. The operation of the VFS exhaust fans provides the system with the ability for monitoring of radioactivity releases from containment following a fuel handling accident and, if operating, will provide filtration of the containment atmosphere.

If a personnel air lock or spare containment penetration is open during movement of irradiated fuel assemblies within containment, then the containment air filtration system (VFS) shall be OPERABLE and operating to monitor for the release of radioactivity and to provide filtration of the air inside containment. These penetrations open into the auxiliary building. Upon detection of high radiation in the exhaust air from the auxiliary building, VFS will provide filtered exhaust of these areas. Considering that these penetrations open into the auxiliary building and not directly to the atmosphere, and that the VFS is in operation, an alternate barrier to the release of radioactivity directly to the environment is provided.

APPLICABLE SAFETY ANALYSES

For the AP1000, there are no safety analyses that require containment closure during movement of irradiated fuel assemblies within containment, other than those discussed in LCO 3.6.8. Fuel handling accidents, analyzed in Reference 1, include dropping a single irradiated fuel assembly and handling tool or a heavy object onto other irradiated fuel assemblies. The requirements of LCO 3.9.4, “Refueling Cavity Water Level,” ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are well within the

BASES

APPLICABLE SAFETY ANALYSES (continued)

guideline values specified in 10 CFR 50.34. Standard Review Plan, Section 15.0.1 (Reference 2), defines the dose acceptance limit to be 25% of the limiting dose guideline values.

This specification is included as defense-in-depth.

LCO

This LCO provides defense-in-depth against the consequences of a fuel handling accident in containment by limiting the potential escape paths for fission product radioactivity released within containment. This LCO requires that if an equipment hatch, personnel air lock, or spare containment penetration is open during movement of irradiated fuel assemblies within containment, then the containment air filtration system (VFS) shall be OPERABLE and operating to monitor for the release of radioactivity and to provide filtration of the air inside containment.

The VFS is OPERABLE when:

a. One VFS exhaust fan is operating; the associated HEPA filter and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration function; and air circulation can be maintained;

b. An alternative barrier between the containment atmosphere and the outside atmosphere is in place. The alternate barrier may consist of the staging area in the auxiliary building, or may consist of the staging areas in the auxiliary building and the radiologically controlled areas in the annex building provided the doors from the annex building to the outside atmosphere are closed.

   Doors in the alternate barrier which are normally closed may be opened for short periods of time for ingress and egress. The alternate barrier may also consist of a temporary equipment hatch cover that provides equivalent isolation capability.

APPLICABILITY

The containment penetration requirements are applicable during movement of irradiated fuel assemblies within containment because this is when there is a potential for a fuel handling accident. In MODES 1, 2, 3, and 4, containment penetration requirements are addressed by LCO 3.6.1. In MODES 5 and 6, when movement of irradiated fuel assemblies within containment are not being conducted, the potential for a fuel handling accident does not exist. Containment closure capability in MODES 5 and 6 are addressed by LCO 3.6.8.

BASES

ACTIONS

LCO 3.0.8 is applicable while in MODE 5 or 6. Since irradiated fuel assembly movement can occur in MODE 5 or 6, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, the fuel movement is independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

The required status for the containment equipment hatch, air locks or spare penetration is either closed, or open with the VFS OPERABLE and operating. The required status for the containment penetrations that provide direct access from the containment atmosphere to the outside atmosphere is either closed by a manual or automatic isolation valve, blind flange or equivalent, or capable of being closed by an OPERABLE Containment Isolation Signal. If the containment equipment hatch or air locks, or any containment penetration that provides direct access from the containment atmosphere to the outside atmosphere is not in the required status, the unit must be placed in a condition where the isolation function is not needed. This is accomplished by immediately suspending movement of irradiated fuel assemblies within containment. Performance of these actions shall not preclude completion of movement of a component to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.5 1

This Surveillance verifies that each of the containment penetrations required to be in its closed position is in that position or the VFS is OPERABLE and operating. For the VFS to be considered OPERABLE, this surveillance also requires that an alternate barrier is in place.

SR 3.9.5.2

This Surveillance demonstrates that each containment purge and exhaust valve actuates to its isolation position on manual initiation. The Surveillance on the open purge and exhaust valves will demonstrate that the valves are not blocked from closing. The Frequency is in accordance with the Inservice Testing Program.

The SR is modified by a Note stating that this Surveillance is not required to be met for valves in isolated penetrations. The LCO provides the option to close penetrations in lieu of requiring automatic actuation capability.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.5.3

This SR verifies the ability of the VFS to maintain a negative pressure (≤ -0.125 inches water gauge relative to outside atmospheric pressure) in the containment and the portions of the auxiliary and/or annex building that comprise the envelope defined as the alternate barrier. This surveillance is performed with the VFS in containment operating. Doors in the alternate barrier which are normally closed may be opened for ingress and egress. The portion of the VAS which services the area enclosed by the alternate barrier is aligned to the VFS exhaust subsystem, and the VAS auxiliary/annex building supply fans and VFS containment purge supply fans not operating. The Frequency of 24 months is consistent with the guidance provided in NUREG-0800, Section 6.5.1 (Ref. 3).

SR 3.9.5.4

The VFS should be checked periodically to ensure that it functions properly. As the operating conditions on this system are not severe, testing each train within 31 days prior to fuel movement provides an adequate check on this system. Operation of the heater dries out any moisture accumulated in the charcoal from humidity in the ambient air.

B 3.9 REFUELING OPERATIONS

B 3.9.6 Containment Air Filtration System (VFS)

BASES

BACKGROUND

The radiologically controlled area ventilation system (VAS) serves the fuel handling area of the auxiliary building, and the radiologically controlled portions of the auxiliary and annex buildings, except for the health physics and hot machine shop areas which are provided with a separate ventilation system (VHS). If high airborne radioactivity is detected in the exhaust air from the fuel handling area, the auxiliary building, or the annex buildings, the VAS supply and exhaust duct isolation dampers automatically close to isolate the affected area from the outside environment and the containment air filtration exhaust subsystem starts. The VFS exhaust subsystem prevents exfiltration of unfiltered airborne radioactivity by maintaining the isolated zone at ≤ -0.125 inches water gauge pressure relative to the outside atmosphere. Monitoring of potential releases of radiation is performed in accordance with Administrative Controls Section 5.5.2, “Radioactive Effluent Control Program.”

For a fuel handling accident, the AP1000 dose analysis does not rely on the OPERABILITY of the VAS or VFS exhaust subsystem to meet the offsite radiation exposure limits. This LCO is provided as an additional level of defense-in-depth against the possibility of a fission product release from a fuel handling accident in the fuel building. The plant vent radiation detectors monitor effluents discharged from the plant vent to the environment.

Each VFS exhaust subsystem includes one 100 percent capacity exhaust air filtration unit, and the associated exhaust fan, heater and ductwork.

The filtration units are connected to a ducted system with isolation dampers to provide HEPA filtration and charcoal adsorption of exhaust air from the containment, fuel handling area, radiologically controlled areas of the auxiliary and annex buildings. A gaseous radiation monitor is located downstream of the exhaust air filtration units to provide an alarm if abnormal gaseous releases are detected. The plant vent exhaust flow is monitored for gaseous, particulate and iodine releases to the environment. During conditions of abnormal airborne radioactivity in the fuel handling area, auxiliary and/or annex buildings, the VFS exhaust subsystem provides filtered exhaust to minimize unfiltered offsite releases.

BASES

BACKGROUND (continued)

The VAS is described in Reference 1 and the VFS is described in Reference 2.

APPLICABLE SAFETY ANALYSES

The VFS is not required to mitigate the consequences of the limiting Design Basis Accident (DBA), which is a fuel handling accident. The analysis of the fuel handling accident, given in Reference 3, assumes that all fuel rods in an assembly are damaged. The DBA analysis of the fuel handling accident does not assume that the VFS provides a filtered exhaust, and its operation would reduce the consequences of the fuel handling accident.

This specification is included for defense-in-depth.

LCO

One VFS exhaust subsystem is required to be OPERABLE to reduce the consequences of a fuel handling accident by filtering the fuel building atmosphere.

A VFS exhaust subsystem is considered OPERABLE when its associated:

a. Exhaust fan is capable of operating;

b. HEPA filter and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration function;

c. The associated heater and ductwork are capable of operating.

APPLICABILITY

During movement of irradiated fuel in the fuel handling area, one VFS exhaust subsystem is OPERABLE to alleviate the potential consequences of a fuel handling accident.

ACTIONS

LCO 3.0.3 is applicable while in MODE 1, 2, 3, or 4. Since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3 while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

BASES

ACTIONS (continued)

LCO 3.0.8 is applicable while in MODE 5 or 6. Since irradiated fuel assembly movement can occur in MODE 5 or 6, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, the fuel movement is independent of shutdown reactor operations. Entering LCO 3.0.8 while in MODE 5 or 6 would require the optimization of plant safety, unnecessarily.

A.1

When the required VFS exhaust subsystem is inoperable during movement of irradiated fuel assemblies in the fuel building, action must be taken to place the unit in a condition in which the LCO does not apply. Action must be taken immediately to suspend movement of irradiated fuel assemblies in the fuel building. This does not preclude the movement of fuel to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.6.1

Each VFS exhaust subsystem should be checked 31 days prior to fuel movement in the fuel handling area to ensure that it functions properly. As the operating conditions on this subsystem are not severe, testing each subsystem within one month prior to fuel movement provides an adequate check on this system. Operation of the heater dries out any moisture accumulated in the charcoal from humidity in the ambient air.

SR 3.9.6.2

This SR verifies that the VAS fuel handling area subsystem aligns to the VFS and that the VFS exhaust subsystem starts and operates on an actual or simulated actuation signal. During the post-accident mode of operation, the VAS fuel handling area subsystem aligns to the VFS filtered exhaust subsystem. The 24 month Frequency is consistent with Reference 4.

SR 3.9.6.3

This SR verifies the integrity of the fuel handling area of the auxiliary building enclosure. The ability of the VAS and VFS to maintain negative pressure (≤ -0.125 inches water gauge relative to outside atmospheric pressure) in the fuel handling area of the auxiliary building is periodically tested to verify proper function of the VAS and VFS exhaust subsystem. During this surveillance, the VAS fuel handling area subsystem is aligned

BASES

SURVEILLANCE REQUIREMENTS (continued)

to the operating VFS exhaust subsystem. The fan for the VAS fuel handling area subsystem is off. In this configuration, the VFS exhaust subsystem is designed to maintain a negative pressure in the fuel handling area of the auxiliary building (≤ -0.125 inches water gauge relative to outside atmospheric pressure), to prevent unfiltered and unmonitored leakage. Doors may be opened for short periods of time to allow ingress and egress. During this surveillance, the VAS may be servicing the remaining portions of the auxiliary and annex buildings. The Frequency of 24 months is consistent with the guidance provided in NUREG-0800, Section 6.5.1 (Ref. 5).

B 3.9 REFUELING OPERATIONS

B 3.9.7 Decay Time

BASES

BACKGROUND

The movement of irradiated fuel assemblies within containment or in the fuel handling area inside the auxiliary building requires allowing at least 48 hours for radioactive decay time before fuel assembly handling can be initiated. During fuel handling, this ensures that sufficient radioactive decay has occurred in the event of a fuel handling accident (Refs. 1 and 2). Sufficient radioactive decay of short-lived fission products would have occurred to limit offsite doses from the accident to within the values reported in Chapter 15.

APPLICABLE SAFETY ANALYSES

During movement of irradiated fuel assemblies, the radioactivity decay time is an initial condition design parameter in the analysis of a fuel-handling accident inside containment or in the fuel handling area inside the auxiliary building, as postulated by Regulatory Guide 1.183 (Ref. 1).

The fuel handling accident analysis inside containment or in the fuel handling area inside the auxiliary building is described in Reference 2. This analysis assumes a minimum radioactive decay time of 48 hours.

Radioactive decay time satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

A minimum radioactive decay time of 48 hours is required to ensure that the radiological consequences of a postulated fuel handling accident inside containment or in the fuel handling area inside the auxiliary building are within the values calculated in Reference 2.

APPLICABILITY

Radioactive decay time is applicable when moving irradiated fuel assemblies in containment or in the fuel handling area inside the auxiliary building. The LCO minimizes the possibility of radioactive release due to a fuel handling accident that is beyond the assumptions of the safety analysis. If irradiated fuel assemblies are not being moved, there can be no significant radioactivity release as a result of a postulated fuel handling accident. Requirements for fuel handling accidents in the spent fuel pool are also covered by LCO 3.7.5, “Spent Fuel Pool Water Level.”

BASES

ACTIONS

LCO 3.0.8 is applicable while in MODE 5 or 6. Since movement of irradiated fuel assemblies with less than 48 hours of decay time can occur in MODE 6 after removing the reactor vessel head following the reactor shutdown, the ACTIONS have been modified by a Note stating that LCO 3.0.8 is not applicable. If moving irradiated fuel assemblies while in MODE 6, the fuel movement is independent of shutdown reactor operations since the reactor is already shutdown. Entering LCO 3.0.8 while in MODE 6 would not specify any action.

A.1

With a decay time of less than 48 hours, all operations involving movement of irradiated fuel assemblies within containment or in the fuel handling area inside the auxiliary building shall be suspended immediately to ensure that a fuel handling accident cannot occur.

The suspension of fuel movement shall not preclude completion of movement to safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.7.1

Verification that the reactor has been subcritical for at least 48 hours prior to movement of irradiated fuel in the reactor pressure vessel to the refueling cavity in containment or to the fuel handling area inside the auxiliary building ensures that the design basis for the analysis of the postulated fuel handling accident during refueling operations is met. Specifying radioactive decay time limits the consequences of damaged fuel rods that are postulated to result from a fuel handling accident (Ref. 2).

5.0 ENVIRONMENTAL IMPACTS OF OPERATION

Chapter 5 presents the potential environmental impacts of operation of Units 6 & 7. In accordance with 10 CFR Part 51, impacts are analyzed, and a single significance level of potential impact to each resource (i.e., SMALL, MODERATE, or LARGE) is assigned consistent with the criteria that NRC established in 10 CFR Part 51, Appendix B, Table B-1, Footnote 3 as follows:

SMALL — Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, NRC has concluded that those impacts that do not exceed permissible levels in NRC's regulations are considered small.

MODERATE — Environmental effects are sufficient to alter noticeably, but not to destabilize, any important attribute of the resource.

LARGE — Environmental effects are clearly noticeable and are sufficient to destabilize any important attributes of the resource.

Mitigation of adverse impacts, if appropriate, is presented. This chapter is divided into 12 subsections:

- Land Use Impacts (Section 5.1)
- Water-Related Impacts (Section 5.2)
- Cooling System Impacts (Section 5.3)
- Radiological Impacts of Normal Operations (Section 5.4)
- Environmental Impacts of Waste (Section 5.5)
- Environmental Impacts of Transmission System (Section 5.6)
- Uranium Fuel Cycle and Transportation Impacts (Section 5.7)
- Socioeconomic Impacts (Section 5.8)
- Decommissioning (Section 5.9)
- Measures and Controls to Limit Adverse Impacts During Operations (Section 5.10)
- Cumulative Impacts Related to Station Operation (Section 5.11)
- Nonradiological Health Impacts (Section 5.12)

5.1 LAND USE IMPACTS

The following subsections describe the impacts of Units 6 & 7 operations on land use at the Turkey Point plant property and the 6-mile vicinity, including impacts to historical properties and cultural resources. Subsection 5.1.1 describes impacts to the site and vicinity. Subsection 5.1.2 describes impacts along transmission corridors and offsite areas. Subsection 5.1.3 describes impacts to historical properties and cultural resources. Table 5.1-1 summarizes the permanent land disturbance.

5.1.1 THE SITE AND VICINITY

5.1.1.1 The Site

Land use impacts from construction are described in Subsection 4.1.1.1. The new Units 6 & 7 power block, cooling towers and reservoir, substation, and associated infrastructure would permanently occupy the 218-acre Units 6 & 7 plant area (Figure 3.9-1). Additional permanent supporting facilities would be located outside of the Units 6 & 7 plant area but on the Turkey Point plant property. These facilities would include the FPL reclaimed water treatment facility, reclaimed water pipelines, radial collector wells and pipelines, nuclear administration and training buildings, parking areas, laydown areas, expanded equipment barge unloading area, security buildings, heavy haul road improvements, transmission infrastructure, sanitary waste pipelines, potable water supply pipelines, access road improvements, and the spoils areas. The radial collector well laterals would be drilled horizontally in the subsurface from the well caisson to locations beneath the floor of Biscayne Bay. Table 5.1-1 identifies the permanent facilities and dedicated areas. Below-grade facilities such as pipelines are not considered permanent facilities since they are underground and the land at grade could be utilized for other uses. The laydown areas are considered permanently dedicated since they may not be fully restored to pre-construction conditions and may be used during the operation of Units 6 & 7.

As addressed in Sections 2.2 and 4.1, the Miami-Dade County Comprehensive Development Master Plan land use designation for the location of Units 6 & 7 is *Environmental Protection, Subarea F*. Necessary electrical generation and transmission facilities are permitted in this area. The Units 6 & 7 plant area and most of the surrounding land is zoned as GU (interim district), with the exception of Units 1 through 5 and the area to the north of the Units 6 & 7 plant area, which are zoned as IU-3 (Industrial, Unlimited Manufacturing District). The GU zoning district allows nuclear reactors, provided that approval by Miami-Dade County of an *Unusual Use* for the site is obtained. FPL applied for *Unusual Use* approval for the proposed Units 6 & 7 site from Miami-Dade County, which was granted in Resolution No. Z-56-07 by the Miami-Dade Board of County Commissioners in December 2007. There would be no additional changes to land use within the Turkey Point plant property for operation of Units 6 & 7.

Land use impacts on the Turkey Point plant property from the operation of Units 6 & 7 could occur from salt and other particulate deposits associated with the operation of the six mechanical draft cooling towers. Salt deposits from cooling tower operation would have a small impact on onsite vegetation, fish, waterbirds, and also critical habitat for crocodiles, including hatchlings and juveniles, in the nearby cooling canals of the industrial wastewater facility, and further afield within the 6-mile vicinity. The potential impacts of salt deposits, fogging, and shadowing are presented in Section 5.3.

Based on the limited and localized impact to permanent land use and the small, localized impacts of the cooling towers with respect to salt deposits, fogging, and shadowing, impacts to land use as a result of operation of Units 6 & 7 would be SMALL and would not warrant mitigation.

5.1.1.2 The Vicinity

As described in Subsection 2.2.1.2, current land use within 6 miles of Units 6 & 7 is described in Table 2.2-2. The vicinity includes areas that have the land use designation Environmental Protection and Open Land in the Miami-Dade County Comprehensive Development Master Plan. Biscayne National Park, Biscayne Bay Aquatic Preserve, Homestead Bayfront Park, the Model Lands Basin, and the Everglades Mitigation Bank are located in the vicinity adjacent to the plant property.

Most permanent facilities associated with the operation of Units 6 & 7 would be contained within Turkey Point plant property boundaries except for portions of the reclaimed water pipelines, potable water pipelines, transmission corridors, public access roads, and the FPL-owned fill source. The reclaimed water pipelines and transmission corridors would follow the existing transmission corridors within the vicinity of Units 6 & 7. The potable water pipelines would follow existing linear facilities (e.g., existing roads). The radial collector wells would be drilled horizontally from the Turkey Point plant property to subsurface positions of the lateral screens located below Biscayne Bay. Pipelines would be below grade, thus having minimal impact on permanent land use.

The FPL-owned fill source and portions of the reclaimed water pipelines, potable water pipelines, transmission corridors, and roads are located within the 6-mile vicinity of Units 6 & 7. The potential land use impacts of these facilities from the operation of Units 6 & 7 are described in Subsection 5.1.2.

No land use impacts from operation of Units 6 & 7 would occur to recreational or protected areas in the 6-mile vicinity. Most permanent facilities associated with Units 6 & 7 are contained within the boundaries of the Turkey Point plant property, and operational activities for these facilities would not impact land use in nearby park areas. Additionally, the Miami-Dade County Unusual Use Approval for Units 6 & 7 stipulates several mitigative actions/plans to minimize impacts to the

vicinity. Therefore, impacts to land use in the 6-mile vicinity from the operation of Units 6 & 7 would be SMALL and would not warrant mitigation.

5.1.2 TRANSMISSION CORRIDORS AND OFFSITE AREAS

The preferred transmission corridors, offsite substations, FPL-owned fill source, reclaimed water pipelines, and potable water pipelines are located offsite of the Turkey Point plant property. The potential land use impacts from operation of Units 6 & 7 associated with these offsite facilities and areas are presented in the following subsections.

5.1.2.1 Transmission Corridors and Substations

Transmission Corridors

The land proposed as transmission corridors for Units 6 & 7 is described in Subsection 2.2.2 and Section 3.9. FPL would acquire new transmission line rights-of-way and would restrict incompatible uses in the rights-of-way. FPL requires that the landowners' uses in rights-of-way be compatible with the safe and reliable transmission of electricity. In areas that are in active agricultural cultivation, FPL typically allows farmers to grow feed for livestock and tree crops within the transmission line rights-of-way, subject to height limitations for vegetation and operation. FPL has established rights-of-way vegetation management and line maintenance programs and procedures that would be used to maintain the rights-of-way and transmission lines associated with Units 6 & 7 to minimize impacts. The same procedures establish strict guidelines for use of herbicide application according to federal, state, and local regulations. In addition, environmental best management practices would be used to reduce soil erosion and sedimentation. Vegetation management in forested wetlands would comply with Florida Statute 403.814 General Permits. Accordingly, impacts from the operation of Units 6 & 7 to land use in transmission corridors would be SMALL and would not warrant additional mitigation.

Substations

As described in Sections 3.7 and 4.1, construction and/or expansion of several substations would meet applicable environmental regulatory requirements for their construction and operation; accordingly, potential land use impacts from operations would be SMALL and would not warrant additional mitigation.

5.1.2.2 Makeup Water Sources

As described in Sections 3.3 and 3.4, during normal operation of Units 6 & 7, waste heat would be dissipated by mechanical draft cooling towers. Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. The primary source would be water reclaimed for reuse after processing by the Miami-Dade Water and Sewer Department, conveyed via pipelines

to the Turkey Point plant property. An onsite FPL reclaimed water treatment facility would further treat the reclaimed water for use in the cooling system. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. The well caissons would be located on the Turkey Point peninsula, east of the existing units. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. Potential land use impacts of Units 6 & 7 operational activities for these cooling water sources are described below.

The land that would be used for the below-ground reclaimed water pipelines is identified in Figure 2.2-5. Upon completion of construction activities, the reclaimed water pipelines would be underground, functional, and permanent. Miami-Dade County or FPL would access the right-of-way during operations for maintenance along public roads or through access agreements with adjacent landowners. As a result, impacts to offsite land use from operation of the reclaimed water pipelines for Units 6 & 7 would be SMALL and would not warrant mitigation.

As described in Subsection 2.2.2, upon completion of construction activities, the radial collector well caissons and pumping station would be on Turkey Point plant property and would be functional and permanent. The subterranean lateral screens would be located on the Turkey Point plant property and offsite, with laterals projecting horizontally from a location on the property to positions underneath Biscayne Bay, and would not impact land use of the offsite land area or Biscayne Bay. Accordingly, impacts to offsite land use from operation of the radial collector wells would be SMALL and would not warrant mitigation.

5.1.2.3 FPL-Owned Fill Source

Backfill for the construction of Units 6 & 7 would be obtained from an FPL-owned fill source located on a 300-acre plot near Homestead Air Reserve Base approximately 4.5 miles northwest of the Units 6 & 7 plant area (Figure 3.9-1), other regional sources, or reused material. The FPL-owned fill source area would cease operation with the completion of Units 6 & 7 construction activities. Once its use as a borrow mining facility is completed, plans are that the area would be maintained as a surface water management area, under FPL or other local or regional ownership, management, and control. The land use impact would be SMALL.

Fill borrow material for use during operation and maintenance of Units 6 & 7 would likely be supplied through commercial providers.

5.1.2.4 Access Roadways

As described in Sections 3.9 and 4.1, the Units 6 & 7 project includes road improvements to allow access to the Turkey Point plant property for construction and operations. The improvements

include the widening of three existing roadways and the development of existing unpaved roads to four paved roadways (Figure 3.9-1).

The roadways would impact approximately 128 acres of land that would not be available for other uses. However, the locations of the road improvements were selected to use, to the greatest extent practical, existing roadways to minimize environmental impacts. With local government approval for the location of the roadway improvements and the granting of easements for the roadway use, the land use impacts would be SMALL and would not require additional mitigation.

Roadway improvements installed during construction could be removed during operation. If it is determined to remove access roadway improvements, this activity would be conducted with environmental best management practices to reduce impacts to wetlands and canals. Restoration, at a minimum, would result in removal of previous building materials, maintenance of historical hydrology, and regrading to previous contours. Impacts to terrestrial and aquatic flora and fauna, including possible interactions with crocodiles and panthers along remote sections, would be reduced by removal of the road and reduction/cessation of traffic flow. Potential mitigation for impacts of roadway removal would be covered by mitigation associated with roadway improvements (see Subsection 4.3.1).

Waste Management

As described in Sections 3.4 and 3.6, cooling tower blowdown and other site wastewater streams would be collected in a common blowdown sump and injected through deep injection wells.

As described in Section 5.5, Units 6 & 7 would generate radioactive solid wastes that would be disposed of in permitted radioactive waste disposal facilities and nonradioactive solid wastes that would be disposed of in permitted landfills off of the Turkey Point plant property. Both types of solid waste are commonly generated, and permitted disposal facilities and landfills are located throughout the United States. Additionally, Units 6 & 7 would generate spent nuclear fuel, which would be safely and securely stored on the Turkey Point plant property until such time as the DOE constructs, and the NRC licenses, a high-level waste disposal facility.

Because wastewaters and wastes would be properly dispositioned, meeting regulatory permitting requirements, impacts to offsite land use from waste management activities associated with Units 6 & 7 would be SMALL and would not warrant mitigation.

5.1.3 HISTORIC PROPERTIES AND CULTURAL RESOURCES

FPL has initiated consultation with the State Historic Preservation Officer (SHPO) regarding the proposed project. FPL prepared and submitted a *Cultural Resource Assessment Survey for the Turkey Point Units 6 & 7 Site, Associated Non-Linear Facilities, and Spoils Area on Plant Property* (FPL 2009a). In addition, FPL prepared and submitted a *Cultural Resource Assessment*

Survey Work Plan for the Turkey Point Units 6 & 7 Site and Associated Non-Linear Facilities (FPL 2009b). Based on the findings contained in these two reports, which included historical research, pedestrian surveys, and field archaeological investigation (e.g., shovel testing), no further surveys or investigations are warranted at the plant or associated non-linear facilities due to the lack of any cultural resources in these areas. The SHPO has concurred with these recommendations (FDOS Jul 2009a).

FPL also prepared and submitted to SHPO a *Preliminary Cultural Resources Report for the Turkey Point Units 6 & 7 Associated Linear Facilities* (FPL 2009c) and a *Cultural Resource Assessment Survey Work Plan for the Turkey Point Units 6 & 7 Associated Linear Facilities* (FPL 2009d). These reports described (1) areas of potential effects (APEs) for physical disturbance and visual impacts to historic properties from the proposed Units 6 & 7 Project, and (2) what investigations, if any, will be required in those APEs to determine potential effects to historic properties. The SHPO concurred with the recommendations made in these submittals (FDOS Jul 2009b). FPL will proceed with the necessary research and field reconnaissance and/or investigations at the linear facilities once the locations for these facilities are finalized. The results of the field assessments conducted and FPL's recommendations on effects to historic properties will be submitted to the SHPO.

Operational activities, including maintenance, would occur in areas that were previously disturbed during construction of Units 6 & 7. It is unlikely that these areas would contain any intact historic properties once construction has been completed. FPL anticipates that operational activities would have no impacts on historic properties and would not warrant mitigation beyond that being implemented to mitigate any adverse effects associated with construction.

With operational activities, there remains the possibility for inadvertent discovery of previously unknown archaeological materials or human remains. The Unanticipated Finds Plan implemented during construction, as described in Section 4.1.3, would be slightly modified for operational activities and included in the operational procedures for Units 6 & 7.

(3) Acreage will be restored to pre-existing conditions.

(4) Acreage will be below grade.

(5) Actual disturbed acreage will be based on required right-of-way.

5.2 WATER-RELATED IMPACTS

Water-related impacts from the operation of Units 6 & 7 could result from: (1) hydrologic alteration of local surface water bodies, including streams and wetlands, and groundwater as a result of operational diversions, (2) ground surface elevation changes as a result of subsidence caused by the withdrawal of groundwater, (3) groundwater elevation changes as a result of groundwater withdrawal operations, and (4) groundwater impacts from the deep injection wells. Impacts could also occur to water quality as a result of erosion and sedimentation and to surface water and groundwater resulting from spills of fuels, lubricants, and other operational-related pollutants. Because of this potential for impacting surface water and groundwater resources, applicants are required to obtain a number of permits as outlined in Table 1.2-1.

As described in Subsection 2.3.1, water bodies on the Turkey Point plant property that could be affected by the operation of Units 6 & 7 are the industrial wastewater facility and the barge turning basin. Offsite water bodies that could be impacted by the operational activities include Biscayne Bay, named and unnamed surface water drainage canals, and unnamed surface water drainage features that could be impacted primarily by maintenance activities along the reclaimed water pipelines, potable water pipelines, and the transmission line rights-of-way.

As described in Subsection 2.3.1, the surficial aquifer at the Turkey Point plant property is the Biscayne aquifer. The Biscayne aquifer at the Turkey Point plant property is not used as a source of potable water due to the presence of saline water. However, in Miami-Dade County, the aquifer is used as a sole-source aquifer.

During normal operation of Units 6 & 7, waste heat would be dissipated by mechanical draft cooling towers. Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. The primary source would be water reclaimed for reuse after processing by the Miami-Dade Water and Sewer Department, conveyed via pipelines to the Turkey Point plant property. An onsite FPL reclaimed water treatment facility would further treat the reclaimed water for use in the cooling system. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. The well caissons would be located on the Turkey Point peninsula, east of the existing units. Radial collector well operation is described as the makeup water supply throughout this section.

5.2.1 HYDROLOGIC ALTERATIONS AND PLANT WATER SUPPLY

Impacts resulting from surface water runoff are similar for each of the facilities described below. Any impacts resulting from Units 6 & 7 operation would be mitigated, as required by appropriate permitting authorities. Examples of permitting requirements applicable to surface water impacts

include Florida Department of Environmental Protection (FDEP) requirements included in the FDEP Industrial Wastewater (IWW) permits.

These subsections identify operational activities on the Turkey Point plant property and offsite that could or would result in impacts to the hydrology at Turkey Point and in the offsite areas. These operations include:

- Operation of Units 6 & 7 and associated support facilities
- Use of the equipment barge unloading area and the heavy haul road to support maintenance activities during operations, such as heavy component replacement
- Transmission line right-of-way maintenance, reclaimed water and potable water pipelines right-of-way maintenance, deep injection well maintenance, and radial collector well maintenance
- The Units 6 & 7 plant property during operations would be subject to stormwater requirements of the existing industrial wastewater (IWW) permit applicable to the industrial wastewater facility.
- The removal of offsite road improvements added during the construction phase and restoration of the area to preconstruction conditions.

For project facilities and areas offsite of the Turkey Point plant property, including roads and transmission line and pipeline corridors, rules and guidance under the authority of FDEP (FAC 62-25) and SFWMD (FAC 40E-4) would apply to operations. Project stormwater sources would also be subject during operations to rules and guidance of the Miami-Dade County (MDC) Department of Environmental Resource Manager under MDC Code, Chapter 24.

5.2.1.1 Facilities on the Turkey Point Plant Property

5.2.1.1.1 Units 6 & 7 Plant Area

Surface Water

The Units 6 & 7 plant area would contain the principal structures, including the power blocks, makeup water reservoir and cooling towers, switchyard, and other infrastructure. Surface water that could be impacted during operation of these facilities is limited to the cooling canals of the industrial wastewater facility. Because the cooling canals of the industrial wastewater facility surround the Units 6 & 7 plant area and the berm located seaward of the eastern segment of the industrial wastewater facility provide a barrier to surface water movement, impacts to Biscayne

Bay would not occur. There is no major surface water body that discharges to Biscayne Bay in the vicinity of Units 6 & 7 where the presence of these facilities could alter hydrologic flow.

Overland flow of stormwater within the Units 6 & 7 plant area during operations would ultimately be to the industrial wastewater facility under a new or modification of the existing IWW facility permit. Overland flow to the industrial wastewater facility when compared to the amount of water circulating in the industrial wastewater facility would be insignificant.

The operation of the makeup water reservoir would alter the surface water hydrologic flow in the vicinity of the reservoir since it is a closed system and would be constructed and lined with concrete. Seepage from the makeup water reservoir could increase the level of flow within the industrial wastewater facility. Seepage could also raise the groundwater level in close proximity to the reservoir and create a greater flow to Biscayne Bay in the immediate area.

Considering all of the above influences to surface water hydrology from operations in the Units 6 & 7 plant area, impacts from hydrologic alteration would be SMALL and would not warrant mitigation.

Groundwater

The operation of the approximately 37-acre makeup water reservoir could slightly alter the groundwater hydrologic flow in the vicinity of the reservoir as a result of installation into the upper portion of the water table aquifer.

Potential seepage from the makeup water reservoir could locally alter the groundwater flow direction in the immediate vicinity of the reservoir. The alteration would depend on the amount of seepage. In the vicinity of the plant area, there are no groundwater users that would be impacted by the potentially altered flow. A local change in flow direction could result in additional groundwater flow to the surrounding industrial wastewater facility and increase locally the amount of groundwater discharging to Biscayne Bay.

Considering the limited influences to groundwater from operations in the Units 6 & 7 plant area, impacts would be SMALL and would not warrant mitigation.

5.2.1.1.2 Spoils Areas

Surface Water

Spoils areas would be established at three locations on the Turkey Point plant property to allow dewatering of materials from clearing, grubbing, and other excavation(s) (see Subsection 3.9.1.6 and Figure 3.9-1). Three separate spoils areas would be established at the southern end of the industrial wastewater facility. The spoils areas would be bermed to direct drainage from the spoils

piles to the industrial wastewater facility. The potential impacts resulting from hydrologic alteration of surface water would be SMALL and would not require mitigation.

Groundwater

The spoils piles would be dewatered as part of the construction effort. Surface water runoff from the spoils areas during Units 6 & 7 operation would not result in any additional runoff to the industrial wastewater facility compared to conditions prior to spoils placement. For these reasons, there would be no impacts on groundwater from the spoils areas during operation. Impacts would be SMALL and would not require mitigation.

5.2.1.1.3 Access Roads, Heavy Haul Road, and Equipment Barge Unloading Area

Surface Water

No dredging of the equipment barge unloading area would be required to support the operation of Units 6 & 7.

As described in Section 3.9, a road system is currently in place to support existing unit operations within the Turkey Point property. These roads, especially in the vicinity of Units 3 & 4, would support the operational activities for Units 6 & 7. The heavy haul road leading from the existing equipment barge unloading area location to Units 6 & 7 and other site roads used in support of Units 6 & 7 could require maintenance during operations including repaving or other modifications. Should regrading of graveled roads be required, the impacts would be temporary and limited to the area being serviced. Surface water runoff from road maintenance activities would be managed onsite or routed to the industrial wastewater facility. Potential impacts would be temporary and could be mitigated through the use of silt fencing that would limit runoff. The use of sedimentation control could also temporarily block surface water flow. Impacts to surface water flow from road operational use and maintenance would be SMALL and would not require mitigation other than described above.

The onsite road improvements described in Chapter 4 associated with construction activities could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction conditions by removing the improvements, recontouring the area and reseeded or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities. Impacts would be similar to those during construction and limited to the area of the road removal activity. Therefore, impacts to surface water hydrology would be SMALL and not require further mitigation.

Groundwater

Operational use or general maintenance of site roads would not alter groundwater flow directions. However, should extensive maintenance be required that would involve the need to excavate along the roads or a portion of the road beds, the groundwater flow direction could be temporarily altered. The potential impacts would be temporary and groundwater levels and flow direction would return to those encountered before maintenance activities began. Therefore, impacts would be SMALL and would not require mitigation.

As discussed in the surface water section above, onsite road improvements made during the construction phase of the project could be removed and the areas restored to preconstruction conditions during the operational phase. Dewatering would not be required during the restoration activities. Therefore, impacts to groundwater from the restoration to preconstruction conditions would be SMALL and not require mitigation.

5.2.1.1.4 Security Facilities

Surface Water

Operation and maintenance of security facilities, through the disturbance of surface soils, could divert surface water flow within the immediate area of the facility. For example, the use of non-flow-through temporary barriers used for security or to direct vehicular traffic could alter the flow of surface water in the vicinity of the barrier. Impacts from permanent structures would be similar to those during construction. Maintenance of security buildings or other permanent security facilities could require temporary construction activities be performed. Potential impacts would be temporary and local to the activity. Because of the relatively small size of these security stations and support infrastructure (fencing, gates, turnouts, etc.), impacts to surface water flow would be SMALL and would not require mitigation.

Groundwater

As described above, the maintenance to security facilities would result primarily in impacts from the disturbance of surface soils. Impacts to groundwater from the alteration of groundwater flow could occur. However, any impacts would be temporary. Once maintenance activities cease, any alteration to groundwater flow would cease. Impacts to groundwater from the alteration of groundwater flow would be SMALL and would not require mitigation.

5.2.1.1.5 Operational Utilities

Surface Water

As described in Section 3.9, permanent utilities would be installed during construction that would support Units 6 & 7 operation. These would include above ground and underground infrastructure

for power, lights, communications, potable and cooling water systems, water treatment facilities, wastewater and waste treatment facilities, fire protection, and operational maintenance gas and air systems.

Maintenance requiring the excavation of any of these utilities could impact surface water flow in the vicinity of the maintenance being performed. The use of sedimentation control could also temporarily block surface water flow. Maintenance activities performed on overhead utilities would not alter surface water flow unless the work area becomes rutted and begins to hold or redirect the flow of surface water. Should this situation occur, the area would undergo recontouring to redirect flow to its prior direction. These activities would, therefore, result in the short-term potential for impacts in relatively small areas. Impacts from these activities would be SMALL and would not require mitigation other than those specified through permit requirements.

Groundwater

Groundwater could be encountered during the maintenance excavation for underground utilities requiring the use of curtain drains or other forms of cutoff wall technologies during excavation operations. Dewatering activities, if needed, may require a permit and could require the use of a detention basin or other sedimentation control measures such as check dams, riprap, and sediment barriers based on site-specific permit requirements before discharge to a permitted outfall. Impacts to groundwater from hydrologic alteration during maintenance activities would be temporary and flow would return to normal when maintenance activities cease. Impacts would be SMALL and would not require mitigation other than that specified in the required permits.

5.2.1.1.6 Water and Sanitary Treatment Facilities

Surface Water

The FPL reclaimed water treatment facility would further treat the reclaimed water from Miami-Dade County before use. Sanitary treatment would be provided by a packaged sanitary treatment plant located on the Units 6 & 7 plant area. The sanitary treatment plant would be designed to process sanitary effluent from Units 1 through 7. None of the wastewater streams would be released to surface water bodies or to the ground surface.

Potential operational impacts of these facilities could, however, include those associated with maintenance activities. The disturbance of surface soils during maintenance activities could result in impacts similar to those resulting from the construction of the facility. Soil retention techniques such as silt barriers would be used to reduce impacts in accordance with prescribed environmental best management practices plan developed for Units 6 & 7. Should dewatering be necessary during maintenance activities, the water would be released to sediment control devices before being released in accordance with all state and local requirements. Potential impacts due to maintenance operations would be temporary and limited to the work area.

Impacts to surface water from the operations of the reclaimed water treatment facility and sanitary treatment plant would be SMALL and would not require mitigation.

Groundwater

The routine operational maintenance of the reclaimed water treatment facility and sanitary treatment plant would not result in direct impacts to groundwater. The discharge of treated wastewater and sanitary waste to the deep injection wells is addressed in Subsection 5.2.1.1.9. Maintenance activities performed at the facilities could, however, require limited dewatering. This could temporarily alter the flow of groundwater in the vicinity of the maintenance activity. Once dewatering ceases, the groundwater flow would return to normal.

Impacts to groundwater flow from the operations of reclaimed water treatment facility and the sanitary treatment plant would be SMALL and would not require mitigation.

5.2.1.1.7 Operation of the Reclaimed Water Pipelines

Surface Water

The reclaimed water delivery pipelines would connect to the FPL reclaimed water treatment facility. Therefore, a portion of the pipelines would be located within the Turkey Point plant property. Operational impacts could result from maintenance activities performed along the pipelines that could include maintaining a grassed or graveled/paved surface cover. Maintenance could require the excavation of the pipelines, which would require compliance with the environmental best management practices. The excavation and temporary stockpiling of soils would alter surface water flow. Once the maintenance activities are complete, the excavation would be filled and the area would be restored to its prior condition. The potential impact to surface water during operation of the reclaimed water pipelines would be SMALL and would not require mitigation.

Groundwater

The maintenance of the onsite portion of the reclaimed water pipelines could require the use of cutoff wall technology to limit potential impacts to groundwater flow during dewatering. The use of cutoff wall technology would alter the flow of groundwater in the vicinity of the excavation activity. Impacts would be short term and localized around the point of the dewatering. Once dewatering activities come to an end, the groundwater hydrologic flow would return to its previous conditions. Impacts during maintenance would be short term and limited to the area of maintenance activity. Therefore, impacts would be SMALL and would not require mitigation.

5.2.1.1.8 Operation of the Radial Collector Wells

A groundwater flow model (MODFLOW 2000/Visual MODFLOW) was used to assess the impacts of radial collector well operation to surface water and groundwater. The calibrated and verified groundwater model, as previously discussed in Subsection 2.3.1.2.3, was used as the basis for the predictive runs for radial collector well operation. The radial collector well conceptual model design is summarized as follows:

- The water level in Biscayne Bay was set to the long-term average of -0.81 feet NAVD 88.
- The Unit 6 & 7 plant area was assumed complete and the relevant recharge/ evapotranspiration zones were altered to reflect as-built conditions. The muck layer was removed from the plant area, as discussed in Section 3.9, and replaced with backfill.
- Three of the four radial collector wells were operational. To provide a conservative estimate of the source of water from inland areas to the radial collector wells, the three wells closest to the shore were modeled as operational.
- Four pumping wells were placed on the last 300 feet of each lateral to represent the screened intervals. Flows were distributed along the laterals to reflect friction losses and distributed flow along the length.
- The radial collector wells laterals were located within the Upper Higher Flow Zone.
- The simulation was executed at steady-state conditions.

The groundwater drawdown in Model Layer 1 (muck and rock/sandy material) and Model Layer 4 (Upper Higher Flow Zone) is depicted in Figures 5.2-1 and 5.2-2, respectively. The operational impacts of the radial collector wells to groundwater and surface water are discussed in the following sections.

Surface Water

Four radial collector wells would be installed adjacent to Biscayne Bay to provide cooling water for Units 6 & 7 (see Figure 3.1-3). The well caissons would be located on the Turkey Point peninsula, east of the existing units. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The four radial collector wells would provide up to 86,400 gpm (124.4 million gallons per day [mgd]) to supplement the reclaimed water source for cooling water makeup for Units 6 & 7 (Table 3.3-2).

As previously discussed in Subsection 2.3.1, surface water features within the local area of the radial collector wells included Biscayne Bay, Card Sound, the cooling canals of the industrial wastewater facility, and several surface water control canals (e.g., L-31 Canal). The surface water elevation in each of these features was set to known values based on seasonal or long-term data. Notably, the water levels in the predominant surface water features in the site were stipulated as follows: Biscayne Bay/Card Sound (-1.05 feet NAVD 88); cooling canals of industrial wastewater system (discharge side: 1.28 feet NAVD 88; intake structure: -3.38 feet NAVD 88).

As part of the steady-state radial collector well groundwater simulation, the volumetric flow rates were calculated for each of the boundary conditions (e.g., general head at Biscayne Bay/Card Sound, river boundary at the cooling canals of the industrial wastewater facility). Based on this calculation, it was observed that 97.8 percent (121.7 mgd) of the groundwater recharge originated from Biscayne Bay and 2.2 percent (2.7 mgd) originated from inland areas. Notably, 2.0 percent (2.5 mgd) originated from the cooling canals of the industrial wastewater facility. The recharge from Biscayne Bay would be predominately localized in the area of the radial collector wells.

Maintenance activities for the radial collector wells, including such activities as localized dewatering, below grade water pipeline/utility maintenance, above grade mechanical maintenance, etc. could be performed during the operation of Units 6 & 7. Water produced would be released to the industrial wastewater facility or controlled locally though the use of environmental best management practices to mitigate the potential impacts to surface water in the vicinity of the maintenance activities being performed. In summary, impacts to surface water from maintenance activities associated with operation of the radial collector wells would be SMALL and not require mitigation.

Groundwater

As previously discussed, groundwater modeling was performed to simulate the steady-state conditions resulting from operation of the radial collector wells. The cone of depression in Model Layer 1 (onshore — muck; offshore — rock/sand) ranged from 3 to 0.1 feet and was generally confined to the area local to the radial collector wells (areal extent of 211 acres based on the 0.1 foot drawdown contour in Biscayne Bay) and the Units 1 though 5 plant area, as depicted on Figure 5.2-1. The drawdown in Model Layer 4 (Upper High Flow Zone) ranged from 3 to 0.1 feet and was also generally confined to the area local to the radial collector wells (areal extent of 729 acres based on the 0.1 foot drawdown contour in Biscayne Bay) as depicted in Figure 5.2-2.

The model indicates that the uplands could be dewatered on the Turkey Point peninsula during steady-state conditions; however this would be confined to the areas immediately around the radial collector wells. Drawdown in the muck layer on the eastern shoreline, based on the results of the groundwater model, is not anticipated (Figure 5.2-1).

Based on the results of the groundwater modeling, approximately 97.8 percent of groundwater recharge to the radial collector wells would originate from Biscayne Bay and 2.2 percent would come from areas inland, including 2.0 percent from the cooling canals of the industrial wastewater facility. The remaining 0.2 percent will be from boundaries representing precipitation onshore. The 0.2 percent from precipitation recharge represents a relatively small amount of water. Because the precipitation is fresh water, it will tend to remain in the upper layers of the aquifer. Since the radial collector wells draw water at depth, the 0.2 percent is a conservative prediction of the water entering the radial collector wells. Therefore, the amount of fresh water drawn by the radial collector wells will be inconsequential and will not adversely impact the environment. Thus, impacts to the Biscayne Aquifer west of the Turkey Point property would be insignificant.

Typical maintenance on the radial collector well screens to prevent fouling could be required every 15–20 years. The well lateral screen and sand packs around the screens could be cleaned by several techniques including airbursts and jetting. The resulting impacts would be temporary and localized to the radial collector well area. Based on the above analyses, radial collector well operational impacts to groundwater, including groundwater flow and maintenance activities, would be SMALL and not warrant mitigation.

5.2.1.1.9 Operation of Deep Injection Wells

Surface Water

Wastewater, including the treated effluent from the sanitary wastewater generated by the operation of Units 6 & 7 and cooling tower blowdown, would be discharged to the Boulder Zone of the lower Floridan aquifer via twelve deep injection wells. No plant process waste streams would be discharged to surface water.

Surface water impacts could occur from deep injection well pipeline maintenance activities, including excavation to expose the pipeline between the blowdown sump and the deep injection wells, but these effects would be temporary and SMALL. Accordingly, impacts to surface water from underground injection activities would be SMALL and would not require mitigation.

Groundwater

The operation of the deep injection wells was evaluated to estimate the areal extent of groundwater influence (the injectate effective radius) in the Boulder Zone over an assumed operational lifespan of Units 6 & 7. An assumed maximum flow rate of 90 mgd was used, which is slightly higher than the expected maximum flow rate of 85 mgd. It is important to note that as described in Subsection 2.3.2.2.2.2, it is estimated that each deep injection well would have a maximum permitted injection capacity of 18.6 million gallons per day at a peak hourly flow.

However, it is estimated that each well would be operated at an injection rate of approximately 10 million gallons per day. The injectate effective radius was calculated using the equation:

$$\text{Volume} = \text{radius}^2\ \pi\ H\ n\ (7.48\ \text{g/ft}^3)$$

Where:

- Volume is the amount of water to be injected in gallons over a given period of years
- Radius (r) is the radius (miles) of injectate
- H is the vertical effective injection thickness
- n is the porosity of the formation through the injection zone

Based on a porosity of 20 percent and an effective injection thickness of 200 feet, the 60-year areal extent of injected fluid created by this injection rate would have a radius of approximately 9 miles. The results assumed the Boulder Zone is homogeneous and capable of exhibiting radial flow.

The effective thickness of the injection zone is at least in part dependent upon the density difference between the wastewater being injected and the groundwater within the Boulder Zone. This is due to stratification that would be caused in the Boulder Zone by this difference in water density. The density of the wastewater injectate is a function of both its temperature and total dissolved solid (TDS) concentration. Injectate that is denser than Boulder Zone water would migrate downward in the formation, thus increasing the vertical effective injection thickness. This would be the scenario during 100 percent saltwater injectate at a lower temperature. Injectate that is less dense than the Boulder zone water would stratify and decrease the vertical effective injection thickness. This would be the scenario during 100 percent reclaimed water injectate at higher temperatures. Based on these differences in Units 6 & 7 operation and the resultant injectate density differences, a range of effective thickness was included in the evaluation.

A sensitivity analysis was performed that varied the porosity and vertical effective injection thickness, as discussed above. As summarized in Table 5.2-1, a change in the porosity across the unit or a change in the estimated vertical effective injection thickness, based on potential density/stratification effects, would change the radius of influence, varying between 3.2 and 12.3 miles for 60 years.

The Underground Source of Drinking Water (USDW), as defined by the Florida Department of Environmental Protection (FDEP), is an aquifer that contains a TDS concentration of less than 10,000 mg/L and contains a sufficient quantity of water to supply a public water system. In the

area of the Turkey Point plant property, the base of the USDW is approximately 1450 feet below land surface.

As discussed in Subsection 2.3.1.2, in the area of the Turkey Point plant property, the base of the USDW is below the base of the Upper Floridan aquifer and above the top of the Avon Park Permeable Zone. The top of the Boulder Zone (i.e., the injection zone) is estimated to be approximately 2900 feet below land surface. The Middle Confining Unit, which separates the USDW from the injection zone, is at least 1000 feet thick. Based on reported data from southeast Florida, the vertical hydraulic conductivity of this unit is anticipated to be between 1.3E-04 ft/day and 0.24 ft/day. The effective thickness of the Boulder Zone in the area of the Turkey Point plant property is estimated to be 200 feet for permitting applications; and the transmissivity is reported to be between 3.2E06 ft^2/day and 24.6E06 ft^2/day.

During 2003, the EPA evaluated the Miami-Dade County deep injection wells due to water quality issues. During that evaluation, the EPA regarded the pressure head resulting from injection to be negligible due the Boulder Zone's high karstification and fracturing. The pressure head buoyancy in the Boulder Zone was determined to be approximately 70 feet when injecting fresh domestic effluent at a rate of 112.5 mgd. That evaluation would indicate that the total head pressure due to injection and buoyancy resulting from deep injection well operation for Units 6 & 7 would be less than 70 feet using reclaimed water as the source for cooling water. The use of seawater as the source of cooling water would result in even less total head pressure than that when using reclaimed water.

The deep injection wells would be installed in accordance with an FDEP underground injection well permit and local permit requirements. The injection casing in the deep injection wells for Units 6 & 7 would be seated at a greater depth than other regional injection wells to maximize the thickness of the confining strata between the injection zone and base of the USDW. The current standard practice of grouting the pilot hole would also be employed to prevent the possible development of the double borehole conditions. The data collected during drilling and testing of the exploratory well would be used to evaluate the proposed system and would be submitted to the FDEP in support of the Class I injection well construction permit application for the Units 6 & 7 deep injection wells.

Water quality and pressure monitoring would be conducted in two separate intervals in the Floridan aquifer as mandated by the UIC permit. General UIC permit requirements include monthly reporting of the average, minimum, and maximum injection pressure, flow rate, volume, and annular pressure. The UIC permit would also require mechanical integrity tests in the deep injection wells to be performed every 5 years. The monitoring program objective would be to detect vertical migration of injected fluids into the Upper Floridan aquifer through the confining layer overlying the Boulder Zone. Sections 6.3 and 6.6 describe the operational monitoring of the deep injection wells.

Based on the above analyses, potential impacts from the operation of the deep injection wells to groundwater would be SMALL and not warrant mitigation beyond that described previously.

5.2.1.1.10 Transmission Rights-of-Way

Surface Water

Potential operational impacts along the proposed transmission rights-of-way would result from maintenance activities. These transmission lines would include the underground lines from Units 6 & 7 to the Clear Sky substation and the overhead lines from the Clear Sky substation to offsite substations. As described in Section 3.7, FPL regularly inspects transmission lines. Vehicular traffic could result in the rutting of the access roads along the rights-of-way that could impact surface flow in the vicinity of the disturbances. FPL would repair any areas of disturbed soils, recontour the area, and reestablish the vegetative cover, if necessary, in a timely manner that would reduce the potential for erosion through surface water runoff.

It could be necessary to perform maintenance that would require excavation and dewatering along the transmission lines. Water from the dewatering process would be routed to a detention basin or other sediment removal process before being released in accordance with FDEP-approved methods and in accordance with FDEP permit requirements.

Impacts to hydrologic flow from operation and maintenance of the transmission lines on the Turkey Point plant property would be SMALL and would not require mitigation in addition to those described.

Groundwater

It could be necessary to perform maintenance that would require excavation and dewatering along the transmission lines. The dewatering activity would create temporary drawdown of the water table. Water from the dewatering process would be routed to a retention basin or other sediment removal process before being released in accordance with approved methods and permit requirements. The water table and flow would return to normal once dewatering has ceased.

Impacts to groundwater hydrologic flow from operation and maintenance of the transmission lines on the Turkey Point plant property would be SMALL and would not require mitigation in addition to those described.

5.2.1.2 Offsite Facilities

5.2.1.2.1 Fill Borrow Areas

Surface Water

Fill borrow material for use during operation and maintenance of Units 6 & 7 would be supplied through a commercial provider. The FPL-owned fill source would not be restored to preexisting conditions. The water management feature that would be created from the excavation activities would be designed to store excess stormwater to complement regional wetland rehydration projects. A perimeter berm could also be used to restrict the flow of surface water onto the property and used to reroute the surface water flow to maintain the original flow direction. Impacts on surface water flow would be SMALL.

Groundwater

Surface water resulting from precipitation routed to the FPL-owned fill source for disposal/storage could increase the elevation of the water in the borrow pit. An increase in elevation of the ponded water could also raise the level of the adjacent groundwater that could alter the groundwater flow direction in the vicinity of the borrow pit. However, the elevation change would be temporary and the water table would return to normal once the storm event ends. The impacts from hydrologic alteration would be SMALL and would not require additional mitigation.

5.2.1.2.2 Transmission Rights-of-Way Maintenance

Surface Water

Potential operational impacts along the offsite portions of the proposed transmission rights-of-way would be similar to the segments on the Turkey Point plant property. During operations, potential impacts from maintaining hydrologic flow could occur. As described in Section 3.7, FPL regularly inspects the transmission lines. Vehicular traffic could result in the rutting of the access roads along the rights-of-way, which could impact surface flow in the vicinity of the disturbances. Should soil disturbance be required during maintenance operations within the rights-of-way, silt fence technology would be used to minimize impacts to nearby surface waterbodies/drainage features.

To reduce the potential for erosion through surface water runoff, areas of disturbed soils would be repaired, areas recontoured, and vegetative cover reestablished, if necessary, in a timely manner. Accordingly, impacts to hydrologic flow from operation of the offsite transmission lines would be SMALL and would not require further mitigation.

Groundwater

It could be necessary to perform maintenance that would require excavating and dewatering along the transmission lines. The dewatering activity could create temporary drawdown of the water table. Dewatering could impact areas off the right-of-way. However, the water table and flow would return to normal once dewatering ceased. Impacts to groundwater hydrologic flow from operation of the offsite transmission lines would be SMALL and would not require mitigation.

5.2.1.2.3 Reclaimed and Potable Water Pipelines

Surface Water

Potential operational impacts along the reclaimed and potable water pipelines would result from maintenance activities. Impacts would be to areas previously disturbed during construction of the pipelines. Vehicular traffic could result in the rutting of the access roads along the rights-of-way which could impact surface flow in the vicinity of the disturbances. Maintenance activities would be accomplished in accordance with established protocols and applicable regulations.

Impacts to surface water hydrologic flow from operation of the reclaimed and potable water pipelines would be SMALL and would not require mitigation.

Groundwater

It could be necessary to perform maintenance that would require excavation and dewatering along the reclaimed and potable water pipelines. The dewatering activity could create temporary drawdown of the water table. Dewatering could impact areas off the right-of-way. However, the water table and flow would return to normal once dewatering ceased. Impacts to groundwater hydrologic flow from operation of the reclaimed and potable water pipelines would be SMALL and would not require mitigation.

5.2.1.2.4 Offsite Roads

Surface Water

Once construction activities cease, the offsite construction access roads would not normally be used by operations workers to access Units 6 & 7. However, the offsite construction access roads could be used, if needed, to access the Turkey Point plant property for special events or for the special delivery of equipment or supplies. Impacts to surface water from the use of the offsite roads during operations would, therefore, be less than that encountered during the period of construction. Impacts could still occur from any necessary maintenance activities to the roadways which would include excavation activities or the addition of surface water culverts should they be needed, but these impacts would be temporary. Impacts to surface water hydrology resulting from these activities during operations would be SMALL and would not require mitigation.

However, the offsite roadway improvements described in Chapter 4 could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction conditions by removing the improvements, recontouring the area, and reseeded or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities. Impacts would be similar to those during construction, limited to the area of the road removal activity, and be of short duration. Therefore, impacts to surface water hydrology would be SMALL and not require further mitigation.

Groundwater

Once construction activities cease, the offsite construction access roads would not normally be used by operations workers to access Units 6 & 7. The construction access roads could be used, if needed, to access the Turkey Point plant property for special events or for the special delivery of equipment or supplies. Impacts to groundwater from the use of the offsite roads during operations would be less than that encountered during the period of construction. However, impacts could still occur from any necessary maintenance activities. These activities could also require dewatering. Impacts resulting from these activities would be temporary and groundwater levels would return to normal. Impacts to groundwater hydrology resulting from these activities during operations would be SMALL and would not require mitigation.

As described in the surface water section above, offsite road improvements made during the construction phase of the project could be removed and the areas restored to preconstruction conditions during the operation phase. Dewatering would not be required during the restoration activities. Therefore, impacts to groundwater from the restoration to preconstruction conditions would be SMALL and not require mitigation.

5.2.2 WATER USE IMPACTS

As described in Section 3.3, public water in the amount of 936 gpm (1.35 mgd) to 2553 gpm (3.68 mgd) would be supplied by Miami-Dade a new potable water pipelines for the operation of Units 6 & 7. Operational impacts to existing public infrastructure are described in Section 5.8.

Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. The primary source would be reclaimed water from the Miami-Dade Water and Sewer Department (MDWASD) South District Wastewater Treatment Plant (SDWWTP). When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. The ratio of water supplied by the two makeup water sources would vary based on the availability and/or quality of reclaimed water from MDWASD.

5.2.2.1 Surface Water

5.2.2.1.1 Reclaimed Water and Potable Water

Reclaimed water from the SDWWTP would supply approximately 60 mgd for the operation of Units 6 & 7. Based on MDWASD data from 2006, the MDWASD was disposing of 295 mgd of wastewater by deep well injection and surface water discharge to offshore locations. Of the 295 mgd, 106 mgd was being injected into south Florida aquifers. The South District of the MDWASD alone discharged 94 mgd to the Boulder Zone of the Floridan Aquifer. As of 2006, the MDWASD was treating and reusing 18 mgd of wastewater (SFWMD 2008). The South Florida Water Management District (SFWMD) will require the MDWASD to increase their reuse of treated wastewater to at least 170 mgd during the period of their current permit which will expire in 2030 (SFWMD 2010). The SFWMD estimates that MDWASD will increase the output of water available for reuse to 193 mgd by 2025 which would represent a usage of 51% of the MDWASD's wastewater output (SFWMD 2008). The additional reuse water will be used for a number of proposed projects, which include the discharge of reuse water for Everglade restoration projects (SFWMD 2007).

The Florida legislature recently enacted new legislation that eliminates the option for coastal communities to use ocean outfalls for the disposal of effluent from a wastewater treatment plant. The MDWASD has initiated a review of the changes necessary to the wastewater system to meet the mandates. One result is the addition of high-level disinfection to facilities that currently do not have this level of treatment. These facilities then could either discharge their reclaimed water to injection wells (in the Boulder Zone) or find other reuse options.

Use of reclaimed water was also addressed by the water use permit for the Miami-Dade consolidated public water supply, issued by the South Florida Water Management District (November 1, 2010). The permit contained several limiting conditions (Nos. 39–43) that apply to the reuse of reclaimed water. Condition 39 requires the MDWASD to implement 170 mgd of reuse projects. Exhibit 14 of the permit presents a table of reuse projects and deadlines to meet the permit limiting condition. Also presented in Exhibit 14 and Limiting Condition 41 of the permit is the requirement that MDWASD work with FPL to provide up to 70 mgd of reclaimed water for nuclear projects and 14 mgd for Unit 5. The reuse projects listed in Exhibit 14 for the SDWWTP total 188 mgd of reclaimed water. The largest of the reuse projects planned for the SDWWTP are: (1) furnishing 75.7 mgd of reclaimed water for the Biscayne Bay Coastal Wetlands Project, a component of the Comprehensive Everglades Restoration Plan, scheduled for implementation in 2022, and (2) a proposed well field mitigation project that is projected to need 18.6 mgd of reclaimed water. If the largest reuse projects listed in the exhibit are met as projected, reclaimed water from the SDWWTP may not be sufficient to meet all of the water demand for the operation of Units 6 & 7. To compensate for this potential shortfall, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay.

The potential water use impacts resulting from operation of the radial collector wells are described in Subsection 5.2.2.1.2.

The use of reclaimed water for Units 6 & 7 would be a beneficial and cost-effective means of increasing the use of reclaimed water in Miami-Dade County and would help the County meet its reclaimed water compliance requirements. In the absence of reuse opportunities, this treated domestic wastewater would likely continue to be discharged to the ocean or deep injection wells. Miami-Dade County has challenging water goals to eliminate ocean outfalls and increase the amount of water that is reclaimed for environmental benefit and other beneficial uses. The beneficial use of reclaimed water for Units 6 & 7 would enable the County to meet approximately half of its reclaimed water goal and provide environmental benefits by reducing the volume of wastewater discharged to ocean outfalls or deep injection wells. For these reasons, the use of reclaimed water for Units 6 & 7 would have a positive impact on surface water.

Potable water supplied by Miami-Dade County for Units 6 & 7 operation would be covered under MDWASD's consumptive use permit from the SFWMD. The potable water would come from the Biscayne Aquifer and not from surface water sources. Therefore, there would be no surface water impacts.

5.2.2.1.2 Radial Collector Wells

As described in Subsection 2.3.1, Biscayne Bay is hydrologically connected to the upper zone of the Biscayne aquifer. Based on groundwater modeling described above, the radial collector wells would be recharged at a rate of 97.8 percent (121.7 mgd) from Biscayne Bay. This would be predominately localized in the area of the radial collector wells. The remaining recharge would be from surface water (e.g., cooling canals) and groundwater beneath the plant property. The amount of saltwater used (up to approximately 121.7 mgd if 97.8 percent saltwater) compared to the size of the saltwater resource available would be insignificant. Impacts to Biscayne Bay surface waters would be SMALL and would not require mitigation.

Monitoring of the water quality from the radial collector wells would be performed to determine whether the water being pumped is saltwater by monitoring the groundwater elevation data in the near shore areas adjacent to the radial collector well locations. (See Sections 6.3 and 6.6 regarding planned pilot studies and monitoring associated with the radial collector wells.)

5.2.2.1.3 Offsite Facilities

Water use impacts for off-site facilities during operations would be minimal. Operational water requirements would primarily be for personnel use at these facilities. This could include potable and sanitary water use. Off-site potable and sanitary water use would likely be provided by groundwater supplied by Miami-Dade County where plans are to build facilities to support extended operations; for example switchyard facilities. These would likely support small

intermittent work activities and would not likely be a major user of water. Therefore impacts to surface water would be anticipated to be SMALL.

Water requirements during operational maintenance construction activities not associated with personnel use would likely include water associated processes, for example the use of water during the mixing of concrete. Any water use during this type of activity would be associated with the commercial concrete supplier and not directly related to Unit 6 & 7 activities. Any water directly required by FPL during maintenance activities could be transported from an existing FPL facility and would likely be supplied by county potable supply. Therefore, minimal impacts would result from off-site water use to surface water resources at these facilities.

5.2.2.2 Groundwater

5.2.2.2.1 Reclaimed Water and Potable Water

As previously described, the reclaimed water that would be supplied by the Miami-Dade SDWWTP currently is being injected into the Boulder Zone of the lower Floridan aquifer. The Boulder Zone is used in south Florida for industrial and municipal wastewater disposal. MDWASD plans to distribute the reclaimed water once the water has undergone additional treatment. This system is anticipated to be in place by 2013.

The appropriate use of reclaimed water would reduce the rate of increase of groundwater used in the Miami/Dade County area by public water users. A reduction in the amount of wastewater currently being injected by MDWSD would also allow the district to process wastewater currently being discharged offshore.

The use of reclaimed water as makeup water for Units 6 & 7 would reduce the amount of reclaimed water that would be discharged to deep injection wells by 18 mgd to 60 mgd. The use and deep injection of reclaimed water by Units 6 & 7 would represent up to approximately 64% of the wastewater injected by the South District of the MDWSD, approximately 57% of the total wastewater injected by MDWSD, and approximately 19% of the total amount of wastewater treated by the MDWSD during 2006. By the time of Units 6 & 7 operation, MDWSD is projected to be producing up to 193 mgd of reclaimed water for use. Units 6 & 7 usage would represent up to 31 percent of the reclaimed water projected to be available by 2025. As MDWSD increases their ability to raise the quality of wastewater treatment, the availability of reclaimed water for reuse would also increase.

The use of reclaimed water by Units 6 & 7 and injection of the wastewater could increase the current amount of water being injected into the Boulder Zone via deep well injection depending on whether MDWSD service area grows to continue the need to inject or decides to reduce offshore discharges by performing deep injection of these waters. The Boulder Zone is used as a disposal zone and not as a source of water production. The Units 6 & 7 deep injection wells

would be in accordance with FDEP permit requirements requiring the installation of multiple surface casings and grouting processes to limit the potential of creating pathways from the Boulder Zone upward to the USDW which could impact use. Therefore, impacts to groundwater use from the use of reclaimed water would be SMALL and would not require mitigation.

5.2.2.2.2 Radial Collector Wells

The radial collector well laterals would be installed beneath Biscayne Bay in areas where the bottom of the bay would readily facilitate the vertical movement of saltwater from the bay to the underlying aquifer formation where the collection screens would be located.

As described in Subsection 5.2.1.1.8, it is estimated that the radial collector wells would be recharged at a rate of 97.8 percent (121.7 mgd) from Biscayne Bay. This would be predominately localized in the area of the radial collector wells. The remaining recharge would be from the inland area west of the radial collector wells, including the cooling canals of the industrial wastewater facility, estimated at 2.5 mgd, and other areas, estimated at 0.2 mgd, including groundwater beneath the plant property. Recharge from groundwater would occur in an area where the groundwater is too brackish for potable use.

Based on the amount of expected recharge from groundwater sources and the non-potable classification of the groundwater at the site (due to its salinity), the predicted impacts to groundwater use due to the operation of the radial collector wells would be SMALL.

Monitoring wells would be installed and used to monitor whether the system is pumping seawater or groundwater by monitoring the groundwater elevation data in the nearshore areas adjacent to the radial collector well locations.

Based on the groundwater modeling of the radial collector wells and the resultant modeled impacts of the influence of the wells on groundwater flow, impacts to groundwater use from the operation of the radial collector wells as a cooling water makeup source would be SMALL and would not require mitigation.

5.2.2.2.3 Offsite Facilities

Water use impacts for off-site facilities during operations would be minimal. Operational water requirements would primarily be for personnel use at these facilities. This could include potable and sanitary water use. Off-site potable and sanitary water use would likely be provided by groundwater supplied by Miami-Dade County where FPL currently has or plans to build facilities to support extended operations; for example switchyard facilities. These would likely support small intermittent work activities and would not likely be a major user of water. Therefore, impacts to groundwater resources would be SMALL.

Water requirements during operational maintenance construction activities not associated with personnel use would likely include water associated processes, for example, the use of water during the mixing of concrete. Any water use during this type of activity would be associated with the commercial concrete supplier and not directly related to FPL activities. Any water directly required during maintenance activities could be transported from an existing FPL facility and would likely be supplied by county potable water supplies. Therefore, minimal impacts would result from off-site water use to groundwater resources at these facilities.

5.2.3 WATER QUALITY IMPACTS

Surface water and groundwater quality data are summarized in Subsection 2.3.3. Impacts to the existing water quality from the operations of Units 6 & 7 are described below.

5.2.3.1 Surface Water

5.2.3.1.1 Onsite Operations

The surface water bodies that could be impacted by operation of Units 6 & 7 are Biscayne Bay, wetlands, and the cooling canals of the industrial wastewater facility. Because of the existing operational layout of the Turkey Point plant property, surface water flow is primarily to the industrial wastewater facility, which would limit impacts to offsite areas.

Impacts to surface water quality could occur from soil disturbance and erosion from maintenance activities, which could result in increased sediment loading to nearby water bodies. Also, pollutants associated with vehicular traffic and equipment operation and maintenance could impact nearby surface water bodies. The use of environmental best management practices along with a spill prevention plan would prevent or minimize the potential impacts of releases to the environment.

Any ground-disturbing activities that meet federal, state, and local regulations requiring approval permits would be permitted and overseen by state and federal regulators, and guided by environmental best management practices and spill prevention plans. Any impacts to surface water quality during operations would be SMALL and would not require mitigation beyond environmental best management practices and other permit requirements.

The onsite roadway improvements described in Chapter 4 could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction conditions by removing the improvements, recontouring the area, and reseeding or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities and a spill prevention plan. Impacts to water quality would be similar to those during construction and limited to the area

of the road improvement removal activity. Therefore, impacts to onsite surface water quality would be SMALL and not require further mitigation.

5.2.3.1.2 Radial Collector Wells

Operation of radial collector wells installed beneath Biscayne Bay would not impact the water quality of the bay. Although recharge would occur from the bay, it is estimated to be a small percentage of natural freshwater recharge. Additionally, although 2.0 percent of recharge (2.5 mgd) is predicted to originate from the cooling canals of the industrial wastewater facility, which are hypersaline, this recharge water drawn towards the radial collector wells will remain at depth within the aquifer due to the placement of the radial collector well laterals below the seabed and due to the higher density of this hypersaline water relative to seawater. Effects on salinity of the bay, based on the predicted amount of withdrawal versus the natural recharge, would be minimal.

Monitoring wells would be installed and used to monitor the groundwater level and water quality at and near the radial collector well locations to ensure impacts to local water quality, particular surface water quality, are minimal.

Impacts to water quality from operation of the radial collector wells would be SMALL and not require mitigation.

5.2.3.1.3 Offsite Facilities

Operational maintenance activities along the transmission rights-of-way, the reclaimed water pipelines, substations, potable water pipelines, and other off-site facilities could result in impacts to surface water quality. These impacts could result from surface water runoff, which could include the transport of chemical releases to the environment or from the transport of sediment to nearby surface water features. Any minor spills of diesel fuel, hydraulic fluid, lubricants, or other construction-related pollutants along the routes or offsite facilities would be cleaned up quickly to prevent potential contaminants from moving into nearby surface waters. Impacts would be small, localized, and temporary. A new SWPPP and a spill prevention plan would be prepared or an existing SWPPP and spill prevention plan would be modified to include the operations and maintenance activities associated with Units 6 & 7.

In the unlikely event small amounts of pollutants escape into the environment during operations and maintenance, because Units 6 & 7 would operation under a SWPPP and spill prevention plan, any impacts to surface water quality would be SMALL and would not require mitigation beyond those described in this subsection or required by permit.

The offsite roadway improvements described in Chapter 4 could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction

conditions by removing the improvements, recontouring the area, and reseeding or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities. Impacts to water quality would be similar to those during construction and limited to the area of the road improvement removal activity. Therefore, impacts to offsite surface water quality would be SMALL and not require further mitigation.

5.2.3.2 Groundwater

5.2.3.2.1 Onsite Operations

The Turkey Point plant property overlies a portion of the Biscayne aquifer, which is saline in this area. The Biscayne aquifer beneath the Turkey Point plant property is connected hydrologically to both Biscayne Bay and the cooling canals of the industrial wastewater facility. As described in Subsection 2.3.1, the Biscayne aquifer in the vicinity of the Turkey Point plant property is not used as a source of drinking water due to the encroachment of saltwater into the aquifer up to 6 to 8 miles inland. Groundwater does provide one of the sources of water for the industrial wastewater facility along with surface runoff and natural precipitation that percolates to the water table and then moves laterally to the industrial wastewater facility. Should the area undergo a period of drought, the lowering of the water table would create flow from the industrial wastewater facility to groundwater. This could allow the water in the canals to recharge groundwater in the area.

In the unlikely event small amounts of contaminants escape into the environment, they would have only a small, localized, and temporary impact on the water table aquifer.

Impacts to groundwater quality would be SMALL and would not require mitigation beyond that described or required by federal and state permits.

The onsite roadway improvements described in Chapter 4 could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction conditions by removing the improvements, recontouring the area, and reseeding or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities. Impacts to groundwater water quality would be similar to those during construction and limited to shallow groundwater in the area of the road improvement removal activity. Impacts to onsite ground water quality would be SMALL and not require further mitigation.

5.2.3.2.2 Makeup Water Reservoir

Potential seepage from the makeup water reservoir could flow to the Biscayne aquifer within the industrial wastewater facility that discharges hypersaline water to the Biscayne aquifer. The

Biscayne aquifer beneath the Turkey Point plant property consists of saltwater. The makeup water reservoir would not be used for the storage of water from the radial collector wells.

The reclaimed water and radial collector well water would be collected in basins beneath the cooling towers, isolated from the cooling water reservoir. However, cooling tower plumes would impact the water stored in the cooling water reservoir. Water in the cooling water reservoir would dilute the fallout from the cooling tower plumes.

Potential seepage would flow into the Biscayne aquifer which contains saltwater and receives hypersaline water from the industrial wastewater facility. Therefore, impacts to the water quality of the Biscayne aquifer as the result of seepage from the cooling water reservoir would be SMALL and would not require mitigation.

5.2.3.2.3 Radial Collector Wells

As described in Subsection 5.2.2.2, it is estimated that the radial collector wells would be recharged at a rate of 97.8 percent (121.7 mgd) from Biscayne Bay. This would be predominately localized in the area of the radial collector wells. The remaining recharge would be from surface water (e.g., cooling canals) and groundwater beneath the plant property, thereby having minimal effect on the Biscayne aquifer where used as a water source. The majority of recharge flow would come from the local area of the radial collector wells where the groundwater is too brackish for potable water use. As discussed above, any hypersaline water drawn into the aquifer from the cooling canals would not impact potable water supplies, which are further inland, due to the presence of brackish, non-potable water near the coast. Therefore, impacts to groundwater quality as a result of radial collector well operations would be SMALL and not require mitigation.

5.2.3.2.4 Deep Injection Wells

Wastewater generated from the operation of Units 6 & 7, including water from blowdown sump discharge and treated liquid radwaste, would be injected into the Boulder Zone of the lower Floridan aquifer through the use of twelve deep injection wells. The Boulder Zone is used in south Florida for the disposal of industrial and municipal waste. The Units 6 & 7 deep injection wells would be permitted by FDEP and installed in accordance with FDEP requirements which include the installation and grouting to surface a series of well casings designed to prevent the flow of water between the various aquifer units encountered.

The estimated total injection rate would range from approximately 85 mgd for the 100 percent radial collector well supply to 18 mgd for the 100 percent reclaimed water cooling water makeup supply. Operation of Unit 6 & 7 would follow the FDEP permitting process for injection well permits including monitoring requirements for groundwater quality and groundwater elevation data in overlying aquifers. Tables 3.6-2 (as amended in ER Revision 3) and 3.6-3 summarize the

expected water quality of the effluent discharged to the deep injection wells based on the reclaimed water and radial collector well cooling water makeup options, respectively.

As discussed in Subsection 5.2.1.1.9, the impacts from hydrologic alterations in the USDW resulting from the use of the deep injection wells would be SMALL. The potential impacts to water quality of the USDW would also be SMALL if there are no hydrologic impacts to the USDW. Within the Boulder Zone, groundwater quality impact from operations would be SMALL. Deep injection well operation would be in accordance with other deep injection waste disposal operations currently taking place in south Florida and in accordance with rules and regulations developed by the state of Florida as represented by the current deep well injection permitting process. The overlying USDW would be monitored for hydrologic impacts and water quality.

5.2.3.3 Offsite

Due to the existence of shallow groundwater at or just below ground surface in south Florida, groundwater impacts are more likely to occur than in areas where the water table is deeper. As described above, Unit 6 & 7 would operate its offsite facilities under a SWPPPs/spill prevention plans or procedures which would include the use of environmental best management practices. Any minor spills of diesel fuel, hydraulic fluid, lubricants, or other operational/maintenance-related pollutants along the proposed routes or at offsite facilities would be cleaned up quickly to prevent potential contaminants from moving into the groundwater.

In the unlikely event small amounts of pollutants escape into the environment during offsite facility operations and maintenance, because of operation under a SWPPPs/spill prevention plans or procedures including environmental best management practices, impacts would have only a small, localized, and temporary impact on the water quality at the release. Any impacts to groundwater quality would be SMALL and would not require mitigation beyond those described in this subsection or required by permit.

The offsite roadway improvements described in Chapter 4 could be removed some time after the units are in operation. Should this occur, these locations would be returned to preconstruction conditions by removing the improvements, recontouring the area, and reseeding or replanting native plant species. During restoration activities, environmental best management practices would be followed in accordance with the SWPPP for construction activities. Impacts to groundwater quality would be similar to those during construction and limited to the area of the road improvement removal activity. Therefore, impacts to offsite groundwater quality would be SMALL and not require further mitigation.

5.3 COOLING SYSTEM IMPACTS

This section describes the impacts of the cooling systems associated with operation of Units 6 & 7. The different aspects of cooling system impacts are addressed separately in the following sections:

- Intake system (Subsection 5.3.1)
- Discharge system (Subsection 5.3.2)
- Heat dissipation (Subsection 5.3.3)
- Impacts to members of the public (Subsection 5.3.4)

5.3.1 INTAKE SYSTEM

During normal operations of Units 6 & 7, waste heat would be dissipated by mechanical draft cooling towers. Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. The primary source would be water reclaimed for reuse after processing by the Miami-Dade Water and Sewer Department (MDWASD), conveyed via pipelines to the Turkey Point plant property. An onsite FPL reclaimed water treatment facility would further treat the reclaimed water for use in the cooling system. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. The well caissons would be located on the Turkey Point peninsula, east of the existing units. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson.

Approximately 60 million gallons per day (mgd) of reclaimed water would be delivered to Units 6 & 7 via pipelines from the MDWASD South District Wastewater Treatment Plant (SDWWTP), a distance of approximately 9 miles. An alternate supply of up to 124.4 mgd would be obtained from the radial collector wells.

Hydrodynamic and physical impacts are described in Subsection 5.3.1.1. Potential impacts to important aquatic resources from operation of the cooling water makeup sources for Units 6 & 7 are addressed in Subsection 5.3.1.2.

5.3.1.1 Hydrodynamic Descriptions and Physical Impacts

Reclaimed Water

Treated wastewater from the SDWWTP would be used as cooling tower makeup for Units 6 & 7. The water would undergo secondary treatment and high-level disinfection at the SDWWTP

before being piped to Turkey Point, where it would undergo further treatment for use in the mechanical draft cooling towers (see Subsection 3.4.2).

The reclaimed water would not be hydraulically connected to any aquatic habitats. The reclaimed water would be transported via closed pipelines from the SDWWTP to the FPL reclaimed water treatment facility and then to the makeup water reservoir. No hydrodynamic or physical impacts would result from the delivery of reclaimed water to Units 6 & 7.

Radial Collector Wells

As described in Subsection 5.2.1.1.8, four radial collector wells (Figure 3.1-3) with multiple collection screens for each well would be installed in the Biscayne aquifer formation beneath Biscayne Bay to provide up to 124.4 mgd of makeup water. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The radial collector wells would collect groundwater recharged from saltwater through the porous limestone subsurface beneath Biscayne Bay.

The operation of the radial collector wells and the potential impacts on water bodies including Biscayne Bay and the cooling canals in the industrial wastewater facility have been evaluated through groundwater modeling. Based on the evaluation, impacts would be SMALL. Collection of Biscayne Bay water via the radial collector wells would not affect the surface waters of Biscayne Bay. The volume of water drawn into the wells would be minor compared with the volume of water in Biscayne Bay, which is connected directly to the Atlantic Ocean.

5.3.1.2 Aquatic Resources

The use of reclaimed water would not impact any aquatic resources because aquatic organisms would have no contact with this water, which would be subjected to secondary treatment and high level disinfection, then transported via pipelines to the FPL reclaimed water treatment facility. Withdrawal of saltwater from Biscayne Bay through the radial collector wells would not affect aquatic resources in Biscayne Bay. Biscayne Bay, which is connected directly to the Atlantic Ocean, would not experience a noticeable loss of water to the radial collector wells. Also, because the water is not collected directly by the wells, but instead flows through the porous limestone approximately 25 to 40 feet below the bottom of Biscayne Bay, no aquatic organisms in Biscayne Bay would be affected. The flow rate at the sediment-water interface resulting from the radial collector well operation would be approximately 0.00002 feet per second.

Operation of the radial collector wells is not anticipated to result in significant adverse effects on seagrasses. Seagrasses have low nutrient requirements and are able to recycle nutrients efficiently, so that they are strong competitors under low nutrient levels (Koch, 2001; Armitage et

al., 2005). *Thalassia testudinum* is the dominant species of seagrass in the area and is more tolerant of low phosphorus/nutrient environments that could potentially result from induced flow through the seabed.

There are several macroinvertebrates and vertebrate species that utilize the seagrass beds of Biscayne Bay, including the areas over which the proposed radial collector well laterals will be located. Based on studies performed in 2009, the fish and invertebrates observed in the area are well adapted to living in areas of relatively swift currents associated with tidal exchange and wind and wave-driven shallow water turbulence. There is little likelihood that they would be affected by the very minor velocity changes at the seabed expected from operation of the radial collector wells.

Therefore, the impacts to aquatic life as a result of radial collector well operation would be SMALL and not warrant mitigation.

The operation of the radial collector wells and the potential impacts on water bodies including Biscayne Bay and the cooling canals in the industrial wastewater facility have been evaluated through groundwater modeling (Section 5.2 and FSAR Appendix 2CC). Based on the model results, the steady-state operation of the radial collector wells could dewater the upland layer (areas above the high water shoreline) on the Turkey Point peninsula. Drawdown in the uplands on the Turkey Point peninsula would range from 1 to 3 feet. Drawdown west of Turkey Point would be generally confined to the shoreline adjacent to Units 1 through 5 and would be approximately 0.1 feet (Figure 5.2-1). Based on the evaluation, impacts with respect to aquatic vegetation (e.g. shoreline mangroves) would be SMALL and not warrant mitigation. Additionally, impacts to important aquatic species from operation of the radial collector wells would be SMALL and would not require mitigation.

A small, localized drop in the water table may affect wetlands in the area; however, no important aquatic species would be impacted. When the elevation of surface water in a wetland is gradually reduced, whether through natural or human causes, most mobile organisms, such as fish and many invertebrates, would simply relocate to deeper, more suitable water. Rooted vegetation may extend their roots to reach the deeper groundwater. Some invertebrates (and even a few types of fish) can produce dormant cysts that can “hatch” or become active later when water levels return to normal. The only aquatic species in the wetlands near the radial collector wells that is afforded special status is the mangrove rivulus. The rivulus is a Florida species of special concern that inhabits crab burrows in mangrove areas (Smithsonian 2008). The rivulus can swim to another location when its habitat becomes unsuitable. In fact, the rivulus is capable of moving across mud even after most surface water has disappeared. This fish can survive for up to 60 days in damp leaves and surface litter (Florida Museum of Natural History 2008). Any potential drawdown of water in mangrove wetlands would not significantly impact the rivulus.

5.3.2 IMPACTS OF COOLING SYSTEM DISCHARGE SYSTEM ON AQUATIC ECOSYSTEMS

The blowdown from the cooling towers would be discharged by way of the blowdown sump to the Boulder Zone, a deep (approximately 2900 feet below grade) and highly cavernous zone of saline groundwater that is used for underground injection of industrial and domestic wastes in South Florida. Radionuclide transport analysis for the deep injection wells was performed to determine impacts (i.e., dose) to potential receptors present at the closest point(s) to the Turkey Point plant property (Section 5.4). Based on the analysis and resulting receptor doses, impacts to the Boulder Zone from cooling system discharge containing radioactive effluent were found to be SMALL. Based on these results, the operation of the deep injection wells would meet the requirements established by the EPA, and imposed by the underground injection control permit.

No aquatic organisms would be exposed to chemical or thermal effects of the blowdown. There is no reasonably foreseeable pathway by which groundwater in the Boulder Zone could reach surficial aquifers or surface waters. No impacts to aquatic resources would result from cooling water discharge.

5.3.3 HEAT DISCHARGE SYSTEM

5.3.3.1 Heat Dissipation to the Atmosphere

As described in Section 3.4, a closed-cycle circulating water system would be used for Units 6 & 7 consisting of three mechanical draft cooling towers for each unit to remove excess heat from the circulating water system. In addition, a single mechanical draft cooling tower would be used for heat removal from the service water system for each unit. The service water system cooling tower would be much smaller than the circulating water system cooling towers. Therefore, the analysis focuses on the circulating water system cooling towers.

Cooling towers evaporate water to dissipate heat to the atmosphere. Evaporation is followed by partial recondensation, which, with the right atmospheric conditions, creates a visible mist or plume. The plume creates the potential for shadowing, fogging, icing, and localized increases in humidity. In addition, small water droplets are blown out of the tops of the cooling towers. These water droplets are referred to as drift and could be deposited, along with any dissolved salts, on vegetation and surfaces surrounding the cooling towers.

For Units 6 & 7, the EPA CALPUFF (U.S. EPA 2007a) and AERMOD (U.S. EPA 2007b) dispersion models were used to evaluate cooling tower plume behavior and to estimate the frequency of occurrence and length of visible cooling tower plumes. These models are the preferred models for calculating deposition and fogging by the Florida Department of Environmental Protection (FDEP) and were used for consistency between the FDEP review and this ER. Five years (2001 through 2005) of hourly meteorological data from the Miami

International Airport (surface and upper air observations) were used. Physical and performance characteristics of the mechanical draft cooling towers (as presented in Table 3.4-2) relevant to the modeling effort are as follows:

Parameter	Value
Number of Towers (Per Unit)	3
Circulating Water flow (Per Tower)	210,367 gpm
Cycle of Concentrations (COC)[(a)]	1.5 to 4
Approximate Height	67 feet
Approximate Base Diameter	246 feet
Number of cells (Per tower)	12
Number of fans per cell	1
Exit air delivery per fan	1,764,500 actual cubic feet per minute
Design Wet Bulb Temperature	83.9°F
Design Range	24.4°F
Design Approach	7.1°F
Drift Rate	0.0005% (of the flow rate)
Heat Rejection Rate (million BTU/hr)	7,628
Solids Concentration (ppm)	50,000

(a) COC for marine water is 1.5 and COC for reclaimed water is 4

5.3.3.1.1 Length and Frequency of Elevated Plumes for Mechanical Draft Cooling Towers

The analysis of cooling tower plume behavior for the five year simulation period (2001-2005) indicated that the predicted plumes would remain primarily onsite. Visible vapor plumes would occur approximately 1722 hours per year, or about 20 percent of the year. Visible vapor plumes would occur during the winter months (719 hours), the spring (387 hours) and fall (387 hours) months. Only about 13 percent (230 hours) of the total hours with visible vapor plumes occur during the summer. During daylight hours, visible vapor plumes are predicted to occur for only 584 hours/year (7 percent of the time). Visible vapor plumes during daylight hours are predicted to occur at a higher frequency during the winter (213 hours) than other seasons.

Visible vapor plumes from the cooling towers would remain close to each of the towers during the daylight, when the plumes are the mostly visible. The results for daylight hours indicate that for the majority of the time, plume heights would be less than 400 meters and plume lengths would be less than 300 meters. Plume heights greater than 1000 meters are predicted to occur only one hour per year, while plume lengths in excess of 5000 meters would only occur 40 hours per year.

The design of the cooling towers minimizes tower visibility and improves plume dissipation. The additional water and heat released to the atmosphere by the cooling tower plumes would have a SMALL impact on the local environment, and no mitigation would be required.

5.3.3.1.2 Ground-Level Fogging and Icing

Fogging from mechanical draft cooling towers occurs when the visible plume intersects with the ground, appearing like fog to an observer**.** An analysis of cooling tower fogging and icing was performed using the EPA CALPUFF dispersion model. The results indicated that there were no predicted occurrences of ground-level fogging during the summer season, and minimal localized occurrence of fogging during the autumn and spring seasons at the Units 6 & 7 plant area. During the winter season, fogging was observed to occur for a total maximum of 20 hours during daylight hours (for the 5-year simulation period) at offsite areas on the eastern and southeastern perimeter of the Turkey Point plant property.

Icing from the mechanical draft cooling towers could be the result of ground-level fogging when ambient temperatures are below freezing. However, the CALPUFF model predicted that no ground-level icing would occur as a result of cooling tower operation. Therefore, there would be no ground-level icing impacts as a result of cooling tower operation.

The impacts attributable to fogging and icing as a result of the operation of the Units 6 & 7 cooling towers would be SMALL and no mitigation is required.

5.3.3.1.3 Solids Deposition

Water droplets blown from the mechanical draft circulating water system cooling towers (known as “drift”) would have the same concentration of solids as the water in the makeup water reservoir. As the water droplets blown from the cooling towers evaporate, either in the air or on vegetation or equipment, these solids would be deposited. The dissolved and suspended solid concentrations in the makeup water reservoir would be controlled through use of the makeup and blowdown water lines. As described in Section 3.4, makeup water to the circulating water system cooling towers may be provided via the use of reclaimed water and/or saltwater from radial collector wells installed below Biscayne Bay. For conservatism, the maximum total dissolved solids value was used from the radial collector wells, which would be in the range of 30,000 parts per million (ppm) during normal operating conditions.

The estimated amount of dissolved solids that could potentially escape from all of the cooling towers as drift is 75 kg/hour during normal operation. This amount of material could be released and dispersed over the area surrounding the Turkey Point plant property once both units are operational. A description of the results of an analysis of cooling tower plume drift and deposition is provided in Subsection 5.3.3.2.2.

5.3.3.1.4 Cloud Formation, Cloud Shadowing, and Additional Precipitation

Although there would be visible plumes during some periods of operation, adverse effects attributable to cloud shadowing or additional precipitation would not be significant. Given the

large distance from Units 6 & 7 to the boundary of the Turkey Point plant property on the western and northern perimeters, the lack of permanent residences at the eastern and southern perimeters (where fogging is predicted to be most prevalent), and the low profile of the mechanical draft cooling towers, the cooling tower plumes would not be visible from offsite locations except on rare occasions. The impacts of cloud shadowing or additional precipitation, therefore, would be SMALL and no mitigation is required.

5.3.3.1.5 Interaction with Existing Pollution Sources

No synergistic effects of cooling tower plumes mixing with plant radiological (see Section 5.4) or any other gaseous releases (see Subsection 5.5.1.3) would occur. Any gaseous effluents released from the plant during operation would be at a different elevation or at a location well removed from the cooling towers. Any such releases would also be at or near ambient temperature, and no significant plume rise from those releases would occur. The plume from the service water cooling towers would be small when compared to the main cooling towers. The potential for the mixing of the plumes would be minimal and at different locations from where any water droplets in the cooling tower plume would still be present.

Interactions with other sources of air pollution would be SMALL and no mitigation is required.

5.3.3.1.6 Ground-Level Humidity Increase

Increases in the absolute and relative humidity could result from the operation of the mechanical draft cooling towers. Based on CALPUFF modeling, no discernible increase in atmospheric humidity at offsite locations would result from the operation of the Units 6 & 7 cooling towers. Ground-level humidity increases would be SMALL and no mitigation is required.

5.3.3.2 Impacts of Heat Discharge System on Terrestrial Ecosystems

The approximately 9400-acre Turkey Point plant property consists primarily of wetlands, including an approximate 5900-acre industrial wastewater facility as well as wetland areas that were filled for industrial/developed land associated with the existing units (see Subsection 2.4.1). Plant communities within the Turkey Point plant property are those common to disturbed soils in this region (see Subsection 2.4.1). Upland areas are occupied by Australian pine, Brazilian pepper, and buttonwood. Wetland species include mangrove species and salt-tolerant herbaceous plants such as saltwort and glassworts. Four federally listed animal species have been observed within the Turkey Point plant property boundaries (primarily American crocodiles), as well as numerous state-listed species and state species of special concern (primarily water birds). Additional “important” species, as defined in NUREG-1555, found on the plant property include game animals common to this region, whitetail deer, and dove and rabbit species. Given that wetland habitats predominate, impacts to the small number of terrestrial game species found on the Turkey Point plant property would be SMALL.

Impacts of cooling system operation on terrestrial biota could occur from operation of the makeup water reservoir, cooling towers, and the supply of makeup water. Potential impacts of the makeup water reservoir are described in Subsection 5.3.3.2.1. Potential cooling tower operational impacts on terrestrial biota could result from increased salt deposits, vapor plumes, icing, precipitation modifications, noise, and avian collisions with structures (e.g., the cooling towers). Each potential impact of cooling tower operation is addressed in Subsection 5.3.3.2.2.

5.3.3.2.1 Makeup Water Reservoir

The makeup water reservoir at the southern end of the Units 6 & 7 plant area would occupy approximately 37 acres of land currently occupied by hypersaline mudflats, wetland spoil areas, mangrove heads, and a remnant canal (see the habitat descriptions in Subsection 2.4.1; Figure 2.4-2).

The makeup water reservoir would be lined with concrete; thus, no shoreline vegetation would be developed. Potential use of the makeup water reservoir by resting or roosting wintering waterbirds is unknown but likely, given the location of the reservoir within the Atlantic migration pathway and the proximity of the reservoir to other open water habitats (i.e., the cooling canals of the industrial wastewater facility, Biscayne Bay, Card Sound) historically used by migratory waterbirds. Given the sources of makeup water and the treatment of the water before use in the reservoir, fish occurrence in the reservoir is not anticipated and, therefore, use of the reservoir as foraging habitat by piscivorous birds is not anticipated. There are no uses of this reservoir other than providing a source of makeup water.

5.3.3.2.2 Cooling Towers

Salt Drift

Three mechanical draft cooling towers would be associated with each unit, and the six towers would be located within the makeup water reservoir. Habitat surrounding the cooling towers consists of the reservoir, Units 6 & 7 facilities to the north, the cooling canals of the industrial wastewater facility to the south and west, and Biscayne Bay to the east. Vegetation near the cooling towers would be subjected to salt deposits attributable to drift from the towers. Salt deposits could possibly cause vegetative stress, either directly by salts onto foliage or indirectly from accumulation of salts in the soil.

To evaluate the effect of salt deposits on plants, an order-of magnitude approach was used because some plant species are more sensitive to salt deposits than others, and tolerance levels of most species are not well known. Deposits of salt drift at rates of 1 to 2 kilogram/hectare/month (kg/ha/mo) is generally not damaging to plants, while deposition rates approaching or exceeding 10 kg/ha/mo in any month during the growing season could cause leaf damage in many species (NUREG 1437).

The AERMOD model was used to predict the amount of salt deposits from operation of the Units 6 & 7 cooling towers. The simulation was modeled based on the cooling tower operational parameters previously presented, and the 2001 through 2005 Miami meteorological data for upper air and surface data. The monthly depositions rates, based on an annual basis, are depicted in Figure 5.3-1. These monthly deposition rates are a conservative representation of depositional rates calculated for the four seasons (e.g., northeast-southwest bearing of depositional plume). Maximum salt deposition is predicted near the makeup water reservoir (up to 105 kg/ha/mo).

Beyond the makeup water reservoir, the deposition rates are predicted to decrease rapidly. The monthly salt deposition in the cooling canals of the industrial wastewater facility ranges from 1 to 70 kg/ha/month. This depositional rate is considered both conservative and bounding since evaporation of the solution drift has not been considered and it has been assumed that the saltwater is from the radial collector wells, which are assumed to operate on a full time basis. The radial collector wells are a backup water source, reclaimed water is the primary source, and operation of these wells is anticipated to be on an intermittent, as needed basis. Salt deposition of greater than 10 kg/ha/mo would generally be confined to the plant property, with the exception of the adjacent southeastern perimeter, as depicted on Figure 5.3-1. However, the vegetation surrounding the plant property is dominated by coastal mangroves, specifically the salt-tolerant red mangrove (Rhizophora mangle), which has developed physiological characteristics to allow the plants to survive in highly saline soils and areas of salt spray. Due to the mangroves' ability to tolerate elevated salinity, they are often found near monocultures in areas that are uninhabitable by freshwater and/or terrestrial vegetation. Considering the existing salt-tolerant vegetative community surrounding the plant area, the potential impacts of salt drift to vegetation would be SMALL and not warrant mitigation.

The industrial wastewater facility and nearby/adjacent canals and wetlands have been designated as critical habitat for the federally threatened American crocodile. The maximum predicted salt deposition rate to the industrial wastewater facility in the vicinity of the cooling towers ranges from 1 to 70 kg/ha/month (annual basis; see Figure 5.3-1). This annualized salt deposition range of 1 to 70 kg/ha/month was normalized to salinity based on the annual site rainfall (approximately 58 inches annually). The resulting salinity range was calculated to be approximately 0.0008 to 0.06 parts per thousand (ppt). This range in salinity concentration is about 3 orders of magnitude lower than the existing salinity in the industrial wastewater facility. Salt deposited within the industrial wastewater facility would be circulated within the system with subsequent combination with much higher salinity water. Salinity levels within the cooling canals of the industrial wastewater facility are typically 40–50 parts per thousand, a level that could adversely impact young crocodiles. Hatchlings and juvenile crocodiles have underdeveloped osmoregulatory capabilities and need fresh- to brackish water at least once per week to maintain normal growth rates. FPL’s crocodile program collects hatchling crocodiles and transfers them to juvenile refugia constructed by FPL, many on the tops of the cooling canal berms. The juvenile

crocodile refugia, based on observations performed in 2008 are depicted on Figure 5.3-2. Several types of refugia have been used, including refugia in the test canals north of the cooling canals of the industrial wastewater system, ponds excavated on berms of the active canals and test cooling canals, refugia resulting of dredging of berms, refugia at the Everglades Mitigation Bank, and natural refugia outside of the cooling canals of the industrial wastewater system. As is depicted in Figure 5.3-2, the majority of juvenile crocodile refugia are south of the area where the majority of salt deposition occurs (i.e., areas greater than 10 kg/ha/month).

Salinity levels in these juvenile crocodile refugia vary depending on conditions such as seasonal rainfall and evaporation rates. Additionally, due to precipitation, a freshwater lens typically develops in these refugia during the late summer months, during the post-hatching period when exposure to low-salinity water is necessary. The increase in salinity corresponding to the maximum salt deposition rate is approximately 0.06 ppt. Growth rates of Turkey Point crocodile hatchlings are equal to or greater than those from reference populations. Based on the locations of the juvenile crocodile refugia with respect to the predicted salt deposition, the predicted impact to salinity, and FPL's ongoing management activities that include monitoring and providing habitats for young crocodiles, predicted salt depositions from operation of the Units 6 & 7 cooling towers into the industrial wastewater facility and refugia would not sufficiently alter relevant salinity levels to impact crocodile growth and/or survival rates.

Waterbirds constitute a major component of terrestrial fauna found within the industrial wastewater facility. These birds forage on the fish inhabiting the canals, primarily hardy species of fish that can tolerate the harsh conditions (high salinities and temperatures) within the industrial wastewater facility. Salt deposits would not impact canal salinities sufficiently to eliminate or reduce fish populations and, therefore, would not impact waterbird use of the industrial wastewater facility.

Any impacts from salt drift on local terrestrial ecosystems would be SMALL and would not warrant mitigation beyond the crocodile management program identified above.

Vapor Plumes and Icing

As described in Subsection 5.3.3.1.1, plumes would be visible during daylight hours less than 7 percent of the time during all seasons. Most of the visible plume would be during the winter season.

As described in Subsection 5.3.3.1.2, ground-level fogging as a result of cooling tower operation is predicted to occur for only a maximum of 55 hours (5-year simulation period) at the Units 6 & 7 plant area and less than 5 hours (5-year simulation period) at any offsite areas**.** Icing resulting from cooling tower operation would not occur. Therefore, the impacts of vapor plumes, fogging, and icing on terrestrial ecosystems would be SMALL and would not warrant mitigation.

Clouds and Precipitation Modification

As described in Subsection 5.3.3.1.4, no significant increase in local precipitation would occur as a result of cooling tower operation. Any additional precipitation would be small in comparison with the average rainfall in the region, which has been shown to range from 45 inches (114 centimeters [cm]) to 66 inches (168 cm) (Refer to Table 2.7-3).

Because operation of the cooling towers would not result in a significant increase in precipitation, the impacts would be SMALL, and no mitigation is required.

Noise

Noise generated from cooling tower operations would be approximately 73 decibels adjusted (dBA) at 200 feet from the tower (Subsection 5.3.4.2). This is below the 80 to 85 dBA level known to startle or frighten some birds and small mammals (Golden et al. 1980). Therefore, noise from the towers would not disturb wildlife at distances greater than 200 feet from the towers. Additionally, the estimated noise level (73 dBA) associated with the new cooling towers at 200 feet would drop below 60–65 dBA, the level the NRC considers of small significance (NUREG-1437), within an additional 200–300 feet due to attenuation. Noise impacts to terrestrial biota would be SMALL and not warrant mitigation.

Avian Collisions

The mechanical draft towers would rise approximately 67 feet above the basin curb (Table 3.4-2). Taller, natural draft cooling towers have been associated with bird kills, but the shorter mechanical draft cooling towers would pose little risk to birds and cause minimal mortality (NUREG-1437). Therefore, impacts to birds from collisions with new cooling towers would be SMALL and would not warrant mitigation.

5.3.4 IMPACTS TO MEMBERS OF THE PUBLIC

This subsection describes the potential health impacts associated with the cooling system for Units 6 & 7. These include impacts to human health from etiological agents and from noise resulting from operation of the cooling system.

As described in Section 3.4, the circulating water system for Units 6 & 7 would use a closed-cycle, wet cooling system with mechanical draft cooling towers for heat dissipation.

5.3.4.1 Etiological Agent Impacts

Etiological agents that are associated with cooling ponds or towers and thermal discharges can have negative impacts on human health. The presence and concentration of these agents can be increased by the addition of heat. These agents include the enteric pathogens *Vibrio* spp.,

Salmonella spp., *Shigella* spp., and *Plesiomonas shigelloides*, as well as *Pseudomonas aeruginosa*, thermophilic fungi, noroviruses, and toxin-producing algae such as *Karenia brevis*, which causes red tide when present in high concentrations. They also include the bacteria *Legionella* spp., which causes Legionnaires' disease, and free-living amoebae of the genera *Naegleria, Acanthamoeba*, and *Cryptosporidium*. Exposure to these agents, or in some cases the endotoxins or exotoxins they produce, can cause illness or death (NUREG-1555).

These agents are the cause of potentially serious human infections, the most serious of which is attributed to *Naegleria fowleri*. *Naegleria fowleri* is a free-living amoeba that occurs worldwide. It is present in soil and virtually all natural surface waters such as lakes, ponds, and rivers. *Naegleria fowleri* grows and reproduces well at high temperatures (104ºF to 113ºF) and has been isolated from waters with temperatures as low as 79.7ºF. *Naegleria fowleri* thrives in warm, fresh water, particularly if the water is stagnant or slow-moving. These protozoa are found in a variety of water bodies, including lakes, ponds, and poorly maintained swimming pools and hot tubs. Since a primary food source for the amoebae is coliform bacteria, the presence of significant numbers of coliform bacteria would promote growth of this amoeba. Although exposure to this organism is very common, the chance is less than 1 in 100 million that a person exposed to water inhabited by *Naegleria* would become infected. Symptoms of these infections include changes in the ability to taste or smell, rapidly followed by headache, fever, nausea, and vomiting. While the disease is not transmissible from person to person, it is usually fatal (GBRA May 2002).

As presented in Section 3.4, makeup water for the circulating water system would be provided from two sources. Reclaimed water would be provided by the MDWASD. This reclaimed water would undergo pretreatment as well as the addition of biocide and algaecide. The Florida Department of Environmental Protection regulations require high-level disinfection prior to MDWASD supplying the reclaimed water for industrial use in open cooling towers. High-level disinfection includes additional total suspended solids control (beyond secondary treatment levels) to maximize disinfection effectiveness to result in reclaimed water in which fecal coliform values (per 100 milliliter of sample) are below detectable limits. These treatments would eliminate or minimize etiological agents from this makeup water source.

Saltwater makeup from radial collector wells could also be supplied for the circulating water system. Since the etiological agents of concern are primarily found in freshwater, they would not be present in the makeup water from the radial collector wells.

The cooling tower blowdown and other plant wastewater streams would be collected in a common blowdown sump and injected underground via the deep injection wells. These waste streams would not be discharged to waters that have the potential for direct contact by members of the public.

The makeup water reservoir would be located within the Turkey Point plant property, precluding access by members of the public. Personnel access to the makeup water reservoir would be strictly controlled by administrative controls and security patrols. Personnel protective measures (i.e., personal protective equipment, personnel monitoring) related to work activities requiring personnel contact with reservoir systems would be controlled by the worker protection plan. The risk to personnel health from etiological agents associated with the makeup water reservoir would be SMALL and would not warrant mitigation.

The risk to public health from etiological agents associated with the cooling system for Units 6 & 7 would be SMALL and would not warrant mitigation.

5.3.4.2 Noise

A noise survery was conducted in June 2008. The highest recorded noise level for onsite measurements was 68 dBA. The noise impacts of Units 6 & 7 were evaluated using the equipment associated with normal operation of the facility. The noise level generated by each cooling tower would be on the order of 88 dBA at 3 feet from the towers, 73 dBA at 200 feet from the towers, and 65 dBA at 400 feet from the towers**,** which is within the Units 6 & 7 plant area.

The design of Units 6 & 7 includes components that mitigate noise from being emitted to the surrounding environment. Most of the noise sources associated with Units 6 & 7 cooling systems would be cooling water pumps and cooling towers. The cooling water pumps would be in buildings that mitigate sounds emitted by equipment. The noise from cooling towers would be mitigated by their inherent design (e.g., splash guards on air inlets to mitigate sounds generated by falling water. stacks on mechanical fans that direct noise vertically).

As reported in NUREG-1437, and referenced in NUREG-1555, noise levels below 65 dBA are considered of small significance. In addition, there are no applicable state or local environmental noise regulations for unincorporated areas of Miami-Dade County, where Turkey Point is located (Subsection 2.7.7). Therefore, noise impacts would be SMALL and would not warrant mitigation.

5.3.4.3 Conclusion

Human health impacts to the surrounding population associated with the operation of the cooling system would be SMALL and would not warrant mitigation.

5.4 RADIOLOGICAL IMPACTS OF NORMAL OPERATION

This section describes the radiological impacts of normal plant operation on members of the public, plant workers, and biota. Subsection 5.4.1 describes the offsite radiological exposure pathways. Subsection 5.4.2 estimates the maximum doses to the public from the operation of each new unit. Subsection 5.4.3 evaluates the impacts of these doses by comparing them to regulatory limits. Subsection 5.4.4 considers the impact to nonhuman biota that are present along the exposure pathways. Finally, Subsection 5.4.5 describes the radiation doses to plant workers.

5.4.1 EXPOSURE PATHWAYS

Small quantities of radioactive liquids and gases would be discharged to the environment during normal operation. The impacts of these releases and any direct radiation to individuals, population groups, and biota in the vicinity of the new units were evaluated by considering the most important pathways from the release points to the receptors of interest. The most important pathways are those that could yield the highest radiological doses for a given receptor. The relative importance of a pathway is based on the type and amount of radioactivity released, the environmental transport mechanism, and the consumption or usage factors of the receptor.

The exposure pathways considered and the analytical methods used to estimate doses to the maximally exposed individual (MEI) and to the population within 50 miles of the new units are based on RG 1.109, *Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I,* and RG 1.111, *Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors.* An MEI is a hypothetical member of the public who receives the maximum possible calculated dose. Use of the MEl allows comparisons with established dose criteria for the public. Population doses were calculated for the year 2090, the assumed end of plant life, when the population is projected to be at its peak after the currently projected 60 years of plant operation. This is based on 40 years of operation under the initial operating license plus one 20-year license renewal. In 2090, food production rates within 50 miles of Units 6 & 7 are projected to increase at the same rate as population growth. Population doses are calculated considering the following three counties located within 50 miles of the plant: Broward, Miami-Dade, and Monroe. The southeast corner of Collier County also falls within 50 miles, but this is less than 10 percent of the total county land area and there is no population in this region. Therefore, the impact on this county would be negligible.

5.4.1.1 Liquid Pathways

Treated liquid radioactive waste from the operation of Turkey Point Units 6 & 7 would be diluted with the blowdown sump discharge flow before injection into the Boulder Zone via the deep well injection system (DIS) (Section 3.5). As described in Subsection 2.3.2, the highly saline Boulder Zone of the Lower Floridan aquifer is used for deep well injection of treated municipal wastewater

and reverse osmosis concentrate in Miami-Dade County. Injection occurs below the middle confining layer at depths of approximately 2700 feet or greater.

An analysis of potential liquid effluent pathways was performed to determine the affected member of the public and the doses that may result from the injection of treated liquid radioactive waste into the Boulder Zone and subsequent member-of-the-public exposure. This analysis is summarized below. FSAR Subsection 11.2.3.5 contains a more detailed presentation of this analysis.

Three exposure pathway modes—normal operation, off-normal operation, and inadvertent intrusion—are considered for the member-of-the-public screening analysis. These modes are defined as follows:

Normal Operation — Operation within specified operational limits and conditions. This mode assumes that the DIS and subsurface hydrogeological units operate as designed or expected with no system failures, such as deep injection well seal failure or subsurface confining unit fracture/failure.

Off-Normal Operation — An operational process beyond specified operational limits or conditions that, while not expected, may occur during the operating lifetime of a facility, e.g., a deep injection well seal failure or subsurface confining unit fracture/failure.

Inadvertent Intrusion — This is a special case mode whereby, while highly unexpected, a member of the public is unknowingly exposed to injectate while otherwise engaging in normal activities.

The locations for the potential receptors have been assigned to three areas based on their placement locations relative to Turkey Point Units 6 & 7 site. They are described as follows:

Plant Area — This area includes the location of Turkey Point Units 6 & 7 and includes the DIS. No current or future member of the public or populations has access to effluent at this location. Plant workers, however, may be exposed to effluent.

Property Area — This area includes all FPL-owned property between the plant area and the Turkey Point property boundary. No current or future member of the public or population has access to effluent at this location. Plant workers, however, may be exposed to effluent.

Beyond Property Area — This area includes the area beyond the Turkey Point property boundary. Members of the public and populations that are part of the general public may access effluent at these locations. The land ownership in this area includes private, government, and significant FPL ownership.

Based on both a preliminary and detailed screening analysis, several liquid effluent pathway scenarios were retained for detailed dose analysis (FSAR Subsection 11.2.3.5.2). An additional category was created to distinguish between a “credible” and a “non-credible” member of the public located beyond the property boundary. These categories are based on actual/predicted potential dose pathways. They are defined as follows:

- Credible — Such a scenario may be expected to occur during the operational lifetime of the plant (or beyond) based on current and projected water/land usage local to Turkey Point.

- Non-Credible — Such a scenario is not likely to occur during the operational lifetime of the plant or beyond based on current and projected water/land usage local to Turkey Point; however, it is included to provide a bounding dose for the off-normal event category.

The retained scenarios are summarized in Table 5.4-1. A detailed description of the dose analyses for the retained members of the public is summarized in the following paragraphs.

Beyond Property Area – Off-Normal Operation

Middle Confining Unit Failure and Member-of-the-Public Exposure (Credible)

The Ocean Reef Club community is approximately 7.7 miles from the effluent injection point. This community represents the only member of the public in the vicinity of Turkey Points Units 6 & 7 to currently use Upper Floridan aquifer water for any application. While Upper Floridan aquifer water is currently only being used by Ocean Reef Club for irrigation purposes, the most credible off-normal receptor was identified as a member of the public in the Ocean Reef Club community. This scenario assumes the water supply well is directly over the middle confining unit failure and takes no credit for further dilution, resulting in the same radionuclide concentrations in the Upper Floridan than is observed in the Boulder Zone. Based on groundwater modeling (FSAR Subsection 11.2.3.5.1), the Boulder Zone groundwater radionuclide concentration at this location for all radionuclides of interest is expected to remain at non-consequential levels for the full 100-year simulation duration. Therefore, no dose has been calculated.

Middle Confining Unit Failure and Member-of-the-Public Exposure (Non-Credible)

The nearest privately owned land parcel to the property boundary, which is located 2.2 miles from the centroid of the DIS, has been selected as the location for the non-credible member of the public. The local source term is evaluated at this location. Groundwater modeling was performed to determine the radionuclide concentrations in groundwater at this point (FSAR Subsection 11.2.3.5.1). The maximum tritium, cesium-134, cesium-137, and strontium-90 concentrations occur at 25, 15, 42 and 41 years, respectively. Tritium, cesiuim-134, cesium-137, and strontium-90 concentrations at these times were 3.1E04, 7.7E-03, 7.6E-01, and 5.6E-04 pCi/L, respectively. These maximum concentrations are conservatively assumed to occur concurrently

and, therefore, will be used collectively for the source term for the dose analyses conducted at this location.

The member of the public is assumed to use the Upper Floridan aquifer water for drinking water ingestion only via a water supply well. This water supply well is assumed to be directly over a conduit in the middle confining unit that allows injectate from the Boulder Zone to travel vertically to the Upper Floridan aquifer. The tritium, cesium-134, cesium-137 and strontium-90 concentrations in the Upper Floridan aquifer are assumed to instantaneously equal the maximum tritium, cesium-134, cesium-137 and strontium-90 concentrations in the Boulder Zone as described above. No additional consideration is given to upward migration time or retardation.

The NRC-endorsed LADTAP II computer program is used to calculate doses to the member of the public from drinking water ingestion of Upper Floridan groundwater. A separate LADTAP II run is made for each isotope (tritium, cesium-134, cesium-137, strontium-90). Table 5.4-2 summarizes the doses (for conservatism, a child was considered as the member of the public). The total body dose is lower than the 10 CFR Part 50, Appendix I, limit for a member of the public (annual limit of 3 mrem per unit). The organ dose (dose to child's liver as maximum organ) is lower than the 10 CFR Part 50, Appendix I, limit for a member of the public (annual limit of 10 mrem per unit). As can be seen, tritium is the dominant dose contributor.

Beyond Property Area – Inadvertent Intrusion

The doses associated with the inadvertent intrusion scenario represent a non-credible worst case, bounding estimate for dose. Farming and the raising of milk animals and livestock are not currently performed and are not anticipated to be performed in the region adjacent to Turkey Point. However, to present this worst-case dose, a subsistence driller is assumed exposed through these pathways as well as through effluent ingestion subsequent to the inhalation, immersion, and deposition exposure that occurs during the actual drilling operations. This scenario assumes that a water supply well is installed in the Upper Floridan aquifer directly above the conduit in the middle confining unit at the 2.2-mile location that allows deep well injectate to instantaneously travel to the Upper Floridan aquifer from the Boulder Zone. Therefore, the location as well as the radionuclide concentrations for this member of the public are the same as those for the beyond property area—off-normal operation, non-credible member of the public, as previously described.

Doses to the total body and maximum organ (liver) due to inhalation, immersion, and deposition incurred during the drilling activity by the member-of-the-public age group receiving the maximum doses are first calculated. For purposes of this calculation, the total duration of exposure during drilling operations is determined as follows:

- A water supply well in the Upper Floridan aquifer typically requires 75 days to complete. The Upper Floridan aquifer, which is assumed to contain the radionuclides, is not encountered until 1000 feet have been completed (or 66 percent of the 75 days). Therefore, exposure due to drilling is assumed to be for 25 days.

- The time to complete and develop a water supply well in the Upper Floridan aquifer is 20 days. Exposure is assumed to occur during this entire time period.

Therefore, the exposure time for the driller is 45 days total. A 12-hour shift is assumed for each day.

These doses are then conservatively combined with the annual doses to the maximum dose age group from ingestion of drinking water and irrigated foods to arrive at the total annual doses for the subsistence driller. The LADTAP II computer program is used to calculate doses to the member of the public from ingestion and consumption of drinking water, milk, meats and vegetables irrigated with Upper Floridan groundwater. Drilling-related doses to the total body and maximum organ (liver) due to inhalation, immersion, and deposition are determined using the appropriate RG 1.109 methodology, with the exception that immersion-related dose conversion factors are obtained from Federal Guidance Report No. 12 (US EPA 1993).

To determine the inhalation and immersion pathway doses resulting from a driller standing in an evaporating puddle of liquid effluent brought to the surface by the drilling operations, the resultant concentration of radionuclides in the air must first be determined. As RG 1.109 does not provide guidance on establishing airborne activity concentrations due to puddle evaporation, an empirical relationship for determining puddle evaporation rates developed by the EPA is used (US EPA 2009). In all cases, values for the various parameters used in determining the doses due to inhalation, immersion, and deposition are conservatively selected. For further conservatism, the as-calculated doses due to these exposure pathways are then doubled before being combined with the annual doses from ingestion of drinking water and irrigated foods to arrive at the total annual doses for the subsistence driller.

Table 5.4-3 summarizes the resultant doses to the subsistence driller (the maximum dose age group for drilling-related doses is the teen, while for conservatism, a child was considered as the member of the public for purposes of determining the ingestion-related doses). The member of the public's total body and total organ doses are both determined to be lower than the associated 10 CFR Part 50, Appendix I, annual design objectives of 3 mrem and 10 mrem, respectively, for a single unit. Table 5.4-4 summarizes the doses for all retained scenarios.

5.4.1.2 Gaseous Pathways

The NRC-endorsed GASPAR II computer program (PNL Mar 1987) was used to calculate doses to the MEI, the population, and biota from gaseous effluents. This program implements the radiological exposure models describe in RG 1.109 to estimate the doses. The following exposure pathways are considered in GASPAR II:

- External exposure to immersion/submersion by an airborne plume
- External exposure to standing on contaminated ground
- Inhalation of airborne radioactivity
- Ingestion of radioactivity in meat and milk
- Ingestion of radioactivity in garden vegetables

The input parameters for the gaseous effluent exposure pathway are presented in Table 5.4-5 and the receptor locations are shown in Table 5.4-6. The receptor locations are those at which the maximum atmospheric dispersion and deposition factors occur for each exposure pathway.

5.4.1.3 Direct Radiation

Contained sources of radiation at Units 6 & 7, including the refueling water storage tank, will be shielded such that the direct dose rate at the Turkey Point plant property boundary is negligible (WEC 2011). Therefore, the impact of direct radiation would be SMALL and would not warrant additional mitigation. No further consideration of direct radiation is provided.

5.4.2 RADIATION DOSES TO MEMBERS OF THE PUBLIC

Based on the parameters in Tables 5.4-5 and 5.4-6, the GASPAR II computer program was used to calculate annual doses from gaseous effluents from one new unit to the MEI, the population, and biota. As stated above, there is no dose due to liquid effluents during normal operations. The MEI doses were determined by considering the maximally exposed adult, teenager, child, and infant at the following locations:

- Nearest site boundary (nearest boundary of the Turkey Point plant property)
- Nearest residence (2.7 miles)
- Nearest vegetable garden
- Nearest meat cow pasture

There are no milk animals within five miles of Units 6 & 7. The maximum total body and organ doses are presented in Table 5.4-7. In this table, the contributions from viable pathways are summed to obtain a total dose for each organ and age group. Although Table 5.4-6 shows the vegetable garden is farther away than the residence and the meat animal, the garden doses were added to the doses from the other two pathways. For comparison, Table 5.4-6 includes dose estimates at the limiting Turkey Point plant property boundary location, where no established human exposure pathways have been identified. In effect, doses were calculated at two locations: Turkey Point plant property boundary and the merged residence/garden/meat animal location. The latter location represents the MEI. Table 5.4-7 shows that the maximum doses from each unit occur at the Turkey Point plant property boundary and that most of the dose is a result of the external exposure pathways. The maximum total body dose is 3.9 mrem/year to the adult, the teen, and the child while the maximum organ doses are 14 mrem/year to the skin and 7.5 mrem/year to the thyroid of the child. These are theoretical doses based on conservative assumptions. Table 5.4-9 shows comparable doses from the operation of Units 3 and 4 are negligible.

5.4.3 IMPACTS TO MEMBERS OF THE PUBLIC

Table 5.4-8 shows that even the site boundary doses, which bound the MEI, are within the design objectives of 10 CFR Part 50, Appendix I. Table 5.4-9 shows that the total site doses from the two new units as well as the two existing units are within the regulatory limits of 40 CFR Part 190. Since the dose limits for members of the public in 40 CFR Part 190 are more restrictive than those in 10 CFR 20.1301(a)(1), demonstration of compliance with the limits of 40 CFR Part 190 is also a demonstration of compliance with the 0.1 rem total effective dose equivalent (TEDE) limit of 10 CFR 20.1301(a)(1). Table 5.4-10 shows that collective doses from the new units to the population within 50 miles of the plant are extremely low compared to collective doses from natural background radiation. Based on the estimated doses from the new units, impacts to members of the public would be SMALL and would not warrant additional mitigation.

5.4.4 IMPACTS TO BIOTA OTHER THAN MEMBERS OF THE PUBLIC

Radiation exposure pathways to biota other than members of the public were examined to determine if these pathways could result in doses to biota greater than those predicted for humans. Immersion and ground deposition doses are largely independent of organism size, and the doses to humans, calculated as described in Subsection 5.4.2, can be applied to biota except that the location of the biota is as shown in Table 5.4-6. The maximum total body dose to a human from inhalation, vegetable, plume, and ground deposition pathways, as calculated by GASPAR II, was applied to biota except that the ground deposition dose was increased by a factor of two to account for the proximity of terrestrial organisms to the ground. The resulting dose to biota species represented by muskrat, raccoon, heron, and duck is 26 mrad/year or 0.07 mrad/day per unit. The International Council on Radiation Protection states that “if man is

adequately protected, then other living things are also likely to be sufficiently protected," (ICRP 1977), and the National Council on Radiation Protection concurs with this conclusion (NCRP 1991). Furthermore, the International Atomic Energy Agency (IAEA) concludes that there is no scientific evidence that chronic dose rates below 100 mrad per day are harmful to plants and animals (IAEA 1992). It is seen that the biota dose is well within the IAEA guideline. Therefore, impacts to biota other than members of the public would be SMALL and would not warrant additional mitigation.

5.4.5 OCCUPATIONAL DOSES

For Units 6 & 7, the estimated annual occupational dose, including outage activities, is 67 person-rem per unit (WEC 2011). By comparison, the annual collective dose per operating PWR in the U.S. was 87 person-rem in 2006 (US NRC, 2007). The health physics program described in FSAR Section 12.5 and the radiation protection features described in FSAR Section 12.3 would ensure that occupational exposures are maintained ALARA. The dose to Unit 7 construction workers during the operation of Unit 6 and the existing units is addressed in Section 4.5. With the collective worker dose smaller than that for existing reactors, the impact on occupational doses would be SMALL and no new mitigation measures or controls would be warranted.

	Inadvertent Intrusion	Middle confining unit failure and member-of-the-public drilling and ingestion exposure (Worst Case)	Beyond Property Boundary at closest private parcel	5.6 mrem/year total body dose for 2 units

Table 5.4-5
Gaseous Effluent Exposure Pathway Parameters

Parameter	Value	Basis/Source
Release source terms	See DCD Table 11.3-3	The DCD table shows the expected annual activity releases by isotope.
Atmospheric dispersion and deposition factors	See Tables 2.7-16, 2.7-17, 2.7-18	Table 2.7-16 shows the dispersion and deposition data for the nearest site boundary, residence, vegetable garden, and meat animal. Tables 2.7-17 and 2.7-18 show dispersion and deposition data for 160 sectors representing 16 directions and 10 distance segments out to 50 miles. The dispersion and deposition data at the assumed biota location at a distance of 0.25 mile were obtained from Table 2.7-17.
Individual consumption rates	See RG 1.109	The values from Tables E-5 and E-4 of RG 1.109 were used for the MEI and the average person within the population, respectively.
50-mile population	6.28E06	This is the projected population for the year 2090, the end of plant life. It was used to conservatively maximize population doses. This projection represents an increase of a factor of 1.81 over the 2010 population.
50-mile population distribution	See Table 2.5-1	Table 2.5-1 shows the population distribution in 2090 for 160 sectors representing 16 directions and 10 distance segments out to 50 miles.
50-mile milk production	7.89E04 L/yr	Milk cows in the four counties within 50 miles represent approximately 0.046% of the state total (USDA Jun 2004). The annual production of milk in the state (USDA 2008) was multiplied by 0.046% to estimate the production within 50 miles as 4.36E04 L/yr. Assuming production to increase with the population, this production rate was multiplied by the population growth factor of 1.81 to project the production in 2090.
50-mile meat production	1.18E05 kg/yr	Beef cows and broilers in the four counties within 50 miles represent approximately 0.21% and 0.0017%, respectively, of the state totals (USDA Jun 2004). The annual productions of red meat (USDA 2007) and broiler (USDA 2008) in the state were multiplied by these percentages and summed to estimate the total meat production within 50 miles as 6.53E04 kg/yr. Assuming production to increase with the population, this production rate was multiplied by the population growth factor of 1.81 to project the production in 2090.
50-mile vegetable production	1.09E08 kg/yr	The harvested land area in the four counties within 50 miles represents approximately 2.6% of the state total (USDA Jun 2004). The annual production of vegetables in the state (USDA 2008) was multiplied by 2.6% to estimate the production within 50 miles as 6.04E07 kg/yr. Assuming production to increase with the population, this production rate was multiplied by the population growth factor of 1.81 to project the production in 2090.
Fraction of year leafy vegetables grown	1	This is the most conservative value.
Fraction of year milk cows on pasture	1	This is the most conservative value.
Fraction of maximum individual's vegetable intake from own garden	0.76	This is the default value from RG 1.109, Table E-15.
Fraction of milk-cow feed from pasture	1	This is the most conservative value.
Average absolute humidity for growing season	8 g/m^3	This is the default value in GASPAR II (PNL Apr 1987). It was used when a value of zero is input.
Fraction of year goats at pasture	1	This is the most conservative value.
Fraction of goat feed from pasture	1	This is the most conservative value.
Fraction of year beef cattle at pasture	1	This is the most conservative value.
Fraction of beef cattle feed from pasture	1	This is the most conservative value.

5.5 ENVIRONMENTAL IMPACTS OF WASTE

Operation of Units 6 & 7 would generate several identifiable waste streams. These wastes would be regulated, as appropriate, during all stages including generation, management, handling, treatment, storage, transportation, and disposal. This section describes the potential environmental impacts associated with these wastes. The description is divided into subsections that address both nonradioactive and mixed wastes.

5.5.1 NONRADIOACTIVE WASTE SYSTEM IMPACTS

Descriptions of the Units 6 & 7 nonradioactive waste systems, waste stream discharges, and chemical concentrations are presented in Section 3.6. The following summarizes the impacts resulting from nonradioactive discharges to the environment.

Nonradioactive wastes would be managed in accordance with applicable federal, local laws and regulations, and permit requirements, as identified in Section 1.2. Management practices would include:

- Recyclable wastes, such as scrap metal, lead acid batteries, and paper collected at Units 6 & 7 would be recycled offsite at an approved recycle facility, as is currently performed for the existing units.

- Wastes (e.g., used oil, antifreeze, rags) would be collected and stored temporarily onsite until recovered at an offsite permitted recycling/recovery facility or disposed of at an offsite licensed commercial waste disposal facility, if found to be hazardous.

- Hazardous waste (e.g., paint and solvent wastes) would be disposed of in accordance with 40 CFR Parts 261 and 262.

- Water discharges from cooling and auxiliary systems (e.g., cooling tower blowdown, sanitary wastewater treatment effluent, and other wastewater effluent streams collected in the blowdown sump) from routine plant operations would be discharged to the Boulder Zone via deep injection wells as permitted by the Florida Department of Environmental Protection.

- Storm water would be discharged to the cooling canals of the industrial wastewater facility as permitted by the Florida Department of Environmental Protection.

- Waste sludge generated at the tertiary water treatment plant and sanitary wastewater treatment plant would be disposed of in an offsite landfill.

The assessment of potential impacts resulting from the discharge of nonradioactive wastes is presented in the following subsections.

5.5.1.1 Impacts of Discharges to Land

Operation of Units 6 & 7 would result in the generation of solid wastes, including trash, water treatment resins, water and sanitary treatment residuals, and waste generated from the removal of access roads. Applicable Florida requirements and standards would be met regarding the handling, transporting, and disposal of solid wastes offsite (e.g., Solid Waste Management Facilities Rule 62-701, Florida Administrative Code [F.A.C.]). Onsite disposal of uncontaminated sediment and excavated material would be stockpiled in areas with appropriate engineering controls to limit surface water runoff. The impacts of the disposal of these wastes to land are discussed in the following paragraphs.

As discussed in Section 3.6, Turkey Point Units 6 & 7 would produce approximately 1000 tons annually of nonradioactive, nonhazardous waste requiring disposal in landfills, including spent filters from water and wastewater treatment. In 2008, Miami- Dade County disposed of approximately 2.2 million tons of waste in both commercial and private landfill facilities (Miami-Dade County, undated). The percent of waste requiring disposal in landfills from Turkey Point Units 6 & 7 represents approximately 0.05 percent of the total tons disposed in landfills by Miami-Dade County in 2008. It is likely that the quantities of construction rubble would be low when compared to the overall waste volumes disposed in landfills. Therefore, the potential impacts from land disposal of nonradioactive, nonhazardous solid wastes would be SMALL and not warrant mitigation.

The FPL Reclaimed Water Treatment Facility is expected to produce approximately 435 tons of waste sludge per day, which would be disposed of at an offsite permitted landfill. This amount of waste sludge requiring disposal in landfills per day represents approximately seven percent of the 2.2 million tons of waste disposed in landfills by Miami-Dade County in 2008. Therefore, the potential impacts from land disposal of the Reclaimed Water Treatment Facility waste sludge would be SMALL and not warrant mitigation.

The sanitary wastewater treatment facility will be constructed to treat sanitary waste from Turkey Point Units 1 through 4, Units 6 & 7, Land Utilization Facilities, and the FPL reclaimed water treatment facility. Approximately 1300 gallons per day of 1.5-2 percent residual sludge, or biosolids, are anticipated to be produced daily. The residual sludge will be transported and disposed of offsite by a licensed contractor. Based on the small amount of residual biosolids anticipated to be produced from the Turkey Point Units 1 through 4, Units 6 & 7, Land Utilization Facilities, and the FPL reclaimed water treatment facility, the potential impacts from land disposal of the sanitary wastewater treatment waste sludge would be SMALL and not warrant mitigation.

5.5.1.2 Impacts of Discharges to Water

Nonradioactive wastewater from routine plant operations would include cooling tower blowdown, plant auxiliary systems, and water treatment. Ambient or baseline water quality characteristics are described in Subsection 2.3.3. Table 3.6-1 lists potential water treatment chemicals that would be used. Tables 3.6-2 and 3.6-3 list the estimated constituent and concentrations in the nonradioactive liquid waste stream from Units 6 & 7 that would be discharged to the deep injection wells for the reclaimed water and saltwater water makeup water to the circulating water system, respectively. Sanitary waste would be collected and treated in an onsite sewage treatment plant, the design and operation of which would ensure that the effluents meet the applicable effluent requirements.

The wastewater and sanitary waste treatment effluent would be disposed of using deep injection wells under the provisions of the Underground Injection Control (UIC) Rule in 62-528 F.A.C. Therefore, the effluent limits would be set by the underground injection control permit, thus regulating the effluent concentrations and operation of the deep injection wells. The wastewater would be discharged into the Boulder Zone approximately 2900 feet underground.

Considering the anticipated amount of dilution for wastewater discharged to the Boulder Zone and the limits that would be placed on discharges by the underground injection control permit, the potential impacts from wastewater/sanitary discharge from Units 6 & 7 on groundwater would be SMALL. There would be no impacts on surface water or groundwater from wastewater/sanitary waste discharge. As identified in Section 1.2, the current zero discharge National Pollutant Discharge Elimination System permit (62-620 and 62-621 F.A.C, promulgated by the U.S. EPA to the state of Florida through 403.0885 Florida Statutes) for industrial wastewater identifies the limits on various chemical constituents that can be released to the industrial wastewater facility. The impacts of the addition of impervious surfaces would be negligible because environmental best management practices (e.g., oil-water separators) would be employed to control storm water runoff. Therefore, environmental impacts from storm water discharges would be SMALL and would not warrant mitigation.

5.5.1.3 Impacts of Discharges to Air

Operation of Units 6 & 7 would result in small amounts of gaseous emissions to the air from equipment associated with plant auxiliary systems (e.g., diesel generators, diesel-driven fire pumps, etc.). This equipment would operate only infrequently (e.g., during startup/shutdown or testing), and, thus, the related emissions would be intermittent. Projected emissions from the diesel-fueled equipment are provided in Table 3.6-4.

Under state of Florida prevention of significant deterioration review requirements, all major new or modified sources of air pollutants under the Clean Air Act must be reviewed and a

preconstruction permit issued. The EPA has promulgated prevention of significant deterioration regulations under 40 CFR Part 51.166. Florida's prevention of significant deterioration rules, promulgated from EPA CFR Part 51.166, are codified under 62-212.400, F.A.C. The air emission sources as a result of operation of Units 6 & 7 would be permitted under this rule. Included in this rule are limits for regulated pollutants.

Based on the estimated amount of potential air emissions, the intermittent nature of the potential emissions, and the requirement to adhere to prevention of significant deterioration requirements, impacts to air quality would be SMALL and would not warrant mitigation.

5.5.2 MIXED WASTE IMPACTS

The term mixed waste refers specifically to waste that is regulated as both radioactive waste and hazardous waste. Radioactive materials at nuclear power plants are regulated by the NRC under the Atomic Energy Act of 1954 (Atomic Energy Act, 42 USC 2011 et seq.). Hazardous wastes are regulated by the state of Florida, which is an EPA-authorized state (i.e., a state authorized by the EPA to regulate those portions of the federal act) under the Resource Conservation and Recovery Act (RCRA 42 USC 6901 et seq).

Mixed waste generated from the operation of Units 6 & 7 was assessed based on the following laws and regulations. The radioactive component of mixed waste must satisfy the definition of low-level waste in the Low-Level Radioactive Waste Policy Amendments Act of 1985. The hazardous component must exhibit at least one of the hazardous waste characteristics identified in 40 CFR Part 261, Subpart C, or be listed as a hazardous waste under 40 CFR Part 261, Subpart D.

5.5.2.1 Plant Systems Producing Mixed Waste

A 1990 survey conducted by the NRC identified the following types of mixed low-level waste at reactor facilities (NUREG-1437):

- Waste oil from pumps and other equipment.
- Chlorinated fluorocarbons resulting from cleaning, refrigeration, degreasing, and decontamination activities.
- Organic solvents, reagents, compounds, and associated materials such as rags and wipes.
- Metals such as lead from shielding applications and chromium from solutions and acids.
- Metal-contaminated organic sludge and other chemicals.
- Corrosive liquids consisting of organic and inorganic acids.

The types of mixed waste generated by the AP1000 would be consistent with the types identified by the NUREG-1437 survey, and an AP1000 unit would generate a limited volume of mixed waste (i.e., approximately 25 cubic feet annually) per the DCD. However, it is anticipated that little to no mixed waste would be produced by Units 6 & 7. The following paragraphs contain proposed procedures for the handling and minimization of mixed waste, should it be generated as a result of the operation of Units 6 & 7.

5.5.2.2 Mixed Waste Storage and Disposal Plans

The volume of mixed waste would be reduced or eliminated by one or more of the following methods before disposal: decay, stabilization, neutralization, filtration, or chemical/thermal destruction by an outside vendor. Some small quantities of mixed waste, if generated, would be temporarily stored onsite until suitable treatment options or disposal sites are available. Possible options would be shipment to a permitted mixed waste disposal facility, shipment to a treatment facility, or storage onsite. Occupational chemical and radiological exposures could occur during the testing of mixed wastes to determine if the constituents are chemically hazardous. Appropriate hazardous chemical control and radiological control measures would be applied during testing, handling, and storage of mixed wastes, in accordance with 10 CFR Part 20 guidelines, and could include any of the following:

- Segregate mixed wastes from nonhazardous wastes.
- Designate and use an area only for storage of mixed waste and exclude its use for storage of unrelated materials or equipment or for other functions.
- Provide a secondary containment for liquid mixed wastes being stored (for example, berm and line areas where drums are stored).
- Label the containers properly and in accordance with regulatory requirements.
- Post and/or provide applicable material safety data sheets, emergency spill response procedures, and a spill kit in the area.
- Fence and lock the gate to the accumulation area or long-term storage area when authorized personnel are not present.
- Post signs at the entrance to the storage area indicating, for example: “MIXED HAZARDOUS WASTE AREA” and “DANGER—UNAUTHORIZED PERSONNEL—KEEP OUT.”

5.5.2.3 Waste Minimization Plan

A waste minimization program could be developed and implemented, if necessary. The following elements of such a program may include:

- Maintenance Program — Equipment maintenance programs would be periodically reviewed to establish improvements in corrective and preventive maintenance that would reduce equipment failures that could generate mixed waste. Maintenance procedures would be reviewed to address activities that result in the production of waste in the form of process materials, scrap, and cleanup residue. In addition, the need for revising operational procedures, modifying equipment, and segregating and recovering the mixed wastes would be addressed.

- Recycling and Reuse — Opportunities for reclamation and reuse of waste materials would be used whenever feasible. Tools, equipment, and materials would be decontaminated for reuse or recycle whenever practical to minimize the amount of waste for disposal. Impediments to recycling would be challenged to enable generators to recycle whenever practical.

- Segregation — If radioactive or hazardous waste is generated, proper handling, containerization, and separation techniques would be employed. This would minimize cross-contamination and the unnecessary generation of mixed waste.

- Decay in Storage — Some portion of the mixed waste would be radionuclides with relatively short half-lives. The NRC generally allows facilities to store waste containing radionuclides with half-lives of less than 120 days until 10 half-lives have elapsed and the radiation emitted from the unshielded surface of the waste is indistinguishable from background levels. The waste could then be disposed of as a nonradioactive waste. Radioactive waste could also be stored for decay under certain circumstances in accordance with 10 CFR Part 20. For mixed waste, storage for decay would be particularly advantageous because the waste could be managed solely as a hazardous waste after the radionuclides decayed to background levels, thereby simplifying the management of these wastes to meet applicable requirements.

- Work Planning — Pre-job planning would be performed to determine what materials and equipment would be needed to perform the anticipated work. One objective of this planning would be to prevent pollution and minimize the amount of mixed waste that may be generated and to use only the materials necessary to accomplish the work. Planning would also prevent mixing of materials or waste types.

- Tracking Systems — Development of a tracking system to monitor waste generation data and identify waste minimization opportunities to reduce environmental impacts would be considered. This would provide essential feedback to successfully guide future efforts. The

data collected by the system would be used for internal reporting. The tracking system would provide feedback on the progress of the waste minimization program, including the results of the implementation of pollution prevention technologies.

- Training and Awareness Programs — Educate employees in the principles and benefits of the waste minimization plan, solutions to current and potential environmental management problems could be found. Details of the training program would be outlined in the Nuclear General Employee Training.

5.5.2.4 Environmental Impacts of Mixed Waste

Industry-accepted chemical handling techniques, pre-job planning, and compliance with an approved facility waste minimization plan (as addressed in Subsection 5.5.2.3) would ensure that only small quantities of mixed wastes would be generated by the new units. Therefore, environmental impacts of mixed waste would be SMALL and would not warrant mitigation.

5.5.3 CONCLUSIONS

Small quantities of chemical constituents would be released to the water and air from operation of the new units. These constituents would be limited and permitted under the Florida Department of Environmental Protection permits. Waste minimization programs would reduce the amount of wastes, including mixed wastes, generated by operation of the new units. To the extent practical, nonradioactive liquids and solid wastes would be recycled. For wastes that cannot be recycled, applicable federal, Florida, and local requirements and standards would be met with regard to the handling, transporting, and disposal of solid wastes offsite. Therefore, the impacts of waste generation would be SMALL and would not warrant mitigation.

5.6 ENVIRONMENTAL IMPACTS OF TRANSMISSION SYSTEMS

The potential environmental impacts of transmission system operation are described in this section. Environmental impacts of transmission facility construction (new rights-of-way and/or modification of existing rights-of-way) are described in Section 4.3. Possible impacts from transmission system operation, including transmission line vegetation management and transmission system maintenance, are described in this section relative to terrestrial and aquatic resources and members of the public.

Power generated at Units 6 & 7 would be transmitted over new circuits using new and existing rights-of-way (see Subsection 2.2.2). To the extent practicable, the proposed transmission lines would be collocated with FPL's existing transmission lines.

As part of the state certification proceeding, FPL is proposing transmission corridors of variable widths up to 3700 feet wide connecting the terminal points of the proposed transmission lines. The new transmission lines would be located in a much narrower right-of-way somewhere within these corridors. Once the certification proceeding is concluded and FPL obtains the property interests required to construct the proposed transmission lines, the boundary of the corridors would narrow to only that land in the transmission line rights-of-way. After constructing the new transmission lines, the proposed transmission corridors would have no further legal significance. Therefore, this section addresses the environmental impacts of operation and maintenance of the transmission lines within the rights-of-way.

The 500 kV and 230 kV rights-of-way are variable in width and total approximately 89 miles in length. All existing and proposed rights-of-way are located in Miami-Dade County. Subsection 2.2 describes the land characteristics of the area contained in these rights-of-way. One short 230 kv (0.4-mile) line, completely within the Turkey Point plant property and traversing previously developed land, would connect the new Clear Sky substation to the existing Turkey Point substation.

FPL conducts routine maintenance in existing rights-of-way in compliance with applicable federal, state, and local laws, regulations, and permit requirements. Right-of-way maintenance activities in new and/or modified rights-of-way also would be the responsibility of FPL and would comply with local, state, and federal requirements.

5.6.1 IMPACTS TO TERRESTRIAL RESOURCES

Line maintenance and vegetation management for the proposed transmission lines would be site-specific, based on location, terrain, and the surrounding environment. Consistent with existing practices, vegetation would be managed by trimming, mowing, and application of approved growth regulators and herbicides, targeting species that are incompatible with the safe access, operation, and maintenance of the transmission system (Subsection 3.7.3.2). In the

transmission line rights-of-way, plant species that attain heights greater than 14 feet would typically removed to maintain proper clearance to conductors. The buildup of vegetation in the transmission line rights-of-way would also be monitored and reduced if it reaches levels that may threaten the operation of the transmission lines. Many segments of these transmission line rights-of-way cross cultivated lands and other open land use characteristics (e.g., sawgrass marsh), where the height of the vegetation would not threaten transmission operation. Maintenance operations would be rarely required in these areas.

As identified in Subsection 2.4.1.2, multiple federal- and state-listed endangered and threatened species, candidate species, and state species of special concern are found in Miami-Dade County, the county containing all of the proposed and existing transmission corridors (see Table 2.4-3). During a recent reconnaissance (April and June 2008) of these corridors, a single Everglade snail kite was the only federally listed fauna observed in or near the corridors (ENP segment). These kites feed almost exclusively on apple snails and, thus, use extensive marsh systems or lake littoral zones as foraging habitat.

Subsequent to the 2008 transmission corridor reconnaissance, an Eastern indigo snake was observed at two locations on the Eastern Preferred transmission corridor in 2011. Eastern indigo snakes inhabit a variety of habitats.

Portions of the transmission corridors on the Turkey Point plant property cross canals/wetlands designated as critical habitat for the federally threatened crocodile. State canals crossed by the transmission corridors may be used by the endangered Florida manatee. Wood storks periodically nest in four colonies along Tamiami Trail near the south-to-north leg of the proposed Clear Sky-to-Levee corridor. Critical habitat has not been defined for the stork, but habitat management guidelines (USFWS 1990) for the species include recommendations relating to transmission structures and other construction activities near stork breeding colonies. FPL's commitment to the preservation of the environment led to the development and implementation, in consultation with the U.S. Fish and Wildlife Service (USFWS), of the FPL Avian Protection Plan. This plan provides for guidelines and avian-friendly design standards that minimize the likelihood of collisions and electrocutions of wood storks and other birds from electrical facilities. The Florida panther is an endangered species that inhabits saw palmetto thickets and hardwood areas in the Everglades. There have been approximately 60 sightings of panthers during the last 20 years in the Everglades area crossed by the two alternative corridors for the Clear Sky-to-Levee transmission corridor. Routing the transmission line along either corridor could temporarily disturb Florida panthers, although actual operation of the transmission lines should have little to no impact on panthers. Several species that are state-listed or species of special concern were observed during recent reconnaissance of this area: snowy egret, tricolored heron, and white ibis. Surveys of the transmission corridors for listed plants documented approximately 30 plant species within/adjacent to the corridors. Given that the sensitive plants discovered within the transmission corridor already exist within managed and/or maintained habitats and FPL's

practice to avoid these sensitive plants to the extent practicable, impacts of continued operation and maintenance of the transmission lines on sensitive plants would be SMALL.

FPL considers threatened or endangered species in its selection of corridors in transmission line rights-of-way and in its transmission line right-of-way maintenance program. For example, FPL's collocation of the proposed transmission lines in existing transmission line rights-of-way would minimize the impacts on plant and animal populations as a result of construction, maintenance, and operation of the proposed transmission lines. FPL would consult with the USFWS and the Florida Fish and Wildlife Conservation Commission on appropriate avoidance or mitigation methods in a post-certification process pursuant to conditions of the state's certification of the Turkey Point project under the Florida Electrical Power Plant Siting Act.

Other important species, as defined in NUREG-1555, likely to use these transmission line rights-of-way include game species such as white-tailed deer, feral hog, and rabbit and dove species. However, the short-term and infrequent vegetation management activities employed to maintain these transmission lines would only disturb these species for the duration of the maintenance activity and would not permanently disrupt or displace them. Maintaining the rights-of-way in an early stage of vegetative succession may benefit some of these wildlife species.

The NRC evaluated the potential impacts of transmission line maintenance and vegetation management practices on terrestrial biota, including practices similar to those employed by FPL, in the Generic Environmental Impact Statement (GEIS) for License Renewal of Nuclear Plants (NUREG-1437). The GEIS concluded that typical line maintenance and vegetation management practices do not lower habitat diversity or produce significant changes in surrounding habitats, and generally result in impacts to wildlife of SMALL significance. FPL's maintenance procedures are site-specific, based on local terrain and plant communities, and therefore minimize impacts of transmission line maintenance activities on terrestrial resources. Most of the habitats crossed by the proposed transmission corridors are agricultural and/or open (e.g., sawgrass marsh) and will require only infrequent management. Given the types of habitats within the rights-of-way, the infrequency of required maintenance, and the NRC (1996) evaluation of potential impacts, the impacts of maintenance activities on terrestrial biota would be SMALL.

Impacts of maintenance activities on existing transmission line rights-of-way are typically found to be insignificant with only SMALL impacts to floodplains and wetlands (NUREG-1437). Construction and/or clearing of rights-of-way typically have greater potential for impacts than maintenance activities, but they too can be completed with little or no impacts. For example, most herbaceous, shrub-dominated, and open water wetlands would be spanned during maintenance or repair activities and would not be affected by transmission line maintenance.

Even though most of the aquatic habitat between spans will still function as wetlands, pads and foundations built to support transmission poles and access roads for maintenance will replace

some wetland habitats and may alter local hydrology. FPL will be required by the Florida Department of Environmental Protection and the U.S. Army Corps of Engineers to avoid and minimize such impacts to the extent practical, and where impacts are unavoidable, to mitigate the value and functions of any wetlands disturbed by construction Given the amount of wetland habitats disturbed during construction in the vicinity of the proposed transmission lines associated with this project, impacts of maintenance and operation of these transmission lines are expected to be SMALL. Mitigation methods pertaining to wetlands in transmission corridors were discussed in Subsection 4.3.1.3.1.

Avian mortalities resulting from collisions with transmission lines, as evaluated in the GEIS (NUREG-1437), are typically insignificant and any associated impacts are SMALL for operating nuclear plants. However, given that a new transmission line right-of-way, including transmission poles, would be established close to four wood stork colonies and the operation of new transmission lines within 3 miles of colonies is not recommended (USFWS 1990), regulatory agencies would be consulted once a corridor is approved and the final right-of-way alignment is chosen. In addition, FPL would employ environmental best management practices and implement the FPL Avian Protection Plan for maintenance activities.

No significant impacts from electromagnetic fields associated with transmission lines were identified in the GEIS for terrestrial resources (NUREG-1437); therefore, such impacts would be SMALL. Florida established limits on electric and magnetic field exposure from electric facilities in 1989. The Florida legislature granted the Florida Department of Environmental Protection (F.A.C. 62-814.100) exclusive jurisdiction to regulate electric and magnetic fields associated with electric facilities and required it to establish rules regulating electric and magnetic field exposure from those facilities. FPL facilities comply with the rules established by the FDEP.

Multiple studies quantified the amount of ozone generated by transmission lines and concluded that the amount produced was insignificant and too low to cause significant effects to terrestrial biota (NUREG-1437).

Based on the maintenance procedures established by FPL and the analysis of transmission system operation impacts on terrestrial resources the NRC completed for the GEIS (NUREG-1437), potential impacts associated with routine right-of-way maintenance activities on terrestrial resources would be SMALL. However, the presence of known populations of certain threatened and endangered species near these rights-of-way would result in agency consultations and possible mitigation actions, as discussed in Subsection 4.3.1.3.1.

5.6.2 IMPACTS TO AQUATIC RESOURCES

Existing transmission lines generally pass through typical habitats associated with the coastal plain region of southeast Florida. These transmission rights-of-way include wetlands, agricultural

fields, pasture/rangeland, and residential/developed lands (Table 2.2-2). The proposed transmission line rights-of-way are described earlier in this section. Impacts to wetland habitats are described in Subsection 5.6.1. Aside from wetlands, several SFWMD canals cross or parallel in the proposed rights-of-way, but these canals would not be impacted by transmission line maintenance. Therefore, impacts would be limited to aquatic resources living in wetland habitats.

Other than the mangrove rivulus addressed later in this section, none of the 13 freshwater fish listed as imperiled by the Florida Fish and Wildlife Conservation Commission (FWC 2008) are known to exist in the project area. The only important aquatic resource, as defined in NUREG-1555, that could potentially exist along the proposed transmission corridors, is the mangrove rivulus. The mangrove rivulus is a state and federal species of special concern. The range of the mangrove rivulus closely parallels that of the red mangrove, which is the preferred habitat of this fish (FMNH 2008). This fish species is not known to exist within the proposed transmission corridors.

In Florida, the mangrove rivulus is locally rare (FMNH 2008). This primarily saltwater or brackish water species has limited existence in freshwater. It can tolerate salinities from 0 to 68 parts per thousand. In the Everglades, this fish exists in stagnant seasonal ponds and sloughs as well as in mosquito ditches in mangrove habitats. Along the east coast of Florida, it exists in elevated marsh habitats above the intertidal zone, often in the burrows of the great land crab (*Cardisoma guanhumi*) (FMNH 2008).

Potential impacts on aquatic resources from transmission line maintenance activities include heating of water bodies from removal of shade trees, siltation and turbidity resulting from increased runoff and erosion, and runoff of defoliants and herbicides (NUREG-1555). Access roads built for transmission maintenance crews may be misused by off-road vehicle enthusiasts, creating erosion and sedimentation challenges. FPL's right-of-way maintenance program is customized for each habitat type within the transmission line right-of-way to minimize impacts to living resources. The exact manner in which maintenance would be performed would depend on location, type of terrain, and the surrounding environment. FPL maintains existing transmission rights-of-way using a combination of trimming, mowing, and herbicide application (NUREG-1437). Safe and reliable operation of the transmission lines sometimes requires that vegetation be trimmed, which can reduce shade and indirectly allow temperatures to increase in nearby water. In wet areas, such as mangrove swamps, FPL trims trees at the 14-foot level to maintain clearances required by safety and reliability standards. Typically, FPL only needs to do this at mid-span (NUREG-1437). Growth regulators and herbicides are selectively used in accordance with federal, state, and local regulations.

FPL uses environmental best management practices during right-of-way maintenance activities to reduce erosion and sedimentation to minimize impacts on aquatic resources. For example, siltation resulting from storm water runoff would be controlled by stacked hay bales and silt

curtains. Removal of vegetation can also lead to soil erosion and subsequent sedimentation in wetlands. Therefore, maintenance practices leave roots in place to maintain soil structure.

The NRC analyzed transmission system operation impacts on wetland resources for the GEIS (NUREG-1437) and found that routine maintenance practices had little impact on aquatic resources. The routine maintenance procedures established by FPL, which were designed to minimize ecological impacts along the transmission line rights-of-way, would have a SMALL impact on aquatic resources and not require additional mitigation.

5.6.3 IMPACTS TO MEMBERS OF THE PUBLIC

As described in Subsection 3.7.2, the proposed transmission system for Units 6 & 7 would consist of the following transmission lines:

- One 230 kV line from the Clear Sky substation to Davis substation
- Two 500 kV lines from the Clear Sky substation to the Levee substation
- One 230 kV line from the Clear Sky substation to the Pennsuco substation
- One 230 kV line from the Davis substation to the Miami substation
- One onsite 230 kV line from Clear Sky substation to the Turkey Point substation

The proposed transmission corridors have been situated away from densely populated areas when practical. Potential impacts to members of the public resulting from the operation and maintenance of the transmission lines would be visual changes, electric shock hazards, electromagnetic field exposure, noise impacts, or radio and television interference.

5.6.3.1 Visual Impacts

Transmission tower maintenance, vegetation, and rights-of-way management operations would be carried out as necessary by FPL to comply with the requirements of the National Electrical Safety Code (NESC) and the reliability standards of the North American Electrical Reliability Corporation and of Florida statutes. The exact manner in which maintenance would be performed would depend on the location, type of terrain, and surrounding environment. Vegetation removal would be minimized consistent with safe and reliable operation of the transmission lines. For example, when possible to do so safely, natural vegetation could be allowed to grow up to 14 feet within the transmission line rights-of-way to minimize impacts.

Consequently, the visual impacts of transmission line maintenance would be SMALL.

5.6.3.2 Induced Current

Objects near transmission lines can become electrically charged as a result of their immersion in the lines' electric field. This charge results in an induced current that flows through the object to the ground. The current is called induced because there is no direct connection between the line and the object. The induced current can also flow to the ground through the body of a person who touches the object. An object that is insulated from the ground can actually store an electrical charge, becoming capacitively charged. A person standing on the ground and touching a vehicle or a fence can receive an electrical shock because of the sudden discharge of the capacitive charge through the person's body to the ground. After the initial discharge, a steady-state current can develop, the magnitude of which depends on several factors, including:

- Strength of the electric field which depends on the voltage of the transmission line
- Height and geometry of the individual transmission wires
- Size of the object on the ground
- Extent to which the object is grounded

Analysis of this issue, detailed in the GEIS (NUREG-1437), concludes that "potential electrical shock impacts are of small significance for transmission lines that are operated in adherence with the NESC." The NESC describes how to establish minimum vertical clearances to the ground for electric lines having voltages exceeding 98 kV. The clearance must limit the induced current as a result of electrostatic effects to 5 milliamperes if the largest anticipated truck, vehicle, or equipment were short-circuited to ground (IEEE Aug 2006). By way of comparison, the short-circuit setting of ground fault circuit interrupters (used in residential wiring of special breakers for outside circuits or those with outlets in kitchens and bathrooms) is 4–6 milliamperes. FPL is required by Florida statutes to construct (IEEE Aug 2006) its proposed transmission lines in compliance with NESC, C2-2007.

The proposed lines would be built in compliance with the NESC. In addition, all transmission lines constructed by FPL would conform to standards established by ANSI, NESC, and other applicable codes and standards that are generally accepted by the industry, except as modified by Florida statutes. During construction of the lines, FPL would ground existing fences and gates that cross or parallel the right-of-way to mitigate shock hazards. Therefore, the incidence of induced current impacting the public would be rare, and no mitigation measures would be needed.

During the license renewal process for Units 3 & 4, the existing eight 230 kV circuits that extend from Turkey Point to the Davis and Florida City substations were analyzed. Calculation of the maximum induced current was performed based on the methodology described in the Electric

Power Research Institute guidance and assumed the largest vehicle under the lines would be a semi tractor trailer, 13.5 feet high by 8.5 feet wide by 53 feet long. The maximum induced current for these circuits was determined to be 4.3 milliamperes, which is below the allowable 5 milliamperes. The proposed transmission lines for Units 6 & 7 would display similar induced current results because the proposed lines would be built in compliance with the NESC limit.

The impacts to members of the public of induced current would be SMALL and would not warrant additional mitigation.

5.6.3.3 Electromagnetic Field Exposure

Although studies continue to be conducted and additional information is published regarding the effects of exposure to electric and magnetic fields (e.g., WHO Dec 2005), there continues to be no conclusive evidence of a link between electric and magnetic fields and possible health impacts, including the development of cancer, reproductive disorders, or other abnormalities in humans. Florida established limits on electric and magnetic field exposure from electric facilities in 1989. The Florida legislature granted the FDEP exclusive jurisdiction to regulate electric and magnetic fields associated with electric facilities and required it to establish rules regulating electric and magnetic field exposure from those facilities. FPL facilities comply with the rules established by the FDEP.

Therefore, impacts to members of the public attributable to electric and magnetic field exposure from transmission system operations would be SMALL. No additional mitigation measures or controls are warranted.

5.6.3.4 Noise

High-voltage transmission lines can emit noise when the electric field strength surrounding them is greater than the breakdown threshold of the surrounding air, creating a discharge of energy. This energy loss, known as corona discharge, is affected by ambient weather conditions such as humidity, air density, wind, and precipitation, and by irregularities on the energized surfaces. FPL's proposed transmission lines would be designed with hardware and conductors that have features to minimize corona discharge up to their maximum operating voltage.

Corona-induced noise along the existing transmission lines is very low or inaudible, except directly below the line on a quiet, humid day. Under wet conditions, higher noise levels are experienced than would occur under dry conditions. However, background noise from various sources (inclement weather, traffic, agricultural activity, etc.) has the effect of masking transmission line noise. The GEIS (NUREG-1437) concluded that corona discharge resulting in audible noise, radio and television interference, energy losses, and the production of ozone is generally not an issue with transmission lines below 345 kV.

With respect to the 500 kV transmission lines, during wet conditions, the median A-weighted sound pressure level of the noise from the proposed transmission lines would be up to 55 decibels adjusted at the edge of the right-of-way. The noise levels would decrease as one moves away from the edge of the right-of-way. The EPA reports that the average background noise of quiet undeveloped land is between 20 and 30 decibels adjusted and between 59 and 78 for urban or built-up areas (U.S. EPA Mar 1974 and 1979). The potential noise from the 500 kV lines would be louder than the range for undeveloped land but quieter than urban or built-up areas. Such noise would not pose a risk to humans and would likely be masked by background noise unless a person was directly below the transmission line. Additionally, in wet conditions such as rain, the ambient noise levels would be higher, further masking corona noise.

The GEIS (NUREG-1437) indicated that monitoring of ozone levels for 2 years near a Bonneville Power Administration 1200 kV prototype line revealed no increase in ambient ozone levels caused by the line. Therefore, production of ozone from 500 kV lines would be minimal.

Should complaints related to transmission line noise occur, FPL would investigate the cause and, if necessary, take steps to correct the issue.

Complaints regarding nuisance noise from the proposed transmission lines would not be expected and impacts would be SMALL.

5.6.3.5 Radio and Television Interference

Radio interference and television interference can occur from corona, electrical sparking, and arcing between two pieces of loosely fitting hardware or burrs or edges on hardware. This noise occurs at discrete points and can be minimized with good design and maintenance practices. The effect of corona on radio and television reception depends on the radio/television signal strength, the distance from the transmission line, and the transmission line noise level. As described in Subsection 5.6.3.4, the proposed transmission lines would be designed to minimize corona discharge up to their maximum operating voltage.

Should complaints related to radio and television interference occur, FPL would investigate the cause and, if necessary, take steps to correct the issue.

FPL's transmission lines would have no impact on digital television signals, including cable and satellite television. Television interference occurs only with analog television signals, and as of June 2009, the Federal Communications Commission has mandated the use of digital television signals. Therefore, FPL's transmission lines would cause no television interference.

Complaints regarding radio and television interference from the proposed transmission lines would not be expected and impacts would be SMALL.

5.7 URANIUM FUEL CYCLE AND TRANSPORTATION IMPACTS

Subsection 5.7.1 addresses the environmental impacts from the uranium fuel cycle for the AP1000. Subsection 5.7.2.1 addresses the conditions in subparagraphs 10 CFR 51.52(a)(1) through (5) regarding use of Table S-4 to characterize the impacts of radioactive materials transportation in this environmental report. Because the AP1000 does not meet all of the conditions set forth in 10 CFR 51.52(a), a further analysis of the transportation effects was performed. Subsection 5.7.2.2 addresses the incident-free transportation of radioactive materials to and from Units 6 & 7. Transportation accidents are described in Section 7.4.

5.7.1 URANIUM FUEL CYCLE IMPACTS

This section describes the environmental impacts from the uranium fuel cycle for the AP1000. The uranium fuel cycle is defined as the total of those operations and processes associated with provision, utilization, and ultimate disposal of fuel for nuclear power reactors.

Table S-3 of 10 CFR 51.51(b) was used to assess environmental impacts resulting from the uranium fuel cycle. Its values are normalized for a reference 1000 MWe light water reactor (LWR) at 80 percent capacity factor. The 10 CFR 51.51(b) Table S-3 values are reproduced as the “Reference Reactor” column in Table 5.7-1. The AP1000 was analyzed with an estimated gross electrical output of 1115 MWe[1] operating at 93 percent capacity factor. The results of this analysis for Units 6 & 7 are also included in Table 5.7-1.

Specific categories of natural resource use are included in Table S-3 (and duplicated in the *Reference Reactor* column of Table 5.7-1). These categories relate to land use, water, and fossil fuel consumption; chemical and thermal effluents; radiological releases; disposal of transuranic, high-level, and low-level wastes; and radiation doses from transportation and occupational exposure. In developing Table S-3, the NRC considered two fuel cycle options that differed in the treatment of spent fuel removed from a reactor. “No recycle” treats all spent fuel as waste to be stored at a federal waste repository; “uranium only recycle” involves reprocessing spent fuel to recover unused uranium and return it to the fuel cycle. Neither cycle involves the recovery of plutonium. The contributions in Table S-3 resulting from reprocessing, waste management, and transportation of wastes are maximized for both of the two fuel cycles (uranium only and no recycle). That is, the identified environmental impacts are based on the cycle that results in the greater impact.

The following assessment of the environmental impacts of the fuel cycle for two AP1000s at Turkey Point is based on the values in Table S-3 and the NRC’s analysis of the radiological

1. Gross electrical output for the AP1000 was used to provide conservatism in the estimates of potential fuel cycle impacts, which are obtained by scaling the values for the reference reactor to reflect the increased electrical output of the AP1000.

impacts from Rn-222 and Tc-99 in NUREG-1437. NUREG-1437 and Addendum 1 to the Generic Environmental Impact Statement (GEIS) for License Renewal provide a detailed analysis of the environmental impacts from the uranium fuel cycle. Although NUREG-1437 is specific to those impacts related to license renewal, the information provided insights to this review because the AP1000 design considered here uses the same type of fuel.

The fuel cycle impacts in Table S-3 are based on a reference 1000 MWe LWR operating at an annual capacity factor of 80 percent for an average electrical output of 800 MWe. The evaluation of the environmental impacts of the fuel cycle for the AP1000, assumed a 1115 MWe (gross) reactor with a capacity factor of 93 percent for an average electrical output of 1037 MWe per unit. The two AP1000 units for Units 6 & 7 would have a combined total of 2,074,074 MWe. The output of Units 6 & 7 is approximately 2.6 times greater than the output used to estimate impact values in Table S-3 (reproduced here as the first column of Table 5.7-1) for the reference reactor. The analyses presented here are scaled from the reference reactor impacts to reflect the output of Units 6 & 7.

Recent changes in the fuel cycle may have some bearing on environmental impacts; however, as described below, the contemporary fuel cycle impacts are bounded by impact values in Table S-3. The NRC calculated the impact values in Table S-3 from industry averages for the performance of each type of facility or operation associated with the fuel cycle. They chose assumptions so the calculated impact values will not be underestimated. This approach was intended to ensure that the actual impact values will be less than the quantities shown in Table S-3 for all LWR nuclear power plants within the widest range of operating conditions. Changes in the fuel cycle and reactor operations have occurred since Table S-3 was promulgated. For example, the estimated quantity of fuel required for a year's operation of a nuclear power plant can now reasonably be calculated assuming a 60-year lifetime (40 years of initial operation plus a 20-year license renewal term). This was done in NUREG-1437 for both BWRs and PWRs, and the highest annual requirement (35 metric tons of uranium [MTU] made into fuel for a BWR) was used in NUREG-1437 as the basis for the reference reactor year. A number of fuel management improvements have been adopted by nuclear power plants to achieve higher performance and to reduce fuel and enrichment requirements, reducing annual fuel requirements. An AP1000 reactor will require approximately 23 MTUs per year, approximately 34 percent less than the BWR refueling requirement evaluated in NUREG-1437, but its electrical output will be approximately 30 percent greater than the reference reactor. Therefore, Table S-3 remains a conservative estimate of the environmental impacts of the fuel cycle fueling nuclear power reactors operating today.

Another change is the elimination of the U.S. restrictions on the importation of foreign uranium. Until recently, the economic conditions of the uranium market favored use of foreign uranium at the expense of the domestic uranium industry. These market conditions forced the closing of most U.S. uranium mines and mills, substantially reducing the environmental impacts in the

United States from these activities. There is renewed interest in uranium mining and milling in the United States. The NRC recently received the first license application for a uranium recovery facility since 1988 (U.S. NRC Oct 2007). The NRC anticipates 20 applications for new facilities—including in-situ operations and conventional uranium mills—through fiscal year 2011. The majority of these applications are expected to be for in-situ leach solution mining that does not produce tailings. (U.S. NRC Aug 2008) Factoring in changes to the fuel cycle suggests that the environmental impacts of mining and milling could drop to levels below those in Table S-3. However, Table S-3 impact estimates have not been reduced for this analysis. Section 6.2.3 of NUREG-1437 describes the sensitivity of these changes in the fuel cycle on the environmental impacts.

5.7.1.1 Land Use

The total annual land requirements for the fuel cycle supporting the two AP1000 Units 6 & 7 would be approximately 300 acres. Approximately 34 acres would be permanently committed land, and 260 acres would be temporarily committed. A “temporary” land commitment is a commitment for the life of the specific fuel cycle plant (e.g., a mill, enrichment plant, or succeeding plants). Following decommissioning, the land could be released for unrestricted use. “Permanent” commitments represent land that may not be released for use after decommissioning because decommissioning does not result in the removal of sufficient radioactive material to meet the limits of 10 CFR Part 20, Subpart E for release of an area for unrestricted use.

In comparison, a coal-fired plant with the same MWe output as two AP1000s using strip-mined coal requires the disturbance of approximately 520 acres per year for fuel alone. Considering common classes of land use in the United States, the fuel cycle impacts on land use would be SMALL and would not warrant mitigation.

5.7.1.2 Water Use

Principal water use for the fuel cycle supporting the two AP1000s would be that required to remove waste heat from the power stations supplying electricity to operate the enrichment process. Scaling the values from Table S-3, of the total annual water use of 2.95E10 gallons for the fuel cycle, approximately 2.87E10 gallons (approximately 97 percent) are required for the removal of waste heat. Evaporative losses from fuel cycle process cooling are approximately 4.15E08 gallons per year and mine drainage accounts for 3.29E08 gallons per year. The NRC estimated the consumptive water use for the uranium fuel cycle to be approximately 2 percent of that from the reference reactor using cooling towers. The maximum consumptive water use (assuming that all plants supplying electrical energy to the nuclear fuel cycle used cooling towers) was estimated to be approximately 6 percent of that for the reference reactor using cooling towers (NUREG-1437). The water consumption attributed to the uranium fuel cycle would

be small relative to the water consumption of the two proposed AP1000 units. Impacts on water use would be SMALL and would not warrant mitigation.

5.7.1.3 Fossil Fuel Impacts

Electric energy and process heat are required during various phases of the fuel cycle process. The electric energy is usually produced by the combustion of fossil fuel at conventional power plants. Electric energy associated with the fuel cycle represents approximately 5 percent of the annual electric power production of the reference reactor. Process heat is primarily generated by the combustion of natural gas. This gas consumption, if used to generate electricity, represents less that 0.4 percent of the electrical output of the reference reactor. The direct and indirect consumption of electric energy for fuel cycle operations would be small relative to the power production of the two AP1000s. Therefore, impacts from fossil fuels would be SMALL and would not warrant mitigation.

5.7.1.4 Chemical Effluents

The quantities of liquid, gaseous, and particulate discharges associated with the fuel cycle are given in Table S-3 (Table 5.7-1) for the reference 1000 MWe LWR. The quantities of effluents for two AP1000s would be approximately 2.6 times greater than those in Table S-3 (Table 5.7-1 column 3). The principal effluents are sulfur oxides, nitrogen oxides, and particulates. Based on the EPA's National Air Pollutant Emissions Estimates (U.S. EPA 2006), these emissions constitute less than 0.08 percent of all sulfur dioxide emissions in 2005, and less than 0.02 percent of all nitrogen oxide emissions in 2006.

Liquid chemical effluents produced in the fuel cycle processes are related to fuel enrichment and fabrication and may be released to receiving waters. As stated in Subsection 5.7.1 of NUREG-1555, all liquid discharges into the navigable waters of the United States from plants associated with the fuel cycle operations will be subject to requirements and limitations by an appropriate federal, state, regional, local or affected Native American tribal regulatory agency. Solids are generated during the milling process and are not released in quantities sufficient to have a significant impact on the environment. Impacts from chemical effluents would be SMALL and would not warrant mitigation.

5.7.1.5 Radioactive Effluents

Radioactive gaseous effluents estimated to be released to the environment from waste management activities and certain other phases of the fuel cycle are shown in Table S-3 (Table 5.7-1). Using Table S-3 data, Section 6.2.2.1 of NUREG-1437 estimates the 100-year environmental dose commitment to the U.S. population from the fuel cycle (excluding reactor releases and dose commitments due to Rn-222 and Tc-99) to be approximately 400 person-rem

per reference reactor year. The estimated dose commitment to the U.S. population is approximately 1000 person-rem per year of operation for two AP1000s.

Section 6.2.2.1 of NUREG-1437 estimates the additional 100-year whole body dose commitment to the U.S. population from radioactive liquid waste effluents due to all fuel cycle operations (other than reactor operation) to be approximately 200 person-rem per reference reactor year. The estimated dose commitment to the U.S. population is approximately 520 person-rem per year of operation for two AP1000s. Thus, the estimated 100-year dose commitment to the U.S. population from radioactive gaseous and liquid releases from fuel cycle operations would be approximately 1600 person-rem to the whole body per reactor-year for two AP1000s.

The radiological impacts of Rn-222 and Tc-99 releases are not included in Table S-3. Principal radon releases occur during mining and milling operations and as emissions from mill tailings. Principal Tc-99 releases occur as releases from the gaseous diffusion enrichment process. The NRC provided an evaluation of these Rn-222 and Tc-99 releases in NUREG-1437. The NUREG-1437 evaluation was reviewed, it was considered applicable, and has been included as part of the evaluation in this Environmental Report.

Section 6.2 of NUREG-1437 estimates Rn-222 releases from mining and milling operations, and from mill tailings for a year of operation of the reference 1000 MWe LWR. The estimated release of Rn-222 for two AP1000s is 13,500 curies per year. Of this total, approximately 78 percent would be from mining, 15 percent from milling, and 7 percent from inactive tailings before stabilization. Radon releases from stabilized tailings were estimated to be 2.6 curies per year for two AP1000s; that is, approximately 2.6 times greater than the NUREG-1437 estimate for the reference reactor year. The major risks from Rn-222 are from exposure to the bone and lung, although there is a small risk from exposure to the whole body. The organ-specific dose weighting factors from 10 CFR Part 20 were applied to the bone and lung doses to estimate the 100-year dose commitment from Rn-222 to the whole body. The 100-year estimated dose commitment from mining, milling, and tailings before stabilization for two AP1000 units would be approximately 2400 person-rem to the whole body. From stabilized tailing piles, the 100-year estimated dose commitment would be approximately 47 person-rem to the whole body. These values were derived by scaling the reference reactor values provided in the Appendix to Section 5.7.1 of NUREG-1555 to two AP1000s.

NUREG-1437 considered the potential health effects associated with the releases of Tc-99 for the reference reactor. The estimated Tc-99 releases for two AP1000s are 0.018 curies from chemical processing of recycled uranium hexafluoride before it enters the isotope enrichment cascade and 0.013 curies into the groundwater from a high-level waste repository. The major risks from Tc-99 are from exposure of the gastrointestinal tract and kidneys and a small risk from whole-body exposure. Applying the organ-specific dose-weighting factors from 10 CFR Part 20 to

the gastrointestinal tract and kidney doses, the total body 100-year dose commitment from Tc-99 was estimated to be 260 person-rem for two AP1000s. This value was derived by scaling the 100-year dose commitment (person-rem per year) for Tc-99 for the reference reactor specified in NUREG-1437 to two AP1000s.

To be conservative, radiation protection experts assume that any amount of radiation may pose some risk of cancer, or a severe hereditary effect, and that higher radiation exposures create higher risks. Therefore, a linear, no-threshold dose response relationship is used to describe the relationship between radiation dose and detrimental effects. Based on this model, risk to the public from radiation exposure can be estimated using the nominal probability coefficient (730 fatal cancers, nonfatal cancers, or severe hereditary effects per 1E06 person-rem) from the International Commission on Radiological Protection Publication 60 (ICRP 1991). This coefficient was multiplied by the sum of the estimated whole-body population doses (from gaseous effluents, liquid effluents, Rn-222, and Tc-99) described above for two AP1000s to estimate that the U.S. population could incur a total of 3.1 fatal cancers, nonfatal cancers, or severe hereditary effects from the annual fuel cycle for two AP1000s. This risk would be small compared to the number of fatal cancers, nonfatal cancers and severe hereditary effects that are estimated to occur in the U.S. population annually from exposure to natural sources of radiation using the same risk estimation methods.

Based on these analyses, the environmental impacts of radioactive effluents from the fuel cycle will be SMALL and will not warrant mitigation.

5.7.1.6 Radioactive Waste

The quantities of radioactive waste (low-level, high-level, and transuranic wastes) associated with fuel cycle processes are presented in Table S-3 (Table 5.7-1). For low-level waste disposal, the NRC notes in 10 CFR 51.51(b) that there will be no significant radioactive releases to the environment. For high-level and transuranic wastes, the NRC notes that these wastes are to be disposed of at a federal repository, such as the candidate repository at Yucca Mountain, Nevada. No release to the environment is expected to be associated with such disposal because it was assumed that all of the gaseous and volatile radionuclides contained in the spent fuel are released to the atmosphere before disposal of the waste.

There is some uncertainty associated with the high-level waste and spent fuel disposal component of the fuel cycle. The regulatory limits for offsite releases of radionuclides for the current candidate repository site were set in September 2008 using a two-tiered approach. The radiation dose for the first 10,000 years has been set to 15 mrem/yr. The radiation dose for the period between 10,000 and 1 million years was set to 100 mrem/yr (Federal Register 73,61256 Oct 2008). These standards would result in doses that are consistent with the 100 mrem /yr or less dose defined in NUREG-1437. Therefore, it is reasonable to conclude that the offsite

radiological impacts of spent fuel and high-level waste disposal would not be significant enough to preclude construction of new units at Turkey Point.

If necessary, FPL would take measures to reduce the generation of Class B and C LLW, such as reducing the service run length of resin beds or mixing spent resins to limit radioactivity concentrations. The volume of generated waste would still be bounded by the estimates in Table S-3, and the environmental impacts would likewise be bounded by those shown in Table S-3 (U.S. NRC 2011).

If needed, FPL would also construct additional temporary storage facilities onsite for Class B and C LLW. Such facilities would be designed and operated to meet the guidance in Appendix 11.4-A of the Standard Review Plan, NUREG-0800.

NRC's regulations (10 CFR 50.59) allow licensees operating nuclear power plants to make facility changes, including the construction and operation of certain additional onsite LLW storage facilities, without seeking approval from the NRC, provided licensees evaluate the safety and environmental impacts of such facilities before constructing the facilities. The 10 CFR 50.59 evaluations must be made available to NRC inspectors. Using this regulatory approach, a number of nuclear power plant licensees have constructed and operate such facilities in the United States. Typically, these additional facilities are constructed near the power block inside the security fence on land that has already been disturbed during initial plant construction (U.S. NRC 2011). Therefore, the impacts of constructing the facilities on environmental resources (e.g., land use and aquatic and terrestrial biota) would be SMALL.

All of the NRC (10 CFR Part 20) and EPA (40 CFR Part 190) dose limitations would apply to the additional onsite LLW storage facilities, both for public and occupational radiation exposure. The radiological environmental monitoring programs around nuclear power plants that operate additional onsite LLW facilities show that the increase in radiation dose at the site boundary is not significant; the radiation doses continue to be below 25 mrem/yr, the dose limit of 40 CFR Part 190 (U. S. NRC 2010). The NRC has concluded that doses to members of the public that do not exceed NRC and EPA regulatory limits are SMALL (U.S. NRC 2011). In addition, the NRC in NUREG-1437 assessed the impacts of LLW storage onsite at currently operating nuclear power plants and concluded that the radiation doses to offsite individuals from interim LLW storage are insignificant. The types and amounts of LLW generated by the proposed reactors at Units 6&7 would be similar to those generated by currently operating nuclear power plants and the construction and operation of any additional onsite LLW storage facilities would be similar to the construction and operation of the currently operating facilities. Therefore, the impacts of constructing and operating additional onsite LLW storage facilities would be SMALL.

For the reasons stated above, the environmental impacts of radioactive waste disposal would be SMALL and would not warrant mitigation.

5.7.1.7 Occupational Dose

The estimated occupational dose attributable to all phases of the fuel cycle is approximately 1600 person-rem per year for two AP1000s. This is a scaled value based on a 600 person-rem per year occupational dose estimate attributable to all phases of the fuel cycle for the reference reactor (NUREG-1437). The dose to any individual worker is restricted to the dose limit of 10 CFR Part 20 (5 rem/year). The environmental impacts from this occupational dose would be SMALL.

5.7.1.8 Transportation

The transportation dose to workers and the public is estimated in Table S-3 (Table 5.7-1) to be 2.5 person-rem per year for the reference reactor. This corresponds to a dose of 6.5 person-rem per year for two AP1000s. For comparative purposes, the estimated collective dose from natural background radiation to the population within 50 miles of Units 6 & 7 is 907,000 person-rem per year. On the basis of this comparison, the environmental impacts of transportation from the fuel cycle would be SMALL and would not warrant mitigation.

5.7.1.9 Summary

The environmental impacts of the uranium fuel cycle as given in Table S-3 were evaluated along with the effects of Rn-222 and Tc-99 releases based on the information presented in NUREG-1437. Based on this evaluation, the impacts would be SMALL and mitigation would not be warranted.

5.7.2 TRANSPORTATION OF RADIOACTIVE MATERIALS

Transport of radioactive materials is an important activity associated with operating new reactors at Units 6 & 7. The analysis in this section is based on the AP1000 characteristics described in Section 3.2 and radioactive waste management systems described in Section 3.5. Information regarding preparation and packaging of the radioactive materials for transport offsite can be found in Section 3.8.

5.7.2.1 Transportation Assessment

The NRC evaluated the environmental effects of transportation of fuel and waste for LWRs in *Environmental Survey of Transportation of Radioactive Materials to and From Nuclear Power Plants* (WASH-1238, AEC Dec 1972) and Supplement 1 (NUREG-75/038,) and found the impacts to be SMALL. These NRC analyses provided the basis for Table S-4 in 10 CFR 51.52, which summarizes the environmental impacts of transportation of fuel and radioactive wastes to and from a reference reactor (see Table 5.7-2). The table addresses two categories of

environmental considerations: (1) normal conditions of transport, and (2) accidents during transport.

To analyze the impacts of transporting AP1000 fuel and radioactive waste for comparison to Table S-4, the characteristics for the AP1000 were normalized to a reference reactor-year. The reference reactor is an 1100 MWe reactor that has an 80 percent capacity factor, for an electrical output of 880 MWe per year. For Units 6 & 7, two 1000 MWe (net) reactors[1] with a 93 percent capacity factor was assumed. The standard configuration (a single unit) for the AP1000 was used to evaluate transportation impacts relative to the reference reactor.

Subparagraphs 10 CFR 51.52(a)(1) through (5) delineate specific conditions the reactor licensee must meet to use Table S-4 as part of its environmental report. For reactors not meeting all of the conditions in paragraph (a) of 10 CFR 51.52, paragraph (b) of 10 CFR 51.52 requires further analysis of the transportation effects.

The conditions in paragraph (a) of 10 CFR 51.52 establishing the applicability of Table S-4 are reactor core thermal power, fuel form, fuel enrichment, fuel encapsulation, average fuel irradiation, time after discharge of irradiated fuel before shipment, mode of transport for unirradiated fuel, mode of transport for irradiated fuel, radioactive waste form and packaging, and mode of transport for radioactive waste other than irradiated fuel. The following sections describe the characteristics of the AP1000 relative to the conditions of 10 CFR 51.52 for use of Table S-4.

5.7.2.1.1 Reactor Core Thermal Power

Subparagraph 10 CFR 51.52(a) (1) requires that the reactor have a core thermal power level not exceeding 3800 MWt. The AP1000 has a maximum thermal power level of 3400 MWt that meets this condition (WEC 2011).

The core power level was established as a condition because, for the LWRs being licensed when Table S-4 was promulgated, higher power levels indicated the need for more fuel and therefore more fuel shipments. This is not the case for the new LWR designs due to the higher unit capacity factor and higher burnup for these reactors. The annual fuel reloading for the reference reactor analyzed in WASH-1238 was 30 MTU. The annual fuel loading for the AP1000 is approximately 23 metric tons of uranium (MTU). When normalized to equivalent electric output, the annual fuel requirement for the AP1000 is approximately 22 MTU or 73 percent that of the reference LWR.

WASH-1238 states:

1. Net electrical output for the AP1000 was used to provide conservatism in the estimates of normalized transportation impacts for comparison with the reference reactor and Table S-4.

The analysis is based on shipments of fresh fuel to and irradiated fuel and solid waste from a boiling water reactor or a pressurized water reactor with design ratings of 3000 MWt to 5000 MWt or 1000 MWe to 1500 MWe.

The AP1000 falls within these bounds for thermal rating.

5.7.2.1.2 Fuel Form

Subparagraph 10 CFR 51.52(a)(2) requires that the reactor fuel be in the form of sintered uranium dioxide pellets. The AP1000 uses a sintered uranium dioxide pellet fuel form (WEC 2011) and, therefore, meets this condition.

5.7.2.1.3 Fuel Enrichment

Subparagraph 10 CFR 51.52(a)(2) requires that the reactor fuel have a U-235 enrichment not exceeding 4 percent by weight. For the AP1000, the enrichment of the initial core is 2.35 percent in Region 1, 3.40 percent in Region 2, and 4.45 percent in Region 3 (WEC 2011). The average fuel enrichment for reloads is 4.54 percent. The AP1000 fuel exceeds the 4 percent U-235 enrichment condition for both initial core load and subsequent reloads.

5.7.2.1.4 Fuel Encapsulation

Subparagraph 10 CFR 51.52(a)(2) requires that the reactor fuel pellets be encapsulated in Zircaloy rods. The AP1000 fuel uses ZIRLO^{TM} cladding, which is a special zircaloy material alloyed with niobium, tin, and iron and is a successor of Zircaloy-4 (WEC 2011) and meets this condition.

5.7.2.1.5 Average Fuel Irradiation

Subparagraph 10 CFR 51.52(a)(3) requires that the average burnup not exceed 33,000 MW-days per MTU. For the AP1000, the average burnup after achieving an equilibrium core is 50,553 MW-days per MTU, which exceeds this condition.

5.7.2.1.6 Time After Discharge of Irradiated Fuel Before Shipment

Subparagraph 10 CFR 51.52(a)(3) requires that no irradiated fuel assembly be shipped until at least 90 days after it is discharged from the reactor. The WASH-1238 analysis for Table S-4 assumes 150 days of decay time before shipment of any irradiated fuel assemblies. NUREG/CR-6703 (Ramsdell et al. 2001), which updated this analysis to extend Table S-4 to burnups of up to 62,000 MW-days per MTU, assumes a minimum of 5 years between removal from the reactor and shipment. Five years is the minimum decay time expected before shipment of irradiated fuel assemblies. The NRC specifies 5 years as the minimum cooling period when it issues certificates of compliance for casks used for shipment of power reactor fuel

(NUREG-1437). As described in Section 3.8, the AP1000 units would have storage capacity exceeding that needed to accommodate 5-year cooling of irradiated fuel before transport offsite. This condition is met.

5.7.2.1.7 Transportation of Unirradiated Fuel

Subparagraph 10 CFR 51.52(a)(5) requires that unirradiated fuel be shipped to the reactor site by truck. Typical shipment of fuel from the Westinghouse fuel fabrication facility in Columbia, South Carolina is by truck. Fuel would be received via truck shipments for Units 6 & 7.

Table S-4 includes a condition that the truck shipments will not exceed 73,000 pounds. The fuel shipments would comply with federal or state weight restrictions. These conditions are met.

5.7.2.1.8 Transportation of Irradiated Fuel

Subparagraph 10 CFR 51.52(a)(5) allows for truck, rail, or barge transport of irradiated fuel. This condition would be met for Units 6 & 7. For the impacts analysis described in Subsection 5.7.2.2, all spent fuel shipments were assumed to be made using legal weight trucks. The DOE is responsible for spent fuel transportation from reactor sites to the repository and will make the decision on transport mode.

5.7.2.1.9 Radioactive Waste Form and Packaging

Subparagraph 10 CFR 51.52(a)(4) requires that, with the exception of spent fuel, radioactive waste shipped from the reactor be packaged and in a solid form. As described in Subsection 3.5.3, the low-level radioactive waste generated by the AP1000 units would be solidified and packaged. Additionally, these shipments would comply with the NRC (10 CFR Part 71) and the DOT (49 CFR Parts 173 and 178) packaging and transportation regulations for the shipment of radioactive material. This condition is met.

5.7.2.1.10 Transportation of Radioactive Waste

Subparagraph 10 CFR 51.52(a)(5) requires that the mode of transport of low-level radioactive waste be either truck or rail. Radioactive waste would be shipped from Units 6 & 7 by truck. Table S-4 specifies the following conditions for shipments of radioactive waste: less than 73,000 pounds per truck over 100 tons per cask per rail car. Radioactive waste from Units 6 & 7 would be shipped in compliance with federal or state weight restrictions. This condition is met.

5.7.2.1.11 Number of Truck Shipments

Table S-4 specifies the following conditions for traffic density: less than one truck shipment per day or three rail cars per month. The number of truck shipments that would be required was

estimated assuming that all radioactive materials (fuel and waste) are received at the site or transported offsite via truck.

For the AP1000, the initial core load is estimated at 85 MTU per unit and the reload requirements are estimated at 23 MTU per year per unit. This equates to approximately 157 fuel assemblies in the initial core (assuming 0.5383 MTU per fuel assembly) and 43 fuel assemblies per year for refueling. Westinghouse estimates that a transportation container could accommodate up to seven fuel assemblies for the initial core load and nine fuel assemblies for core reloads.

Table 5.7-3 summarizes the number of truck shipments of unirradiated fuel. The table also normalizes the number of shipments to the electrical output for the reference reactor analyzed in WASH-1238. When normalized for electrical output, the number of truck shipments of unirradiated fuel for the AP1000 is less than the number of truck shipments estimated for the reference LWR.

The numbers of spent fuel shipments were estimated as follows. For the reference LWR analyzed in WASH-1238, the NRC assumed that 60 shipments per year will be made, each carrying 0.5 MTU of spent fuel. This amount is equivalent to the annual refueling requirement of 30 MTU per year for the reference LWR. For this transportation analysis, shipments of spent fuel from the AP1000 were assumed to occur at a rate equal to the annual refueling requirement. As stated above, this would require the shipment of approximately 23 MTU per year per unit. The shipping cask capacities used to calculate annual spent fuel shipments were assumed to be the same as those for the reference LWR (0.5 MTU per legal weight truck shipment). This results in 46 shipments per year for one AP1000. After normalizing for the reference LWR electrical output, the number of spent fuel shipments is 44 per year for the AP1000. The normalized spent fuel shipments (44) for the AP1000 would be less than the reference reactor (60) that was the basis for Table S-4.

Table 5.7-4 presents estimates of annual waste volumes and numbers of truck shipments. The values are normalized to the reference LWR analyzed in WASH-1238. The normalized annual waste volumes and waste shipments for the AP1000 will be less than the reference reactor that was the basis for Table S-4.

The total number of truck shipments of fuel and radioactive waste to and from the reactor are estimated to be 72 per year for the AP1000. Thus, these radioactive material shipment estimates are well below the one truck shipment per day condition given in 10 CFR 51.52, Table S-4. The estimated number of truck shipments remains below the one shipment per day condition, if the number was doubled to account for empty truck return shipments.

5.7.2.1.12 Summary

Table 5.7-5 compares the values for the reference conditions in paragraph (a) of 10 CFR 51.52 used in Table S-4 and the values for the AP1000. The AP1000 does not meet the conditions for fuel enrichment or average fuel irradiation. Therefore, Subsection 5.7.2.2 and Section 7.4 present additional analyses of fuel transportation effects for normal conditions and accidents, respectively.

5.7.2.2 Incident-Free Transportation Impacts Analysis

The environmental impacts of radioactive materials transportation were estimated using the most recent version of the RADTRAN 5 computer code (Weiner et al. Dec 2007). RADTRAN is a nationally accepted standard program and code for calculating the risks of transporting radioactive materials. RADTRAN was used in estimating the radiological doses and dose risks to populations and transportation workers resulting from incident-free transportation and to the general population from accident scenarios. For the analysis of incident-free transportation risks, the code used scenarios for people who would share transportation routes with shipments, people who live along the route of travel, and people exposed at stops. For accident risks, RADTRAN was used to evaluate the range of possible accident scenarios from high probability and low consequence to low probability and high consequence. Environmental impacts of incident-free transportation of fuel are described in this section. Transportation accidents are described in Section 7.4.

5.7.2.2.1 Transportation of Unirradiated Fuel

Table S-4 of 10 CFR 51.52 includes conditions related to radiological doses to transport workers and members of the public along transport routes. These doses, based on calculations in WASH-1238, are a function of the radiation dose rate emitted from the unirradiated fuel shipments, the number of exposed individuals and their locations relative to the shipment, the time of transit (including travel and stop times), and the number of shipments to which the individuals are exposed.

One of the key assumptions in WASH-1238 for the reference LWR unirradiated fuel shipments is that the radiation dose rate at 1 meter from the transport vehicle is approximately 0.1 millirem per hour. This assumption was also used by the NRC to analyze advanced LWR unirradiated fuel shipments for ESP sites (e.g., NUREG-1811, Section G.1.2.4). This assumption is reasonable for all of the advanced LWR types because the fuel materials will all be low dose rate uranium radionuclides and will be packaged similarly (inside a metal container that provides little radiation shielding). The per-shipment dose estimates are “generic” (i.e., independent of reactor technology) because they were calculated based on an assumed external radiation dose rate rather than the specific characteristics of the fuel or packaging. Thus, the results can be used to evaluate the impacts for any of the advanced LWR designs. Other input parameters used in the

radiation dose analysis for advanced LWR unirradiated fuel shipments are summarized in Table 5.7-6. The RADTRAN results for this “generic” unirradiated fuel shipment are as follows:

Population Component	Dose
Transport workers	0.00171 person-rem per shipment
General public (Onlookers — people at stops and sharing the highway)	0.00292 person-rem per shipment
General public (Along Route — people living near a highway)	0.0000299 person-rem per shipment

Based on the parameters used in the analysis, these per-shipment doses would conservatively estimate the impacts for fuel shipments to Turkey Point or an alternate site in the region of interest. For example, the average shipping distance of 2000 miles used in the NRC analysis is not expected to exceed the shipping distance for fuel deliveries to Units 6 & 7. The fuel shipments would likely originate at the Westinghouse fuel fabrication facility located in Columbia, South Carolina, and travel approximately 690 miles to Units 6 & 7.

The unit dose values were combined with the average annual shipments of unirradiated fuel to calculate annual doses to the public and workers that can be compared to Table S-4 conditions. The numbers of unirradiated fuel shipments were normalized to the reference reactor analyzed in WASH-1238. The numbers of shipments per year were obtained from Table 5.7-3. The results are presented in Table 5.7-7. As shown, the calculated radiation doses for transporting unirradiated fuel to Units 6 & 7 are within the Table S-4 conditions.

As described in Subsection 5.7.1.5, the risk to the public from radiation exposure is estimated using the nominal probability coefficient for total detriment (730 fatal cancers, nonfatal cancers, and severe hereditary effects per million person-rem) from International Commission on Radiation Protection Publication 60 (ICRP 1991). All the public collective doses presented in Table 5.7-7 are less than 0.1 person-rem per year. Therefore, the total detriment estimates associated with these doses would all be less than 1E–04 fatal cancers, nonfatal cancers, and severe hereditary effects per year. These risks are small compared to the fatal cancers, nonfatal cancers, and severe hereditary effects that the same population will incur annually from exposure to natural sources of radiation.

5.7.2.2.2 Transportation of Spent Fuel

This section provides the environmental impacts of transporting spent fuel from Units 6 & 7 to a spent fuel disposal facility, using Yucca Mountain, Nevada, as a possible location for a geologic repository. The impacts of the transportation of spent fuel to a potential repository in Nevada provide a reasonable bounding estimate of the transportation impacts to a monitored retrievable storage facility because of the distances involved and the representative exposure of members of the public in urban, suburban, and rural areas.

Incident-free transportation refers to transportation activities in which the shipments reach their destination without releasing any radioactive cargo to the environment. Impacts from these shipments would be from the low levels of radiation that penetrate the heavily shielded spent fuel shipping cask. Radiation doses would occur to (1) people residing along the transportation corridors between Units 6 & 7 and the proposed repository; (2) people in vehicles passing a spent-fuel shipment; (3) people at vehicle stops for refueling, rest, and vehicle inspections; and (4) transportation crew workers.

This analysis is based on shipment of spent fuel by legal-weight trucks in casks with characteristics similar to casks currently available (i.e., massive, heavily shielded, cylindrical metal pressure vessels). Each shipment is assumed to consist of a single shipping cask loaded on a modified trailer. These assumptions are consistent with assumptions made in evaluating the environmental impacts of spent fuel transportation in Addendum 1 to NUREG-1437. As described in NUREG-1437, these assumptions are conservative because the alternative assumptions involve rail transportation or heavy-haul trucks, which would reduce the overall number of spent fuel shipments.

The environmental impacts of spent fuel transportation were estimated using the most recent version of the RADTRAN 5 computer code (Weiner et al. Dec 2007). This analysis assumed the spent fuel would be transported by legal weight trucks to the potential Yucca Mountain repository over designated highway route-controlled quantity highway route-controlled quantity routes. A transportation route was evaluated that was consistent with highway route-controlled quantity requirements and traveled a total of approximately 3100 miles.

Although shipping casks have not been designed for the advanced LWR fuels, the advanced LWR fuel designs would be similar to the existing LWR designs. Thus, current shipping cask designs were used for analysis.

Radiation doses are a function of many parameters, including vehicle speed, traffic count, dose rate at 1 meter from the vehicle, packaging dimensions, number in the truck crew, stop time, and population density along the route and at stops. The values of the key variables used in this analysis are presented in Table 5.7-8. Most of the variables are extracted from literature and are considered to be standard values used in many RADTRAN applications, including environmental impact statements and regulatory analyses.

The transportation route selected for a shipment determines the total potentially exposed population and the expected frequency of transportation-related accidents. For truck transportation, the route characteristics most important to the risk assessment include the total shipping distance between each origin-destination pair of sites and the population density along the route.

Representative shipment routes for Turkey Point and alternative sites were identified using the TRAGIS (Version 1.5.4) routing model (Johnson and Michelbaugh Apr 2000). The Highway data network in TRAGIS is a computerized road atlas that includes a complete description of the interstate highway system and of all U.S. highways. The TRAGIS database version used was Highway Data Network 4.0. The population densities along a route are derived from 2000 census data from the U.S. Bureau of the Census. This transportation route information is summarized in Table 5.7-9.

Based on the transportation route information shown in Table 5.7-9, the impacts of spent fuel shipments originating at Units 6 & 7 would be similar to the impacts for the alternative sites (St. Lucie, Martin, Glades, and Okeechobee 2). The radiation dose estimates to the transport workers and the public for spent fuel shipments from Turkey Point and alternative sites are as follows:

	Population Dose (person-rem per shipment)		
Site	**Transport workers**	**General public (Onlookers)**	**General public (Along Route)**
Turkey Point	0.228	0.157	0.0165
St. Lucie	0.218	0.154	0.0141
Martin	0.219	0.145	0.0139
Glades	0.220	0.145	0.0140
Okeechobee 2	0.219	0.145	0.0139

These per-shipment dose estimates are independent of reactor technology because they were calculated based on an assumed external radiation dose rate emitted from the cask, which was fixed at the regulatory maximum of 10 millirem per hour at 2 meters. For the purpose of this analysis, the transportation crew consists of two drivers. The numbers of spent fuel shipments for the transportation impacts analysis were derived as described in Subsection 5.7.2.1. The normalized annual shipment values and corresponding population dose estimates per reactor-year are presented in Table 5.7-10. The population doses were calculated by multiplying the number of spent fuel shipments per year by the per-shipment doses. For comparison to Table S-4, the population doses were normalized to the reference LWR analyzed in WASH-1238.

As shown in Table 5.7-10, population doses to the crew and onlookers for both the AP1000 and the reference LWR exceed Table S-4 values. Two key reasons for these higher population doses relative to Table S-4 are the number of spent fuel shipments and the shipping distances assumed for these analyses relative to the assumptions used in WASH-1238.

- The analyses in WASH-1238 used a “typical” distance for a spent fuel shipment of 1000 miles. The shipping distance used in this assessment is approximately 3100 miles.

- The number of spent fuel shipments are based on shipping casks designed to transport shorter-cooled fuel (i.e., 150 days out of the reactor). This analysis assumed that the shipping

cask capacities are 0.5 MTU per legal-weight truck shipment. Newer cask designs are based on longer-cooled spent fuel (i.e., 5 years out of reactor) and have larger capacities. For example, spent fuel shipping cask capacities used in the Yucca Mountain environmental impact statement (U.S. DOE 2002a**,** Table J-2) were approximately 1.8 MTU per legal-weight truck shipment. Use of the newer shipping cask designs will reduce the number of spent fuel shipments and decrease the associated environmental impacts because the dose rates used in the impacts analysis are fixed at the regulatory limit rather than based on the cask design and contents.

If the population doses in Table S-4 are adjusted for the longer shipping distance and larger shipping cask capacity, the population doses from incident-free spent fuel transportation from the site will fall within Table S-4.

Other conservative assumptions in the spent fuel transportation impacts calculation include:

- Use of the regulatory maximum dose rate (10 millirem per hour at 2 meters) in the RADTRAN five calculations. The shipping casks assumed in the Yucca Mountain environmental impact statement (U.S. DOE Feb 2002a) transportation analyses were designed for spent fuel that has cooled for 5 years. In reality, most spent fuel will have cooled for much longer than 5 years before it is shipped to a possible geologic repository. The NRC developed a probabilistic distribution of dose rates based on fuel cooling times that indicates that approximately three-fourths of the spent fuel to be transported to a possible geologic repository will have dose rates less than half of the regulatory limit (Sprung et al. Mar 2000). Consequently, the estimated population doses in Table 5.7-10 could be divided in half if more realistic dose rate projections are used for spent fuel shipments from Units 6 & 7.

- Use of 30 minutes as the average time at a truck stop in the calculations. Many stops made for actual spent fuel shipments are short duration stops (i.e., 10 minutes) for brief visual inspections of the cargo (checking the cask tie-downs). These stops typically occur in minimally populated areas, such as an overpass or freeway ramp in an unpopulated area. Based on data for actual truck stops, recent NRC transportation analyses (e.g., NUREG-1811, Section 6.2.2.1) concluded that the assumption of a 30-minute stop for every 4 hours of driving time used to evaluate potential early site permit sites will overestimate public doses at stops by at least a factor of two. Consequently, the doses to onlookers given in Table 5.7-10 could be reduced by a factor of two to reflect more realistic truck shipping conditions.

5.7.2.2.3 Transportation of Radioactive Waste

As shown in Table 5.7-4, the transportation of radioactive waste meets the applicable conditions in 10 CFR 51.52(a) and no further analysis is required.

5.7.2.2.4 Maximally Exposed Individual

The incident-free radiation doses to maximally exposed individuals for fuel and waste shipments were also considered. A maximally exposed individual is a person who may receive the highest radiation dose from a shipment to and/or from the site. The radiological doses to the workers who would load casks, drive trucks, and inspect vehicles in transit would be higher than doses to individuals in the general public. Radiological protection programs would manage and limit doses to workers whose jobs would cause them to receive the greatest exposures.

Truck crew members would receive the highest radiation doses because of their proximity to the loaded shipping container for an extended period of time. DOE will take title to the spent fuel at the reactor site. Consequently, the DOE administrative control level of 2 person-rem per year (U.S. DOE Mar 2005) is expected to apply to spent fuel shipments from Turkey Point to a disposal facility. Spent fuel represents the majority of the radioactive materials shipments to and from reactor sites, and comprises those shipments with the highest radiation dose rates. Crew doses from unirradiated fuel and radioactive waste shipments would be lower than the spent fuel shipments.

5.7.2.3 Conclusion

The NRC evaluated the environmental effects of transportation of fuel and waste for LWRs in WASH-1238 (AEC Dec 1972) and Supplement 1 (NUREG-75/038) and found the impacts to be SMALL. These NRC analyses provided the basis for Table S-4 in 10 CFR 51.52. Incident-free transportation of unirradiated and spent fuel to and from Units 6 & 7 was evaluated. The Turkey Point results are consistent with the environmental impacts associated with transportation of radioactive materials from current generation reactors presented in Table S-4 of 10 CFR 51.52. Thus, the impacts of accident-free transportation would be SMALL and would not warrant additional mitigation.

(a) In some cases where no entry appears in Table S-3 it is clear from the background documents that the matter was addressed and that, in effect, the table should be read as if a specific zero entry had been made. However, there are other areas that are not addressed at all in the table. Table S-3 does not include health effects from the effluents described in the table, or estimates of releases of Rn-222 from the uranium fuel cycle or estimates of Tc-99 released from waste management or reprocessing activities. Radiological impacts of these two radionuclides are addressed in NUREG-1437, and it was concluded that the health effects from these two radionuclides posed a small significance. Data supporting Table S-3 are given in the *Environmental Survey of the Uranium Fuel Cycle*, WASH-1248 (AEC 1974); NUREG-0116 (Supplement 1 to WASH-1248); NUREG-0216 (Supplement 2 to WASH-1248); and in the record of final rule making pertaining to *Uranium Fuel Cycle Impacts from Spent Fuel Reprocessing and Radioactive Waste Management*, Docket RM-50-3. The contributions from reprocessing, waste management and transportation of wastes are maximized for either of the two fuel cycles (uranium only and fuel recycle). The contribution from transportation excluded transportation of cold fuel to a reactor and of irradiated fuel and radioactive wastes from a reactor which are considered in Table S-4 of § 51.20(g). The contributions from the other steps of the fuel cycle are given in columns A-E of Table S-3A of WASH-1248.

(b) The contributions to temporarily committed land from reprocessing are not prorated over 30 years, because the complete temporary impact accrues regardless of whether the plant services one reactor for 1 year or 57 reactors for 30 years.

(c) Estimated effluents based on combustion of coal for equivalent power generation.

(d) 1.2 percent from natural gas use and processes.

(e) Radiological impacts of Rn-222 and Tc-99 are addressed in NUREG-1437. The GEIS concluded that the health effects from these two radionuclides pose a small risk.

Table 5.7-2
Summary of Environmental Impacts of Transportation of Fuel and Waste to and from One LWR, Taken from 10 CFR 51.52 Table S-4[a]

Normal Conditions of Transport			
Environmental Impacts			
Heat (per irradiated fuel cask in transit)		250,000 Btu/hr.	
Weight (governed by Federal or State restrictions)		73,000 lbs. per truck; 100 tons per cask per rail car.	
Traffic density:			
Truck		Less than 1 per day	
Rail		Less than 3 per month	
Exposed Population	**Estimated Number of People Exposed**	**Range of Doses to Exposed Individuals[b] (per reactor year)**	**Cumulative Dose to Exposed Population (per reactor year)[c]**
Transportation workers	200	0.01 to 300 millirem	4 person-rem.
General pubic:			
Onlookers	1100	0.003 to 1.3 millirem	3 person-rem.
Along Route	600,000	0.0001 to 0.06 millirem	
Accidents in Transport			
Types of Effects		**Environmental Risk**	
Radiological effects		Small[d]	
Common (nonradiological) causes		1 fatal injury in 100 reactor years; 1 nonfatal injury in 10 reactor years; $475 property damage per reactor year.	

(a) Data supporting this table are given in the Commission's *Environmental Survey of Transportation of Radioactive Materials to and from Nuclear Power Plants,* WASH-1238, December 1972, and Supp. 1 NUREG-75/038, April 1975.

(b) The Federal Radiation Council has recommended that the radiation doses from all sources of radiation other than natural background and medical exposures should be limited to 5000 millirem per year for individuals as a result of occupational exposure and should be limited to 500 millirem per year for individuals in the general population. The dose to individuals due to average natural background radiation is approximately 360 millirem per year (U.S. NRC 2004).

(c) Person-rem is an expression for the summation of whole body doses to individuals in a group. Thus, if each member of a population group of 1000 people were to receive a dose of 0.001 rem (1 millirem), or if 2 people were to receive a dose of 0.5 rem (500 millirem) each, the total person-rem dose in each case will be 1 person-rem.

(d) Although the environmental risk of radiological effects stemming from transportation accidents is currently incapable of being numerically quantified, the risk remains small regardless of whether it is being applied to a single reactor or a multi-reactor site.

Table 5.7-3
Number of Truck Shipments of Unirradiated Fuel

Reactor Type	Number of Shipments per Unit			Unit Electric Generation, MW(e)[d]	Capacity Factor	Normalized Shipments Total[e]	Normalized Shipments Annual[f]
	Initial Core[a]	Annual Reload	Total[c]				
Reference LWR	18[b]	6.0	252	1100	0.8	252	6.3
AP1000	23	4.7	208	1000	0.93	196	4.9

(a) Shipments of the initial core have been rounded up to the next highest whole number.
(b) The initial core load for the reference BWR in WASH-1238 was 150 MTU. The initial core load for the reference PWR was 100 MTU. Both types result in 18 truck shipments of fresh fuel per reactor.
(c) Total shipments of fresh fuel over 40-year plant lifetime (i.e., initial core load plus 39 years of average annual reload quantities).
(d) AP1000 unit net generating capacity from DCD, Rev. 19, Table 1.3-1.
(e) Normalized to electric output for WASH-1238 reference plant (i.e., 1100 MWe at 80 percent or an electrical output of 880 MWe).
(f) Annual average for 40-year plant lifetime.

Table 5.7-4
Number of Radioactive Waste Shipments

Reactor Type	Waste Generation, ft^3 per yr, per unit	Electrical Output, MWe, per unit	Capacity Factor	Normalized Waste Generation Rate, ft^3 per reactor-year[a]	Normalized Shipments per reactor-year[b]
Reference LWR	3800	1100	0.80	3800	46
AP1000	1947	1000	0.93	1842	22.3

(a) Annual waste generation rates normalized to equivalent electrical output of 880 MWe for reference LWR analyzed in WASH-1238.
(b) The number of shipments was calculated assuming the average waste shipment capacity of 82.6 ft^3 per shipment (3800 ft^3 per yr divided by 46 shipments per yr) used in WASH-1238.

Table 5.7-5
AP1000 Comparisons to Table S-4 Reference Conditions

Characteristic	Table S-4 Condition	AP1000
Thermal Power Rating (MWt)	not exceeding 3,800 per reactor	3,400
Fuel Form	sintered uranium dioxide pellets	sintered uranium dioxide pellets
U-235 Enrichment (percent)	Not exceeding 4	Region 1 — 2.35% Region 2 — 3.40% Region 3 — 4.45%
Fuel Rod Cladding	Zircaloy rods; NRC has also accepted ZIRLO per 10 CFR 50.46	ZIRLO
Average fuel irradiation (MWd per MTU)	Not exceeding 33,000	50,553
Unirradiated Fuel (Table 5.7-3)		
Transport Mode	truck	truck
No. of shipments for initial core loading		23
(normalized number)		(25)[(a)]
No. of reload shipments per year		4.7
(normalized number)		(5)[(a)]
Irradiated Fuel		
Transport mode	truck, rail or barge	truck, rail
Decay time before shipment	Not less than 90 days is a condition for use of Table S-4; 5 years is per contract with DOE	minimum of 5 years
No. of spent fuel shipments by truck		45.9 per year
(normalized number)		(444 per year)
No. of spent fuel shipments by rail		not analyzed
Radioactive Waste (Table 5.7-4)		
Transport mode	truck or rail	Truck
Waste form	solid	Solid
Packaged	yes	yes
No. of waste shipments by truck		23.6 per year
(normalized number)		(23 per year)
Traffic Density		
Trucks per day	Less than 1	Less than 1
(normalized total)		(72 per year)
Rail cars per month	Less than 3	not analyzed

(a) Total shipments of unirradiated fuel averaged over 40-year plant lifetime (Table 5.7-3) were used to calculate the total traffic density.

Table 5.7-6
RADTRAN 5 Input Parameters for Analysis of Unirradiated Fuel Shipments

Parameter	RADTRAN 5 Input Value	Source
Shipping distance, miles[(a)]	2,000	AEC Dec 1972
Travel Fraction — Rural	0.90	NUREG-0170
Travel Fraction — Suburban	0.05	
Travel Fraction — Urban	0.05	
Population Density — Rural, people per square mile	25.9	U.S. DOE Jul 2002b
Population Density — Suburban, people per square mile	904	
Population Density — Urban, people per square mile	5,850	
Vehicle speed, miles per hour	55	Conservative in transit speed of 55 mph assumed; predominantly interstate highways used.
Traffic count — Rural, vehicles per hour	530	U.S. DOE Jul 2002b
Traffic count — Suburban, vehicles per hour	760	
Traffic count — Urban, vehicles per hour	2,400	
Dose rate at 1 meter from vehicle, person-rem per hour	0.1	AEC Dec 1972
Packaging length, feet	24	Approximate length of two LWR fuel element packages placed on end
Number of truck crew	2	AEC Dec 1972, NUREG-0170, U.S. DOE Feb 2002a, DOE 2002b
Stop time, hour per trip	4.0	Based on one 30-minute stop per 250 miles
Population density at stops, people per square mile	77,700	Sprung et al. Mar 2000
Population density surrounding truck stops, people per square mile	881	Sprung et al. Mar 2000

(a) WASH-1238 had a range of shipping distances between 25 and 3000 miles for unirradiated fuel shipments. A 2000-mile "average" shipping distance was used for this analysis consistent with the assumptions in NRC analyses of early site permit sites.

Table 5.7-10
Population Doses from Spent Fuel Transportation, Normalized to Reference LWR

Exposed Population	Cumulative dose limit specified in Table S-4, person-rem per reactor year	Reactor Type	
		Reference LWR	AP1000
		Normalized Number of Spent Fuel Shipments per year	
		60	44
		Environmental Effects, person-rem per reactor year[a]	
Transport Workers	4	13.7	10.0
General Public — onlookers	3	9.4	6.9
General Public — along route	3	0.99	0.73

(a) Doses are the product of the RADTRAN dose results along the TRAGIS generated shipment routes multiplied by the number of shipments per year.

5.8 SOCIOECONOMIC IMPACTS

This section addresses the socioeconomic impacts of the operation of Units 6 & 7 at the Turkey Point plant property in Miami-Dade County, Florida. The evaluation assesses impacts from the operation of Units 6 & 7 and from the demands placed on the region by the workforce. Subsection 5.8.1 describes and presents an assessment of the physical impacts of operations. Subsection 5.8.2 describes the impacts of operations to the region in the areas of demography, economy, taxes, land use, transportation, aesthetics and recreation, housing, public services, and education. Subsection 5.8.3 assesses the operation of Units 6 & 7 with regard to disproportionate adverse impacts to minority and low income populations.

The significance of the impacts as small, moderate, or large, has been identified in accordance with the criteria that U.S. NRC established in 10 CFR Part 51, Appendix B, Table B-1, Footnote 3, as follows:

- SMALL — Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small.

- MODERATE — Environmental effects are sufficient to alter noticeably, but not to destabilize, any important attribute of the resource.

- LARGE — Environmental effects are clearly noticeable and are sufficient to destabilize any important attributes of the resource.

These impact significance terms (SMALL, MODERATE, LARGE) are assigned to both the county-level and combined city-level analyses.

5.8.1 PHYSICAL IMPACTS OF STATION OPERATION

This section assesses the potential physical impacts as a result of the operation of the new units on the nearby communities or residences. Potential impacts include noise, odors, exhausts, thermal emissions, and visual intrusions. These physical impacts would be managed to comply with applicable federal, state, and local environmental regulations and would not significantly affect the Turkey Point plant property and its vicinity.

As presented in Subsection 2.5.2.4, Miami-Dade County has more than 1946 square miles of land, of which approximately 510 square miles have been developed for urban uses. The predominant existing land uses around the Turkey Point plant property are undeveloped and protected areas. Biscayne Bay and the Atlantic Ocean border the plant property to the east. The closest incorporated communities are Homestead and Florida City. Florida City is located 8 miles

west of the plant property and the municipal limits of Homestead is located 4.5 miles west (Subsection 2.2.1.2). Recreational areas in the community include Homestead Bayfront Park, Biscayne National Park, Mangrove Preserve, Everglades National Park and the Homestead Miami Speedway (Subsection 2.5.2.5). There are no residential areas or public roads located within the Turkey Point plant property. Homestead Air Reserve Base is within 6 miles of Units 6 & 7. No significant industrial or commercial facilities other than the Turkey Point units are planned for this area; however, a portion of the former Air Reserve Base (717 acres) is to be set aside for mixed economic uses (commercial, residential, or recreational uses) by Miami-Dade County (Subsection 2.2.1.2).

5.8.1.1 Noise

As described in Subsection 2.7.7, an ambient noise monitoring survey was performed in June 2008 to assess existing ambient noise in areas adjacent to the existing units. The highest recorded noise level for onsite measurements was 68 dBA. From two sampling points located at the Turkey Point plant property boundary (monitoring points S2 and S3), daytime noise level equivalent (Leq) readings ranged from 60 to 68 dBA and nighttime L_{eq} readings ranged from 60 to 67 dBA.

The noise impacts from the operation of Units 6 & 7 were evaluated using the equipment associated with normal operation. The noise level generated by the circulating water system cooling towers would be on the order of 88 dBA at 3 feet from the towers, 73 dBA at 200 feet from the towers, which is within the Units 6 & 7 plant area. In contrast, the nearest distance to the Turkey Point plant property boundary from the cooling towers is 1452 feet. At the plant property boundary the estimated noise level would be approximately 35 dBA. This noise level would be below the range of the existing noise levels at the plant property boundary.

The design of Units 6 & 7 would include components that mitigate noise from being emitted to the surrounding environment. The majority of the noise sources associated with Units 6 & 7 would be steam generators, electric generators, compressors, cooling water pumps, and cooling towers. All, except for the cooling towers, would be located within buildings that mitigate sounds emitted by equipment. The noise from electric transformers would be partially shielded by walls that also mitigate noise. The standby and ancillary diesel generators and diesel fire pumps would operate only 4 hours per month for testing and maintenance. The noise from cooling towers would be mitigated by their inherent design (e.g., splash guards on air inlets to mitigate sounds generated by the falling water, mechanical fans with stacks that direct noise vertically).

As reported in NUREG-1437, and referenced in NUREG-1555, noise levels below 65 dBA are considered of small significance. In addition, there are no applicable state or local environmental

noise regulations for unincorporated areas of Miami-Dade County, where Turkey Point is located. Therefore, noise impacts would be SMALL and would not warrant mitigation.

Other noise generated by the operation of Units 6 & 7 would be the noise levels resulting from the transmission system, substation operations, and increase in traffic by the operation workforce on access roadways and onsite roads. The noise generated from the transmission lines and substations, called corona noise, would be affected by weather. During dry conditions, the corona discharge is low and is not distinguishable from background or ambient noise. During wet conditions, a louder corona discharge occurs, however, the corona noise is not readily distinguishable from other background noise such as rain or traffic. Noise generated by the operation of the transmission systems and substations would be in accordance with state and local code requirements and, therefore, would be SMALL and would not warrant mitigation. Good road conditions and appropriate speed limits would minimize the noise level generated by the workforce commuting to the plant property. The access roads would be paved and local traffic would be controlled by speed limits. Impacts from the noise of traffic during operation activities would be SMALL and would not require mitigation.

5.8.1.2 Air

The Turkey Point plant property is located in Miami-Dade County, Florida, which is part of the Southeast Florida Intrastate Air Quality Control Region (AQCR). The Clean Air Act establishes National Ambient Air Quality Standards (NAAQS), which include the following criteria pollutants: sulfur dioxide, particulate matter with aerodynamic diameters of 10 microns or less (PM_{10}), particulate matter with aerodynamic diameters of 2.5 microns or less ($PM_{2.5}$), carbon monoxide, nitrogen dioxide, ozone, and lead. Areas of the United States having air quality as good as or better than the NAAQS are designated by EPA as attainment areas. Areas having air quality that is worse than the NAAQS are designated by EPA as non-attainment areas. The entire Southeast Florida Intrastate AQCR is currently classified as an attainment area under the NAAQS criteria (Subsection 2.7.2).

The new units would have standby diesel generators. The diesel generators would be operated periodically on a limited short-term basis and the related emissions would be intermittent. Emissions from these sources are described in Subsection 2.7.2.2. The standby diesel generators would be operated under air permits issued by the state of Florida for cooling tower particulates. The operation of a nuclear power plant involves the emission of some greenhouse gases, primarily carbon dioxide (CO_2). The NRC has conservatively estimated for a 1000 MW(e) nuclear plant that the total carbon footprint for the operation of a plant for 40 years is on the order of 320,000 metric tons of CO_2 equivalent (NRC, 2010). Thus, for two AP1000 reactors, the total carbon footprint would be on the order of 640,000 metric tons (not including uranium fuel cycle). Periodic testing of diesel generators and normal plant operation accounts for about 60 percent of the total or approximately 380,000 metric tons. Workforce transportation accounts for most of the

rest or approximately 260,000 metric tons. As a comparison, the total United States annual CO_2 emission rate is 6,000,000,000 metric tons (EPA 2009). Additionally, Subsection 9.2.3.1.1 estimates a yearly CO_2 emission for comparable fossil fuel plants (coal- fired and natural gas-fired) as 14,000,000 metric tons and 5,900,000 metric tons, respectively. Based on the relatively small plant operations carbon footprint compared to the United States annual CO_2 emissions and comparable fossil fuel plants annual CO_2 emissions, the atmospheric impacts of greenhouse gases from plant operation would not be noticeable and therefore impacts would be SMALL. Given the periodic and short-term operation of these pollution sources, the impact from the operation of Units 6 & 7 on air quality would be SMALL and would not warrant mitigation.

The operation of Units 6 & 7 would increase the commuting workforce. Well-maintained access roads and appropriate speed limits would minimize the amount of dust generated by this increase in traffic. As stated in Subsection 5.8.2, approximately 403 new residents, in addition to 403 individuals already residing in, and therefore a part of the area's existing traffic profile, would migrate to the area for the operation of the new units. It is expected that these additional employees would be dispersed into surrounding communities in much the same way as the existing workforce. Because of the size and population of the surrounding areas, the emissions from the small increase in local traffic would not affect the air quality in the area. Air quality impacts from traffic during operation activities would be SMALL and would not require mitigation.

5.8.1.3 Aesthetics

The viewscape from north to south or from south to north would be similar to that of the existing units. However, the viewscape perpendicular to the Turkey Point plant property, that seen by commercial and recreational boating traffic on the eastern side of the plant property, would have a broader view of the entire area of the existing and new units, and would have an open view of Units 6 & 7. However, the viewscape with the new units would be similar to that of the existing plant property. Visual impacts of the new units would be SMALL and would not warrant mitigation.

The visual impacts from the operation of the cooling towers would be the towers themselves and plumes resembling lines of clouds. The plumes from the cooling towers would be seen during the early morning in cool weather generally during the winter months. The average plume lengths and heights would be relatively short. The visible plumes may prevent direct sunlight from reaching the ground, causing shadowing only for a short amount of time in the morning, but dispersing after sunrise. As described in Subsection 5.3.3.1, because of the varying directions and low frequency of the longest plumes and the short average plume lengths, impacts from elevated plumes would be SMALL and would not warrant mitigation.

Outdoor lighting would be necessary to satisfy NRC and Occupational Safety and Health Administration (OSHA) requirements for security, worker, and plant safety, including lighting walkways, parking areas, and various equipment areas. Unconstrained lighting can cause light

pollution and light trespass. Light pollution or sky glow is the term used to describe sky brightness caused by scattering of light in the atmosphere. Light trespass is the term used to describe light that strays from its intended purpose and becomes an annoyance.

Light pollution and light trespass would be addressed when designing the outdoor lighting systems. Guidelines specifically addressing potential lighting issues from the Illuminating Engineering Society of North America would be followed. These guidelines would be incorporated into the outdoor lighting design to the extent practicable while meeting NRC and OSHA requirements. Typical features to be incorporated are minimize upward light from luminaries, minimize upward light in general so that light reaches its intended target, turn off lighting not needed for safety and security between 11:00 p.m. and sunrise, contain light within its intended target area by suitable choice of luminaries for light distribution, by selection of mounting height and physical location, and by minimizing glare in the horizontal or vertical directions.

Outdoor light monitoring was conducted in 2008. The monitoring was performed from ten locations surrounding Turkey Point such as the race track, cooling canals, and Biscayne Bay. The results of the outdoor light monitoring indicated that while light from the existing units is visible, the light is localized. Sky glow was observed from the major urban areas such as Homestead and Miami. The use of the Illuminating Engineering Society of North America guidelines to the extent practicable, while meeting NRC and OSHA security and safety requirements, would result in low lighting impacts from Units 6 & 7. Thus, lighting impacts would be SMALL and would not warrant mitigation.

The visual impacts of the eastern transmission line corridors (Clear Sky to Turkey Point, Clear Sky to Davis, and Davis to Miami) would consist of 230 kV lines on 80- to 105-foot-high concrete poles. The Clear Sky to Turkey Point line would be fully contained on the Turkey Point plant property and would be similar to the existing lines between the Turkey Point switchyard and the McGregor switchyard. The Clear Sky to Davis line would be in an established transmission right-of-way that is currently being used for seven other transmission lines. The addition of another single line and new poles collocated within this corridor would be similar to the current linear facilities established. The Davis to Miami line would be collocated in an established transmission line right-of-way that is currently being used for several other transmission lines and collocated with the MetroRail and a major transportation highway. A short section of the proposed Davis-Miami 230-kV transmission line, at the crossing of the Miami River adjacent to the existing Miami substation, would be underground. Therefore, the presence of these new transmission lines would have a SMALL visual impact and would not warrant mitigation.

The visual impacts of the western transmission line facilities (Clear Sky to Levee and Clear Sky to Pennsuco) would consist of two 500 kV lines and a single 230 kV line. These lines would follow an existing right-of-way up to the Everglades National Park (ENP). These lines would then follow

a right-of-way in, or adjacent to, the ENP. Then, the two 500 kV lines would terminate at the Levee substation, and the 230 kV line would continue to the Pennsuco substation. The existing right-of-way is currently used by a single 138 kV line. The visual impacts of the additional lines would consist of new 80- to 105-foot-high concrete poles and new galvanized lattice steel or concrete guyed single-circuit structures at heights of 135-150 feet approximately 1000 feet apart. The addition of these new structures would alter and inhibit the viewscape, however, the visibility would be reduced with increased distance. At the present time, most of the views into the park from the Tamiami Trail are obstructed by vegetation growing along the highway. Because opportunities for views into the park from the highway are greatly reduced or eliminated due to the vegetation, the adverse impacts of the transmission lines and structures would be minimal. The 230 kV line that continues past Levee substation to Pennsuco substation would be largely in existing rights-of-way where the transmission line would be collocated with existing transmission lines and would consist of a single line on 80- to 105-foot-high concrete poles through heavily industrial and urban areas. Impacts would be minimized to the natural and built environment to the extent feasible through the selection process, engineering options, and construction techniques used. Therefore, the presence of these new lines would have a MODERATE impact and would warrant mitigation, such as those described above.

5.8.1.4 Traffic

The current road network in the Homestead and Florida City area is detailed in Subsection 2.5.2.2.1. The operation workforce for both units is expected to be 806 persons (Table 5.8-1). The principal arterial roads could accommodate an increase in operation workforce traffic (Table 5.8-10c).

After completion of construction, FPL would remove a portion of the roadway improvements on SW 359th Street and return it to a transmission patrol road. All workforce traffic for Units 1-7, including outage workers, would access the site via SW 344th/Palm Drive. Palm Drive runs east-west. Workers from the west, northwest, north and south can access the west end of SW 344th/ Palm Drive from U.S. Highway 1, Krome Avenue or Florida's Turnpike. Workers from the north can also access Palm Drive by traveling south on SW 137th/Tallahassee Road or SW 117th Avenue, a north-south street east of Tallahassee Road.

SW 328th /North Canal Drive runs east-west several blocks north of SW 344th/Palm Drive, and also can be accessed from Krome Avenue, U.S. Highway 1 or Florida's Turnpike. SW 328th / North Canal Drive intersects with SW 137th/Tallahassee Road, north of SW 137th/Tallahassee Road's intersection with SW 344th/Palm Drive, and therefore provides an alternative access to Turkey Point from the west for part of the commute. Sections of Tallahassee Road, North Canal Drive and Palm Drive would be improved to accommodate construction traffic (Subsection 4.4.2.2.4.2).

Trip distributions and traffic assignments for the new operation workforce traffic were based on the traffic patterns of the existing workforce. Most existing traffic arrives from and departs to the north via SW 137th/Tallahassee Road. The second most traveled access/egress route is SW 344th/Palm Drive to U.S. Highway 1. Most of the remainder of the existing workforce uses SW 328th /North Canal Drive.

5.8.1.5 Conclusion

Physical impacts to the surrounding population as a result of the operation of the proposed units would be SMALL and would not warrant mitigation.

5.8.2 SOCIAL AND ECONOMIC IMPACTS OF STATION OPERATION

This section evaluates the demographic and community impacts to the region as a result of operating Units 6 & 7 in Miami-Dade County, Florida. The evaluation assesses impacts of operation-related activities and of the operation workforce in the region.

The population data in this section was updated to reflect the American Community Survey Estimates for 2005-2009. The population projections in Table 2.5-1 and FSAR Subsection 2.1.3, however, used the 2010 Census dataset in order to be consistent with the base population utilized by the Florida Office of Economic Development and Research for the state projected population growth between 2010 and 2030. The 2010 Census dataset was also used in FSAR Subsection 2.1.3 to calculate the same base growth rate multiplier as the state, so that the population projections would be consistent with those projected by the state through 2030.

The operation of Units 6 & 7 would continue at least 40 years, with the possibility of a 20-year extension, for an operational life of as much as 60 years. The projected operation schedule estimates a commercial operation date of 2022 for Unit 6 and 2023 for Unit 7. A two-unit facility would require approximately 806 onsite employees (Subsection 3.10.3). Refueling outages for each unit would occur every 18 months, last approximately 30 days, and require the addition of approximately 600–1000 temporary workers.

Major factors in determining socioeconomic impacts are the number of workers and family members that relocate to an area and where they settle. Assumptions regarding workforce characteristics, migration, and family characteristics for Units 6 & 7 are presented in Table 5.8-1. Assumptions regarding families, children, and the indirect workforce are described in more detail in Subsection 5.8.2.1. As stated in Subsection 3.10.3, it is assumed that 50 percent of the operation workforce (403 workers) would migrate to Miami-Dade County for this project.

As presented in Table 2.5-3, approximately 83 percent of the 977 current operation workers at Turkey Point reside in Miami-Dade County. Approximately 43 percent or 418 workers reside in the Homestead and Florida City area. For Units 6 & 7, it could be assumed that 83 percent of the

in-migrating operation workforce would reside in Miami-Dade County, but the county's population is so large and resources are so plentiful that it can be conservatively assumed that all of the 403 workers would migrate to the county. On a more local level, it could be assumed that, based on the residential distribution of the current operation workforce, approximately 43 percent of the in-migrating workers (172 workers) would reside in the Homestead and Florida City area. Therefore, the impact analyses in Subsection 5.8.2 are based on the socioeconomics of Miami-Dade County, as a whole, and the Homestead and Florida City area, in particular.

In Subsections 2.5.1 and 2.5.2, resource capacity information is presented for Miami-Dade County and the Homestead and Florida City area. The data for Homestead and Florida City was summed to provide a baseline for the Homestead and Florida City area. In Subsection 5.8.2, the incremental increases in resource use caused by the in-migrating workforce for Units 6 & 7 at both the county and combined cities levels are assessed.

5.8.2.1 Demography

Both new units would be operating by 2023 and potentially continue for 60 years, to 2083. The population, as determined by the USCB, within 50 miles of Units 6 & 7 was 3,459,894 in 2010, and is projected to grow to approximately 6,278,881 by 2090 (Table 2.5-1). The population in Miami-Dade County was 2,496,435 in 2010, and is projected to grow to 2,722,889 by 2020 (Table 2.5-4). The 2000 populations of Homestead and Florida City were 31,909 and 7843, respectively (Subsection 2.5.1). The 2005-2009 population for the two cities was 55,036 and 9808, respectively (Subsection 2.5.1). Population projections for the two cities in 2020 are not available.

It is anticipated that 403 workers (Table 5.8-1) would migrate into Miami-Dade County to support the operation of the new units. It is anticipated that 172 (approximately 43 percent) of those workers would migrate to the Homestead and Florida City area.

An in-migration of 403 workers would create additional indirect jobs in the region because of the multiplier effect. Multipliers are used to estimate how much a one-time or sustained increase in economic activity, such as the operation of Units 6 & 7, in a particular region, such as Miami-Dade County, will impact a defined region. Employment multipliers are used to estimate the number of indirect jobs created in a region. Indirect jobs are created when new, directly employed workers spend their earnings and, hence, create a greater demand for goods and services than existed before the new worker wages were introduced to the region. The in-migration of 403 operation workers would create new indirect jobs because of the multiplier effect.

Earnings multipliers are also used to predict the impact of wages spent in the region. The U.S. Department of Commerce's Bureau of Economic Analysis (BEA), Economics and Statistics Division, provides multipliers for jobs and earnings (BEA 2009). Their economic model, RIMS II,

incorporates buying and selling linkages among regional industries, and provides multipliers by industry sector to estimate the impacts of changes in that sector to a regional economy. This analysis used the detailed employment and earnings multipliers for the power generation and supply industry to estimate the number of indirect jobs and the impact of Units 6 & 7-related expenditures in Miami-Dade County. Table 5.8-2 provides project-related direct and indirect employment data for Miami-Dade County.

As stated in Subsection 4.4.2.1, for every in-migrating operation worker, an estimated additional 2.1696 jobs would be created in Miami-Dade County (BEA 2009). The influx of 403 operation workers would create approximately 874 indirect jobs in Miami-Dade County, for a total of 1277 new jobs (both direct and indirect) (Table 5.8-2). It is expected that the indirect jobs could be filled by people already residing within Miami-Dade County. As shown in Table 2.5-7, there were 156,562 unemployed individuals in Miami-Dade County in 2011.

To estimate the family characteristics of the operation workforce, the Batelle Memorial Institute (BMI) study, *Migration and Residential Location of Workers at Nuclear Power Plant Construction Sites* (BMI 1981), which was commissioned by the NRC, and U.S. Census Bureau (USCB) data was evaluated. Published in 1981, the BMI study was based on 49,000 observations from 28 surveys at 13 nuclear power plant construction sites. The study sought to improve the accuracy of socioeconomic impact assessments by providing an improved methodology for predicting the number of in-migrating workers and their residential location patterns at future nuclear power plant construction projects. Though the study was an analysis of construction workforce, in general, information about nuclear plant nonconstruction workers (i.e., managers, engineers, supervisors, clerical, security, and medical personnel who were on the site during construction) was also included. Because nonconstruction workers have some similar characteristics to the operation workforce, their data is useful for this analysis. The study is the most current of its nature and there is little evidence that the observations of fundamental worker characteristics and behaviors detailed in the BMI study have changed meaningfully since the study's publication. Therefore, the worker migration patterns and family characteristics described in the 1981 study are considered a valid proxy for assumptions made for nuclear power plant construction and operation workforce today.

As stated previously, it was assumed that all of the 403 in-migrating workers would migrate to Miami-Dade County and would bring families. According to the BMI study, the average family size of a nuclear plant nonconstruction worker was slightly less than 3.25. According to the USCB (USCB 2010b), the average family size in Miami-Dade County in 2010 was 3.33, while the average family size for the state of Florida was 3.01. Therefore, it was assumed that the average family size of 3.25, the value used for the construction workforce in Subsection 4.4.2.1, would also be a reasonable estimate for the operation workforce. Therefore, 403 in-migrating operation workers would bring 907 family members, for a total of 1310 additional people in Miami-Dade County (Table 5.8-1). The 172 workers that would migrate to the Homestead and Florida City

area would bring 387 family members, for a total of 559 additional people to that area (Table 5.8-1).

The BMI study reported that, while construction workers averaged 0.8 school-age children per family, nonconstruction workers had an average of 0.6 children per family. However, to provide a more conservative impact estimate, it was estimated that, like the construction worker families, each of the 403 operation worker families would bring 0.8 school-age children, for a total of 322 additional children in Miami-Dade County (Table 5.8-1). Likewise, it was estimated that the 172 operation workers that would settle in the Homestead and Florida City area would bring 138 additional children to that area (Table 5.8-1).

The Units 6 & 7-related population increase in Miami-Dade County during operation would be 1310 people (Table 5.8-1). This represents an increase of 0.05 percent over the 2005-2009 population for Miami-Dade County and 0.05 percent over Miami-Dade County's projected 2020 population (Table 2.5-4). Therefore, Units 6 & 7-related population impacts to Miami-Dade County would be SMALL.

The Units 6 & 7-related population increase in the Homestead and Florida City area during operations would be 559 people (Table 5.8-1). This represents an increase of 1.4 percent over the 2000 populations of the two cities' areas, combined, and 0.9 percent over the 2005-2009 population estimates of the two cities' areas, combined. Therefore, Units 6 & 7-related population impacts to the Homestead and Florida City area would be SMALL.

5.8.2.2 Impacts to the Community

This section evaluates the social, economic, infrastructure, and community impacts to the region of influence (ROI) which is Miami-Dade County, and, specifically, the Homestead and Florida City area, as a result of operating Units 6 & 7. As many as 806 workers, 50 percent of which would migrate into Miami-Dade County, would be employed.

5.8.2.2.1 Economy

The impact of the operation of Units 6 & 7 on the local and regional economy would depend on the region's current and projected economy and population. The economic impacts of a potential 40-year period of operation plus 20 years of a license renewal period are described below.

The employment of the permanent operation workforce for such an extended period of time would have economic impacts throughout Miami-Dade County. The property tax revenues from the new units would be assessed and distributed throughout Miami-Dade County including the Homestead and Florida City area. It was assumed that incoming workers would choose residences in a similar pattern to the existing Turkey Point workforce (i.e., primarily in Miami-Dade County, with approximately 43 percent electing to live in the Homestead and Florida City

area), although the residence patterns of the incoming operation workers may vary somewhat, and therefore the location of some impacts cannot be exactly determined. However, the influx of people spending wages, paying taxes, building new houses or occupying existing houses, and using public services and utilities could have a more noticeable impact on the smaller communities in Miami-Dade County, particularly in the Homestead and Florida City area than in the county as a whole because of their smaller populations.

In addition to the permanent operation workforce of 806, workers would be brought in periodically to support refueling outages (Subsection 5.8.2.2). Regular outages would occur approximately every 18 months for each unit, using 600 workers and lasting 30 days. Extended outages would occur every 5 years per unit, using 1000 workers and lasting 45 days. For this analysis, it was assumed that the two units would not experience simultaneous outages, and therefore, one regular outage would occur every 9 months and one extended outage would occur every 2.5 years for Units 6 & 7. These outages would be in addition to those scheduled for Units 3 & 4. It was further assumed that outages for all four nuclear units would be non-concurrent.

Income Impacts from Permanent Operation Workers

As part of the analysis of income impacts to Miami-Dade County, wages for all industry sectors combined, the utilities industry, and the nuclear electric power generation industry were examined. As available, these wages are presented in Table 2.5-12. Nuclear electric power generation information was not disclosed for Florida or Miami-Dade County. Therefore, Florida data from the Bureau of Labor Statistics for annual average wages for nuclear power reactor operators ($81,980) (BLS 2012b) were obtained. While Technicians, along with administrative and support personnel, would comprise the majority of the operation workforce, Nuclear Technician annual wages are not currently available. As such, the nuclear power reactor operator’s wage was used to revise the impacts analysis. Based on the average annual nuclear power reactor operator’s wage of $81,980, the total annual payroll for the in-migrating operation workers was estimated at $33 million (Table 5.8-3).

The in-migrating operation workforce would purchase goods and services, creating an earnings multiplier effect that would result in an increase in business activity, particularly in the retail and service industries. As noted in Subsection 5.8.2, it was assumed that 50 percent of the operation workforce would migrate into Miami-Dade County, and therefore would spend some portion of their worker wages within Miami-Dade County. To estimate these economic impacts, the regional earnings multiplier of 1.7880 for the power generation and supply industry (BEA 2009) is applied to the annual payroll of the in-migrating workers. According to these calculations, the total impact of in-migrating worker wages in Miami-Dade County would be about $59.1 million (Table 5.8-3). This multiplied impact would represent an increase of 0.06 percent over the total personal income in Miami-Dade County in 2009, a SMALL and positive impact. It is likely that personal income in Miami-Dade County will grow between 2009 and the beginning of the operation of Units 6 & 7,

resulting in a smaller percentage increase in county personal income. However, the wage impact would remain positive and SMALL.

It is not possible to accurately predict the magnitude of wages spent within the Homestead and Florida City area, because so many opportunities exist to spend earnings within metropolitan Miami-Dade County. However, some wages would be spent in the Homestead and Florida City area and the impacts would be positive, but likely SMALL.

Employment Impacts from Permanent Operation Workers

As stated in Table 5.8-2, an estimated additional 2.1696 indirect jobs would be created for each of the 403 in-migrating workers (BEA 2009a)[1]. These 403 direct jobs would create an additional 874 jobs, for a total of 1277 (403 direct + 874 indirect) jobs.

In 2011, Miami-Dade County had a total employment of 1.15 million (Table 2.5-7). Therefore, the 1277 jobs would represent a 0.1 percent increase over 2011 employment levels (Table 5.8-4). However, by the time the new units and indirect jobs come into existence, it is likely that the total county employment would be greater, and that the new jobs would comprise a smaller percentage of the total. In any case, this would be a SMALL and positive impact to the Miami-Dade County economy.

Many of the 874 indirect jobs would be in retail or services, and not highly specialized. The operation workforce for both units would reach full staffing in 2022. Available workers to fill the indirect jobs could come from local unemployed workers and construction workers or their family members remaining in Miami-Dade County, or others in the region.

In 2011, the annual average unemployment rate in Miami-Dade County was 12.0 percent, representing 156,562 workers. The unemployment rate had increased from 6.1 percent a decade ago (Table 2.5-7). At a rate of 12.0 percent unemployment in 2011, there would be an ample labor force to fill the indirect jobs created by the incoming operation workers.

The creation of direct and indirect jobs, via the multiplier effect, would have a positive impact on the local economy, and to the extent that jobs were filled by unemployed local workers, would reduce unemployment, an additional beneficial impact. Miami-Dade County would experience SMALL beneficial impacts, and mitigation would not be warranted.

1. Workers currently residing in Miami-Dade County have already generated indirect service jobs, so only in-migrating workers were used to calculate new indirect jobs.

Impacts from Temporary Outage Workers

Regular outages would be approximately 30 days in duration and require 600 workers, and would occur approximately every 18 months per unit. Extended outages would be approximately 45 days in duration and require 1000 workers, and would occur approximately every 5 years per unit. For this analysis, it was assumed that all workers would come from outside Miami-Dade County. To estimate the economic impacts of each outage, the average annual wage for nuclear power reactor operators ($81,980), Table 5.8-5 is divided by 250 workdays per year to obtain a daily average wage of $328.

The wage impacts for regular and extended outages are estimated, with wage totals annualized for comparison to annual total personal income for Miami-Dade County. These calculations are provided in Table 5.8-5, which shows that the total annualized payroll for regular outage workers would be $7,870,080. When the earnings multiplier (1.7880) is applied, impacts to the region would be $14.1 million, representing an increase of 0.015 percent of Miami-Dade County's total personal income in 2009. When the earnings multiplier (1.7880) is applied to the annualized of worker wages during an extended outage, impacts to Miami-Dade County would be $10.6 million, representing an increase of 0.012 percent of the Miami-Dade County total personal income in 2009. Some of the regular and extended outage workers' wages would likely be spent in the Homestead and Florida City area.

Because of the short duration of the routine and extended outage periods, it is unlikely that permanent indirect employment impacts would occur in the region of influence as a result of the worker influx. However, there could be temporary and short-term job opportunities for lodging and restaurant workers to serve the outage workforce, along with SMALL and positive impacts to motels, restaurants, retailers, and other businesses patronized by the outage workers.

5.8.2.2.2 Taxes

Several types of taxes would be generated by the operation of Units 6 & 7. Unit 6 would begin operation in 2022, and Unit 7 in 2023. FPL would pay corporate income tax, sales and use taxes, and property (also known as *ad valorem*) taxes based on the value and power generated by Units 6 & 7 and on operating expenditures. Workers and their families would also contribute sales and property tax revenues to the area.

Subsection 4.4.2.2.2 provides a detailed description of the significance categories applicable to tax impacts, which are derived from the analysis in the Generic Environmental Impact Statement (GEIS), NUREG-1437. This methodology was reviewed and it was determined that the significance levels were appropriate to apply to an assessment of tax impacts as a result of the operation of Units 6 & 7. In summary, significance levels are considered SMALL if new tax

payments are under 10 percent of the taxing jurisdiction's revenue, MODERATE if payments are 10 to 20 percent, and LARGE if payments represent more than 20 percent of revenue.

Personal and Corporate Income Taxes

As presented in Subsection 2.5.2.3, Florida has no personal income tax, but does levy a corporate income tax on corporations that conduct business in Florida. The tax liability is computed using federal taxable income, modified by certain Florida adjustments, to determine adjusted federal income.

At the present time, FPL is subject to Florida corporate income tax as a result of owning and operating power plants and other properties throughout the state, including the existing Turkey Point generation facility. FPL currently files as a member of a consolidated group for federal and state income tax purposes. At the time when FPL places the units in service, in 2022 for Unit 6 and 2023 for Unit 7, they will be included in the consolidated federal and state income tax filings. Because of the many factors involved in computing the amount of tax liability, it is not possible at this time to estimate an amount by which corporate income taxes may increase, and how much of the total would be attributable to Units 6 & 7. In 2011, the state of Florida collected approximately $1.9 billion in corporate income tax revenues. The expectation is that Turkey Point 6&7 would have a SMALL and positive impact to the state’s overall corporate income tax collections.

In addition to direct taxes paid for Units 6 & 7, local operating expenditures as well as purchases by the operation workforce would have a multiplier effect on the local economy, where money would be spent and re-spent within the region (Subsections 4.4.2.2.1 and 5.8.2.2.1). Because of this multiplier effect, Miami-Dade County businesses, particularly retail and service sector firms, could experience revenue increases, and there may be prospects for new startup firms. Existing and new firms could generate additional profits, which would further contribute to increased corporate income taxes, although the exact amount is unknown. Impacts would be positive, and SMALL relative to overall state corporate income tax revenues.

Sales and Use Taxes

The state of Florida and Miami-Dade County would experience an increase in the amount of sales and use taxes collected. The additional taxes would be generated from operating expenditures of Units 6 & 7, and by retail purchases of goods and services by the operation workforce, their families, outage workers, and plant visitors. As described in Subsection 2.5.2.3, Florida imposes a 6 percent sales and use tax, and Miami-Dade County adds a 1 percent discretionary sales tax, bringing the total sales tax in Miami-Dade County to 7 percent. Cities and towns in the county do not levy sales tax.

The primary taxable expenditures by FPL for Units 6 & 7 would be for purchases of labor and services by Miami-Dade County providers (FPL Undated). At the present time, the amount of local operational expenditures associated with Units 6 & 7 is not known. However, to have more than a small impact on local and state sales tax collections, purchases for Units 6 & 7 that would be subject to tax in Miami-Dade County would have to exceed $575.6 million, while purchases subject to Florida state sales tax would have to exceed $32.3 billion (Table 5.8-7). Although sales tax payments to Miami-Dade County and the state of Florida could be large in absolute terms, it is likely that impacts to both entities would be SMALL and positive.

Workers, their family members, and visitors would pay Florida sales or use tax on items purchased within the state (or purchased elsewhere but subject to state use tax), regardless of whether the purchase was made within Miami-Dade County. They would also pay Miami-Dade County sales tax on purchases within the county. In absolute terms, the amount of state sales and use taxes collected from the expenditures of operation-related wages over a potential 60-year operating period could be large, but would provide a SMALL and positive impact when compared to the total amount of taxes collected by Florida and Miami-Dade County.

Other Sales- and Use-Related Taxes

Units 6 & 7 workers who would reside within the state would be subject to the state communications services tax on phone, cable, cellular phone, and related services, and would have to pay the documentary sales tax on deeds and other types of legal documents (Subsection 2.5.2.3.3). If one were to assume conservatively that all workers and their families migrating into Miami-Dade County would come from out of state, the in-migrants would represent an increase of only 0.007 percent over Florida's 2005-2009 population (Table 5.8-8). Therefore, impacts to Florida's tax revenues for the communications services tax and the documentary sales tax would be SMALL but positive.

Property Taxes — Counties and Special Districts

One of the primary sources of economic impact related to the operation of Units 6 & 7 would be property taxes assessed on the facility. In 2007, as shown in Table 5.8-9b, FPL paid real and tangible personal property taxes totaling $4.4 million to Miami-Dade County, representing 0.39 percent of the county's property tax revenues. FPL also pays tangible personal property taxes to four special taxing districts: the Florida Inland Navigation District, the South Florida Water Management District, the Everglades Construction Project, and the Children's Trust Authority. Table 5.8-9a shows FPL's 2010 payments to each tax district, the district's property tax revenues, and the percent FPL contributed to each district. For each of the special taxing entities, FPL's payments represent well under 1.0 percent of the district's property tax revenues. Those payments would increase when Units 6 & 7 go into operation. However, because of the large tax

base for each of these districts, the increases would constitute SMALL and positive impacts to each district.

Table 5.8-8 shows that if all incoming worker families were to reside in Miami-Dade County, they would represent an increase of less than 0.1 percent over Miami-Dade County's 2005-2009 population. If, as expected, approximately 43 percent of the in-migrants choose to reside in the Homestead and Florida City area, they would pay property taxes to the county and special districts where they reside. These increases would have a positive and SMALL impact on tax revenues.

In smaller communities such as Homestead or Florida City, it is unlikely that the percentage of tax revenue increase would be as much as the projected population increase associated with the operation of Units 6 & 7, because much of any jurisdiction's tax base consists of higher-valued industrial or commercial property rather than residences. Therefore, the property tax impacts from new residents would be SMALL but positive.

Property Taxes — Independent School Districts

As described in Subsection 2.5.2.3.5, FPL, the current owner of the Turkey Point units, pays taxes collected by the Miami-Dade county tax collector on behalf on the Miami-Dade County School District. FPL paid $6.6 million in tangible personal property taxes to Miami-Dade schools in 2010 and 2011. However, because of this school district's large tax base (total revenues of $3.5 billion in 2010) (Table 2.5-21), FPL's payments represented less than 0.1 percent of the district's total revenues. In addition, FPL's payment of $6.6 million represents 0.35 percent of the district's locally-sourced tax revenues ($1.9 billion in 2010) (Table 2.5-21). Although property tax payments would increase with the operation of Units 6 & 7, impacts to Miami-Dade County schools would be SMALL but positive.

Summary of Tax Impacts

The overall potential beneficial impacts of taxes collected during the operational period of Units 6 & 7 would be positive and SMALL in Miami-Dade County and the state of Florida. The impacts would also be positive and SMALL in the Homestead and Florida City area. Mitigation would not be warranted.

5.8.2.2.3 Land Use

In the GEIS, the NRC provides the methodology for defining the impact significance of land use during refurbishment (i.e., construction activities) and license renewal (i.e., operations). This methodology was reviewed and it was determined that the significance levels were appropriate to apply to an assessment of land use impacts as a result of operation. Miami-Dade County was the focus of the land use analysis because the new units would be built in Miami-Dade County and it

was assumed that all of the workforce during operation would reside in the county. Impacts to land use would be confined to Miami-Dade County. These impacts would be based on:

- The size of plant-related population growth compared to the area's total population
- The size of the plant's tax payments relative to the community's total revenue
- The nature of the community's existing land use pattern
- The extent to which the community already has public services in place to support and guide development

In NUREG-1437, the NRC concluded that land use changes during refurbishment at nuclear plants would be:

- SMALL — If population growth results in very little new residential or commercial development compared with existing conditions and if the limited development results only in minimal changes in the area's basic land use pattern.
- MODERATE — If plant-related population growth results in considerable new residential and commercial development and the development results in some changes to an area's basic land use pattern.
- LARGE — If population growth results in large-scale new residential or commercial development and the development results in major changes in an area's basic land-use pattern.

Further, the NRC defined the magnitude of population changes as follows:

- SMALL — If plant-related population growth is less than 5 percent of the study area's total population, especially if the study area has established patterns of residential and commercial development, a population density of at least 60 people per square mile, and at least one urban area with a population of 100,000 or more within 50 miles.
- MODERATE — If plant-related growth is between 5 percent and 20 percent of the study area's total population, especially if the study area has established patterns of residential and commercial development, a population density of 30 to 60 people per square mile, and one urban area within 50 miles.
- LARGE — If plant-related population growth is greater than 20 percent of the area's total population and density is less than 30 people per square mile.

Land Use

All or parts of four Florida counties are within 50 miles of Turkey Point: Broward, Collier, Miami-Dade, and Monroe. The 50-mile radius encompasses over 3168 square miles. However, impacts to land would be confined to Miami-Dade County. As described in Subsection 2.2.3, most of the land use and land cover in the 50-mile region consists of wetlands (69 percent) and urban or built-up (18 percent) (Figure 2.2-6 and Table 2.2-8).

As stated in Subsection 2.5.2.4, Miami-Dade County and the municipalities of Homestead and Florida City use comprehensive land use planning to guide residential and commercial development. There are 35 incorporated cities in Miami-Dade County. Only two of the 35 incorporated communities are within 10 miles of Units 6 & 7—Homestead and Florida City.

From the land use perspective, Miami-Dade County and the Homestead and Florida City area are likely to continue to urbanize as the projected population increases. The population related increases (1310 people) associated with the operation of Units 6 & 7 would create an increase in commercial and residential activity. Should the population influx result in new construction, both Miami-Dade County and the Homestead and Florida City area have some undeveloped land currently zoned for residential and commercial uses (Subsection 2.5.2.4). However, the present housing inventory in Miami-Dade County and in the Homestead and Florida City area can support all of the in-migrating workers and their families without the addition of new housing units (Subsection 5.8.2.2.6). Miami-Dade County had 135,004 total vacant housing units in 2005-2009 (Table 2.5-31). The Homestead and Florida City area had 4046 vacant units in 2005-2009 (Table 2.5-32). Because both Miami-Dade County in general, and the Homestead and Florida City area in particular, have well-established residential and commercial districts, little land use conversion from undeveloped to residential or commercial use or residential to commercial, would be expected from the operation–related population increase in the area. Any conversion that did occur would be within the areas that are already well-defined and identified in the applicable comprehensive land use plans.

Using the NRC's NUREG-1437 guidance presented above, it is concluded that impacts to land as a result of Turkey Point related population increases that would cause land use conversions in Miami-Dade County would be SMALL and not warrant mitigation since the population influx would result in very little new residential or commercial development compared with existing conditions, and there would be minimal changes in the area's basic land use pattern.

Operation-Related Population Growth

The 2010 population of Miami-Dade County was 2,496,435, with a population density of 1316 people per square mile (USCB 2012). The 2000 population of the Homestead and Florida City area was 39,752 (Table 2.5-3) and the area had a population density of 2311 people per square

mile. The population for the area in 2010 was 76,757 or 3402 people per square mile (USCB 2012) (Subsection 4.4.2.2.3.2). As a point of reference based on the 2010 census data, the population per square mile in the USA is 87.4 people per square mile (Subsection 4.4.2.2), approximately 1/15th (6.66 percent) of the density of Miami-Dade County.

Operations-related population growth in Miami-Dade County would consist of 1310 people, (Subsection 5.8.2.1), which equates to less than 0.1 percent of the 2005-2009 population. Assuming that approximately 43 percent of the in-migrating operation workers would reside in Homestead and Florida City area, the increase in population would represent 0.9 percent of the total 2005-2009 population. Because the population in 2020 in Miami-Dade County (including population in the Homestead and Florida City area) is expected to be greater than in 2005-2009, the operations-related population growth would be an even smaller percentage by the start of the operation of Units 6 & 7.

Using NUREG-1437 guidance, land use impacts attributed to operation workforce population growth in Miami-Dade County, would be SMALL since the county has established patterns of residential and commercial development, there is a population density of at least 60 people per square mile, and there is at least one urban area with a population of 100,000 or more within 50 miles. The Homestead and Florida City area meets the NRC criteria for a SMALL land use impact because the population increase would be small and the area has established patterns of residential and commercial development. The area also has a population density of at least 60 people per square mile and at least one urban area with a population of 100,000 or more within 50 miles.

Conclusion

Overall, impacts to land use in Miami-Dade County in general, and in the Homestead and Florida City area in particular, would be SMALL. There would be very little new residential or commercial development and basic land use patterns would remain in place. Existing comprehensive plans would guide development. Project-related population increases would represent 0.1 percent of the 2005-2009 population base and not meaningfully alter land use densities or use.

Therefore, overall land use impacts would be SMALL. To mitigate the potential impacts, FPL would maintain communication with local and regional governmental and nongovernmental organizations, including but not limited to the Department of Planning and Zoning and Department of Community and Economic Development, to disseminate project information in a timely manner. This would allow these organizations to be given the opportunity to plan accordingly.

5.8.2.2.4 Transportation

The effect of the operation of Units 6 & 7 was assessed for impacts on transportation infrastructure and traffic from commuting workers. The analysis focuses on the commuting routes east of the major arterials. FPL believes that the excess capacity of U.S. Highway 1 and Florida's Turnpike is adequate to accommodate additional operational traffic (Table 5.8-10a).

FPL commissioned a traffic study to determine impacts of the additional operation workforce, including temporary outage staff on local traffic (FPL 2010). Numbers of trips generated by the new workforce were estimated from traffic counts at the site entrance of the existing workforce during one week during the peak season. During the traffic counts, the plant had 940 workers. Peak daily traffic volume was 3077 trips, and average daily traffic volume was approximately 2800 vehicles. The peak hour volume occurred during the afternoon commute with peak hour traffic volume of 451 and a peak hour average traffic volume of approximately 400 vehicles. (FPL 2010)

Trip distributions and traffic assignments for operation traffic were based on the traffic patterns of the existing workforce. Most existing traffic arrives from and departs to the north via 137th/ Tallahassee Road. The second most traveled access/egress route is SW 344th/Palm Drive to U.S. Highway 1. Most of the remainder of the existing workforce uses North Canal Drive.

5.8.2.2.4.1 Workers Commuting to the Turkey Point Site

Although not all 806 workers would be present every day, the analysis considered that 806 was 86 percent of the 940 existing unit staff on site during the traffic counts, and considered an increased traffic volume of 86 percent as a good estimate of future traffic generated by Units 6 & 7 commuters.

As provided in Table 5.8-10a, FPL believes that the main arterials have adequate surplus capacity to support additional operations traffic. Therefore the traffic study focused on the streets east of these arterials, and the intersections that will be most impacted by operations traffic. The analysis considered existing intersection counts and seasonal adjustments (FPL 2010).

The analysis concluded that, in general, the roadways between the plant and the major arterials have adequate capacity to support new operation workforce-generated trips, based on a link analysis of the roadways which are part of the Miami-Dade Concurrency Management System (Table 5.8-10b).

The two most critical intersections were evaluated for impacts of the normal operation of Units 6 & 7 (Table 5.8-10c).

The analysis assumed that most improvements to the intersections would remain in place. However, improvements associated with the extension of SW 117th Avenue are not required for the normal operation of Units 6 & 7.

Traffic associated with the Homestead Miami Speedway during one of its major events could further impact traffic on the same routes traveled by Turkey Point workers. However, the peak hours for commuting and visitors arriving at the speedway would not overlap and the Speedway uses a detailed traffic management plan including contra-flow lanes during major events.

5.8.2.2.4.2 Workers Commuting to the Turkey Point Site - Outage

The traffic analysis assumed a maximum temporary outage workforce of 2000 for Units 6 & 7, or an increase of 213 percent over the 940 staff on site during the traffic counts on which this analysis is based. Elsewhere in this document, the number of outage workers is assumed to be 600 for regular outages and 1000 for extended outages. Because 2000 is larger than 1000, the traffic analysis is more conservative and bounds the study. The analysis assumes that access/ egress patterns of the outage workforce would be similar to those of the operations workforce. In addition, the normal workforce for Units 1-5 would be estimated to be 1476. The workforce at Units 6 & 7 is estimated to be 806. The total workforce accessing Turkey Point during a regular outage would be 2882 and for an extended outage would be 3282.

The analysis concluded that, in general, the roadways between the plant and the major arterials have adequate capacity to support outage plus new operation workforce-generated trips, based on a link analysis of the roadways which are part of the Miami-Dade Concurrency Management System (Table 5.8-10d). The two most critical intersections were evaluated for impacts of Units 6 & 7 outage operations (Table 5.8-10e).

The trips generated by the Units 6 & 7 workforce and outage workforce meet Miami-Dade County's traffic concurrency standards. With the roadway improvements implemented for construction, the most affected intersections will operate adequately during normal operation and outages.

5.8.2.2.4.3 Roads Miami-Dade County

As stated in Subsection 2.5.2.2, Miami-Dade County has a well-developed road and transportation infrastructure. The population increase of 403 workers to Miami-Dade County (Subsection 5.8.2) and accompanying licensed drivers (403) could add 806 drivers in Miami-Dade County; however, the Miami-Dade County roads support a driving age population in excess of 1.3 million people and the traffic generated by 806 additional drivers represents an increase of less than 1 percent of the adult population, and would be dispersed throughout the county.

5.8.2.2.4.4 Miami-Dade County Public Transportation

Miami-Dade County operates public transportation services including rail, express bus, and buses that have multiple stops (Subsection 2.5.2.2.2) with a daily ridership of 300,000 (MDC 2008). The population increase of 1310 as a result of the in-migrating workers and their families could increase public transportation usage. However, an increase of as many as 1310 passengers daily represents less than 1 percent of the current ridership.

5.8.2.2.4.5 Evacuation Routes

The severe weather evacuation routes of the Florida City and Homestead area are shown in Figure 2.5-8a. The in-migrating families would add 806 vehicles to an evacuation of Miami-Dade County if each in-migrating family evacuated in two vehicles. Approximately forty-three percent (172 families) of the in-migrating operation workforce would live in the Homestead and Florida City area, for a total of 344 maximum additional vehicles evacuating from this area.

5.8.2.2.4.6 Summary

Based on the traffic engineering study, traffic related to the operation of Units 6 & 7 would result in SMALL impacts to all aspects of traffic in the region of interest and no mitigation beyond that provided for construction traffic, and described in this section, would be warranted.

5.8.2.2.5 Aesthetics and Recreation

This subsection describes the impacts to aesthetics and use of recreational opportunities from the operation of Units 6 & 7 and its associated facilities in the 6-mile vicinity and 50-mile region. Subsection 2.5.2.5 presents basic information on recreation in the vicinity and 50-mile region. Section 3.1 details the plant layout and external appearance. Subsection 5.8.1.3 analyzes the aesthetic impacts of the Turkey Point units and associated facilities.

As stated in Section 2.2, the major land uses within 6 miles are wetland and forestland. The topography of the region and the Turkey Point plant property is relatively flat. As stated in Section 3.9, when completed, the tallest building of Units 6 & 7 would be the containment building reaching a height of 229 feet above finished plant grade. The reactor containment buildings for Units 3 & 4 are 210 feet tall. The grade elevation of the Units 6 & 7 power blocks would be 25.5 feet NAVD 88 and slope at a 0.5 percent grade at the perimeter. The aesthetic impact of new Units 6 & 7 would be similar to Units 3 & 4. Therefore, the aesthetic impacts from the operation of Units 6 & 7 would be SMALL.

In addition to the physical structures and infrastructure of the units, operational activities would produce visual and other physical impacts. The operation of Units 6 & 7 would result in visible plumes from the cooling towers (Subsection 5.3.3.1.1). The plumes from the cooling towers

would be seen during the early morning in cool weather, generally the winter months. The average plume lengths and heights would be relatively short. The visible plumes may prevent direct sunlight from reaching the ground, causing shadowing only for a short amount of time in the morning. The operation of the cooling towers would produce limited fogging and salt deposits within the Units 6 & 7 plant area. Fogging from the operation of the cooling tower would occur for approximately 5 hours per year on the eastern perimeter of the plant area.

Aesthetic Impacts to Recreation

Aesthetic impacts can be visual, auditory, and/or tactile (vibratory, etc). With respect to aesthetic impacts to recreation, these impacts can be experienced by humans directly (e.g., visually) and/or indirectly by affecting the flora and fauna used by humans in the pursuit of recreation (e.g., frightening animals from viewing stations).

Changes to the viewscape that would result from the new power block structure heights, elevation gradient changes, and land cover changes, could be seen from approximately 10 miles away since the area is relatively flat; however, trees and vegetation to the west and north screen the view.

The visual impact of the new unit structures would be minimized through use of topography, design, materials, and color. People boating on Biscayne Bay are accustomed to seeing the structures of Units 1 through 5. The additional structures associated with Units 6 & 7 would not appreciably alter the plant's appearance as viewed from Biscayne Bay. Individuals in the recreational facilities that are not adjacent to the Turkey Point plant property boundary would be unable to distinguish the noise from Units 6 & 7 from urban and traffic noise.

The private and public recreational facilities within 6 miles are Biscayne National Park, Homestead Bayfront Park, Mangrove Preserve, and Homestead Miami Speedway. Therefore, these are the recreational opportunities that are analyzed for aesthetic impacts.

Property boundaries of Biscayne National Park and Homestead Bayfront Park are located within 1 mile of the Turkey Point plant property boundary along the western shore of Biscayne Bay. Recreational users would be able to see the taller structures on the property; however, recreational users are accustomed to seeing Units 1 through 5. It is also possible that the recreational users would be able to see the cooling tower plumes. Recreational users would not experience auditory, olfactory, or tactile impacts. Therefore, aesthetic impacts to these resources would be SMALL and would not warrant mitigation.

Only a small portion of the Mangrove Preserve is located within 6 miles. Recreational users of the preserve would not be able to see Units 6 & 7 through the mangroves. With only a portion of the preserve located approximately 6 miles from the Units 6 & 7 power blocks, recreational users

would experience no auditory or tactile impacts. Therefore, aesthetic impacts to this resource would be SMALL and would not warrant mitigation.

As stated in Subsection 2.5.2.5, Homestead Miami Speedway is a privately owned auto-racing track located approximately 5 miles northwest of Units 6 & 7. Subsection 5.8.2.2.4 describes the transportation impacts for Homestead Miami Speedway from Units 6 & 7 traffic. There would be no visual impact to recreational users because trees and vegetation would shield the units from the speedway. Recreational users would not be able to discern the auditory impacts from Units 6 & 7 from Units 1 through 5 and from the racing vehicles. There would be no plant-induced tactile impacts. Therefore, aesthetic impacts to this resource would be SMALL and would not warrant mitigation.

Use Impacts to Recreation

While aesthetic impacts to recreation are driven by the recreation user's proximity to Turkey Point, use impacts to recreation are driven by the proximity of recreational facilities and events to the user's residence. Operation workers and their families would be expected to use recreational facilities near their residences rather than near their place of work (i.e., the Turkey Point plant property). Some recreational opportunities would be sought out because of their uniqueness, a particular national park for example, independently of the recreation area's proximity to the worker's residence.

The influx of workers during operations could affect the use of recreational areas and participation in recreational events in the 50-mile region. Use impacts to recreation would be the result of the Turkey Point plant-related population growth in Miami-Dade County, and, therefore, increased use of recreational facilities and events. Residential distribution of the in-migrating workers in Miami-Dade County is the most important determinant of recreational facility use.

The in-migrating operation workforce would result in a 0.05 percent increase over the 2005-2009 Miami-Dade County's population. Use of recreational facilities and areas would be expected to increase by a similar percentage. For the purpose of this analysis, the recreational facilities were broadly classified into three groups: (1) wildlife management areas, national wildlife refuges, and preserves, (2) state parks, and (3) privately owned recreational facilities expected to be impacted by the operation of Units 6 & 7. Tables 2.5-29 and 2.5-30 present information about these facilities and, where available, information about the current use rates and capacities of those facilities. Subsection 2.5.2.5.2 discusses these facilities and recreational events in the region.

The wildlife management areas, national wildlife refuges, and preserves could be impacted by the Turkey Point-related population increase. There are eight wildlife management areas, national wildlife refuges, and preserves in the region that are open to the public (Table 2.5-29). Generally, agencies managing these properties do not tabulate the number of annual visitors or

determine capacity information. All 1310 residents of the project-induced population increase in the region could use the areas, refuges, and preserves. Because the wildlife management areas, national wildlife refuges, and preserves are so large and have open and wooded lands appropriate for multiple uses (snorkeling/scuba diving, nature walks, picnics, camping, fishing), they can accommodate a large number of people. Impacts to wildlife management areas, national wildlife refuges, and preserves from the in-migrating operation workforce would be SMALL and would not warrant mitigation.

The state park system could be impacted by the Turkey Point-related population increase. The 11 state parks in the region (Table 2.5-30) have a total annual visitors count of 2,739,696 in July 2007 to June 2008 and a total daily capacity of 29,147 visitors, or approximately 10,638,655 annually. Therefore, the 11 state parks within 50 miles could accommodate an additional 21,641 daily visitors. The operations-related population increase of 1310 people represents approximately 6 percent of the available daily capacity. Because the state park system has open and wooded lands appropriate for multiple uses (snorkeling, nature walks, picnics, camping, fishing), the state park system can accommodate additional use more readily than local park systems, which often specialize in dedicated use opportunities (tennis, swimming pools, baseball fields). Impacts to state parks from the in-migrating operation workforce would be SMALL and would not warrant mitigation.

The privately owned Homestead Miami Speedway may be impacted by the operation of the new units. The commuter traffic to Turkey Point is not expected to interrupt traffic flow during the Speedway's main racing events. Subsection 5.8.2.2.4 provides more details. The in-migrating population would not affect the capacity of Homestead Miami Speedway. Recreational impacts would be SMALL and would not warrant mitigation.

The privately owned Mangrove Preserve is not open to the public. Impacts to the preserve were not determined.

Increased use of community, municipal, and neighborhood parks would likely reflect the same rate of project-induced population increase.

In summary, during operation, some employees and their families would use the regional recreational facilities. However, the increase attributable to plant operation would be small compared to overall use of these facilities. Impacts of facility operation on recreation would be SMALL and would not warrant mitigation.

5.8.2.2.6 Housing

Impacts on housing from the operation of Units 6 & 7 would depend on the number of operation workers that would relocate from outside Miami-Dade County and the type and location of housing those workers would desire. As previously described, indirect workers are expected to

already reside in the county, so no indirect worker would require additional housing. Therefore, it was conservatively assumed that a maximum of 403 workers would migrate into Miami-Dade County and require housing as a result of the operation of Units 6 & 7.

Forecasting residential distribution patterns in a large geographical area is inherently problematic because workers' preferred housing is driven by many individual variables. Housing options are varied: owner versus rental occupancy; detached versus attached units; single-unit versus multiple-unit complexes; permanent units versus mobile units (mobile homes), and the need for short-term (motel/hotel) accommodations versus more permanent solutions. To present a more realistic analysis, the impacts to housing during the operation of Units 6 & 7 for Miami-Dade County in general were analyzed as well as the Homestead and Florida City area.

The housing required by the operation workforce would be different than the housing required by the construction workforce for the following reasons: the operation workforce is much smaller than the construction workforce; the operation workers would be permanent residents of the county and therefore require permanent housing (as opposed to temporary housing, as required by the construction workers); and the wages of operation workers are estimated to be higher than construction workers and wages are a proxy for type and location of housing sought.

Permanent housing is generally comprised of single-family units that are frequently owner-occupied. Permanent housing represents a long and large financial commitment. Therefore, operation workers may select housing based on its proximity to family-friendly amenities and on lifestyle choices. Operation workers would likely choose to purchase existing housing, in part, because the urbanized character of Miami-Dade County, particularly that portion of the county with convenient access to transportation infrastructure accessing Turkey Point. Little vacant land exists in those areas that could be converted to new housing. As described in Subsection 5.8.2, little land conversion in the county, in general, would be expected to be the result of in-migrating operation workers. The county has well-defined residential neighborhoods and residential and commercial districts.

Housing choices are determined, in part, by occupant wages. The average annual wage of the Units 6 & 7 operation workforce is expected to be higher than the current mean or average wage in the county. As described in Subsection 4.4.2.2.1, the average annual wage of a nuclear reactor power operator, who would be expected to be employed at Units 6 & 7, is $81,980 (Table 5.8-3). The average annual wage for all industries in Miami-Dade County is $44,042 (Table 2.5-12). Because wages are a proxy for the type, price, and location of housing sought, operation workers could seek some of the county's more expensive priced housing. The median price of an owner-occupied house in the county in 2005-2009 was $277,200. Table 2.5-31 displays Miami-Dade County housing data. Should workers elect to erect new residential units, construction location and standards would be guided by the adopted, applicable comprehensive plans described in Subsections 2.5.2.4 and 5.8.2.

Although there are uncertainties in the Florida and Miami-Dade County housing market, prices of existing higher-priced, single-family and multifamily housing could rise as a result of the increased demand from operation workers. The county and local governments in the county would benefit from an increase in taxable value if housing values rose. Conversely, price pressure on owner-occupied units and higher-priced rental units could change the patterns of residency options for families with lower incomes. Subsection 5.8.3 presents impacts to low-income populations. However, given the abundance of rental units and modestly priced owner-occupied housing in the county, rental housing rates and modestly priced owner-occupied units would likely experience little upward pressure on prices.

Subsection 2.5.2.6 presents data about the existing housing conditions in Miami-Dade County and the Homestead and Florida City area. Subsection 4.4.2.2.6 describes housing conditions during the construction period. The sources for all data presented in this section are Subsections 2.5.2.6 and 4.4.2.2.6, except where cited.

Miami-Dade County (ROI)

As described in Subsection 2.5.2.6, Miami-Dade County had 135,004 total vacant housing units in 2005-2009. In Miami-Dade County, an additional 110,657 housing units were added to the total inventory for between 2000 and 2005-2009, increasing the 2000 housing inventory by an additional 13 percent (Table 2.5-31). Permanent and rental housing could accommodate the entire in-migrating operation workforce.

If the 403 in-migrating operation workers elected to make Miami-Dade County their home, readily available housing could accommodate them. Miami-Dade County could accommodate the entire operation workforce, based on the vacancy of housing units of all types. The entire in-migrating workforce could be accommodated in vacant permanent housing units and the entire in-migrating workforce could be accommodated in vacant rental units. Should workers elect to build new housing, comprehensive plans are in place to guide development (Subsection 2.5.2.4).

Refueling outages would occur at least annually, and sometimes semiannually, when Units 3, 4, 6, & 7 are all operational. It is estimated that the maximum increase in workforce would be 1000 for extended outages. These workers would need temporary (45 days) housing (Table 5.8-5). Most of the outage workers would stay in local extended stay hotels, rent rooms in local homes, or bring their own housing in the form of campers and mobile homes. The outage workforce would not affect the permanent housing market in the region.

The current housing inventory would be sufficient to accommodate all of in the in-migrating workforce. Impacts to housing in the ROI would be SMALL.

Homestead and Florida City Area

As stated in Subsection 5.8.2, approximately 43 percent of Turkey Point's current workforce resides in the Homestead and Florida City area. For this analysis, it was assumed that approximately 172 operation workers could settle in the Homestead and Florida City area.

As described in Subsection 2.5.2.6, Homestead and Florida City area had 4096 total vacant housing units in 2005-2009. If 172 workers and their families moved into the area, as would be expected, the required 172 housing units would represent 4.3 percent of the area's vacant units in 2005-2009, if workers' requirements for type, size, price, condition, or other characteristics were met. However, of the 4096 total vacant housing units, 175 units are considered to be for seasonal, recreational, or occasional use and were assumed to be unavailable to operation workers. The Homestead and Florida City area issued 12,637 single-family building permits between 2001 and 2010, nearly doubling the area's 2000 total housing inventory (Table 2.5-38), which suggests that the area is experiencing and anticipating residential growth. This increase in available housing provides more options for the operation workers to live in the Homestead and Florida City area. As described in Subsection 5.8.2, there is some undeveloped land in the Homestead and Florida City area which is zoned for residential development. Areas already developed include well-defined residential neighborhoods and commercial areas. Should operation workers elect to construct new homes in the area, the applicable comprehensive plan would provide guidance.

The current housing inventory would be sufficient to accommodate all of in the in-migrating workforce. Impacts to the housing in the Homestead and Florida City area would be SMALL.

Conclusion

Miami-Dade County has ample existing housing to accommodate the entire in-migrating operation workers. In addition, the issuance of building permits for new homes suggests that the inventory has continued to grow since 2000. The existing inventory includes a wide range of housing choice by type, location, and by price. The Homestead and Florida City area has enough housing to accommodate all the in-migrating workers. Comprehensive plans are in place to guide development should new housing result from the proposed project. Employment resulting from the operation of Units 6 & 7, beginning with the initial arrival of operation workers during the construction period, would increase gradually, allowing market forces to accommodate the new arrivals.

Also, county and local governments in Miami-Dade County, including Homestead and Florida City, would benefit from the increased taxable value of existing housing and from any new residential construction. It is concluded that Miami-Dade County and the Homestead and Florida City area would benefit from positive tax impacts. Therefore, impacts to the Miami-Dade County

and the Homestead and Florida City areas housing markets would be SMALL and mitigation would not be warranted.

To minimize any potential impacts to housing availability, FPL could initiate early communications with local and regional governmental organizations, including the Miami-Dade Planning and Zoning Department and the Greater Homestead and Florida City Chamber of Commerce, to disseminate information related to Units 6 & 7, such as the schedule of expected worker influx. County and regional planning organizations, and, ultimately, developers and real estate agencies, could factor the details of the emerging housing market into their decision-making and plan accordingly.

Impacts to the housing in Miami-Dade County and the Homestead and Florida City areas would be SMALL and no mitigation would be warranted.

5.8.2.2.7 Public Services

5.8.2.2.7.1 Water Supply Facilities

The impacts of both operation demand and population increases during the operation of Units 6 & 7 on local public water resources have been considered. Operations-related impacts are primarily based on the population increase caused by the number of workers and their families migrating into Miami-Dade County. This in-migrating population is estimated to be 1310 people (Table 5.8-1).

The South Florida Water Management District (SFWMD) is the regional governmental agency that oversees the water resources in the southern half of Florida. SFWMD covers 16 counties, including Miami-Dade County and serves 7.5 million residents. The SFWMD serves local governments by supporting efforts to safeguard existing natural resources and meet future water demands through one of the four water supply planning areas. The four water supply planning areas are the Upper East Coast, the Lower East Coast, the Lower West Coast, and the Kissimmee Basin. The planning areas are generally defined by the drainage divides of major surface water systems in South Florida. The Lower East Coast (LEC) Planning Area of the SFWMD encompasses approximately 6100 square miles and includes Miami-Dade County (SFWMD 2005).

The largest water supplier within Miami-Dade County is the Miami-Dade Water and Sewer Department (MDWASD). MDWASD provides drinking water to approximately two million customers in Miami-Dade County (Table 5.8-11) and, currently, draws drinking water from the Biscayne aquifer. The MDWASD water service area contains interconnected systems and thus, for the most part, functions as a single service area. The MDWASD service area can be broken down into three subareas by water treatment facilities: the Hialeah-Preston Water and Sewer Department (WASD), serving the northern part of Miami-Dade County, the Alexander Orr, Jr.

WASD, serving the central and portions of the southern part of Miami-Dade County and the South Dade WASD, serving the southern part of Miami-Dade County. The MDWASD has a 20 year water use permit issued by the SFWMD which limits its annual allocation to 149,106 million gallons and its monthly maximum allocation to 13,047 million gallons. These allocations are further limited by a wellfield operational plan, described in Limiting Condition 27 of the water use permit. (MDWASD 2008)

In addition to MDWASD, there are four other water suppliers within Miami-Dade County that provide water to parts of unincorporated Miami-Dade County and within their respective municipal boundaries: city of North Miami, city of North Miami Beach, city of Homestead, and Florida City. The city of North Miami and the city of North Miami Beach supply water within their municipal boundary as well as outside of their municipal boundary to certain northern parts of unincorporated Miami-Dade County. The city of North Miami Beach supplies water within its municipal boundary as well as outside its municipal boundaries to certain northern parts of unincorporated Miami-Dade County. The city of Homestead provides water within its municipal boundary and for a portion of unincorporated Miami-Dade County, including the Redavo development, from 6 city-owned withdrawal wells. The city of Homestead also has an agreement with the MDWASD to provide some water service within portions of Homestead municipal boundary. Florida City provides water service within its incorporated boundaries from 4 production wells (MDWASD 2008) and also provides water to portions of unincorporated Miami-Dade County as a water supplier.

Currently, several of the water suppliers in Miami-Dade County have projects being either proposed, initiated, or under construction to increase drinking water capacity. MDWASD has proposed alternative water supply projects to meet MDWASD's anticipated increased water demands through 2030. Projects include: expanding disinfection systems in the aquifer storage recovery system; constructing a reverse osmosis (RO) water treatment plants to treat Floridan aquifer water, hence providing additional capacity; and adding water reclamation plants to the north, south and west districts. These projects are part of MDWASD's commitment to provide a total of 170 mgd of reuse water in accordance with the county's existing 20 year water use permit. MDWASD is also constructing a new water treatment plant (WTP) in south Miami-Dade County, the South Miami Heights (WTP) and wellfield should be complete by 2012 (MDWASD 2008).

Two other projects involve the city of North Miami Beach and the city of Homestead. The city of North Miami Beach is planning for a future expansion, by 2015, to further increase the capacity of the WTP to a total of 42 mgd and the city of Homestead is considering upgrading the existing well pumping capacity or installing additional wells to supply water to the city owned WTP. Additionally, Florida City plans to increase the city owned WTP capacity by installing additional

wells and withdrawing water from the Floridan aquifer, which require further treatment and possible RO facility prior to distribution (MDWASD 2008).

Miami-Dade County (ROI)

As described in Section 3.3, water from the Miami-Dade Water and Sewer Department (MDWASD), which is part of the Miami-Dade County's public water system, would be used to provide the necessary water for potable onsite uses during operation for drinking water, sanitary uses, and fire protection.

It is estimated that Units 6 & 7 would utilize 1.35 mgd of water for normal onsite operational use and a maximum of 3.68 mgd of water for periods of short duration (Table 3.3-1). By the start of the operation of Unit 6 in 2022, the MDWASD system, based on 2007 service area population, should be operating at about 73.95 percent capacity when the 20 mgd South Miami Heights Water Treatment Plant comes online in 2012 (MDWASD 2008). The MDWASD system excess capacity would be reduced by approximately 0.29 percent with normal onsite operations use 0.78 percent under maximum onsite operational demand, for an estimated usage of 74.23 percent (normal operation) to 74.73 percent (maximum use operation) of capacity. The increased use would not stress the public water supplies or infrastructure. Therefore, the impacts would be SMALL and would not warrant mitigation.

As indicated in Table 5.8-1, the operation of Units 6 & 7 could bring as many as 1310 new workers and family members to Miami-Dade County. As described in Subsection 2.5.2.7, municipal water suppliers in the county have excess capacity. The impact to the local water supply systems from operations-related population growth was estimated by calculating the amount of water that would be required by the in-migrating operations-related population and comparing it to the publicly available resources. People in the United States use an average of 100 gpd for all uses (EPA Aug 2008). The increase of 1310 people could increase consumption by 131,000 gpd (0.131 mgd) in Miami-Dade County. The increased use would not stress public water supplies or infrastructure.

Collectively, the major public water suppliers in Miami-Dade County in 2007 are operating at 74.74 percent capacity (Table 5.8-11). If all 1310 operation-related individuals relocated to Miami-Dade County, the service area population would increase by 0.05 percent. The additional demand of approximately 0.1310 mgd would increase the operating capacity to 75.02 percent. The increased use would not stress public water supplies or infrastructure. Impacts to Miami-Dade County would be SMALL and would not warrant mitigation.

Homestead and Florida City Area

The impact to the Homestead and Florida City area, which is a likely area for some of the operation workers to relocate, was estimated by adding the assumed in-migrating operation-

related population to the current population in the area. The increased population would represent approximately 43 percent of the total operation workforce, or 559 people, into the Homestead and Florida City area. This population increase would, in turn, increase demand on the public water infrastructure for Homestead and Florida City systems collectively, from 70.79 percent capacity usage to 71.05 percent capacity usage (Table 5.8-11).

Therefore, the increased demand from the estimated increase in population as a result of the operation-related workforce would not exceed the available capacity of the municipal water supplies within Miami-Dade County. Also, the approximately 43 percent population distribution within the Homestead and Florida City area would not exceed the available capacity of the combined water supplies of the Homestead and Florida City area. Therefore, the impacts in Miami-Dade County and to the Homestead and Florida City area would be SMALL and would not require additional mitigation.

Conclusion

Currently, several of the major water suppliers in Miami-Dade County have projects being either proposed, initiated, or under construction to increase drinking water capacity. MDWASD has proposed alternative water supply projects to meet MDWASD's anticipated increased water demands through 2030. Projects include: expanding disinfection systems in the aquifer storage recovery system; constructing a reverse osmosis (RO) water treatment plants to treat Floridan aquifer water, hence providing additional capacity; and adding water reclamation plants to the north, south and west districts. These projects are part of MDWASD's commitment to provide a total of 170 mgd of reuse water in accordance with the county's existing 20 year water use permit. MDWASD is also constructing a new water treatment plant (WTP) in south Miami-Dade County, the South Miami Heights (WTP) and wellfield should be complete by 2012 (MDWASD 2008).

The city of North Miami Beach is planning for a future expansion, by 2015, to further increase the capacity of the WTP to a total of 42 mgd. The city of Homestead is considering upgrading the existing well pumping capacity or installing additional wells to supply water to the city owned WTP. Florida City plans to increase the city owned WTP capacity by installing additional wells and withdrawing water from the Floridan aquifer, which require further treatment and possible RO facility prior to distribution (MDWASD 2008).

The public water infrastructures in Miami-Dade County would not be stressed from the population related increase in the area and the operational demand of Units 6 & 7. The major suppliers are currently using about 74.74 percent of their capacity. With the combined demand from the additional population and the on-site use, the capacity utilization rate will rise to about 75.02 percent (Table 5.8-11), including the South Miami Heights WTP, but excluding planned

improvements resulting in capacity expansion likely to be in place prior to Unit 6 startup in 2022 and Unit 7 start in 2023.

5.8.2.2.7.2 Wastewater Treatment Facilities

Sanitary treatment would be provided by a packaged sanitary treatment plant located on the Units 6 & 7 plant area. The sanitary treatment plant would be designed to process sanitary effluent from Units 1 through 7. Therefore, onsite operation for Units 6 & 7 would have a SMALL impact on public wastewater services.

Subsection 2.5.2.7 describes the public wastewater treatment systems in Miami-Dade County, their plan-designed average flows, and monthly average wastewater processed. Wastewater treatment facilities in Miami-Dade County have at least 15 percent available capacity with the exception of the City of Homestead (Table 2.5-38).

Reclaimed water from the MDWASD South District Wastewater Treatment Plant would be used as the primary source of makeup water to the Units 6 & 7 circulating water system. The reclaimed water would be further treated in the FPL reclaimed water treatment facility.

Impacts to local wastewater treatment systems would occur as the population increases as a result of the in-migration of the operation-related workers and their families. The magnitude of the impact can be conservatively estimated by assuming all of the water used by this population would go to a wastewater treatment facility. As previously described, the operations-related population increase could require 0.1310 mgd of drinking water and, by extension, 0.1310 mgd additional wastewater treatment capacity. As described in the following paragraphs, the in-migration of the maximum operations-related workforce and their families would increase the current wastewater treatment system use for Miami-Dade County from approximately 79.85 to 79.88 percent (Table 5.8-12).

Miami-Dade County (ROI)

Subsection 2.5.2.7 describes the public wastewater treatment systems in Miami-Dade County, their plant-designed average flows, and monthly average wastewater processed. Yearly average wastewater processed in Miami-Dade County is 298.62 mgd, with a systems capacity of 374.00 mgd. If an additional 0.1310 mgd were processed in the county, the average daily flow of wastewater to be processed would increase by 0.04 percent, which would increase the capacity use rate by 79.88 percent, in the Miami-Dade County's total capacity (Table 5.8-12). Therefore, impacts to wastewater treatment capacity within Miami-Dade County would be SMALL and would not require mitigation.

Homestead and Florida City Area

The Homestead wastewater treatment facilities (WWTF) are currently operating at approximately 102.20 percent (Table 5.8-12) of capacity; however, the city of Homestead's WWTF use the Miami-Dade Water and Sewer Department (MDWASD) system as backup and excess flows are diverted to the county wastewater treatment facilities. These excess flows are included in the MDWASD South District Wastewater Treatment Plant (SDWWTP) flow reports. The wastewater generated in Florida City falls under the jurisdiction of the SDWWTP. The SDWWTP was operating at 78.54 percent of its capacity in 2009 (Table 5.8-12). If the estimated distribution of operations-related workers (559 people) settled in the area of Homestead and Florida City, the overall capacity could accommodate the increase in population, using both the Homestead WWTF and the SDWWTP due to the remaining capacity at the SDWWTP. Therefore, impacts on wastewater treatment facilities due to operation-induced population increases for Homestead and the SDWWTP would be SMALL and would not require mitigation.

To mitigate any potential impacts, FPL could initiate early communication with local and regional governmental organizations, including planning commissions and local and regional economic development agencies, such as the MDWASD, the Miami-Dade Department of Environmental Resources Management, or the Florida Department of Environmental Protection, to disseminate Unit 6 & 7-related information. Local governments and planning groups would have time to plan for the influx. Infrastructure upgrades and expansions could be funded, at least in part, by Unit 6 & 7-related property and sales and use tax payments.

5.8.2.2.7.3 Law Enforcement, Fire Protection, and Medical Services

Law Enforcement

With respect to onsite law enforcement, FPL would employ its own security force. Security services and emergency response are addressed in the Emergency Plan contained in Part 5 of this COL Application.

Miami-Dade County (ROI)

Residents-to-law enforcement officer ratios for Miami-Dade County are presented in Table 5.8-13. Currently, the ratio of residents-to-law enforcement officer is 825 to 1.

With respect to the influx of workers and their families for operation of Units 6 & 7, 1310 people would move into Miami-Dade County (Table 5.8-1), and this population increase would increase the residents-to-law enforcement officer ratio in the county by 0.05 percent, creating a SMALL impact.

Assuming the county is already near or at its capacity to provide law enforcement protection, maintenance of the current residents-to-law enforcement officer ratio would be desirable. Therefore, to accommodate the additional population caused by Units 6 & 7, two additional law enforcement officers (and associated equipment) would be needed in Miami-Dade County during the operation period to maintain the current ratio.

Homestead and Florida City Area

Residents-to-law enforcement officer ratio for the Homestead and Florida City area is presented in Table 5.8-13. Currently, the Homestead and Florida City area ratio of residents-to-law enforcement officers is 480 to 1. With respect to the influx of workers and their families during operation, approximately 43 percent, or 559 people, would increase the 2007 residents-to-law enforcement officer ratio by 0.86 percent, creating a SMALL impact.

This conclusion and its mitigations are based, in part, on a NRC analysis of nuclear plant refurbishment impacts sustained during original plant construction presented in NUREG-1437. The NRC selected seven case study plants whose characteristics resembled the spectrum of nuclear plants in the United States today. The NRC reported that

> "**…** no serious disruption of public safety services occurred as a result of original construction at the seven case study sites. Most communities showed a steady increase in expenditures connected with public safety departments. Tax contributions from the plant often enabled expansion of public safety services in the purchase of new buildings and equipment and the acquisition of additional staff."

This impact could be mitigated by the use of the increased property and sales/use tax revenues that would be generated by operation of the new units. However, expanding law enforcement services, including the hiring of additional personnel, would likely begin before a sufficient amount of these tax revenues would be available to local governments. Therefore, local governments could access other funding sources or issue bonds until the tax revenues would become available. Also, the full operation workforce would not be in place until approximately month 80 of construction activities (Table 4.4-7), giving local governments time to plan and budget accordingly. Additionally, FPL could communicate regularly with local and regional governmental officials about Units 6 & 7 and its schedules, allowing local and regional officials opportunity to plan for the population influx.

During the peak construction period, in order to maintain pre-Units 6 & 7 construction ratios, six additional law enforcement officers would be required in the ROI (Subsection 4.4.2.2.7.3). The operation workforce would not be in place until approximately month 80 of construction, well after the construction peak (Figure 4.4-1). During the period of operation, two additional law enforcement officers from the current level and associated equipment would be required in the

Miami-Dade County (Table 5.8-13). Therefore, assuming that six additional law enforcement officers were hired in the county during peak construction period, only two of those officers would be required by the end of construction (when the number of workers would drop to 806, Figure 3.10-1) to serve the operations-related population increase. This could cause an overstaffing of four officers and an overstock of equipment. In order to reduce ratios to pre-construction of Units 6 & 7 levels, officers could be attritioned from their duties. Alternatively, officers could be retained to supplement the general provision of law enforcement services in Miami-Dade County, thereby reducing the ratios. Units 6 & 7-related tax payments, including both property taxes and sales and use taxes made by the Units 6 & 7 and its employees, could continue to assist in funding these services.

Fire Protection Services

Fire protection services and emergency response are addressed in the Emergency Plan contained in Part 5 of this COL Application.

Miami-Dade County (ROI)

Residents-to-active firefighter ratios for Miami-Dade County are presented in Table 5.8-14. Currently, the residents-per-active firefighter ratio in the county is 702 to 1. If the number of active firefighters in Miami-Dade County remained at this level, the additional population of 1310 would increase the residents-to-active firefighter ratios in the county by 0.05 percent, creating a SMALL impact. To accommodate the additional population, two additional active firefighters (and associated equipment) would be needed in Miami-Dade County during operation of Units 6 & 7.

Homestead and Florida City Area

As noted in Subsection 2.5.2.7.2, Miami-Dade County Fire and Rescue provides fire protection services for the Homestead and Florida City area. Because the population in the Miami-Dade County Fire and Rescue service area cannot be accurately determined, it is not possible to calculate the current residents-to-active firefighter ratio. However, if the Homestead and Florida City area experiences a population increase of 559 people, or 0.86 percent of the 2005-2009 population, the ratio of residents-to-active firefighters in the Miami-Dade Fire and Rescue service area would increase by less than 1 percent (because the service area would have a larger population base), creating a SMALL impact.

This impact could be mitigated by the use of the increased property and sales/use tax revenues that would be generated by operation of the new units. However, expanding fire suppression services, including the hiring of additional personnel, would likely begin before a sufficient amount of these tax revenues would be available to local governments. Therefore, local governments could access other funding sources or issue bonds until the tax revenues would become available. Also, the operation workforce would not be completely in place until

approximately month 80 of construction activities, giving local governments time to plan and budget accordingly. Additionally, FPL could communicate regularly with local and regional governmental officials about Units 6 & 7 and its schedules, allowing local and regional officials opportunity to plan for the population influx.

As with the analysis of the adequacy of law enforcement, this conclusion and its mitigations are also based, in part, on the NRC's nuclear plant refurbishment impact conclusions presented in NUREG-1437.

During the peak construction period, in order to maintain pre-Units 6 & 7 construction ratios, seven additional active firefighters would be required in Miami-Dade County. The operation workforce would reach its peak in month 80 of construction (Table 4.4-7), well after the peak construction period (Figure 4.4-1). During the period of operation, two additional active firefighters and associated equipment would be required in Miami-Dade County to maintain preconstruction ratios (Table 5.8-14). Therefore, assuming that within Miami-Dade County, seven additional active firefighters were hired during the peak construction period (Table 4.4-20), only two of those firefighters would be required by the end of construction (when the number of workers would drop to 403) to serve the operations-related population increase (Figure 3.10-1). This could cause an overstaffing of five firefighters and an overstock of equipment. In order to reduce ratios to preconstruction of Units 6 & 7 levels, firefighters could be attritioned from their duties. Alternatively, firefighters could be retained to supplement the general provision of fire protection services in Miami-Dade County, thereby reducing the ratios. Units 6 & 7-related tax payments, including both property taxes and sales and use taxes made by the Units 6 & 7 and its employees, could continue to assist in funding these services.

Medical Services

Detailed information concerning the medical services in Miami-Dade County is provided in Subsection 2.5.2.7.3.

Medical services and emergency response are addressed in the Emergency Plan contained in Part 5 of this COL Application. Minor injuries to operation workers would be assessed and treated by medical personnel onsite. Other injuries would be treated at hospitals in Miami-Dade County, depending on the severity of the injury. Agreements are in place with some local medical providers to support emergencies.

The opportunities for medical care in Miami-Dade County are provided in Table 2.5-41. According to Table 2.5-41, in 2006, there were 8420 staffed hospital beds in the county. As indicated in Table 2.5-3, the 2005-2009 population of Miami-Dade County was 2,457,044. Adding 1310 residents to the county population would increase the 2005-2009 population by 0.05 percent (Subsection 5.8.2.1). The 0.05 percent increase in the annual admissions and the annual

outpatient visits would not be noticeable or burden existing medical service capacity. Therefore, the potential impacts due to the operation of Units 6 & 7 on medical services would be SMALL and mitigation would not be warranted.

5.8.2.2.8 Education

It is estimated that approximately 322 school-aged children would be part of the operations-related in-migration (Table 5.8-1). Since the Miami-Dade County Public Schools District (M-DCPS) covers the entire county, it was assumed that all of the school-aged children would reside in Miami-Dade County. This subsection describes the public and private school systems and accredited post-secondary institutions in Miami-Dade County. The sources for the data presented are Subsections 2.5.2.8 and 4.4.2.2.8, except where cited.

5.8.2.2.8.1 Miami-Dade County Public School District

It is assumed that each in-migrating operation worker would have 0.8 school-age children. Therefore, an in-migrating operation workforce of 403 persons would bring approximately 322 school-aged children. This analysis conservatively assumed that all school-aged children would attend public schools.

As shown in Table 2.5-42, the new and expanded public primary and secondary facilities would provide capacity for an additional 13,746 students. Since the capacity is greater than the estimated number of in-migrating students, the education system within the county could accommodate all students that would accompany the in-migrating operation workers. The school-aged children would increase Miami-Dade County Public School District's 2010-2011 enrollment by 0.09 percent.

5.8.2.2.8.2 Homestead and Florida City Area

As stated in Subsection 2.5.2.8, the Homestead and Florida City area is part of District IX of the Miami-Dade County public school system. The student population in the Homestead and Florida City area could increase by 138 students (Table 5.8-1). The number of school-aged children likely to locate in the Miami-Dade County Public School system, District IX region, but outside of the immediate Homestead and Florida City area, was not determined. Therefore, the percentage impact to the District IX region could not be specifically determined. However, District IX had 55,860 students enrolled in the 2010-2011 school year. Therefore, the impact would be less than 1 percent even if all 322 children in-migrating to Miami-Dade County were to locate in the District IX region. Hence, the impacts to public schools in the Homestead and Florida City area would be SMALL.

5.8.2.2.8.3 Private Schools — Pre-Kindergarten through 12

Miami-Dade County

The assumption was made that the same percentage of in-migrating school-age children would attend private school as those who currently attended private school (15 percent). Of the 322 in-migrating children (Table 5.8-1), approximately 48 may attend private school. As mentioned in Subsection 2.5.2.8.2, there was a total enrollment of 61,161 students in Miami-Dade County private schools. The 48 new students represent less than 0.1 percent of the total private school enrollment. Impacts to private education in the region of influence would be SMALL and not warrant mitigation.

Homestead and Florida City

The assumption was made that the same percentage of in-migrating school-aged children could attend private schools in the Homestead and Florida City area as school-aged children attending private schools in Miami-Dade County (15 percent). Therefore, of the 138 in-migrating school-aged children, 21 may attend private schools. There was a total private school enrollment of 2263 students in the Homestead and Florida City area. The 21 new students represent less than 1.0 percent of the total enrollment. Impacts to private education in the Homestead and Florida City area would be SMALL and not warrant mitigation.

5.8.2.2.8.4 Conclusion

Increased property tax revenues as a result of the increased population, and property taxes on Units 6 & 7, could fund any needed additional teachers and facilities. The Florida Education Finance Program and equalized funding legislation would ensure that the Miami-Dade County Public School District would receive funding to support additional educational services. However, it also means that the property taxes may not go directly to the Miami-Dade County Public School District (Subsections 2.5.2.3 and 5.8.2.2.2). FPL could provide the local communities with information regarding the Units 6 & 7 construction and subsequent operation schedule, giving the school district, particularly Regional District IX, time to make accommodations for the additional influx of students. It is concluded that impacts to Miami-Dade County and Homestead and Florida City area would be SMALL and would not warrant mitigation. Impacts to the private school system would also be SMALL.

5.8.2.2.8.5 Post-Secondary Institutions

Subsection 2.5.2.8.3 describes post-secondary institutions, colleges and universities, vocational schools, and technical colleges within Miami-Dade County and 50-mile radius. The peak operation workforce would not be reached until 2022. FPL could provide the local education institutions, including post-secondary institutions, with information regarding the Units 6 & 7

construction and subsequent operation schedule, giving the institutions time to make accommodations for the influx of operation workers or worker family members that may seek additional post-secondary education or training. The institutions could also modify curriculum offerings and/or contract with FPL to provide onsite and offsite academic courses and job-specific training.

5.8.3 ENVIRONMENTAL JUSTICE IMPACTS

Environmental justice refers to a federal policy under which each federal agency identifies and addresses, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority or low-income populations. The NRC has a policy on the treatment of environmental justice matters in licensing actions (69 FR 52040). The USCB 2010 data at the block group level was used to identify concentrations of minority and of low-income populations. Subsection 2.5.4 defines minority and low-income populations. Figures 2.5-24 through 2.5-30 (Subsection 2.5.4) identify minority and low-income populations within 50 miles. There are 1627 census block groups that are at least partially within 50 miles, 1222 of which are wholly in Miami-Dade County. It was assumed that all of the in-migrating workforce would settle within Miami-Dade County; therefore, the health and environmental impacts and socioeconomic impacts evaluated in this environmental justice analysis are focused on Miami-Dade County. Of the 1222 block groups in Miami-Dade County, 319 have significant Black Race populations, 335 have significant racial aggregate populations, and 783 have significant Hispanic ethnic populations. The Turkey Point plant property is located in a block group meeting the Other race, the aggregate of races, and the Hispanic ethnicity criteria. Two-hundred-twelve block groups in Miami-Dade County contain a significant percentage of low-income households. The closest low-income block group to the proposed site is approximately 4.7 miles north of the plant property.

For the environmental justice analysis, two types of impacts were evaluated: health and environmental impacts and socioeconomic impacts. The following paragraphs summarize the magnitude of each type of impact to the general population and then describe whether minority or low-income populations would experience disproportionately high and adverse impacts. The most likely pathways by which adverse environmental impacts associated with operations could affect human populations were identified, the level of significance of the impact was determined, and the characteristics of the minority or low-income populations would result in disproportionately high and adverse impacts to those populations were assessed. Several socioeconomic resources were also evaluated to determine if operations-related activities could disproportionately, in a high and adverse manner, impact minority or low-income populations. If the impacts to the general population were found to be SMALL, and there were no cultural practices, subsistence living activities, or pre-existing health conditions that would change the significance level of the impact, it was concluded there would be no disproportionately high and adverse impact on low-income or minority populations.

5.8.3.1 Health and Environmental Impacts

There are three primary pathways for health and environmental impacts: soil, water, and air.

Operation activities would not affect soils at Units 6 & 7. There would be no impacts to nearby residents, and, therefore, no disproportionately high and adverse impacts on minority or low-income populations. Impacts to soils from Units 6 & 7 would be SMALL and would not require mitigation.

As described in Section 3.3, operational activities for Units 6 & 7 would use approximately 55 mgd (100 percent reclaimed water) to 124.4 mgd (100 percent radial collector wells) of makeup water for cooling.

As described in Subsection 5.2.2.1, the makeup water for cooling Units 6 & 7 would be provided by the MDWASD SDWWTP from reclaimed water. Currently, SDWWTP disposes of treated wastewater by injection into the Boulder Zone of the lower Floridan aquifer. Use of reclaimed water is addressed by the water use permit for the Miami-Dade consolidated public water supply, issued by the South Florida Water Management District (November 1, 2010). The permit contains several limiting conditions (Numbers 39–43) that apply to the reuse of reclaimed water. Presented in Exhibit 14 and Limiting Condition 41 of the permit is the requirement that MDWASD work with FPL to provide up to 70 mgd of reclaimed water for nuclear projects and 14 mgd for Unit 5 (a combined cycle unit). There are other projects anticipated to make use of SDWWTP wastewater (Exhibit 14). These other water reuse projects listed in Exhibit 14 for the SDWWTP could use a total of 188 mgd of reclaimed water. The largest of the reuse projects planned for the SDWWTP are: (1) furnishing 75.7 mgd of reclaimed water for the Biscayne Bay Coastal Wetlands Project, a component of the Comprehensive Everglades Restoration Plan, scheduled for implementation in 2022, and (2) a proposed wellfield mitigation project that is projected to need 18.6 mgd of reclaimed water. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay.

Four well caissons would be located on the Turkey Point peninsula, east of the existing units. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay.

The four radial collector wells would provide up to approximately 86,400 gpm (124.4 million gallons per day [mgd]) to supplement the reclaimed water source for cooling water makeup for Units 6 & 7 (Table 3.3-2). Based on groundwater modeling described in Subsection 5.2.1, the radial collector wells would be recharged at a rate ranging from approximately 95 to 99 percent

(118.2 mgd to 123.2 mgd) from Biscayne Bay. This would be predominately localized in the area of the radial collector wells. The remaining recharge would be from groundwater beneath the plant property. The amount of saltwater used (up to a maximum of approximately 123.2 mgd saltwater recharge) compared to the size of the saltwater resource available would be insignificant. Impacts to Biscayne Bay surface waters would be SMALL, and minority and low-income populations would not experience disproportionately high and adverse impacts.

The total liquid and gaseous effluent doses from Units 6 & 7 would be well within the regulatory limits of 40 CFR Part 190. Radiological impacts to members of the public would be SMALL (Subsection 5.4.3). Minority and low-income populations would not experience disproportionately high and adverse impacts.

The operation of Units 6 & 7 would produce noise from the operation of pumps, cooling towers, transformers, turbines, generators, switchyard equipment, and loudspeakers, with the highest level of noise being associated with the operation of the mechanical draft cooling towers. Any noise generated would be attenuated by the distance to the Turkey Point plant property (1452 feet at a minimum) and would be consistent with existing background noise levels. Impacts as a result of noise would be SMALL and would not warrant mitigation (Subsection 5.8.1.1). Minority and low-income populations would not experience disproportionately high and adverse impacts.

Units 6 & 7 would have standby diesel generators that would operate under air permits issued by the state of Florida. This equipment would be operated periodically on a short-term basis; therefore, related emissions would be intermittent. The mechanical draft cooling towers would be equipped with high efficiency drift or mist eliminators to minimize emissions of particulate matter to 0.0005 percent of the circulating water, this is over 99.99 percent control of potential drift emissions based on the circulating water flow. The operation of a nuclear power plant involves the emission of some greenhouse gases, primarily carbon dioxide (CO_2). It is estimated that the total carbon footprint for operation of two AP1000 reactors would be about 640,000 metric tons over the life of the plant. The impact of these emissions on air quality would be SMALL and would not warrant mitigation (Subsection 5.8.1.2). There would be no disproportionately high and adverse impacts to minority or low-income populations.

Health and environmental impacts to the general population from operation of Units 6 & 7 via the three pathways would be SMALL. Therefore, it is concluded that there would be no disproportionately high and adverse impacts to minority or low-income populations within 50 miles via soil, water, or air pathways that would affect the health and environment of populations studied in this environmental justice analysis.

5.8.3.2 Socioeconomic Impacts

Employment as a result from the operation of Units 6 & 7, beginning with the initial arrival of operation workers during the construction period, would increase gradually, allowing market forces to accommodate the new arrivals. Because the in-migrating operation workforce would be much smaller than that of the construction workforce, it is unlikely that the operation workforce would be able to use the entire housing inventory vacated by the construction workforce. As described in Subsection 5.8.2.2.6, it is concluded that the Miami-Dade County could accommodate the entire in-migrating operation workforce and local governments would benefit from positive tax impacts. Therefore, the impact to the region's housing market would be SMALL and mitigation would not be warranted. Minority and low-income block groups are located throughout Miami-Dade County. Low-income block groups are concentrated in the Miami metropolitan area and along U.S. Highway 1 and Florida's Turnpike near Homestead and Florida City. These are also the areas where the current Turkey Point employees reside (Table 2.5-3) and at least a portion of the construction workforce would reside. The excess lower-cost, temporary housing vacated by the construction workforce would come onto the market, driving prices and rents down. The reduction in prices and rents could enable low-income residents displaced by the construction workforce to afford a higher standard of living. Housing for minority and low-income residents in Miami-Dade County would not be adversely or disproportionately impacted by operation of Units 6 & 7.

As presented in Subsection 5.8.2, it is assumed that 322 school-aged children would accompany the in-migrating operation workforce. The public education system within Miami-Dade County will soon have the capacity to seat an additional 13,746 students. Since the capacity is greater than the estimated number of in-migrating students, the education system within the county could accommodate all students that would accompany the operation workers. The school-aged children would increase Miami-Dade County public school's total enrollment by 0.09 percent. As stated in Subsection 2.5.2.8, the Homestead and Florida City area is part of District IX of the Miami-Dade County public school system. The student population in the Homestead and Florida City area could increase by 138 students (Table 5.8-1). The number of school-aged children likely to locate in the Miami-Dade County public school system, District IX region, but outside of the immediate Homestead and Florida City area, was not determined. Therefore, the percentage impact to the District IX region could not be specifically determined. However, District IX had 55,860 students enrolled in the 2010-2011 school year. Therefore, the impact would be less than 1 percent even if all 322 children in-migrating to Miami-Dade County were to locate in the District IX region. Hence, the impacts to public schools in the Homestead and Florida City area would be SMALL and there would be no disproportionately high and adverse impacts to minority or low-income populations.

As described in Subsection 5.8.2.2.3, offsite land use impacts would be concentrated in Miami-Dade County. Impacts would be SMALL within the county because there would be minimal land

conversion needed for new housing because the operation workforce and their families would represent less than 0.1 percent of the 2005-2009 population. The Homestead and Florida City area would also experience SMALL impacts for the same reason; population increases in these areas would represent 0.9 percent of the 2005-2009 population. The SMALL impact to offsite land use would not result in disproportionately high and adverse impacts to minority or low-income populations.

The Units 6 & 7 operation workforce would increase traffic on area roadways. As discussed in Subsection 5.8.2.2.4 and provided in Table 5.8-10a, FPL believes that the main arterials have adequate surplus capacity to support additional operations traffic. In general, the roadways between the plant and the major arterials have adequate capacity to support new operation workforce-generated trips, including outage workforce-generated trips, based on a link analysis of the roadways which are part of the Miami-Dade Concurrency Management System (Tables 5.8-10b and 5.8-10d). The two most critical intersections were evaluated for impacts of the normal operation of Units 6 & 7 (Table 5.8-10c). Because portions of these commuting routes are located within minority/low-income areas, these populations would be impacted by increased traffic from normal operation and scheduled outages. In particular, Black Races, Other Races, Hispanic Ethnicity, and Aggregate block groups are located along SW 328th Street/N. Canal Drive, SW 344th Street/Palm Drive, SW 117th Avenue, and SW 137th Avenue/Tallahassee Road. As described in Subsection 5.8.2.2, FPL could implement mitigation measures, such as staggering arrival and departure times, to minimize the impact to transportation. Because of the location of affected roads, some minority block groups would be affected by the traffic congestion. However, these impacts would be at the significance level characterized above and mitigation measures could be implemented.

As presented in Subsection 5.8.2.2.1, the operation of Unit 6 & 7 would result in the creation of direct jobs and 874 indirect jobs, for a total of 1277 new jobs (Subsection 5.8.2). The increase in employment opportunities would be a positive and SMALL impact to Miami-Dade County's economy and could be a beneficial impact to area residents including minority or low-income populations because of the creation of indirect jobs which are often in the retail and service sectors (Subsection 5.8.2.2.1).

The potential impacts from the operation of Units 6 & 7 on public services in Miami-Dade County (Subsection 5.8.2.2.7) were also assessed. Potable water from the Miami-Dade County public water supply would be used for the operation of Units 6 & 7. The Miami-Dade County public water system has excess capacity; current use is at 74.74 percent of capacity. Units 6 & 7 potable water demand would require 0.39 to 1.06 percent of the current Miami-Dade public water supply, which would not stress the system. Likewise, the Homestead and Florida City area, which is a likely candidate for some of the operation workers to relocate, would have enough excess municipal water supply capacity to accommodate the in-migrating operation workforce. Impacts to municipal water suppliers for Miami-Dade County, including the Homestead and Florida City

area, would be SMALL (Subsection 5.8.2.2.7.1), and would not disproportionately impact minority or low-income communities.

Onsite sanitary treatment would be provided by a packaged sanitary treatment plant located on the Units 6 & 7 plant area. The sanitary treatment plant would be designed to process sanitary effluent from Units 1 through 7. Therefore, there would be no impact to public wastewater facilities. The increased population in Miami-Dade County from in-migration of the operation workers would impact local wastewater treatment systems. As a whole, the Miami-Dade County wastewater facilities have the total capacity to absorb the increase in population, and county-wide impacts would be SMALL. The Homestead wastewater treatment facility is currently operating at above capacity, but are using the MDWASD SDWWTP as backup because that supplier is operating at approximately 78.54 percent capacity and can assist Homestead. Florida City is served by the MDWASD SDWWTP, and it has enough excess capacity to accommodate the in-migrating operation workforce. Impacts to water supply and wastewater treatment facilities in Miami-Dade County would be SMALL (Subsection 5.8.2.2.7.2). There would be no disproportionately high and adverse impacts to minority or low-income population.

Impacts to law enforcement, fire protection services, and medical facilities would also be SMALL within Miami-Dade County (Subsection 5.8.2.2.7.3). There would be no disproportionately high and adverse impacts to minority or low-income populations.

Local government officials, staff of social welfare agencies, and the Miccosukee Indian Tribe were contacted concerning unusual resource dependencies or practices or health conditions that could result in disproportionately high and adverse impacts to minority and low-income populations.

Many agencies had no information concerning activities and health issues of minority populations. Interviews were conducted with the Community Action Agency, Miami-Dade Office of Community Advocacy, Miami-Dade County Community and Economic Development, Countywide Healthcare Planning, Metro Miami Action Plan Trust, and the Miami-Dade Black Advisory Board. No agency reported dependencies or practices, such as subsistence agriculture, hunting, or fishing, or preexisting health conditions through which minority populations could experience disproportionately high or adverse impacts from the proposed project. Several agencies alluded to the extreme urban nature of the study area and implied that there was no possibility of any subsistence activity on the part of any group.

Contact with the Miccosukee Indian Tribe reported that the tribe member residing on the reservation within the 50-mile radius do not depend on hunting, fishing, or gardening for subsistence. The Miccosukee Tribe does lease land from the SFWMD for hunting, fishing, frogging, agriculture, and to carry on the traditional Miccosukee way of life. However, most tribe members rely on modern means to meet their food needs.

Operation and outage activities would increase traffic along the main routes to the Turkey Point plant property. These routes are located in predominantly Black Races, Other Races and Hispanic Ethnicity, Aggregate, and low-income population areas. Improvements would be made to increase capacities, as described in Subsection 5.8.2.2.4. In summary, it is concluded that impacts from operations-related activities to minority or low-income populations would, with the exception of transportation, reflect impacts to the general population. The disproportionate impacts from operations traffic are location-dependent, rather than occurring through a unique pathway.

Table 5.8-1
Assumptions for Workforce Migration and Family Composition During the Operation of Units 6 & 7

	Operations
Workforce Characterization	
Peak number of operation workers on-site	806
Workforce migration	
Percent of workforce that would migrate into Miami-Dade County during operations	50%
Total number of workers that would migrate into Miami-Dade County during operations	403
Percent of in-migrating workforce that would migrate into Homestead and Florida City area during operations[a]	42.78%
Number of workers that would migrate into Homestead and Florida City area during operations	172
Families	
Percent of workers who would bring families[b]	100%
Number of workers who would bring families into Miami-Dade County	403
Average worker family size (worker, spouse, children)[b], [c]	3.25
Total workers plus family members that would migrate into Miami-Dade County (= population increase in Miami-Dade County)	1310
Number of workers who would bring families into Homestead and Florida City area	172
Average worker family size (worker, spouse, children)[b], [c]	3.25
Total workers plus family members that would migrate into the Homestead and Florida City area (= population increase in Homestead and Florida City area)[d]	559
School-age children	
Number of school-age children per family[b]	0.8
Total number of school-age children that would migrate into Miami-Dade County (0.8 per family)	322
Total number of school-age children that would migrate into Homestead and Florida City area (0.8 per family)	138

(a) Based on residential distribution of current operation workforce.
(b) Source: BMI 1981
(c) According to the USCB Profile of the General Population and Housing Characteristics: 2010, (USCB 2010b): average family size in Miami-Dade County in 2010 was 3.33. The average family size in Florida was 3.01. Therefore, FPL assumes that an average family size of 3.25 for the construction workforce, as presented in the Battelle Memorial Institute Study (BMI 1981), would also be a reasonable estimate for the operation workforce.
(d) Note: Presented values may not total component values due to rounding.

Table 5.8-2
Direct and Indirect Employment Created During the Operation of Units 6 & 7

Employment	
Direct jobs — In-migrating operation workforce (50% migrating into Miami-Dade County)	403
Employment multiplier for power generation and supply workers in Miami-Dade County (indirect portion only)[(a)]	2.1696
Indirect jobs resulting from in-migration of operation workers (403 x 2.1696)	874
Total number of new, project-related jobs in Miami-Dade County (direct plus indirect)	1,277

(a) Source: BEA 2009a.

Table 5.8-3
Analysis of Annual Impacts to Miami-Dade County from In-migrating Operation Worker Wages

Average annual operation worker wages[(a)]	$81,980
Number of in-migrating operation workers[(b)]	403
Estimated annual payroll from in-migrating workers	$33,037,940
Earnings multiplier for Power Generation and Supply Sector[(c)]	1.7880
Total economic impact to Miami-Dade County (earnings multiplier applied)	$59,071,837
Total personal income in Miami-Dade County, 2009[(d)]	$90,915,774,000
Annual average in-migrating operation worker wages as percent of 2009 personal income in Miami-Dade County	0.06%

(a) BLS 2012a. Average annual wage for a Nuclear Power Operator (51-8011)
(b) The operation workforce achieves full staffing as of construction month 80 (near the end of year 10) of the construction period (Table 3.10-2)
(c) BEA 2009a (Table 4.4-8)
(d) BEA 2011 (Table 4.4-5)

Table 5.8-4
Operation Workforce and Indirect Workers as Percentage in Miami-Dade County

Workforce Characterization, 40-Year Operation Period Plus 20-Year License Renewal Period	Operation Workforce	Indirect Workers	Total
Operation workers	806	—	—
Percentage of workers assumed to migrate into Miami-Dade County	50%	—	—
Number of workers assumed to migrate into Miami-Dade County	403	—	—
Employment multiplier for Power Generation and Supply sector (indirect portion only)(a)	2.1696	—	—
Indirect workers (2.1696 x 403)	—	874	—
TOTAL New project related jobs (direct and indirect)	—	—	1,277
Miami-Dade County employment, 2011(b)	—	—	1,146,823
In-migrating operation workers and indirect workers as percentage of Miami-Dade County labor force, 2011	—	—	0.1%
Number of unemployed persons, Miami-Dade County, 2011(b)	—	156,562	—
Indirect jobs as percent of number of unemployed individuals, Miami-Dade County, 2011	—	—	0.6%

(a) Source: BEA 2009
(b) Source: BLS 2012c (Table 2.5-7)

Table 5.8-5
Analysis of Annual Impacts to Miami-Dade County from Outage Worker Wages[a]

Average annual outage worker wages[b]	$81,980	
Estimated daily wages (annual wage ÷ 250)	$328	
	Regular Outage	**Extended Outage**
Estimated length of outage in days	30	45
Estimated number of outage workers per unit[f]	600	1,000
Estimated annualized payroll, outage workers[c]	$7,870,080	$5,902,560
Earnings multiplier for power generation and supply sector[d]	1.7880	
Personal income in Miami-Dade County, 2009[e]	$90,915,774,000	
Estimated annualized payroll (earnings multiplier applied), outage workers as percent of personal income in Miami-Dade County, 2009	0.015%	0.012%
Economic impact to Miami-Dade County (earnings multiplier applied)	$14,071,703	$10,553,777

(a) To assess potential impacts, the outage workforce is estimated at 600 workers per unit for each regular outage (30 days) and 1000 workers for extended outages (45 days).
(b) BLS 2012b
(c) FPL assumes that regular outages for Units 6 & 7 would occur at 18-month intervals and last for 30 days. It is assumed for this analysis that outages would not occur simultaneously for the two units, and therefore one outage would occur every 9 months. To compare outage worker wages to annual personal income for Miami-Dade County, outage worker wages were divided by 0.75 to achieve an annualized amount (i.e. to increase a 9-month amount to a 12-month amount for purposes of comparison). FPL states that extended outages would occur at 5-year intervals and last for 45 days. It is assumed for this analysis that outages would not occur simultaneously for the two units, and therefore one outage would occur every 2.5 years (30 months). To compare outage wages to annual total income for Miami-Dade County, the outage worker wages were divided by 2.5 to achieve an annualized amount (i.e. to decrease a 30-month amount to a 12-month amount for purposes of comparison).
(d) BEA 2009 (Table 5.8-3)
(e) BEA 2011 (Table 5.8-3)
(f) Assumes 100% of outage workforce migrates into Miami-Dade County

Table 5.8-6 (Deleted)

Table 5.8-7
Estimated Sales Tax Impacts, the Operation of Units 6 & 7 Compared to 2007 Tax Revenue, Miami-Dade County and Florida

	Miami-Dade County	Florida
Year 2011 — Actual Sales Tax Revenues[a][b]	$57,559,000	$19,352,980,000
5% of total	$2,877,950	$967,649,000
10% of total	$5,755,900	$1,935,298,000
20% of total	$11,511,800	$3,870,596,000
Tax rate [c][d]	1.0%	6.0%
Expenditures Required to Exceed Projected Collections by Specified Percentage		
by 5%	$287,795,000	$16,127,483,333
by 10%	$575,590,000	$32,254,966,667

5.9 DECOMMISSIONING

The NRC defines decommissioning (10 CFR Part 52) as the safe removal of a nuclear facility from service and the reduction of residual radioactivity to a level that permits release of the property for unrestricted use or for use under restricted conditions, and termination of the license. NRC regulation 10 CFR 52.110 specifies the regulatory actions that NRC and a licensee must take to decommission a nuclear power facility. 10 CFR Part 20, Subpart E identifies the radiological criteria that must be met for license termination. These requirements apply to the existing fleet of power reactors and to advanced reactors such as the AP1000.

Decommissioning must occur because NRC regulations do not permit a power reactor licensee to abandon a facility after ending operations. The NRC prohibits licensees from performing decommissioning activities that result in significant environmental impacts not previously reviewed under 10 CFR 52.110. Therefore, the NRC has indicated that licensees for existing reactors can rely on the information in the 2002 Final Generic Environmental Impact Statement (2002 Decommissioning GEIS) on Decommissioning of Nuclear Facilities to determine the environmental impacts of decommissioning for the existing fleet of domestic nuclear power reactors as documented in Supplement 1 to NUREG-0586.

Further, 10 CFR 50.75 delineates the financial requirements for decommissioning. This regulation establishes the requirements for providing reasonable assurance that adequate funds for performing decommissioning are available at the end of plant operations. The DOE funded a study that compares activities and costs required to decommission existing reactors to those required for advanced reactors, including the AP1000 (U.S. DOE May 2004). In addition, the decommissioning cost for Units 6 & 7 has been estimated by calculating the formula in accordance with the provisions of 10 CFR 50.75(c) and the guidance provided in NUREG-1307, Rev. 15 using the DECON alternative.

It is concluded that the generic environmental impacts identified in Supplement 1 to NUREG-0586 bound the impacts that can be reasonably expected from decommissioning the AP1000. The following sections summarize the environmental impacts related to decommissioning, the DOE-funded study on decommissioning costs, general advanced reactor plant design features that would affect eventual decommissioning, the cost estimate for decommissioning, and conclusions regarding the decommissioning of Units 6 & 7 based on this review.

5.9.1 ENVIRONMENTAL IMPACTS RELATED TO DECOMMISSIONING

10 CFR 52.110 specifies the regulatory actions that both the NRC and the licensee must take to decommission a nuclear power facility. These actions include the following:

1. Once the licensee decides to permanently cease operations, it must submit, within 30 days, a written certification to the NRC.

2. The licensee must permanently remove all fuel from the reactor and submit a written certification to the NRC confirming completion of fuel removal.

3. In addition to the certifications, the licensee must submit a post-shutdown decommissioning activities report (PSDAR) to the NRC no later than two years after the date of permanent cessation of operations.

4. The decommissioning process continues until the licensee requests termination of the license and demonstrates that radioactive material has been removed to the levels that permit termination of the license.

NUREG-0586 Supplement 1 was reviewed to determine the environmental impacts during decommissioning. The NRC's stated purpose in developing the 2002 Final Decommissioning generic environmental impact statement (GEIS) was to provide an analysis of environmental impacts from decommissioning activities that can be treated generically so that decommissioning activities for commercial nuclear power reactors conducted at specific sites will be bounded, to the extent practicable, by this and appropriate previously issued environmental impact statements. The 2002 Final Decommissioning GEIS also identifies the decommissioning activities and associated environmental issues that will likely require site-specific analysis before performing a decommissioning activity.

This Supplement incorporated the technological advances in decommissioning operations, experience gained by licensees, and changes made to the NRC regulations since the 1988 Final GEIS on Decommissioning of Nuclear Facilities. In evaluating the environmental impacts arising from those activities included in the scope of the 2002 Final Decommissioning GEIS, the environmental impacts of the following three decommissioning methods were evaluated:

- DECON — The equipment, structures, and portions of the facility and site that contain radioactive contaminants are removed or decontaminated to a level that permits termination of the license shortly after cessation of operations.

- SAFSTOR — The facility is placed in a safe stable condition and maintained in that state (safe storage) until it is subsequently decontaminated and dismantled to levels that permit license termination. During SAFSTOR, a facility is left intact, but the fuel is removed from the reactor vessel and radioactive liquids are drained from systems and components and then processed. Radioactive decay occurs during the SAFSTOR period, thus reducing the quantity of contaminated and radioactive material that must be disposed of during the decontamination and dismantlement of the facility at the end of the storage period.

- ENTOMB — This alternative involves encasing radioactive structures, systems, and components (SSCs) in a structurally long-lived substance, such as concrete. The entombed

structure is appropriately maintained, and continued surveillance is carried out until the radioactivity decays to a level that permits termination of the license.

The scope of the 2002 Final Decommissioning GEIS is based on the decommissioning activities performed to remove radioactive materials from the SSCs from the time that the licensee certifies that it has permanently ceased power operations until the license is terminated. Except for decommissioning planning, the activities performed before permanent cessation of operations, including certification that fuel has been removed from the reactor, and impacts related to the decision to permanently cease operations were outside the scope of the 2002 Final Decommissioning GEIS. Further, any potential radiological impacts following license termination that are related to activities performed during decommissioning were also not considered in the 2002 Final Decommissioning GEIS.

The activities and impacts that NRC considered to be within the scope of the 2002 Decommissioning GEIS include:

- Activities performed to remove the facility from service once the licensee certifies that the facility has permanently ceased operations.
- Activities performed in support of radiological decommissioning, including decontamination and dismantlement of radioactive SSCs and any activities required to support the decontamination and dismantlement process.
- Activities performed in support of dismantlement of nonradiological SSCs, such as diesel generator buildings and cooling towers.
- Activities performed up to license termination and their resulting impacts as provided by the definition of decommissioning.
- Activities related to release of the facility or preparation for facility entombment.
- Human health impacts from radiological and nonradiological decommissioning activities.

Each environmental issue within the scope of the 2002 Final Decommissioning GEIS was evaluated to determine whether each issue was considered generic or site-specific. If the issue was considered generic, a significance level of SMALL, MODERATE, or LARGE was assigned. Of the identified environmental issues assessed, the impacts are generic and SMALL for all plants regardless of the activities and identified variables (Table 5.9-1). For activities within the operational area, only two issues were determined to be site-specific—threatened and endangered species and environmental justice. The operational area is defined as the portion of the plant site where most or all of the site activities occur, such as reactor operation, materials and equipment storage, parking, substation operation, facility service, and maintenance. This

includes areas within the protected area fences, the intake, discharge, cooling, and associated structures as well as surrounding paved, graveled, maintained landscape, or other maintained areas.

Various activities related to decommissioning that were not considered within the scope of the 2002 Final Decommissioning GEIS are regulated by the NRC or are reviewed by the NRC under other regulatory responsibilities. These activities include:

- Spent fuel storage and maintenance. The NRC has independently made a finding that there is reasonable assurance that, if necessary, spent fuel generated in any reactor can be stored safely and without significant environmental impacts for at least 30 years beyond the licensed life for operation (which may include the term of a revised license) of that reactor at its spent fuel storage basin, or at either onsite or offsite independent spent fuel storage installations. This finding is codified in the NRC's regulations in 10 CFR 51.23(a).

- Spent fuel transport and disposal away from the reactor location is governed by regulations in 10 CFR Part 71.

- Low-level waste (LLW) disposal at a licensed LLW site or treatment of LLW at compactor facilities. Regulations related to LLW disposal are in 10 CFR Part 61 and 10 CFR Part 20, Subpart K. A final GEIS supporting the regulations in 10 CFR Part 61, *Final Generic Environmental Impact Statement for 10 CFR Part 61,* was published as NUREG-0945.

- Radiological impacts following license termination. This impact is covered by the Generic Environmental Impact Statement in Support of Rulemaking on Radiological Criteria for License Termination of NRC-Licensed Nuclear Facilities, NUREG-1496.

Definitive plans for decommissioning are required by the NRC after a decision has been made to cease operations. There are three points during the decommissioning process when the licensee performs an evaluation of environmental impacts—during submittal of the PSDAR and during submittal of the license termination plan, and during performance of the final status survey to verify compliance with the license termination plan. When the licensee must submit a PSDAR to the NRC (within two years following permanent cessation of operation), the PSDAR must include a discussion that provides the reasons for concluding that the environmental impacts associated with the licensee's planned site-specific decommissioning activities will be bounded by an appropriate previously issued environmental assessment, including the 2002 Final Decommissioning GEIS. If the licensee identifies environmental impacts that are not bounded by a previous NRC environmental assessment, the licensee must address the impacts in a request for a license amendment regarding the activities and submit a supplement to its environmental report that describes and evaluates the additional impacts. The license termination plan must be a supplement to the FSAR and must include a supplement to the environmental report that

describes any new information or significant environmental change associated with the licensee's proposed termination activities.

In summary, the decommissioning of a nuclear facility that has reached the end of its useful life generally has a positive environmental impact. In many instances, the environmental impacts resulting from the activities associated with decommissioning are expected to be substantially smaller than those of power plant construction or operation because the level of activity and the impacts to the environment are expected to be smaller during decommissioning than during construction and operation.

5.9.2 DOE-FUNDED STUDY ON DECOMMISSIONING COSTS

The total cost of decommissioning depends on many factors, including the sequence and timing of the various stages of the program, location of the facility, current radioactive waste burial costs, and plans for spent fuel storage. To ensure that a lack of funds does not result in delays or in improper conduct of decommissioning that may adversely affect public health and safety, 10 CFR 50.75 requires that operating license applicants and licensees provide reasonable assurance that adequate funds for performing decommissioning will be available at the end of operation. To provide this assurance, the regulation requires that two factors be considered: (1) the amount of funds needed for decommissioning, and (2) the method used to provide financial assurance. At its discretion, an applicant may submit a certification based either on the formulas provided in 10 CFR 50.75 or, when a higher funding level is desired, on a facility-specific cost estimate that is equal to or greater than that calculated using the formula in 10 CFR 50.75, consistent with guidance provided by RG 1.159.

To support development of advanced reactors for production of electric power and to establish the requirements for providing reasonable assurance that adequate funds for performing decommissioning will be available at the end of plant operations, a study was commissioned by DOE (U.S. DOE May 2004). The study presents estimates of the costs to decommission the advanced reactor designs following a scheduled cessation of plant operations. Four reactor types were evaluated in this report: the advanced boiling water reactor (ABWR), the economic simplified boiling water reactor (ESBWR), the advanced passive pressurized water reactor (AP1000), and the advanced CANDU reactor (ACR-700). The cost analysis described in the study is based on the prompt decommissioning alternative, or DECON, as defined in NUREG-0586. The DECON alternative is also the basis for the NRC funding regulations in 10 CFR 50.75.

DECON comprises four distinct periods of effort:

1. Pre-shutdown planning/engineering

2. Plant deactivation and transition (no activities are conducted during this period that will affect the safe operation of the spent fuel pool)

3. Decontamination and dismantlement with concurrent operations in the spent fuel pool until the pool inventory is zero

4. License termination

Because of the delays in development of the federal waste management system, it may be necessary to continue operation of a dry fuel storage facility on the reactor site after the reactor systems have been dismantled and the reactor operating license terminated. However, these latter storage costs are considered operational costs and are not considered part of decommissioning.

The cost estimates described in the DOE study were developed using the same cost estimating methodology used by NRC and consider the typical features of a generic site located in the southeast, including the nuclear steam supply systems, power generation systems, support services, site buildings, and ancillary facilities. This is considered to be a valid approach for Units 6 & 7. The estimates are based on numerous fundamental assumptions, including labor costs, low-level radioactive waste disposal costs and practices, contaminated tools and equipment present at the end of operations, regulatory requirements, and project contingencies. The primary cost contributors identified in the study are either labor-related or associated with the management and disposition of the radioactive waste.

Advanced reactors have several design features that will impact the ultimate cost of decommissioning (U.S. DOE May 2004). These principal cost influences include:

- Quantity of plant equipment — The quantity of plant equipment requiring disposition has been reduced in the advanced reactor designs. This reduction will have a noticeable impact on the decommissioning cost, including reduced labor costs associated with removal and radiation protection, reduced decommissioning equipment and material costs, reduced waste processing and disposal costs, as well as reduced equipment survey costs.

- Level of contamination or activation — The advanced reactor designs are expected to have improved material selection and water chemistry resulting in reduced radiation levels during plant operation.

- Extent of building contamination — The level of effort to decontaminate the advanced reactor buildings as part of the decommissioning scope is expected to be less than contemporary reactor designs and is believed to be principally due to plant layout.

Overall, the DOE study concluded that with consistent operating and management assumptions, the total decommissioning costs projected for the advanced reactor designs are comparable to those projected by NRC for operating reactors with appropriate reductions in costs due to reduced physical plant inventories (U.S. DOE May 2004).

5.9.3 UNITS 6 & 7 DECOMMISSIONING COST ESTIMATE

A decommissioning cost estimate has been performed for each of the AP1000 units in order to assess the financial obligations pertaining to the eventual decommissioning of the two units. Part 1 of this COL Application describes the plans for providing financial assurance for the decommissioning of the two units and includes a certification regarding the cost estimate for each unit. The cost estimate or “formula amount” for the minimum certification is calculated in accordance with the provisions of 10 CFR 50.75(c) and the guidance provided in NUREG-1307, Rev. 15, which assumes the DECON decommissioning alternative. The estimate assumes the removal of all contaminated and activated plant components and structural materials such that the owner may then have unrestricted use of the site with no further requirements for an operating license. Similar to the DOE study, the primary cost contributors identified are labor-related or associated with the management and disposition of the radioactive waste.

The projected cost to decommission two AP1000s is estimated to be approximately $1.034 billion**,** reported in year 2013 dollars. This minimum certification amount for each unit was calculated using the formula delineated in 10 CFR 50.75(c) (1) and appropriate escalation indices, including the waste burial factor provided in NUREG-1307, Rev. 15, for the vendor waste processing option.

5.9.4 CONCLUSIONS

The generic environmental impacts associated with decommissioning the existing fleet of domestic nuclear power reactors presented in the 2002 Final Decommissioning GEIS were analyzed along with the expected decommissioning activities for the AP1000. It was determined that the scope of the activities is the same. Projected physical plant inventories associated with advanced reactor designs will generally be less than those for currently operating power reactors due to advances in technology that simplify maintenance and benefit decommissioning. Based on this comparison, it was concluded that the environmental impacts identified in the 2002 Decommissioning GEIS bound the impacts that can be reasonably expected from decommissioning the AP1000.

A total decommissioning cost estimate using the NRC’s formula amount in accordance with 10 CFR 50.75(c) (1) has been projected. The cost projected to decommission two AP1000s using the DECON alternative is estimated to be $1.034 billion, reported in year 2013 dollars.

5.10 MEASURES AND CONTROLS TO LIMIT ADVERSE IMPACTS DURING OPERATIONS

Sections 5.1 through 5.9 describe potential environmental impacts that could result from construction of Units 6 & 7. Such adverse environmental impacts would be reduced or eliminated through implementation of measures and controls such as:

- Compliance with applicable local, state, and federal ordinances, laws, and regulations
- Compliance with environmental requirements compelled by permits and licenses
- Compliance with site procedures, plans, and programs

In Table 5.10-1, the environmental impacts and corresponding measures and controls described in previous sections of Chapter 5 are summarized along with the significance of potential impacts (i.e., SMALL, MODERATE, or LARGE).

Table 5.10-1 (Sheet 1 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.1 Land Use Impacts			
5.1.1 The Site and Vicinity	Land would be permanently dedicated to Units 6 & 7 infrastructure on the Turkey Point Plant property until decommissioning.	S	No mitigation would be required.
	Potential impacts from salt deposition affecting vegetation and critical habitat for the American crocodile.	S	No mitigation would be required.
	Potential impacts from the reclaimed and potable water pipelines and transmission corridors, located primarily offsite. (Land within the right-of-way would be permanently dedicated until decommissioning, but would be compatible with many uses. In addition, the radial collector wells would be emplaced under Biscayne Bay.)	S	Existing corridors would be used to the extent practical.
5.1.2 Transmission Corridors and Offsite Area	Potential impacts from maintenance practices including mowing and application of herbicides and growth-regulating chemicals for transmission corridors, water pipelines, and access roadways.	S	The right-of-ways would be maintained with management plans designed to protect the land use of contiguous properties. The exact manner in which maintenance would be performed would depend on the location, type of terrain, and surrounding environment. An example of a possible management plan includes cultivation and grazing where compatible.
	Potential impacts to offsite land disposal facilities from disposal of radioactive (low-level radioactive waste and spent nuclear fuel) and nonradioactive wastes that would be generated as a result of operation of Units 6 & 7. (Cooling system blowdown and process wastewaters would be disposed of in deep injection wells.)	S	Disposal area(s) for nonradioactive and low-level radioactive waste would be at a permitted waste disposal facilities with a land use designated for such activities. Disposal area for spent nuclear fuel would be a U.S. Department of Energy facility that is licensed by NRC.

Table 5.10-1 (Sheet 2 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.1.3 Historic Properties and Cultural Resources	Potential impacts from operational activities, including maintenance activities (e.g. repair/ replacement of underground piping), in areas that were previously disturbed during construction of Units 6 & 7. (It is unlikely that plant operations would uncover historical properties that were not discovered and properly processed during plant construction.)	No Impact	The unanticipated finds plan implemented during construction would be slightly modified for operational activities and included in the operational procedures for Units 6 & 7.
5.2 Water-Related Impacts			
5.2.1 Hydrologic Alterations and Plant Water Supply	Potential impacts from the operation of the principal structures of Units 6 & 7 (power blocks, makeup water reservoir and cooling towers, switchyard, and other infrastructure) and associated facilities (security facility). (The groundwater hydrologic flow in the vicinity of these structures may be slightly altered.)	S	No mitigation would be required.
	Potential impacts from the spoils areas. (The proposed spoils areas would be bermed to direct drainage from the spoils piles to the cooling canals/industrial wastewater treatment facility.)	S	No mitigation would be required.
	Potential impacts from the access roads maintenance, heavy haul road, and equipment barge unloading area. (The roads maintenance would use sedimentation control for surface water control.) (The surface water and groundwater hydrologic flow could be temporarily altered.)	S	Water from the dewatering process would be handled by environmental best management practices. Any areas of disturbed soils would be recontoured and reestablished, if necessary, in a timely manner which would reduce the potential for erosion through surface water runoff. Soil retention techniques such as silt barriers would be used to reduce impacts in accordance with best management practices developed for Units 6 & 7.

Table 5.10-1 (Sheet 3 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.2.1 Hydrologic Alterations and Plant Water Supply (cont.)	Potential impacts from operational utilities maintenance (water and sanitary treatment facilities, reclaimed water pipeline and potable water pipeline.) (The surface water and groundwater hydrologic flow could be temporarily altered.)	S	Water from the dewatering process would be handled by environmental best management practices. Soil retention techniques such as silt barriers would be used to reduce impacts in accordance with best management practices developed for Turkey Point Units 6 & 7.
	Potential impacts from the operation and maintenance of the radial collector wells. (Activities could be necessary that would require drawdown of surface water and screen cleaning of the radials under Biscayne Bay.) (The surface water and groundwater hydrologic flow could be altered.)	S	Water from the localized dewatering process would be handled by environmental best management practices and directed to the industrial wastewater facility.
	Potential impacts from the operation and maintenance of the deep injection wells. (Deep injection wells would be operated according to agency regulations.) (The surface water and groundwater hydrologic flow could be altered.)	S	A monitoring program would be utilized to detect vertical migration of injected fluids into the Upper Floridan aquifer through the confining layer overlying the Boulder Zone.
	Potential impacts from transmission right-of-way, potable and reclaimed water pipelines right-of-way maintenance activities. (Activities could be necessary that would require excavation and dewatering. The dewatering activity would create temporary drawdown of the water table. The disturbance of surface soils during maintenance activities could result in impacts.)	S	Water from the dewatering process would be handled by environmental best management practices. Soil retention techniques such as silt barriers would be used to reduce impacts in accordance with best management practices developed for Turkey Point Units 6 & 7.
	Potential impacts associated with vehicular traffic from right-of-way maintenance activities. (Activities could result in the rutting of access roads along the rights-of-way, which could impact surface flow in the vicinity of the disturbance.)	S	Any areas of disturbed soils would be recontoured and reestablished, if necessary, in a timely manner which would reduce the potential for erosion through surface water runoff.

Table 5.10-1 (Sheet 4 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
	Potential impacts from FPL-owned fill source. (The proposed fill areas could be bermed to stabilize surface water flow.) (The surface water and groundwater hydrologic flow could be temporarily altered.)	S	Water from the excavation process would be handled by environmental best management practices and groundwater levels would stabilize after storm events end, no further mitigation would be required.
5.2.2 Water Use Impacts	Potential impacts from diverting public water for other beneficial uses. Potable water in the amount of 936 gpm (1.35 mgd) to 2553 gpm (3.68 mgd) would be supplied to the site by Miami-Dade County.	S	No mitigation would be required.
	Potential impacts from the withdrawal of groundwater from Biscayne aquifer and Biscayne Bay.	S	A monitoring well system would be installed near the location of the radial collector well caissons that would be used to monitor the groundwater elevation and quality during operation of the radial collector wells.
5.2.3 Water Quality Impacts	Potential impacts from operational maintenance activities along the transmission rights-of-way, the reclaimed water pipelines, and potable water pipelines. (Maintenance activities could result in impacts to surface water quality. These impacts could result from surface water runoff, which could include the transport of chemical releases (e.g., spills of hydraulic fluid) to the environment or from the transport of sediment to nearby surface water features.)	S	The use of environmental best management practices along with a spill prevention plan would prevent or minimize the potential impacts of sediment transport or releases to the environment.
	Potential impacts from operation of radial collector wells. (Operation of radial collector wells installed beneath Biscayne Bay would have minimal impact the water quality of the bay. A small percentage of recharge water would come from points under the plant property. The aquifer is not used as a potable water supply near the Turkey Point property.	S	Monitoring wells could be installed and used to monitor the groundwater level and water quality inshore of the radial collector well locations.

Table 5.10-1 (Sheet 5 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.2.3 Water Quality Impacts (cont.)	Potential impacts to water quality from operations. (Any contaminants (e.g., diesel fuel, hydraulic fluid, antifreeze, lubricants, or other pollutant) spilled during operations, and not contained or remediated, could seep, over time, into the water table, affecting the water table if significant in quantity, aquifer and could ultimately over a long period of time move to Biscayne Bay.)	S	Environmental best management practices and a spill prevention plan would be used to minimize and prevent impacts. Any minor spills of diesel fuel, hydraulic fluid, lubricants, or other pollutants would be cleaned up quickly to prevent them from moving into the groundwater.
5.3 Cooling System Impacts			
5.3.1 Intake System	Potential impact from the operation of the radial collector wells.	S – wetlands	Continue FPL crocodile program that mitigates the impacts to American crocodile.
5.3.2 Impacts of Cooling System Discharge System on Aquatic Ecosystems	Potential impacts from the deep injection wells. (Discharge would be via underground injection into the Boulder Zone, which would not afford a pathway for the discharge water to reach surficial aquifers or surface waters.)	S	The FDEP permitting process for the deep injection well permits including monitoring requirements for groundwater quality and groundwater elevation data in overlying aquifers would be adhered to.
5.3.3 Heat Discharge System	Potential impacts from the heat discharge system—mechanical draft cooling towers. (Use of cooling towers would lead to creation of plumes. Plumes have the potential for shadowing, fogging, and increasing humidity and precipitation.)	S	No mitigation would be required.

Table 5.10-1 (Sheet 6 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.3.3 Heat Discharge System (cont.)	Salt deposition was estimated locally at the southern end of the plant area. Salt deposition of 10 Kg/Ha/month is generally confined to the plant property and at the cooling canals, with the exception of the eastern and southeastern perimeters of the site. The terrestrial habitats receiving highest deposits would include the cooling canals of the industrial wastewater facility, industrial/ developed lands, and a narrow band of mangroves along the Biscayne Bay shore immediately east of the facility. The salt deposition to the cooling canals, which are critical habitat for the federally-threatened American crocodile would not impact salinity level significantly to impact existing crocodile growth and/or survival rate.	S	No mitigation would be required beyond the existing crocodile management program that mitigates the impacts to American crocodile hatchlings from the existing elevated salinity levels.
	Potential impacts from the heat discharge system—mechanical draft cooling towers. (Noise from the Units 6 & 7 cooling towers could possibly impact wildlife. Noise from cooling towers would be less than the level the NRC considers of small significance.)	S	No mitigation would be required.
	Potential impacts from the heat discharge system—mechanical draft cooling towers. (The mechanical draft cooling towers would be shorter, 70 feet above grade, than the taller natural draft cooling towers that have been associated with bird kills.)	S	No mitigation would be required.

Table 5.10-1 (Sheet 7 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.3.4 Impacts to Members of the Public	Potential health impact to workers from contact with human disease-causing thermophilic microorganisms in the makeup water reservoir.	S	Personnel would be strictly controlled by administrative controls and security patrols. The makeup water reservoir would be located within the plant area boundary, precluding access by members of the public. Workers would be subject to the worker protection plan, which would provide for personnel protective measures such as personal protective equipment and personnel monitoring.
	Potential impact to members of the public from noise emitted by Units 6 & 7 cooling towers. (Noise levels at 400 feet from the cooling towers are estimated to be on the order of 65 dBA, a level characterized by the NRC in NUREG-1437 as of small significance.)	S	No mitigation would be required.
5.4 Radiological Impacts of Normal Operation			
5.4.3 Impacts to Members of the Public	Potential health impacts to members of the public from exposure to radiological releases. (Modeling using the design and operational parameters of Units 6 & 7 results in estimated doses to the public that are within the design objectives of 10 CFR Part 50 Appendix I and within regulatory limits of 40 CFR Part 190.) Since the dose limits for members of the public in 40 CFR Part 190 are more restrictive than those in 10 CFR 20.1301, demonstration of compliance with the limits of 40 CFR Part 190 is also considered to be a demonstration of compliance with the 0.1 rem limit of 10 CFR 20.1301.	S	Monitor radiological releases as required by radiological monitoring program. Should adverse conditions be indicated, appropriate Units 6 & 7 operating control procedures would be implemented.

Table 5.10-1 (Sheet 8 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.4.4 Impacts to Biota Other than Members of the Public	Potential impacts to terrestrial and aquatic ecosystems from chronic radiation exposure caused by the small discharges of radioactive liquids and gases from the operation of Units 6 & 7. (The calculated dose rate to biota species, 0.14 mrad/day, is much less than the 100 mrad/day criteria—the level at which the International Atomic Energy Agency concludes there are no harmful effects to plants and animals.)	S	Monitor radiological releases as required by radiological monitoring program. Should adverse conditions be indicated, appropriate Units 6 & 7 operating control procedures would be implemented.
5.4.5 Occupational Doses	Potential health impacts to workers from radiation exposure of an annual maximum of dose of 67 person-rem per unit.	S	Monitor radiological releases as required by radiological monitoring program. Should adverse conditions be indicated, appropriate Units 6 & 7 operating control procedures would be implemented.
5.5 Environmental Impacts of Waste			
5.5.1 Nonradioactive Waste System Impacts	Potential impacts to land and groundwater due to the disposal of solid waste.	S	Recycling and waste minimization programs would be employed at Units 6 & 7. Nonradioactive solid waste would be reused or recycled to the extent possible. Solid wastes appropriate for recycling would be managed through use of approved and appropriately licensed commercial waste disposal facilities. Additionally, applicable Florida requirements and standards would be met with regard to the handling, transporting, and disposal of solid wastes offsite. Any onsite waste disposal (e.g., uncontaminated sediment, dredge material) is not under a state regulated program, but the material would be stockpiled in areas with appropriate engineering controls to limit surface water runoff and comply with U.S. Army Corps of Engineers permit.
	Potential impacts to groundwater quality from discharges from the Units 6 & 7 makeup water reservoir. (Treated wastewater and sanitary waste treatment effluent would be disposed through use of the deep injection wells.)	S	Modify the existing Industrial Wastewater Facility Permit for stormwater releases. Obtain the UIC Permit and comply with its permit limits and monitoring requirements.

Table 5.10-1 (Sheet 9 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.5.1 Nonradioactive Waste System Impacts (cont.)	Potential impacts to water quality of surface water due to increased volume of storm water resulting from new impervious surfaces.	S	Environmental best management practices initiated through the IWW permit would be used.
	Potential impacts to air quality from emissions of auxiliary systems operated on an infrequent basis.	S	Comply with the state of Florida PSD permit limits and regulations for operating air emission sources.
5.5.2 Mixed Waste Impacts	Potential impacts to workers health and environment from the handling and disposal of mixed waste generated as a result of the operation of Units 6 & 7.	S	Appropriate hazardous chemical control and radiological control measures would be applied during testing, handling, and storage of mixed wastes. A waste minimization program would be developed and implemented.
5.6 Environmental Impacts of Transmission Systems			
5.6.1 Impacts to Terrestrial Resources	Potential impacts to vegetation and wildlife habitat within the transmission line rights of way from routine maintenance of woody vegetative growth by manual and mechanical methods and herbicides.	S	Maintenance procedures have previously been established. Consultations would be held with appropriate federal, state, and local agencies about mitigation actions for the known populations of multiple threatened and endangered species, as needed.
5.6.2 Impacts to Aquatic Resources	Potential water quality impacts and subsequent impacts to populations of important aquatic species from maintenance activities in transmission corridors that lie at or near water bodies, wetlands, and SFWMD canals.	S	Environmental best management practices would be used to reduce soil erosion and sedimentation to minimize impacts to all aquatic resources, including mangrove rivulus species, a State and Federal species of special concern. Corridor vegetation management and line maintenance programs and procedures have been established to minimize impacts. The same procedures establish strict guidelines for use of herbicides application according to federal, state, and local regulations. In addition, environmental best management practices would be used to reduce soil erosion and sedimentation vegetation management in forested wetlands would be in full compliance with Florida Statute 403.814 General Permits.

Table 5.10-1 (Sheet 10 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.6.3 Impacts to Members of the Public	Potential effects to members of the public resulting from the operation and maintenance of the transmission system. (Impacts may occur as visual impacts, electric shock hazards, electromagnetic field exposure, noise impacts, or radio and television interference.)	S	No mitigation would be required. Transmission lines would conform to standards established by the American National Standards Institute, The National Electrical Safety Code, and such other applicable codes and standards that are generally accepted by the industry, except as modified by Florida statutes.
5.7 Uranium Fuel Cycle and Transportation Impacts			
5.7.1.1 Land Use	Potential impacts to land use from fuel cycle. (Total annual land requirements for fuel cycle support would be approximately 300 acres, 34 acres of which would be permanently committed.)	S	Mitigation would not be required.
5.7.1.2 Water Use	Potential impacts to water resources from fuel cycle. (Total annual water use for the fuel cycle would be 2.95E10 gallons.)	S	No mitigation would be required.
5.7.1.3 Fossil Fuel Impacts	Potential impacts to fossil fuel resources from fuel cycle. (Electric energy needs for fuel cycle would be approximately 5% of the output of one of the proposed units. Natural gas consumption for fuel cycle support if used instead to generate electricity would yield less than 0.4% of the energy output of one of the proposed units.)	S	No mitigation would be required.
5.7.1.4 Chemical Effluents	Potential impacts to air and water quality from fuel cycle. (Gaseous effluents would be less than 0.08% of all 2005 US SO_2 emissions and less than 0.02% of all 2006 US NO_x emissions. Milling process chemical effluents are not released in quantities sufficient to have significant impacts on the environment.)	S	All chemical discharges released into the environment are subject to requirements and limitations set by an appropriate federal, state, local, or Native American tribal regulatory agency.

Table 5.10-1 (Sheet 11 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.7.1.5 Radioactive Effluents	Potential health impacts to members of the public from radioactive effluents from the fuel cycle. The estimated whole-body population dose commitment to the U.S. population would be approximately 4200 person-rem per year, an estimate that correlates with 3.1 fatal cancers, non-fatal cancers, or severe hereditary effects per year to the U.S. population.	S	No mitigation would be required.
5.7.1.6 Radioactive Waste	Potential environmental impacts from disposal of radioactive wastes generated as a result of the fuel cycle. (No significant radioactive releases to the environment are expected from radioactive waste disposal.)	S	No mitigation would be required.
5.7.1.7 Occupational Dose	Potential health impacts to fuel cycle workers caused by radiation exposure. (The estimated occupational dose, attributable to all phases of the fuel cycle, is approximately 1600 person-rem per year for two AP1000 Units.)	S	The dose to any individual would be maintained within the occupational dose limit of 10 CFR Part 20.
5.7.1.8 Transportation	Potential health impacts to transportation workers and members of the public caused by radiation exposure resulting from the loading, unloading, and transport of radioactive materials associated with the fuel cycle. (The estimated dose to workers and the public from transportation associated with the fuel cycle is 6.5 person-rem per year. For comparative purposes, the estimated collective dose from natural background radiation to the population within 50 miles of Units 6 & 7 is 907,000 person-rem per year.)	S	No mitigation would be required.

Table 5.10-1 (Sheet 12 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.7.2 Transportation of Radioactive Materials	Potential health impacts to the public and workers caused by exposure to radiation emitted during incident-free transportation of radiological materials. (Shipments would be less than the one per day condition of 10 CFR 51.52, Table S-4.)	S	Radiological protection programs would manage and limit doses to workers whose jobs would cause them to receive the greatest exposures.
5.8 Socioeconomic Impacts			
5.8.1 Physical Impacts of Station Operation	Potential noise impacts due to the operation of plant systems. The highest levels of noise would be associated with the operation of the mechanical draft cooling towers. (Noise levels at 400 feet from the cooling towers are estimated to be on the order of 65 dBA, a level characterized by the NRC in NUREG-1437 as of small significance.)	S	No mitigation would be required.
	Potential impacts from the increase in traffic noise from the commuting workforce.	S	Noise levels would be minimized by road improvements, including paving the access roads and controlling speed limits.
	Potential impacts to air quality from emissions of auxiliary systems operated on an intermittent basis.	S	Comply with the state of Florida PSD permit limits and regulations for operating air emission sources.
	Potential impacts to greenhouse gases from emissions during operations.	S	No mitigation would be required.
	Potential impacts to air quality from workforce traffic during operations.	S	No mitigation would be required.
	Potential visual impacts to landscape from reactor buildings, cooling towers, and associated plumes.	S	No mitigation would be required.
	Potential impact to area roads from the increase of commuter traffic.	S	No mitigation beyond road improvements installed during construction would be required.

Table 5.10-1 (Sheet 13 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.8.2 Social and Economic Impacts of Station Operation	Potential impacts from the increase in population related to plant operations.	S (Miami-Dade County) S (Homestead and Florida City)	No mitigation would be required.
	Potential impacts from workers' wages on the local economy related to plant operations.	S, positive (Miami-Dade County) S, positive (Homestead and Florida City)	No mitigation would be required.
	Potential impacts related to indirect jobs from plant operation. (This will reduce the unemployment in the ROI.)	S, positive	No mitigation would be required.
	Potential impacts from temporary outage workers impact to the local economy.	S, positive	No mitigation would be required.
	Potential impacts from taxes collected during plant operation.	S, positive (Miami-Dade County) S, positive (Homestead and Florida City)	No mitigation would be required.
	Potential impacts on land use from plant operations. (There would be very little new residential or commercial development and basic land use patterns would remain in place.)	S (Miami-Dade County) S (Homestead and Florida City)	Communication with local and regional governmental and nongovernmental organizations would be maintained, including but not limited to the Department of Planning and Zoning and Department of Community and Economic Development, to disseminate project information. This would allow these organizations to be given the opportunity to plan accordingly.
	Potential impacts from increased traffic on area roadways due to plant operations.	S	No mitigation beyond road improvements installed during construction would be required.
	Potential impacts from increased traffic on area roadways due to outage workers commuting to Turkey Point.	S	No mitigation beyond road improvements installed during construction would be required.

Table 5.10-1 (Sheet 14 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.8.2 Social and Economic Impacts of Station Operation (cont.)	Potential aesthetic impacts from plant operations. (Physical structures and infrastructure of Turkey Point onsite as well as operational activities would produce visual and physical impacts for recreational facilities in the vicinity.)	S	No mitigation would be required.
	Potential aesthetic impacts to recreation from plant operations.	S	No mitigation would be required.
	Potential impacts from increased use of recreational facilities within a 50-mile radius.	S (Miami-Dade County) S (Homestead and Florida City)	No mitigation would be required.
	Potential impacts to housing market affecting prices and rents.	S (Miami-Dade County) S (Homestead and Florida City)	Early communications with local and regional governmental organizations, including the Miami-Dade Planning and Zoning Department and the Greater Homestead and Florida City Chamber of Commerce, could be initiated to disseminate information related to Units 6 & 7, such as the schedule of expected worker influx. County and regional planning organizations, and, ultimately, developers and real estate agencies, could factor the details of the emerging housing market into their decision-making and plan accordingly.
	Potential impacts from the increased water demand due to plant operations-related population increase. (It is estimated that the excess capacity in public water supply will be reduced slightly.)	S (Miami-Dade County) S (Homestead and Florida City)	Communication would be held with local and regional governmental planning organizations such as the Miami-Dade County Department of Planning and Zoning, the Miami-Dade County Water and Sewer Department (MDWASD), and the South Florida Water Management District. FPL could share information such as project activity scheduling, and projected workforce in-migration, thus giving these organizations ample time to prepare for demands on services due to the increased population as a result of Units 6 & 7 operations.

Table 5.10-1 (Sheet 15 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.8.2 Social and Economic Impacts of Station Operation (cont.)	Potential impacts from an increase in wastewater requiring treatment due to operations-related population increase. (It is estimated that the increase in water usage would reduce excess treatment capacity by a small amount.)	S (Miami-Dade County) S (Homestead and Florida City)	Early communication with local and regional governmental organizations, including planning commissions and local and regional economic development agencies, such as the MDWASD, the Miami-Dade Department of Environmental Resources Management (DERM), or the Florida Department of Environmental Protection would be initiated, to disseminate Unit 6 & 7-related information. Local governments and planning groups would have time to plan for the influx. Infrastructure upgrades and expansions could be funded, at least in part, by Unit 6 & 7-related property and sales and use tax payments.
	Potential impacts to police and fire department services due to small increases in the ratio of persons to police and firefighters over pre-construction levels. (The ratio would be less than that during the construction period, which could lead to the dismissal of officers and firefighters hired to provide services at that higher population time.)	S (Miami-Dade County) S (Homestead and Florida City)	Turkey Point-related tax payments, including both property taxes and sales and use taxes made by Turkey Point and its employees, could continue to assist in funding these services.
	Potential impacts to medical services due to medical service needs of operations-related population increase. (This increase remains within current medical service capacity.)	S (Miami-Dade County) S (Homestead and Florida City)	No mitigation would be required.

Table 5.10-1 (Sheet 16 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.8.2 Social and Economic Impacts of Station Operation (cont.)	Potential impacts to schools due to the increase in population from the plant operations workforce resulting in an increase in the student population.	S (Miami-Dade County) S (Homestead and Florida City)	Increased property tax revenues as a result of the increased population, and property taxes on Units 6 & 7, could fund any needed additional teachers and facilities. Florida Education Finance Program and equalized funding legislation would ensure that the M-DCPS receiving the students would receive additional funding to support the educational services; however it also means that the property taxes may not go directly to the M-DCPS. FPL would provide the local communities with timely information regarding the proposed activities at the Turkey Point Plant, giving the school district several years to make accommodations for the additional influx of students.
5.8.3 Environmental Justice Impacts	Potential health and environmental impacts to minority or low-income populations resulting from plant operations. (There would be no disproportionately high and adverse health and environmental impacts to minority or low-income populations within 50 miles via soil, water, or air pathways.)	N/A	No mitigation would be required.
	Potential socioeconomic impacts to minority or low-income populations resulting from plant operations. (There would be no disproportionately high and adverse socioeconomic impacts to minority or low-income populations from operations-related activities. Because portions of commuting routes are located within minority/low-income areas, these populations would experience increased traffic from normal operations and scheduled outages.)	N/A	No mitigation beyond road improvements installed during construction would be required.

Table 5.10-1 (Sheet 17 of 17)
Summary of Potentially Adverse Impacts of Operation

Reference Section	Description of Potential Impact	Significance of Impact[(a)]	Planned Control Program
5.9 Decommissioning			
	Potential impacts from decommissioning the plant. (The decommissioning of a nuclear facility generally has a positive environmental impact, relative to the impacts occurring during operations. In many instances, the environmental impacts resulting from the activities associated with decommissioning are expected to be substantially smaller than those of power plant construction or operation.)	S	Mitigation measures from the operations phase that are applicable to decommissioning would be applied (e.g., radiological control practices).
5.12 Nonradiological Health Impacts			
	Potential nonradiological health impacts from plant operations. (The estimated cases of recordable occupational injuries and illnesses for the onsite worker population of Units 6 & 7 based on U.S., Florida, and Units 3 & 4 incident rates are 25, 31, and 4, respectively.)	(b)	Implement existing Turkey Point industrial safety program at Units 6 & 7.

(a) The assigned significance levels ([S]mall, [M]oderate, or [L]arge) are based on the assumption that for each impact, the associated proposed mitigation measures and controls (or equivalents) would be implemented (10 CFR Part 51, Appendix B, Table B-1, Footnote 3.) Note, for those categories where there is no potential impact and thus no significance of impact, none, is assigned as the significance level.
(b) Impact is potential and estimates are based on national and Florida rates; therefore, impact severity was not assigned.

IWW = Industrial Wastewater
N/A = Not applicable
SWPPP = Stormwater Pollution Prevention Plan
USACE = United States Army Corp of Engineers

5.11 CUMULATIVE IMPACTS RELATED TO STATION OPERATION

This section describes cumulative adverse impacts to the region's environment that could result from the operation of Units 6 & 7. A cumulative impact is defined in Council of Environmental Quality regulations (40 CFR 1508.7) as an "impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time."

To determine cumulative impacts, the impacts of the operation of Units 6 & 7, as described in Chapter 5, were combined with other past, present, and reasonably foreseeable future actions at and near Turkey Point that would affect the same resources, regardless of what agency (federal or nonfederal) or person undertakes such other actions. The cumulative impacts described in this section are those expected to overlap with the impacts of operation of the new units as a result of timing and geographic area. The geographic area that was used when considering cumulative impacts for the various resource areas is found in Table 5.11-1. Not all the impacts of operation of the new units would be cumulative with other past, present, and reasonably foreseeable actions. In addition, the impacts of operation of the new units were based on existing environmental conditions, so the operations impact analyses have already accounted for present actions when the existing state of the resource is used as a comparison for impacts. For example, impacts analysis for water quality and aquatic ecology resources use existing conditions as the baseline for determining impacts. The baseline accounts for the discharges to surface and groundwater from the past as well as the present since discharges directly influence water quality parameters. The aquatic ecology resources baseline would account for past and present actions that play a role in the vitality of aquatic populations and their habitat's ability to sustain a viable population.

With regard to the timing consideration for cumulative impacts from operations, this analysis considers operations impacts from 2022 to the foreseeable future since the time frame for cumulative impacts analysis for construction (Section 4.7) extends to the end of construction activities at Unit 7 in 2022.

During the process of identifying potential projects that could contribute cumulative impacts, a detailed search was conducted for all federal, non-federal and private actions within a 50-mile radius of Turkey Point Units 6 & 7 that had requested either an air or water permit/license or had an environmental impact statement completed. The search was accomplished by searching federal (e.g. USCOE, USGS), state (e.g. FDEP, FDOT), and local (e.g. M-D DERM) websites. The list was refined to projects that were within a 6-mile radius of Turkey Point Units 6 & 7, then within the required timeframe of operation activities of Turkey Point Units 6 & 7, excluding all brownfield and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites.

The timeframe for potential projects that could contribute to cumulative impacts was 2022 to 2063. This timeframe was determined from the schedule for Unit 6 operation activities beginning in the second quarter of 2022 through the initial 40 years license for Units 6 & 7, which would end in 2062 and 2063 respectively. Therefore, the time frame for on-going and future projects to be considered cumulative to those impacts from Units 6 & 7 operation activities is 2022 to 2063.

Other projects in the area considered for cumulative impacts but not retained for analysis are described in Table 5.11-2. Distances listed in Table 5.11-2 are from the Units 6 & 7 plant area unless otherwise noted.

A review of the adopted 2015–2025 Comprehensive Development Plan for Miami-Dade County indicates that land in the 6-mile vicinity, in unincorporated Miami-Dade County, would remain protected land, open land, park land, or agricultural and would not be subject to development. Land farther to the west in the urban areas of Homestead and Florida City had land use designations that would allow development in accordance with local zoning restrictions (MDC Oct 2009). However, given that the time frame for this cumulative impacts analysis is more than 10 years in the future, any information or plans for development in the urban areas would be too speculative for analysis.

5.11.1 LAND USE

As described in Subsection 2.2.1.2, current land use within 6 miles of Units 6 & 7 is described in Table 2.2-2. The vicinity includes areas that have the Land Use Designation “Environmental Protection” and “Open Land” in the Miami-Dade County Comprehensive Development Master Plan (CDMP). Biscayne National Park is northeast of the Turkey Point plant property. The city of Homestead’s Bayfront Park is adjacent to Biscayne National Park.

Most facilities associated with the operation of Units 6 & 7 would be contained in the Turkey Point plant property boundaries except for the reclaimed and potable water pipelines, the portion of the radial collector wells extending under Biscayne Bay, transmission corridors and substation modifications, and the roads improved for use during construction. The potable water and reclaimed water pipelines would follow existing rights-of-way except for areas near the Miami-Dade Water and Sewer Department South District Wastewater Treatment Plant and on the Turkey Point plant property near the FPL reclaimed water treatment facility. New transmission lines would follow existing power transmission corridors to the extent practicable. The laterals for the radial collector wells would be drilled horizontally from the plant property to positions below Biscayne Bay. These features are further described in Subsection 5.1.2. The radial collector wells and portions of the potable water pipelines, reclaimed water pipelines, and transmission corridors are in the 6-mile vicinity. The improved access road, SW 359th Street, would lie within an existing transmission right-of-way and the road improvements, SW 137th Avenue/Tallahassee Road and SW 117th Avenue, would be to existing roads to link to the access road.

Land would be permanently dedicated for Units 6 & 7 and associated infrastructure on the Turkey Point plant property. Additional land would be permanently dedicated for the right-of-ways for new transmission lines, substation modifications, and the reclaimed water and potable water pipelines. The new transmission lines, expanded substations, and the reclaimed water and potable water pipelines would use existing right-of-ways and disturbed areas to the extent practical and right-of-ways are compatible with many agricultural uses. The land use impact for the operation of Units 6 & 7 is described as SMALL in Section 5.1.

As indicated in Table 5.11-3, projects in the vicinity of Homestead and Florida City were considered for cumulative land use impacts. These projects include the continued operation of Units 1 through 5, the Units 3 & 4 Independent Spent Fuel Storage Facility (ISFSI), the Everglades Mitigation Bank (EMB), the INGENCO Resource Recovery Facility, the Homestead-Miami Speedway Improvement project, and the Comprehensive Everglades Restoration Plan (CERP) projects. None of these projects involve a change in land use or acreage during the operation of Units 6 & 7. Future urbanization in the area could contribute to additional decreases in open areas, forests, and wetlands and would generally result in some increase in residential and industrialized areas. Local land-use planning documents describe future construction of residential and commercial buildings (MDC Oct 2009). These urban development projects would have limited impacts on land use because a small incremental amount of land would be converted to a new land use. Overall, the cumulative impact from operation of Units 6 & 7 in conjunction with the projects described above would be SMALL.

Cumulative impacts to historical properties from these projects were also considered. The operation of these projects may potentially involve earth moving activities during maintenance. FPL will develop procedures addressing the inadvertent discovery of historical, cultural, or archaeological resources (Subsection 5.1.3). The operations activities for the CERP projects are overseeing and maintaining pump stations and stormwater treatment impoundments. These operations would likely employ few workers and operations activities are unlikely to impact historical properties outside of the Biscayne Bay Coastal Wetlands (BBCW) project's (Phase 1) objective of positively impacting the Deering Estate by restoring wetlands on this historical property (URS Sep 2006). No impact to historical properties from operation of Units 6 & 7 is anticipated. (Subsection 5.1.3). Given that the other projects considered for cumulative impacts are unlikely to have a significant impact to historical properties, no cumulative impact to historical properties is anticipated.

5.11.2 HYDROLOGY AND WATER USE

5.11.2.1 Surface Water

As described in Section 5.2, Units 6 & 7 would have two sources of makeup water for plant operations and receive potable water from Miami-Dade County for domestic uses. The sources

of makeup water for plant operations would be reclaimed water from Miami-Dade County, via reclaimed water pipelines that would be installed during the construction phase, and water collected in the radial collector wells under Biscayne Bay, where groundwater and the waters of Biscayne Bay are hydrologically connected. Cumulative impacts of using Miami-Dade public water supplies for domestic uses at Units 6 & 7 are considered as a component of overall socioeconomic impacts (Subsection 5.11.4).

Operation of the radial collector wells installed beneath Biscayne Bay would cause a SMALL impact on local hydrology and water use. Based on groundwater modeling, the radial collector wells would be recharged at a rate ranging from approximately 95 to 99 percent (118.2 mgd to 123.2 mgd) from Biscayne Bay. This would be predominately localized in the area of the radial collector wells. The remaining recharge would be from groundwater beneath the plant property. The amount of saltwater used (up to 124.4 mgd if 100 percent saltwater) compared to the size of the saltwater resource available would be insignificant. Impacts to Biscayne Bay surface waters would be SMALL and would not require mitigation. A minimal change in water level elevation would occur.

Operation of Units 6 & 7 would involve cooling towers. The cooling canals of the industrial wastewater facility would be impacted by salt deposition from operation of the Units 6 & 7 cooling towers as described in Subsection 5.3.3. However, the cooling canals already have a high salinity level. Impacts on the American crocodile in the industrial wastewater facility would be mitigated through the existing management/conservation plan that implements measures to protect hatchlings that are more vulnerable to the salinity level. The uprated Units 3 & 4 would have an increased thermal discharge into the cooling canals of a maximum of 2.5°F and would increase salinity by 6 percent. However, the increased temperature and salinity would not adversely impact the thriving American crocodile population. With continued implementation of the management/conservation plan, the cumulative impact on the cooling canals of the industrial wastewater facility would be SMALL.

Cumulative impacts on Biscayne Bay from operation of the radial collector wells and the other projects in the immediate vicinity were considered. The CERP projects would rehydrate wetlands that provide water flow into Biscayne Bay, positively impacting Biscayne Bay. EMB also positively impacts Biscayne Bay by preserving wetlands that provide water flow into Biscayne Bay. Other projects identified in Table 5.11-2 would have no impact on Biscayne Bay. The impact on Biscayne Bay from operation of the radial collector wells would be SMALL (Section 5.1). Therefore, the cumulative impact on Biscayne Bay would be SMALL.

5.11.2.2 Groundwater

As stated above, the operation of Units 6 & 7 would use radial collector wells installed under Biscayne Bay as a makeup water source. Water withdrawals would be a maximum of 86,400 gpm (Section 3.3). The impact of this water withdrawal would be SMALL.

Operation of Units 6 & 7 would also involve injection of plant cooling water and process wastewater into the Boulder Zone of the lower Floridan aquifer via deep injection wells. The operation of these wells is presented in Section 5.2.

Cooling water for Unit 5 and process water for Units 1, 2, and 5 is obtained from the Upper Floridan aquifer (Subsection 2.3.2.2.2.1). The Biscayne aquifer is currently being used for disposal of treated domestic wastewater from the Units 3 & 4 wastewater treatment plant (Subsection 2.3.2.2.2.1). For the new units, sanitary treatment would be provided by a packaged sanitary treatment plant located on the Units 6 & 7 plant area. The sanitary treatment plant would be designed to process sanitary effluent from Units 1 through 7. Units 6 & 7 operations would not lead to cumulative impacts to groundwater resources associated with the existing units, because the uses do not overlap.

The projects described in Table 5.11-3 were considered for cumulative impacts to groundwater. The EMB and CERP projects would not withdraw groundwater and would not have wastewater injection wells. However, the wetland preservation/restoration activities that are included in these projects would likely have a positive impact on groundwater resources since they would promote recharge to groundwater rather than runoff. Other projects identified in Table 5.11-2 would have little to no impact on groundwater resources.

Considering the impact from the radial collector wells and the impacts to groundwater resources from the projects described in Table 5.11-3, the cumulative impact to groundwater resources would be SMALL.

5.11.2.3 Water Quality

Subsection 5.2.3 describes water quality impacts from the operation of Units 6 & 7. The use of environmental best management practices along with a spill prevention plan would prevent or minimize the potential impacts of any releases to the environment. Surface water flow for the existing and new units would primarily be to the cooling canals of the industrial wastewater facility, which would limit impacts to offsite areas. The cumulative impacts to the cooling canals of the industrial wastewater facility are described in Subsection 5.11.2.1.

The non-Turkey Point projects considered for cumulative impacts, CERP projects and EMB, would not withdraw water from surface water or groundwater sources. The CERP projects would provide stormwater treatment to minimize negative impacts to waters ultimately receiving the

treated stormwater, such as the Biscayne Bay and underlying groundwater. Therefore, adverse impacts to surface water or groundwater resources from these projects are not expected. With the determination that the non-Turkey Point projects would not contribute to cumulative impacts to surface water quality, the cumulative impact to surface water quality would stem from the cumulative impacts to the cooling canals of the industrial wastewater facility. The cumulative impact would be SMALL.

As a result of the encroachment of saltwater into the aquifer approximately 6 to 8 miles landward from the coast, groundwater in the vicinity of the Turkey Point plant property is not used as a source of drinking water (Subsection 2.3.1). Impacts to groundwater resources with respect to water quality resulting from the operation of the radial collector well laterals installed beneath Biscayne Bay are described in Subsection 5.2.3.2.3 as SMALL.

Wastewater from the operation of Units 6 & 7, including blowdown, would be injected into the Boulder Zone of the Floridan aquifer via deep injection wells. The FDEP permitting process for injection well permits would be followed, including monitoring requirements for groundwater quality and groundwater elevation data in overlying aquifers. The impact to groundwater resources from this wastewater injection was characterized as SMALL (Subsection 5.2.1.1.9).

Considering that the existing units use of groundwater does not overlap with the uses for operation of Units 6 & 7 (Subsection 5.11.2.2) and that the non-Turkey Point projects would have positive impacts to water quality, cumulative impacts to groundwater quality would not result.

5.11.3 ECOLOGY (TERRESTRIAL AND AQUATIC)

5.11.3.1 Terrestrial

The projects described in Table 5.11-2 that are in the immediate vicinity of the Turkey Point site were considered for cumulative impacts to terrestrial resources. The CERP projects and EMB have positive impacts to terrestrial ecology by restoring and maintaining wetlands allowing plants and animals that depend on wetlands to thrive. Similarly, additional land acquisition and continued conservation activities at the various nature preserves and parks in the area would have positive impacts to terrestrial ecology by preserving natural habitats. Operation of the existing Turkey Point facilities (additional description of Units 3 & 4 uprate below) are subject to management/conservation plans designed to protect important species with particular focus on the threatened American crocodile (Subsection 2.4.1). As described in Subsection 2.4.1, Turkey Point's conservation efforts have contributed to the increase in population of the American crocodile. In addition, other species of special concern are protected with project-specific management plans (Section 4.3). For example, U.S. Fish and Wildlife Service guidelines for the protection of the Eastern indigo snake during construction projects were incorporated into the conservation/management plan for the Unit 5 Expansion Project.

As presented in Subsection 5.11.2.1, the cooling canals of the industrial wastewater facility would experience a cumulative impact from salt deposition from operation of the Units 6 & 7 cooling towers and discharges from the uprated Units 3 & 4 that would increase temperature and saline levels. However, the increased temperature and salinity attributable to the uprated Units 3 & 4 are not anticipated to adversely impact the thriving American crocodile population and salt deposits from the Units 6 & 7 cooling towers into the cooling canals also would not impact salinity levels sufficiently to impact existing crocodile growth and/or survival rates (Subsection 5.3.3).

The impacts to terrestrial ecological resources from operation of the Units 6 & 7 cooling water system and operation and maintenance of the transmission line and pipeline corridors are characterized as SMALL, and SMALL to MODERATE. The impacts to terrestrial resources from the projects considered for cumulative impacts would have a SMALL adverse contribution to cumulative impacts or have a beneficial impact. The overall cumulative impact would be SMALL to MODERATE.

5.11.3.2 Aquatic

The impact to aquatic resources from the operation of Units 6 & 7 was characterized as SMALL in Section 5.3. This SMALL impact along with the projects described above was considered for cumulative impacts to aquatic ecological resources. The CERP projects and EMB would have positive impacts to aquatic ecology by restoring and maintaining wetlands allowing plants and aquatic organisms that depend on wetlands to thrive. As presented above in Subsection 5.11.3.1, the cooling canals of the industrial wastewater facility could experience a cumulative impact from Units 6 & 7 and the uprated Units 3 & 4. As stated in Subsection 5.3.1.2, the fish and aquatic invertebrate species that occur in the cooling canals of the industrial wastewater facility are ubiquitous pioneer species with broad physiological tolerances for salinity and temperature extremes. However, this cumulative impact to the cooling canals of the industrial wastewater facility would have a negligible impact on aquatic biota and would not adversely impact the thriving American crocodile population. The cumulative impacts to aquatic resources would be SMALL.

5.11.4 SOCIOECONOMIC RESOURCES

Impacts to socioeconomic resources stem from the demands placed on the region by the workforce. The facilities and projects described in Table 5.11-2 were considered for their potential to result in cumulative socioeconomic impacts. Because the socioeconomic analysis presented in Subsection 5.8.2 uses existing socioeconomic conditions and forecasts based on existing conditions as a baseline, the impacts of the existing facilities (with the exception of outages) have already been accounted for in the operational impact analysis which concluded that impacts would be SMALL with the exception of transportation, which would be MODERATE.

The projects described in Table 5.11-3 would have no or few workers, which would have a negligible socioeconomic impact. The Units 3 & 4 uprate would lead to greater revenues as a result of the sale of the additional electricity and thus lead to increased corporate taxes. As described in Subsection 5.8.2.2, for every $1 million of net taxable revenues, FPL may pay $55,000 in corporate income tax, which represents an increase of 0.002 percent more than Florida's 2007 corporate income tax revenues. The restored and preserved wetlands of the CERP projects and the EMB would have socioeconomic benefits to the area that are difficult to quantify. The more tangible socioeconomic benefits would include any taxes paid by FPL and other property owners on the compensation paid to the few employees that perform maintenance and monitoring.

In addition to normal operations at the existing units, the nuclear-generating units, Units 3 & 4, would also have periodic outages. With outages occurring at all four nuclear units, the frequency of the temporary impacts from outages would increase. These additional workers (approximately 600 workers for Units 6 & 7) could temporarily increase traffic and housing demand. In addition, there could be temporary and short-term job opportunities for lodging and restaurant workers to serve the outage workforce, along with SMALL and positive impacts to motels, restaurants, retailers, and other businesses patronized by the outage workers.

Given the socioeconomic impacts from the operation of Units 6 & 7 and the other projects considered for cumulative impacts, the cumulative impact to socioeconomic resources would be SMALL with the exception of transportation which would be MODERATE.

An assessment of environmental justice impacts for the operation of Units 6 & 7 concluded that impacts from operations-related activities to minority or low-income populations would, with the exception of transportation, reflect impacts to the general population. Operations and outage activities could cause traffic congestion along several of the main routes to the Turkey Point plant property. These routes travel through minority and/or low-income areas. As stated above, the traffic congestion assessment accounted for the existing units. The outage workforce for Units 3 & 4 averages 600 to 900 workers and would not be concurrent. The potentially larger outage workforce (600 workers for Units 6 & 7 and up to 900 for Units 3 & 4) could increase the traffic on outage days. Therefore, the cumulative impacts to transportation would be MODERATE and cumulative impacts to environmental justice with regard to transportation would also be MODERATE.

5.11.5 ATMOSPHERIC AND METEOROLOGICAL

Impacts to air quality would result from equipment associated with plant auxiliary systems (e.g., diesel generators, diesel-driven fire pumps). Emissions of criteria pollutants from Units 6 & 7 would be from fossil-fired equipment, as presented in Subsection 5.5.1.3. Because such

equipment would be operated infrequently and usually for short periods of time, they would have a SMALL impact to air quality.

As described in Subsection 2.7.2.2, the impact of existing unit operations on air quality conditions at the nearby Florida Everglades Class I Area can be gauged on the basis of air quality monitoring data collected by the National Park Service at the Florida Everglades air quality monitoring station. The National Park Service reported that, based on data collected during the period 1996 through 2005, the trend in National Ambient Air Quality Standards pollutant concentrations during the period was that of a steady-state (Subsection 2.7.2.2).

The uprate project for Units 3 & 4 and Units 3 & 4 ISFSI would not lead to an increase in air pollutants, and the CERP projects and EMB would not have air release, except possibly from the occasional maintenance vehicle. Operation of the INGENCO Resource Recovery Facility would result in criteria pollutant emissions. However, the Florida Department of Environmental Protection (FDEP) concluded that emissions from the INGENCO Resource Recovery Facility would not significantly contribute to, or cause a violation of, any state or federal ambient air quality standards and the INGENCO Resource Recovery Facility's impact on the Everglades Class I area is less than significant (M-D DERM Mar 2010). Therefore, the air pollutants that would be attributable to these projects would have a SMALL impact to air quality and the cumulative impact to air quality would be SMALL.

Operation of the Units 6 & 7 cooling towers would result in plumes, salt deposition, and noise that would have a SMALL impact to atmospheric conditions. The plumes would remain primarily on the Turkey Point plant property. The shadowing and precipitation associated with the plumes would take place primarily onsite (Subsection 5.3.3.1). Modeling predicts maximum salt deposits (105 kg/ha/month) near the makeup water reservoir of the Units 6 & 7 plant area, and salt deposition of 10 kg/ha/month would generally be confined to the Turkey Point plant property and the industrial wastewater facility, with the exception of the southeastern perimeter of the plant property. Additionally, the estimated noise level associated with the Units 6 & 7 cooling towers would drop below 60 to 65 dBA, the level the NRC considers of SMALL significance, at a distance of 500 feet from the cooling towers as a result of attenuation (Subsection 5.3.3). The uprate project for Units 3 & 4, Units 3 & 4 ISFSI, CERP projects and EMB would not have an impact on atmospheric conditions. The Unit 5 cooling tower has plumes that remain primarily on the Turkey Point plant property with shadowing, precipitation, and fogging also staying primarily on the plant property. The salt deposits from the Unit 5 cooling tower would be a maximum average of 6.34 kg/ha/month at 200 meters. Therefore, the cumulative impact to atmospheric conditions would be SMALL.

5.11.6 RADIOLOGICAL

For the purposes of this analysis, the region of interest is the area within the 50-mile radius of the Turkey Point site. The region of interest includes the existing Units 3 & 4, the Units 3 & 4 ISFSI, and a number of hospitals and industrial facilities that use radioactive materials. There are no other new nuclear facilities planned within 50 miles of the site. Because the analysis of radiological impacts presented in Subsection 5.4 uses existing conditions as a baseline, the impacts of the existing facilities have already been accounted for in the operational impact analysis.

Units 6 & 7 would release small quantities of radioactivity to the environment through both permissible liquid and gaseous releases. The permissible liquid releases would be released into deep injection wells approximately 2900 feet underground. Based on a receptor analysis and liquid exposure dose modeling, the predicted doses from radioactive liquid effluent disposal would be negligible. The existing nuclear units, Units 3 & 4, release small quantities of radioactivity. A small radiological dose would be attributable to the Units 3 & 4 ISFSI. Table 5.4-8 shows that the maximum exposed individual doses are within the design objectives of 10 CFR Part 50, Appendix I. Table 5.4-9 shows that the total site doses from the two new units as well as the two existing nuclear units are within the regulatory limits of 40 CFR Part 190. Table 5.4-10 shows that collective doses from the new units to the population within 50 miles of the plant are extremely low compared to collective doses from natural background radiation.

The fuel cycle specific to Units 6 & 7 would contribute to the cumulative impacts of fuel production, storage, and disposal for nuclear units in the United States, but the impacts of the fuel cycle for Units 6 & 7 would be SMALL and the addition of the impacts of Units 6 & 7 would be a SMALL contribution to the cumulative impacts from the nation’s nuclear units. Fuel and waste transportation impacts from Units 6 & 7 would also be SMALL, and would be a minor increase to the cumulative impacts of transportation of nuclear reactor fuel.

5.11.7 WASTE

Units 6 & 7 would generate radioactive and nonradioactive wastes as described in Sections 3.5, 3.6, and 5.5 and implement waste minimization programs and recycling opportunities whenever feasible. The waste management impacts of Units 6 & 7 wastes were characterized as SMALL. The existing units generate nonradioactive wastes that would be disposed of in waste management facilities. In addition, Units 3 & 4 also generate radioactive wastes. Other projects identified in Table 5.11-2 would only generate small quantities of nonradioactive wastes.

Miami-Dade County operates one of the nation's largest integrated solid waste disposal systems, consisting of the Resources Recovery waste-to-energy facility, the North Dade Landfill (a trash-only facility), and the South Dade Landfill (a garbage and trash facility) (MDC 2008). The County

managed 3.8 million tons of solid waste in 2008 (FDEP Aug 2010a). The cumulative waste management impact to the waste management facilities in the area would be SMALL.

The radioactive waste generated by Units 6 & 7 as well as Units 3 & 4 would be disposed of in a permitted disposal facility such as a facility in Clive, Utah, that accepts waste from all states. This facility accepts low-level and mixed radioactive wastes. The facility disposed of 3.9 million cubic feet of low-level waste in 2005 (NRC Mar 2007) and the mixed LLW disposal area is 963,020 cubic yards with additional land for development of future mixed LLW disposal cells (UDEQ May 2005). The cumulative impact from management of low-level and mixed radioactive wastes would be SMALL.

5.11.8 HUMAN HEALTH

The potential impacts to human health from the operation of Units 6 & 7 concern etiological agents promoted by thermal discharge (Subsection 5.3.4), electric shock hazards posed by transmission lines (Subsection 5.6.3), and occupational health hazards (Section 5.12). The potential impacts from these sources were SMALL. The existing units also pose risks to human health. The risk posed by exposure to etiological agents at the existing units is SMALL. The occupational hazards are applicable to workers and not the public. Occupational injury rates at Turkey Point are well below the state and national rates (Section 5.12). Activities associated with operation of projects identified in Table 5.11-3 would also carry a small occupational risk. The potential impact to human health as a result of electrical shock from transmission lines to the public is SMALL. The cumulative potential impact to human health would be SMALL.

5.11.9 SUMMARY

Cumulative impacts associated with land use, hydrology and water use, ecology, socioeconomics, air quality, radiological release, waste, and human health from the operation of Units 6 & 7 along with operation of the existing units, the Units 3 & 4 uprate, the Units 3 & 4 ISFSI, EMB, and CERP projects were assessed. The adverse cumulative impacts are summarized in Table 5.11-3.

Table 5.11-1
Geographic Areas Used in Cumulative Analysis

Resource/Impact	Geographic Area
Land Use	Homestead and Florida City area
Hydrology & Water Use	Surface Water: Surface water at, adjacent to, or downstream of the Turkey Point plant property and offsite areas Groundwater: Biscayne aquifer underlying south Miami-Dade County and the Floridan aquifer
Ecology	Terrestrial: immediate surrounding area Aquatic: Surface water to the north of the Turkey Point plant property encompassing the reclaimed water and potable water pipelines and to the west to U.S. Highway 1 and the downstream points from the Turkey Point plant property (i.e., Biscayne Bay and Card Sound)
Socioeconomics	Local: Homestead and Florida City area Regional: within a 50-mile radius of the Units 6 & 7 project area
Atmospheric and Meteorological	Within a 50-mile radius of the Units 6 & 7 project area
Radiological	Members of the public within a 50-mile radius of the Units 6 & 7 project area
Waste	Nonradiological: Miami-Dade County Radiological: United States
Human Health	Workers and public within a 50-mile radius of the Units 6 & 7 project area

Table 5.11-2 (Sheet 1 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Energy Projects					
FPL - Cutler Power Plant	Two-unit, 205-MW gas- and oil-fired plant	14 miles northeast of Turkey Point site	Operational	M-D DERM Feb 2009	No
FPL - Lauderdale Power Plant	Two-unit, 884-MW gas- and oil-fired plant	45 miles northeast of Turkey Point site	Operational	BCEPGMD Jan 2009	No
FPL - Port Everglades Power Plant	Four-unit, 1205-MW oil- and gas-fired plant	47 miles northeast of Turkey Point site	Operational	BCEPGMD Feb 2010	No
FPL - Turkey Point Power Plant	Five-unit, 3,220-MW power plant. Units 1 & 2 are oil- and gas-fired, Units 3 & 4 are nuclear, Unit 5 is gas-fired.	Turkey Point site	Operational	M-D DERM Mar 2009a	Yes
FPL - Turkey Point Power Plant Units 3 & 4 Uprate	The project will increase the net electrical generation for Units 3 & 4 by 104-MW each.	Turkey Point site	Proposed. Site Certification Application approved by FPSC in October 2008. Application to NRC submitted in 2010. Project completion expected 2nd quarter 2012.	FPL Jan 2008	Yes
Homestead City Utilities - Gordon W. Ivey Power Plant	16-unit, 60-MW oil-fired plant	9 miles northwest of Turkey Point site	Operational	M-D DERM May 2009a	No
INGENCO Resource Recovery Facility	24-unit, 8-MW landfill gas-fired power plant	6 miles northwest of Turkey Point site	Proposed. Draft Air Construction Permit issued March 2010	M-D DERM Mar 2010	Yes
Miami-Dade County Resource Recovery Facility	Four-unit 77-MW municipal solid waste-fired power plant	28 miles northwest of Turkey Point site	Operational	M-D DERM Mar 2008a	No
Wheelabrator South Broward, Inc. - Waste to Energy Facility	Three-unit 67.6-MW municipal solid waste-fired power plant	45 miles northeast of Turkey Point site	Operational	BCEPGMD Dec 2009a	No
Florida Gas Transmission Company Phase VIII Expansion Project	The FGT pipeline will be 6.5 miles long and parallel existing FGT pipelines and FPL transmission lines.	The pipeline will be installed along SW 97 Avenue north of Turkey Point and travel south toward Turkey Point site.	Proposed. The pipeline is planned to be in service in 2010 to 2011	FGT Sep 2008	No

Table 5.11-2 (Sheet 2 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Transportation Projects					
Dade-Collier Training and Transition Airport	Precision instrument landing and training facility for commercial and general aviation.	46 miles northwest of Turkey Point site	Operational. Future development unlikely.	FDOT 2009	No
Fort Lauderdale/ Hollywood International Airport	Full service airport - commercial airlines, air cargo, and general aviation	46 miles northeast of Turkey Point site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009	No
Homestead Air Reserve Base Airport	Military airfield that is the home station to F-16C and F-15A aircraft.	5 miles northwest of Turkey Point site	Operational. Limited development is likely within property.	DOD Oct 2007	No
Homestead General Aviation Airport	General aviation airport.	15 miles northwest of Turkey Point site	Operational. Limited expansion would occur in the future, as described in planning documents.	FDOT 2009	No
Kendall-Tamiami Executive Airport	General aviation airport.	17 miles northwest of Turkey Point site	Operational. Limited expansion would occur in the future, as described in planning documents.	FDOT 2009	No
Miami International Airport	Full service airport - commercial airlines, air cargo, and general aviation. Third busiest international passenger airport in the U.S.	26 miles north of Turkey Point site	Operational. Completion of the $6.2 Billion Miami Intermodal Center capital improvement program expected in 2011.	FDOT 2009	No
North Perry Airport	General aviation airport.	40 miles north of Turkey Point site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009	No
Opa Locka Executive Airport	General aviation and reliever airport for Miami International. The airport is also home to a U.S. Coast Guard Air/ Sea Rescue Station.	33 miles north of Turkey Point site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009	No

Table 5.11-2 (Sheet 3 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Port Everglades	Large full-service deepwater seaport. Florida's main seaport for receiving petroleum products. Current annual throughput of 21.2 million tons of cargo and 128.8 million barrels of petroleum products. Cruise terminal serves 3.1 million passengers annually.	48 miles northeast of Turkey Point site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010	No
Port of Miami	Large full-service deepwater seaport. Current annual cargo throughput of 6.8 million tons. Cruise terminal serves 4.1 million passengers annually.	26 miles northeast of Turkey Point site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010	No
Port of Miami Tunnel & Access Improvement Project	The project will improve access to and from the Port of Miami, serving as a dedicated roadway connector linking the Port with the MacArthur Causeway (SR A1A) and I-395. The project consists of three primary components: widening of the MacArthur Causeway Bridge; tunnel connections between Watson Island and Dodge Island (the Port of Miami); and connections to the Port of Miami roadway system.	26 miles northeast of Turkey Point site	Planned. Construction began in July 2010 and the project could be operational by 2014.	FHWA Undated, Wallis Jul 2010	No
SR826/SR836 Interchange Reconstruction	The project involves a major upgrade to the interchange. Capacity improvements include the reconstruction and widening along both SR826 (Palmetto Expressway) and SR836 (Dolphin Expressway), construction of a four-level interchange, and modifications of the Flagler Street/SR826 and the Milam Dairy Road/NW 72nd Avenue/SR836 interchanges.	26 miles north of Turkey Point site	Planned. Construction began in October 2009 and is scheduled to be completed by late 2014	FHWA Undated	No

Table 5.11-2 (Sheet 4 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Tampa – Orlando – Miami High-Speed Intercity Passenger Rail	This project would provide high-speed rail service from Tampa to Miami (through Orlando) with stops in West Palm Beach and Ft. Lauderdale. The termini for Orlando -Miami corridor are the Orlando International Airport (OIA) and the Miami Intermodal Center at the Miami Airport (MIA).	26 miles north of Turkey Point site	Proposed. Phase 1 (Tampa-Orlando corridor) is ongoing. Project development for Phase 2 (Orlando-Miami corridor) began in May 2010.	FDOT May 2010	No
Parks and Nature Preserve Facilities					
Big Cypress National Preserve	Over 729,000 acres of valuable habitat for a variety of threatened and endangered species, including the Florida panther, West Indian manatee, red cockaded woodpecker, and wood storks. Public recreational activities include bird watching, camping, canoeing, bicycling, off road vehicles, hunting, hiking, and wildlife observation.	44 miles northeast of Turkey Point site	Development limited within property.	NPS Jun 2009	No
Bill Baggs Cape Florida State Park	The upland areas of Cape Florida have undergone a phenomenal transformation since Hurricane Andrew in 1992. Native plant communities have been recreated through continuous staff and volunteer efforts of planting and exotic plant eradication and control. About three miles beach and shoreline are the main attraction for the majority of the park visitors and provides opportunities for picnicking, swimming, bicycling, fishing, primitive camping and nature appreciation.	20 miles north of Turkey Point site	Development limited within property.	FDEP Mar 2001	No

Table 5.11-2 (Sheet 5 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Biscayne National Park	A meld of four distinct ecosystems (mangrove forests, Biscayne Bay, Florida Keys islands, and coral reefs) supporting diverse wildlife including threatened and endangered species such as the West Indian manatee, eastern indigo snake, piping plover, American crocodile, peregrine falcon, Schaus' swallowtail butterfly, least tern, and five species of sea turtle. Public recreational activities include picnicking, hiking, wildlife watching, snorkeling, scuba diving, canoe/ kayaking, and fishing.	Adjacent to eastern edge of Turkey Point site	Development likely limited within property.	NPS Jul 2010a	No
Crocodile Lake National Wildlife Refuge	The Refuge covers 6,700 acres of land, including 650 acres of open water. It contains a mosaic of habitat types, such as tropical hardwood hammock, mangrove forest, and salt marsh. These habitats are vital for hundreds of plants and animals including six federally listed species. The refuge is closed to the public however there is an interpretive butterfly garden adjacent.	12 miles south of Turkey Point site	Additional land acquisition is planned. Development likely limited within property.	USFWS Feb 2006	No
Curry Hammock State Park	The 970 acres represents the remaining example of the natural communities of the Middle Florida Keys and contains tropical hardwood hammocks, salt marshes, and mangrove wetlands. Public recreation activities include swimming, hiking, canoeing/kayaking, and camping.	26 miles southwest of Turkey Point site	Additional 23 acre land acquisition is planned Development likely limited within property.	FDEP Feb 2005	No

Table 5.11-2 (Sheet 6 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Dagny Johnson Key Largo Hammock Botanical State Park	The 2,454 acres of park contain the largest intact West Indian hardwood hammock in the US harboring an extensive list of threatened and endangered plants and animals. In addition a very rare coastal rock barren community, a shoreline dominated by marine tidal swamps, and significant wetland habitat. Public recreation activities include hiking, picnicking, guided nature walks, and educational programs.	12 miles south of Turkey Point site	Development likely limited within property.	FDEP Sep 2004a	No
Everglades National Park	Primarily comprised of internationally important wetlands that cover 1,508,533 acres and are home to rare and endangered species such as the American crocodile, Florida panther, and West Indian manatee.	29 miles west of Turkey Point site	181,000 acres of additional land acquisition is proposed. Development likely limited within property.	NPS Jul 2010b, FNAI 2008, Thomas Reuters 2009	No
Florida Keys Wildlife and Environmental Area	An archipelago of small sites totaling 3,089 acres containing some of the best examples of tropical hardwood hammocks remaining in Florida. These sites protect native plants and animals, many of which are found nowhere else in the US. Recreational facilities or trails have are not developed in order to protect the sites' sensitive natural resources.	31 miles southeast of Turkey Point site	Development of facilities for public use is constrained by the presence of many unique plant and animal species.	USFWS Undated	No
Indian Key Historic State Park	The 110 acre property consists mostly of wetland and water areas that attract boaters for snorkeling and fishing activities. The ruins of the historic settlement on the island are available to the public via guided or self-guided tours.	43 miles southwest of Turkey Point site	Development of facilities for public use limited within property.	FDEP Jun 2000a	No

Table 5.11-2 (Sheet 7 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
John Pennekamp Coral Reef State Park	Submerged land covers over 98% of the 63,836 acres of the park. The water area contains the only living coral reef in the US and the land area consists of over 80,000 linear feet of shoreline with beaches and tropical hammocks. Public recreation activities include swimming, snorkeling, scuba diving, fishing, canoeing, glass bottom boat tours, hiking, camping, and nature appreciation.	17 miles south of Turkey Point site	Additional land acquisition is proposed. Development of facilities for public use limited within property.	FDEP Sep 2004b	No
John U. Lloyd Beach State Park	The park contains 311 acres on the Atlantic Ocean and Intercoastal Waterway and contains natural communities such as beach dunes, coastal strands, maritime hammocks, and tidal swamps. These provide habitat for 11 imperiled plant species and 20 imperiled animals. Public recreation facilities include two large beach use areas, seven large picnic pavilions, a two-lane boat ramp, a pavilion that provides nature study and environmental education opportunities, and a concession stand that provides; food services, and rentals.	47 miles north of Turkey Point site	Development of facilities for public use limited within property.	FDEP May 2001	No

Table 5.11-2 (Sheet 8 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Lignumvitae Key Botanical State Park	Lignumvitae Key is the only Florida Key that is still in its natural state and was chosen as the state's first botanical park. Its rare and delicate ecosystem primarily consists of subtropical hardwood hammock. The smaller island Shell Key is primarily a mangrove island and has been left undisturbed. Islands accessible only by private boat. Public recreation activities include boating, fishing, snorkeling, and diving.	42 miles southwest of Turkey Point site	Development of facilities for public use limited within property.	FDEP Dec 2000	No
Mary Krome Bird Refuge	2.5 acre preserve is bordered on two sides by avocado groves. Public recreation activities include bird and butterfly watching	10 miles northwest of Turkey Point site	Development unlikely in the future.	NABA Undated	No
Oleta River State Park	The park's 1.7 miles of the Oleta River and its associated mangrove wetlands are important habitat for many species The West Indian manatee and golden leather fern are among the 40 designated plant and animal species found in the 1033 acre park. Public recreation activities include picnicking, swimming, canoeing, fishing, bicycling/jogging, and primitive camping.	36 miles north of Turkey Point site	Development of facilities for public use limited within property.	FDEP Dec 2008	No
San Pedro Underwater Archaeological Preserve State Park	The 644 acre preserve consists of the 1733 shipwreck “San Pedro” surrounded by a ring of sandy substrate and seagrass beds. Public recreation activities include snorkeling, scuba diving, and glass bottom boat tours.	45 miles southwest of Turkey Point site	Development unlikely in the future.	FDEP Jun 2000b	No

Table 5.11-2 (Sheet 9 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
The Barnacle Historic State Park	The historic structures in this 9 acre park were built in the late 1800s and include a boat house, carriage house, and the Barnacle house which was originally built as a wooden bungalow four feet off the ground on pilings. About half of the surrounding land supports a tropical hardwood hammock. The primary public activity on the site is visiting the historic home and touring the grounds.	21 miles north of Turkey Point site	Development unlikely in the future.	FDEP Aug 2003	No
Windley Key Fossil Reef Geological State Park	While the upland area at the 32 acre park contains one of the finest hardwood hammocks in the Florida Keys, the park's main attraction is the fossil coral reef exposed by the keystone quarry operations. Public recreation activities include education and interpretation programs, hiking, and nature appreciation.	36 miles southwest of Turkey Point site	Development unlikely in the future.	FDEP May 2003	No
Everglades Mitigation Bank (EMB)	The EMB is a 13,249 acre site permitted by the state of Florida and the Army Corps of Engineers. The EMB consists of land located between U.S. Highway 1 and Card Sound Road and east of Card Sound Road extending to Card Sound, then north along the L-31E Canal. EMB activities would be in accordance with permit conditions.	Just southwest of the Turkey Point site and east of U.S. Highway 1.	Development unlikely in the future.	FDEP Oct 1996, FDEP Oct 2003, USACE and SFWMD Aug 2002	Yes

Table 5.11-2 (Sheet 10 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Comprehensive Everglades Restoration Plan (CERP) Projects					
Biscayne Bay Coastal Wetlands Project - Phase 1	The project would expand and restore wetlands adjacent to Biscayne Bay, and enhance the ecological health of Biscayne National Park. Phase 1 incorporates most of the Deering Estate features, including a spreader canal, culverts, and canal improvements. The Cutler Wetlands features include culverts, a canal and restoration of the Lennar Flow-way. The L-31E Flow-way/ North Canal Flow-way features include a spreader canal and several culverts.	1.5 miles west of Turkey Point site	Proposed. Design and permitting of Phase 1 completed. Construction of L-31E culverts and Deering Estates Flow-way began in 2010. Construction of Cutler Wetlands scheduled to begin in 2011.	SFWMD Jun 2010, USACE Jun 2010	Yes
Broward County Water Preserve Areas	Project serves as a seepage control buffer between developed urban areas and the Everglades. Components include: Water Conservation Areas 3A/3B Levee Seepage Management, C-11 Impoundment, and C-9 Impoundment.	37 miles north of Turkey Point site	Proposed. Basis of Design Report completed. Construction of C-11 Impoundment scheduled to begin in 2012.	SFWMD Jun 2010, USACE Nov 2009	No
C-111 Spreader Canal Western Project	The project would establish more natural water flows in Taylor Slough to improve the timing, distribution and quantity of fresh water flowing into Florida Bay.	6 miles southwest of Turkey Point site	Proposed. Design testing completed. Construction began in 2010.	SFWMD Jun 2010, USACE May 2009	Yes
Central Lake Belt Storage Area	The project would store excess water from Water Conservation Areas 2 and 3 and provide environmental water supply deliveries to Northeast Shark River Slough, Water Conservation Area 3B, and to Biscayne Bay.	30 miles north of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	No

Table 5.11-2 (Sheet 11 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Everglades National Park Seepage Management Project	Project to improve water deliveries to Northeast Shark River Slough and restore wetland in Everglades National Park by reducing levee and groundwater seepage and increasing sheetflow. There are three components: L-31N Levee Improvements for Seepage Management, S-356 Structure Relocation and Bird Drive Recharge.	22 miles northwest of Turkey Point site	Proposed. Construction scheduled to begin in 2014.	USACE Mar 2006, USACE Nov 2009	No
L-31N (L-30) Seepage Management Pilot Project	Project evaluates the uncertainty and constructability of seepage management technology for possible full-scale use along Everglades National Park.	19 miles northwest of Turkey Point site	Proposed. Project activities expected to be completed in 2012.	USACE Nov 2009	No
Melaleuca Eradication and other Exotic Plants	Project enhances efforts to control invasive exotic species in south Florida through mass clearing and controlled release of biological agents.	Throughout the region	Proposed. Project is scheduled to begin in 2011.	USACE Nov 2009	No
Miccosukee Tribe Water Management Plan	Project includes providing water storage capacity and water quality enhancement for Miccosukee Tribe's reservation discharge waters and conversion of 900 acres of tribally owned cattle pasture into a managed wetland retention/detention area.	45 miles northwest of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	No
North Lake Belt Storage Area	Project will include an in-ground storage reservoir with a total capacity of approximately 90,000 acre feet and associated canals, pumps, and water control structures. It will store a portion of the stormwater runoff from the C-6, C-11, and C-9 basins.	34 miles north of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	No

Table 5.11-2 (Sheet 12 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Restoration of Pineland and Hardwood Hammocks in C-111 Basin	This project includes restoring south Florida slash pine and hardwood hammock species on a 200-foot wide strip on each side of two miles (approximately 50 acres) of Florida SR 9336 and the establishment of two, one acre hammocks alongside the road. The project will provide water quality treatment for runoff passing through the hammocks and demonstrate techniques required to re-establish native conifer and hardwood forests.	14 miles west of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	No
South Miami-Dade Reuse	Project will include an expansion in the existing South District Wastewater Treatment Plant to provide additional water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project at sufficient quantity and water quality to meet the ecological goals and objectives of Biscayne Bay. This will require construction of a pretreatment and membrane treatment system.	6 miles north of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	Yes
Water Conservation Area 2B Flows to Everglades National Park	The project purpose is to store excess water from Water Conservation Area 2 in the Central Lake Belt Storage Area through control structures and conveyance features. Additionally, the project will supplement environmental water supply deliveries to North Shark River Slough, Water Conservation Area 3B and Biscayne Bay.	30 miles north of Turkey Point site	Proposed. Currently in preconstruction design.	USACE Undated	No

Table 5.11-2 (Sheet 13 of 17)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Turkey Point Site During the Construction Period (2022-2063)

Project Name	Summary of Project	Location	Status	Reference	Retained
Water Conservation Area 3 Decompartmentalization and Sheetflow Enhancement Project	Construction of new water control structures and modification or removal of levees, canals, and water control structures in Water Conservation Areas 3A and 3B for reestablishment of the ecological and hydrologic connection with Everglades National Park.	25 miles northwest of Turkey Point site	Proposed. EIS currently being drafted.	USACE Nov 2009	No
West Miami-Dade Reuse	The project includes a wastewater treatment plant expansion of a future West Miami-Dade Wastewater Treatment Plant to meet water demands from the Bird Drive Recharge Area, South Dade Conveyance System, and Northeast Shark River Slough.	21 miles northwest of Turkey Point site	Proposed. Currently in pre-construction design.	USACE Undated	No
Modified Water Deliveries to Everglades National Park	Project restores the natural hydrologic conditions in Everglades National Park, which were altered by the construction of roads, levees, and canals. The project includes four major components: an 8.5 mile area flood mitigation, Tamiami trail modifications, conveyance and seepage control features, and a combined operation plan.	22 miles northwest of Turkey Point site	Proposed. Construction underway. Project Completion anticipated in 2013.	USACE Nov 2009	No
C-111 South Dade Project	Project enhances freshwater wetlands and improves freshwater flows in the Southern Glades and in southern Miami-Dade County. It improves the hydrology of the coastal marshlands of northeastern Florida Bay.	6 miles southwest of Turkey Point site	Proposed. Preliminary design of initial Phase completed. Project completion anticipated in 2014.	USACE Nov 2009	Yes

Project Name	Summary of Project	Location	Status	Reference	Retained
Other Actions/Projects					
Central and Southern Florida Flood Control Project	The C&SF Flood Control Project was intended to provide flood control, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources. Today the CS&F project includes 1000 miles of canals, 720 miles of levees, and almost 200 water control structures. It covers 16 counties over an 18,000-square-mile area. The existing project provides water supply, flood protection, water management and other benefits to South Florida. The project has had unintended negative effects on the Everglades and the entire south Florida ecosystem.	Throughout the region.	Operational	HRA Jun 2006	No
Independent Spent Fuel Storage Facility for Turkey Point Power Plant Units 3 & 4	The Units 3 & 4 ISFSI will be a dry storage facility for spent nuclear fuel that would not have a liquid discharge and would only have limited operational activities.	Co-located on the Turkey Point site	Proposed. Facility currently under construction. Loading expected in 2011.	FDEP Jun 2009 FPL Nov 2010	Yes
AAR Landing Gear Center	Repair and rebuild aircraft landing gears and brakes.	30 miles northwest of Turkey Point site	Operational	M-D DERM Jul 2009	No
Aero Kool Corporation	Overhaul aircraft air cycle equipment and heat exchangers and operation of degreaser baths and paint booths	27 miles northeast of Turkey Point site	Operational	M-D DERM Feb 2006	No
American Whirlpool Products Corporation	Acrylic and fiberglass bath and spa manufacturer	43 miles northeast of Turkey Point site	Operational	BCEPGMD Dec 2003	No
Angler Boat Corporation	Fiberglass boat manufacturer	29 miles northeast of Turkey Point site	Operational	M-D DERM Dec 2006	No
Benada Aluminum of Florida Inc	Extruded aluminum products manufacturer	29 miles northeast of Turkey Point site	Operational	M-D DERM Mar 2006	No
Bertram Yacht Inc	Fiberglass boat manufacturer	26 miles northeast of Turkey Point site	Operational	M-D DERM Sep 2009	No
Blumberg Industries -Fine Art Lamps	Lamp manufacturer	33 miles northeast of Turkey Point site	Operational	M-D DERM Nov 2008	No

Homestead-Miami Speedway Improvements.	This project would expand the spectator area to include 120 acres currently used for overflow parking add 12,000 spectator seats.	5 miles northwest of Turkey Point site	Proposed. If approved the project is scheduled to be completed in 2013.	HMS 2010	Yes
Media Printing Corporation	Commercial printer	29 miles northeast of Turkey Point site	Operational	BCEPGMD Dec 2009b	No
Miami Seaquarium	The 38-acre marine park is an entertainment venue that is dedicated to education, wildlife conservation and community involvement.	23 miles northeast of Turkey Point site	Operational	Miami Seaquarium 2009	No
Miami-Dade Water and Sewer Department - Alexander Orr Water Treatment Plant	Water treatment plant also operates a 150 tpd rotary lime kiln	19 miles northwest of Turkey Point site	Operational	M-D DERM Jul 2008	No
Miami-Dade Water and Sewer Department - Hialeah/ Preston Water Treatment Plant	Water treatment plant also operates a 120 tpd rotary lime kiln and 64 air stripping towers	28 miles northeast of Turkey Point site	Operational	M-D DERM Jan 2006	No
Midnight Express Powerboats	Fiberglass boat manufacturer	46 miles northeast of Turkey Point site	Operational	BCEPGMD Jun 2009	No
Ram Investments of South Florida - Sea Enterprise Adventures	Fiberglass boat manufacturer	28 miles northeast of Turkey Point site	Operational	M-D DERM Jun 2006	No
Titan America, LLC - Pennsuco Cement	Cement kiln	31 miles northwest of Turkey Point site	Operational	M-D DERM Sep 2008	No
US Foundry & Manufacturing Company	Gray iron foundry and cast iron products manufacturer	30 miles northwest of Turkey Point site	Operational	M-D DERM Apr 2010	No
Water Reclamation and Wastewater Treatment Plants	Numerous plants	Within 50 miles of Turkey Point site	Operational	FDEP Aug 2010a, FDEP Aug 2010b	No
Future Urbanization	Construction of housing units and associated commercial buildings; road, bridges, and rail; construction of water and/or wastewater treatment facilities and associated pipelines.	Throughout the region.	Construction would occur in the future, as described in state and local land-use planning documents.	MDC Nov 2007	No

Note: All the projects listed in the table would have impacts on land use, water use, ecology, and socioeconomics within the 50-mile radius of the Turkey Point Units 6 & 7 project.

Summary of Adverse Cumulative Impacts

Category	Description of Cumulative Impact	Potential Cumulative Impacts Significance
Human Health	1. Units 6 & 7 – occupational risk 2. Existing units – occupational risk, injury rate below national and state rates 3. Units 3 & 4 Uprate – included with existing units 4. Units 3 & 4 ISFSI – included with existing units 5. EMB – occupational 6. CERP Projects – occupational	SMALL

CERP = Comprehensive Everglades Restoration Plan
EMB = Everglades Mitigation Bank
ISFSI = Independent Spent Fuel Storage Installation

5.12 NONRADIOLOGICAL HEALTH IMPACTS

5.12.1 PUBLIC HEALTH

Public health impacts from the operation of Units 6 & 7 are presented in Subsection 5.6.3 (from transmission line operation) and Subsection 5.8.1.

5.12.2 OCCUPATIONAL HEALTH

Units 3 & 4 have an industrial safety program and safety personnel to promote safe work practices and respond to occupational injuries and illnesses. The program addresses hearing protection, confined space entry, personal protective equipment, electrical safety, ladders, chemical handling, storage and use, and other industrial hazards. At Units 3 & 4, the training manager is responsible for ensuring workers are trained on these safety procedures. The effectiveness of this industrial safety program is reflected in a statistic known as total recordable cases (TRC). TRCs include work-related injuries or illnesses that include death, days away from work, restricted work activity, medical treatment beyond first aid, and other criteria. The average TRC incidence rate for the Units 3 & 4 workforce for 2004 through 2008 was 0.4 cases per 100 workers. This compares favorably to the nationwide rate for nonfatal occupational injuries and illnesses for electrical power generation workers of 2.7 per 100 workers (BLS 2008a) and to the rate of 2.8 per 100 workers for Florida for electrical power generation, transmission, and distribution (BLS 2008b).

To protect workers during operation of Units 6 & 7, an industrial safety program would be instituted that meets applicable federal and state safety requirements. It is estimated that 806 onsite workers would be needed to operate Units 6 & 7 (see Subsection 3.10.3). In addition, the number of outage workers is assumed to be approximately 600 per outage. Using the number of workers and TRC incidence rates, the number of TRCs per year for Units 6 & 7 can be estimated. The estimated TRC incidences are presented in Table 5.12-1. As indicated in Table 5.12-1, the annual estimate for injuries and illnesses at Units 6 & 7 is 3.1, well under the number that would be expected at an electric power generation facility based on national and state incident rates. The nationwide 2007 fatality rate for workers employed in the utility industry of 3.9 per 100,000 workers (BLS 2008c) was used to estimate fatalities at Units 6 & 7. The annual fatality estimate is 0.03 fatalities using the national rate. The TRC incidences occurring in the Units 3 & 4 workforce for 2004 through 2008 (the records used to estimate TRCs for Units 6 & 7) were all nonfatal. The industrial safety program instituted for Units 6 & 7 would be equally effective.

6.0 ENVIRONMENTAL MEASUREMENTS AND MONITORING PROGRAMS

This chapter evaluates the environmental measurements and monitoring related to the construction and operation of Units 6 & 7. This section describes the monitoring programs that were initiated for Units 6 & 7 during the pre-Application phase and would be continued during construction, preconstruction, and operation phases.

This chapter is divided into the following sections:

- Section 6.1 — Thermal Monitoring
- Section 6.2 — Radiological Monitoring
- Section 6.3 — Hydrological Monitoring
- Section 6.4 — Meteorological Monitoring
- Section 6.5 — Ecological Monitoring
- Section 6.6 — Chemical Monitoring
- Section 6.7 — Summary of Monitoring Programs

Information about these six environmental measurements and monitoring programs is summarized in Section 6.7. Additional information on specific permit requirements described throughout Chapter 6 is outlined in Table 1.2-1.

6.1 THERMAL MONITORING

6.1.1 PRE-APPLICATION THERMAL MONITORING

The Units 6 & 7 pre-application thermal monitoring program was performed to establish background water temperatures for the Biscayne aquifer at the plant area prior to construction and operation of Units 6 & 7. As presented in Subsection 2.3.1, there are no freshwater streams, lakes, or impoundments on the Turkey Point plant property. In addition, no lakes or impoundments considered to be waters of the state or the U.S. would be used or affected by the construction or operation of Units 6 & 7. This phase of the monitoring is designed to establish background conditions and support the thermal descriptions that are presented in Section 2.3.

Temperatures at the Units 6 & 7 plant area were reported at twelve monitoring wells at the upper and lower screened intervals (Table 2.3-21) of the Biscayne aquifer and two surface water monitoring locations in the return canals of the industrial wastewater facility to establish baseline temperature conditions. Figure 2.3-25 shows the locations of the monitoring wells and surface water monitoring locations.

6.1.2 CONSTRUCTION AND PREOPERATIONAL THERMAL MONITORING

The construction and preoperational thermal monitoring program is designed to continue monitoring activities during the development stages (site preparation and construction) of Units 6 & 7 until they are operational. The monitoring activities are described in the following paragraphs.

6.1.2.1 Surface Water

Thermal monitoring at the existing units' release to the industrial wastewater facility will continue in accordance with the IWW Facility Permit (FL0001562).

As part of the planned uprates of Units 3 & 4, thermal monitoring of Biscayne Bay will be performed.

No construction or pre-operational thermal monitoring of Units 6 & 7 stormwater releases to the cooling canals of the industrial wastewater facility would be performed because the stormwater would not be thermally altered.

Specific monitoring would be developed as part of the National Pollutant Discharge Elimination System (NPDES) permit process for construction activities that would occur offsite (e.g. linear facilities such as transmission corridors). The need for modifications to the monitoring program would be regularly assessed and implemented as necessary over the duration of the construction and preoperational thermal monitoring program.

6.1.2.2 Groundwater

As part of construction activities, an exploratory deep injection well would be installed to investigate the geology and hydrogeology of the site for the feasibility of disposal of fluids via deep well injection. The deep injection well and a dual zone monitoring well would be installed on the eastern perimeter of the Units 6 & 7 plant area. If the deep injection well is used for the disposal of wastewater during construction, thermal monitoring at the dual zone monitoring well would be performed on a weekly, then monthly (after operational testing) sampling interval in accordance with the UIC permit requirement. Thermal monitoring of the waste stream would likely be performed monthly.

A total of six dual zone monitoring wells would be installed at the Units 6 & 7 plant area to monitor groundwater as part of the operation of the 12 deep injection wells. Preoperational groundwater monitoring using selected zone monitoring wells would begin prior to plant operation to establish a baseline for water temperatures in the aquifers that would be affected by deep well injection from Units 6 & 7.

6.1.3 OPERATIONAL THERMAL MONITORING

The operational thermal monitoring program is designed to monitor surface and groundwater thermal impacts due to the operation of Units 6 & 7. The monitoring activities are described in the following paragraphs.

6.1.3.1 Surface Water

Thermal monitoring at the existing units' release to the industrial wastewater facility will continue in accordance with the IWW Facility Permit (FL0001562).

As part of the planned uprates of Units 3 & 4, thermal monitoring of Biscayne Bay will be performed.

No operational thermal monitoring of Units 6 & 7 stormwater releases to the industrial wastewater facility would be performed because the stormwater would not be thermally altered.

Since the radial collector wells would be a secondary cooling water source for Units 6 & 7, the monitoring frequency would be dependent upon operation. During operation, field measurements of temperature would be collected from the return canal of the industrial wastewater facility and Biscayne Bay in the area of the Turkey Point barge slip.

6.1.3.2 Groundwater

A total of six dual zone monitoring wells would be installed at the Units 6 & 7 plant area to monitor groundwater as part of the operation of the 12 deep injection wells. Thermal monitoring

at the dual zone monitoring wells would be performed on a monthly sampling interval in accordance with the UIC permit requirement. Thermal monitoring of the waste stream in the deep injection wells would likely be performed monthly.

The water pumped from the radial collector wells would be monitored for temperature. Groundwater could also be monitored for temperature at monitoring wells located adjacent to the radial collector wells and along the shoreline.

6.2 RADIOLOGICAL MONITORING

The general features of the Turkey Point radiological monitoring program, currently in place for Units 3 & 4, would not change as a result of the operation of Units 6 & 7. Some additional measurement locations would be identified in support of Units 6 & 7 construction and operations. The current and planned radiological monitoring program is described in the following paragraphs.

6.2.1 RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM BASIS

The existing Radiological Environmental Monitoring Program (REMP) is described in the Turkey Point Offsite Dose Calculation Manual (ODCM) (FPL 2007) and is summarized in the following subsections.

6.2.2 RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM CONTENTS

Preoperational data collected in the early 1970s provides a baseline for the existing units and Units 6 & 7. The measurement of radiation levels, concentrations (including surface area), and/or other quantities of radioactive material are used to evaluate potential exposures and doses to members of the public and the environment.

The following exposure pathways to radiation are monitored:

- Direct (dosimeters)
- Airborne (iodine and particulates)
- Waterborne (surface water, groundwater, and shoreline sediment)
- Aquatic (fish and crustacea tissue)
- Ingestion (fish and crustacea tissue)
- Vegetation (broadleaf vegetation)

The ODCM provides a detailed description of the monitoring program including number and location of sample collection points and measuring devices and the pathway sampled or measured, sample collection frequency and sampling duration, type and frequency of analysis, general types of sample collection and measuring equipment, and lower limit of detection for each analysis. Sampling media and sample size are defined in environmental monitoring and laboratory standard operating procedures.

Sampling results and locations are evaluated to determine effects from seasonal yields and variations. Figures 6.2-1 and 6.2-2 show the existing remote and local radiological sampling locations near the site, respectively. Table 6.2-1 provides details of the radiation exposure pathways monitored and the frequency of monitoring. Tables 6.2-2 and 6.2-3 provide remote and local sample descriptions and locations, respectively. Trending and comparison reviews provide information regarding changes in background levels and determine the adequacy of analytical techniques in light of program results and changes in technology, when compared to baseline measurements. Changes in program implementation (including sampling techniques, frequencies, and locations) may occur as a result of monitoring results.

FPL conducts a supplemental monitoring program in addition to the required program. The sample sites, frequency, and analyses have been agreed to with the Florida Department of Health. These samples are not required to be performed, but based on this agreement, are performed to provide a broader database for the REMP. Sample descriptions and locations are shown in Table 6.2-4.

FPL participates in a voluntary industry initiative on groundwater protection, developed by the Nuclear Energy Institute. Currently, nine wells are sampled quarterly. Samples are analyzed for tritium and principal gamma emitters. Sample results are included in the Annual Radiological Environmental Operating Report and the Annual Radiological Effluent Release Report. This groundwater sampling program is described in Appendix B of the REMP. Sample locations are shown in Table 6.2-5.

6.2.2.1 Preoperational and Operational Radiological Monitoring Programs

The existing Units 3 & 4 radiological monitoring program would serve as the preoperational radiological monitoring program. The existing REMP would be modified for Units 6 & 7 and would be based on *Offsite Dose Calculation Manual Guidance: Standard Radiological Effluent Controls for Pressurized Water Reactors*, 1991 (NUREG-1301) and the NRC's Branch Technical Position Paper, *An Acceptable Radiological Environmental Monitoring Program, Revision 1*, 1979.

The ODCM would be modified for Units 6 & 7 based on the Technical Specifications and would address the requirements of 10 CFR Part 50, Appendix I. One of the requirements is the publication of the Annual Radiological Environmental Operating Report. As noted in the DCD (WEC June 2011) Chapter 16 — Technical Specifications, Section 5.6, a single report can be prepared for a multiple-unit station. Therefore, the Turkey Point REMP would address the releases from the Turkey Point site as a whole. This modified REMP would retain compliance with the Units 3 & 4 Technical Specifications and ODCM.

Additional direct radiation monitoring thermoluminescent dosimeter (TLD) locations would be added at the exclusion area boundary around Units 6 & 7. For preconstruction and construction

monitoring, TLDs would be placed at the Units 6 & 7 reactor locations to determine the external radiation exposure levels.

As described in Sections 3.4 and 3.5, small amounts of radioactivity, well below regulatory limits, would be discharged from Units 6 & 7 to the Lower Floridan aquifer (Boulder Zone) through the deep injection wells. The well casings would be installed to a depth of approximately 2900 feet below grade. Each deep injection well pair would be equipped with a dual zone monitoring well. The upper monitoring zone would extend from approximately 1400 to 1420 feet below grade, and the lower monitoring zone would extend from approximately 1850 to 1870 feet below grade. These monitoring wells would serve as sample points for groundwater monitoring. These new groundwater pathway sample locations are shown on Figure 3.1-3.

The existing REMP is conducted in accordance with RG 4.15, *Quality Assurance for Radiological Monitoring Programs (Normal Operations) — Effluent Streams and the Environment, Revision 1*, 1979. Quality assurance is provided in the existing NRC-approved REMP through quality training, program implementation by periodic tests, the Inter-laboratory Comparison Program, and administrative and technical procedures. The modified REMP would be conducted in accordance with RG 4.15, *Quality Assurance for Radiological Monitoring Programs (Normal Operations) — Effluent Streams and the Environment, Revision 2*, 2007.

6.2.3 RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM REPORTING

An Annual Radiological Environmental Operating Report for Turkey Point is submitted in accordance with the existing units' ODCM. Results from REMP implementation and evaluation are compared to results from previous years for measurement trends, methodology consistency, and indications that the program is adequate and does not need revisions.

A land use census is conducted annually within a designated distance of the site, currently five miles, to determine sampling yields and locations, and to ascertain if changes to the REMP are warranted. Information collected includes locations of nearest residence, milk-producing animal, and garden with broadleaf vegetation in each of the 16 compass directions. The radius of this land use census would be expanded to include the area within six miles of the mid-point between Units 3 & 4 and Units 6 & 7.

Source: FPL 2007

(a) Deviations are permitted from the required sampling schedule if specimens are unobtainable due to circumstances such as hazardous conditions, seasonal unavailability, and malfunction of automatic sampling equipment or other legitimate reasons. If specimens are unobtainable as a result of sampling equipment malfunction, corrective action shall be taken before the end of the next sampling period. All deviations from the sampling schedule will be documented in the Annual Radiological Environmental Operating Report pursuant to Control 1.4.

(b) Specific parameters of distance and direction sector from the centerline of the plant vent stack and additional description where pertinent, will be provided for each and every sample location in tables and figure(s) in the ODCM.

(c) At times, it may not be possible or practicable to continue to obtain samples of the media of choice at the most desired location or time. In these instances, suitable alternative media and locations may be chosen for the particular pathway in question and appropriate substitutions made within 30 days in the Radiological Environmental Monitoring Program given in the ODCM.

(d) The following definition of frequencies shall apply to Table 6.2-1 only:
Weekly — Not less than once per calendar week. A maximum interval of 11 days is allowed between the collection of any two consecutive samples.
Semimonthly — Not less than 2 times per calendar month with an interval of not less than 7 days between sample collections. A maximum interval of 24 days is allowed between collection of any two consecutive samples.
Monthly — Not less than once per calendar month with an interval of not less than 10 days between collection of any two consecutive samples.
Quarterly — Not less than once per calendar quarter.
Semiannually — One sample each between calendar dates (January 1–June 30) and (July 1– December 31). An interval of not less than 30 days will be provided between sample collections.
The frequency of analyses is to be consistent with the sample collection frequency.

(e) One or more instruments, such as a pressurized ion chamber, for measuring and recording dose rate continuously may be used in place of, or in addition to, integrating dosimeters. For the purposes of this table, a TLD is considered to be one phosphor; two or more phosphors in a packet are considered as two or more dosimeters.

(f) Refers to normal collection frequency. Most frequent sample collection is permitted when conditions warrant it.

(g) Airborne particulate sample filters are analyzed for gross beta radioactivity 24 hours or more after sampling to allow for radon and thorium daughter decay. In addition to the requirement for a gamma isotopic on a composite sample, a gamma isotopic is also required for each sample having a gross beta radioactivity which is >1.0 pCi/m3 and which is also >10 times that of the most recent control sample.

(h) Gamma isotopic analysis means the identification and quantification of gamma-emitting radionuclides that may be attributable to the effluents from the facility.

(i) Discharges do not influence drinking water or groundwater pathways.

(j) Offshore grab samples.

(k) Samples of broadleaf vegetation grown nearest each of two different offsite locations of highest predicted annual average ground level D/Q, and one sample of similar Broadleaf vegetation at an available location 15–30 kilometers distant in the least prevalent wind direction based upon historical data in the ODCM.

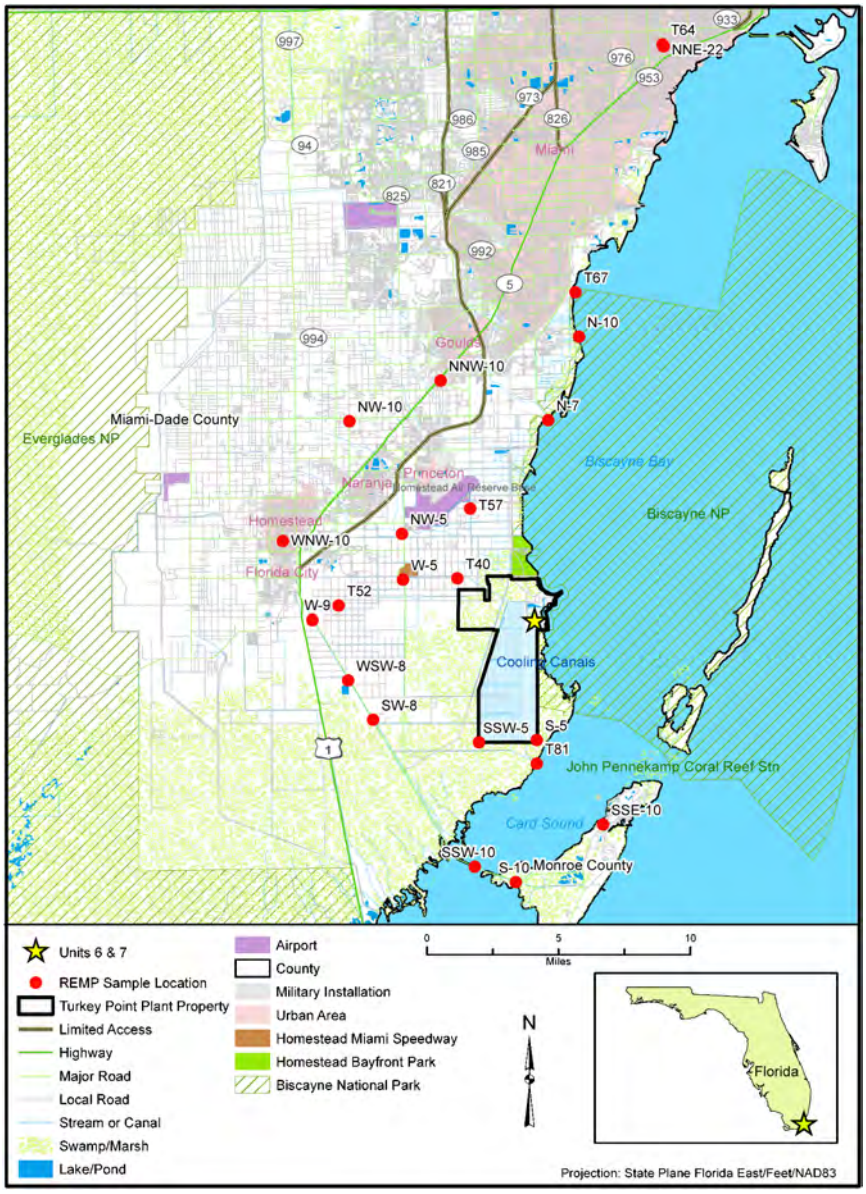

Figure 6.2-2 Units 6 & 7 Remote REMP Sample Locations

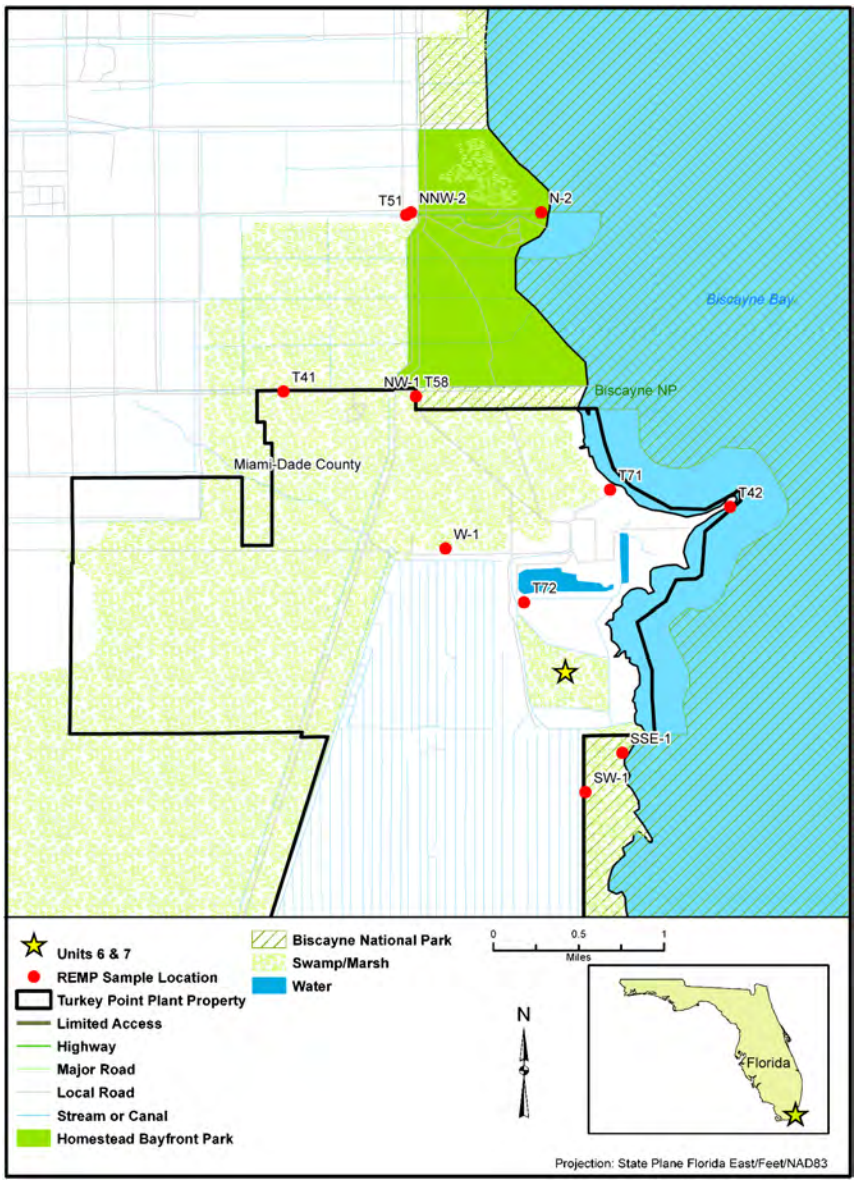

6.3 HYDROLOGICAL MONITORING

This section addresses the hydrologic monitoring program that would be implemented to monitor the effects of Units 6 & 7 on the local hydrology. The hydrological monitoring includes baseline (pre-application) groundwater monitoring, field studies for the radial collector wells and deep injection wells, monitoring of construction dewatering activities and surface water discharge, and operational monitoring of the deep injection wells and radial collector wells.

6.3.1 PRE-APPLICATION HYDROLOGICAL MONITORING

This phase of the monitoring supported the background hydrologic descriptions presented in Section 2.3. The objective of the pre-application hydrologic monitoring program is to document background conditions of local groundwater before the construction and operation of the Units 6 & 7. Additional monitoring was performed during pumping tests at the Units 6 & 7 plant area to provide design-level hydrogeologic data for construction dewatering. The pre-application monitoring is described in the following sections.

6.3.1.1 Groundwater Monitoring — Units 6 & 7 Plant Area

This data consisted of groundwater level measurements obtained from shallow and deep monitoring wells installed at the Units 6 & 7 plant area. The monitoring wells and water level measurements are summarized in Table 2.3-15. Figure 2.3-25 depicts the location of the monitoring wells. In addition, water levels were monitored at several monitoring wells using pressure transducers on an hourly (first month) and continuous 36-hour period per month (remainder of year).

6.3.1.2 Groundwater Monitoring — Pumping Tests

Groundwater pumping tests were performed at the Units 6 & 7 plant area to collect hydrogeologic information to determine the design level data for construction dewatering. Monitoring included baseline water levels to determine tidal influences before and during the pumping tests.

Monitoring of the pumping test included discharge rates at each pumping well and water level measurements at multiple, temporary monitoring wells screened at several levels from approximately 10 feet below grade to 110 feet below grade. Subsection 2.3.1.2.2.3 describes the results of these tests.

6.3.2 CONSTRUCTION HYDROLOGICAL MONITORING

The objective of the construction hydrologic monitoring program is to monitor and control potential effects caused by site preparation and construction. Controls and mitigation measures for anticipated construction effects are presented in Section 4.2.

6.3.2.1 Surface Water

As addressed in Section 4.2, the construction activities for Units 6 & 7 would be performed as required under the existing Florida Department of Environmental Protection (FDEP) National Pollutant Discharge Elimination System (NPDES) permit. FDEP adopted the *Generic Permit for Stormwater Discharge from Large and Small Construction Activities* under Rule 62-621.300(4) of the Florida Administrative Code (F.A.C.). Construction activities would be in accordance with any new permit requirements for Units 6 & 7, including any monitoring requirements. As required, a stormwater pollution prevention plan would be developed or the work would be performed under existing FPL permits/plans for construction activities that would require dewatering. The potential effects of groundwater drawdown on surface water features in the vicinity of the construction would be monitored.

Hydrologic monitoring of surface water during the construction of Units 6 & 7 would include monitoring of the cooling canals (e.g., water level, turbidity) to ensure no adverse impacts on the operations of Units 1 through 4.

In addition, hydrologic monitoring of surface water would be established at surface water monitoring points most likely to be potentially impacted by construction activities. These locations could include the barge turning basin and Biscayne Bay and would be monitored for applicable hydrologic parameters including turbidity to ensure no adverse impacts to surface water.

Specific monitoring would be developed as part of the NPDES permit process for construction activities that would occur offsite (e.g., roadway improvements, transmission substation expansion, and linear facilities such as transmission line rights-of-way, reclaimed water pipelines, and potable water pipelines). The need for modifications to the monitoring program would be regularly assessed and implemented as necessary over the duration of the construction hydrological monitoring program to ensure no adverse impacts.

6.3.2.2 Groundwater

As addressed in Section 4.2, the dewatering required for site preparation and the excavation of the Units 6 & 7 power block area could impact groundwater in the area. Several pre-application monitoring wells (Figure 2.3-25) are located within the construction area for Units 6 & 7, and therefore, would have to be abandoned in accordance with FDEP or South Florida Water Management Department regulatory guidelines before construction activities. Several replacement wells may require installation at appropriate locations to ensure adequate monitoring continues during construction. During dewatering activities associated with the construction of the power blocks, temporary monitoring wells may be installed near construction areas to monitor changes in the water table.

As presented in Section 4.2, construction-related wastewater may be discharged to a deep injection well. As previously described in Section 6.1, an exploratory deep injection well would be constructed, along with a dual zone monitoring well. Once permitted, the deep injection well and dual-zone monitoring well would be operated to monitor the injection process and ensure that no adverse effects occur to the overlying aquifer units. Table 6.3-1 summarizes the monitoring of this deep injection well. The data would be collected and submitted to FDEP in accordance with the underground injection control well permit.

Hydrologic alteration to groundwater from the improvement of existing site roads could occur. However, impacts resulting from the hydrologic alteration of groundwater flow, if it occurs, would be temporary and groundwater would return to pre-existing conditions. Therefore, no hydrologic monitoring of groundwater in these areas would be required during construction activities.

Impacts to groundwater flow from equipment barge unloading area modifications would be temporary and groundwater would return to pre-existing conditions. Therefore, no hydrologic monitoring of groundwater in these areas would be required during construction activities.

Any dewatering activities related to construction activities that would occur offsite (e.g., roadway improvements, transmission substation expansion, and linear facilities such as transmission line rights-of-way, reclaimed water pipelines, and potable water pipelines) would be localized and temporary, therefore, no hydrologic monitoring of groundwater in these areas would be required.

6.3.3 PREOPERATIONAL HYDROLOGICAL MONITORING

The preoperational hydrological monitoring program would be designed to provide the baseline for evaluating hydrologic changes arising from the operation of Units 6 & 7. The preoperational hydrological monitoring program would begin approximately 1 year before Unit 6 operation to establish a refined baseline. Additional monitoring wells may be installed following construction activities and before plant operation.

Surface water monitoring during the preoperational phase would be similar to the construction phase. The water level elevation of the existing cooling canals would continue to be monitored during this phase until groundwater levels in the vicinity of the power blocks return to normal. Once this occurs, surface water elevation data for the cooling canals in the vicinity of Units 6 & 7 would be collected to reestablish a baseline for the operations of the radial collector wells.

6.3.3.1 Surface Water

Surface water monitoring for the cooling canals of the industrial wastewater facility during the preoperational phase would be addressed using the existing surface water monitoring program and would suffice as the preoperational hydrologic baseline.

Pre-operational hydrological monitoring for the radial collector wells could include surface water stage within the return canal of the industrial wastewater facility and in Biscayne Bay in the area of the equipment barge unloading area.

During the preoperational phase, it could be necessary to perform routine maintenance on the offsite facilities (e.g., transmission lines, reclaimed and potable water pipelines, access roads). Any disturbances to surface water flow as a result of the activities would be temporary and would not require hydrologic monitoring.

6.3.3.2 Groundwater

Monitoring would be conducted to reestablish baseline conditions for groundwater levels and flow direction after construction is complete. Permanent monitoring wells at the Units 6 & 7 plant area would continue to be monitored to determine the effects of the construction activities on local groundwater.

Initial startup and monitoring plans would be developed and executed as necessary to demonstrate the operational effectiveness of the radial collector wells and the effects on the local groundwater flow regime and surface water bodies such as the industrial wastewater facility and Biscayne Bay.

As previously described in Section 5.2, the operation of the deep injection wells would consist of 12 deep injection wells and 6 dual zone monitoring wells to monitor the potential impact of the injection process on overlying aquifer units. It is anticipated that hydraulic monitoring would be similar to the construction monitoring summarized in Table 6.3-1. Groundwater monitoring data would be collected and submitted to the FDEP in accordance with the underground injection control well permit.

Preoperational testing of the deep injection wells would be performed to validate the initial construction and monitor the effects on local groundwater at the site. Preoperational startup testing and monitoring plans for the deep injection wells would be developed and implemented.

During the preoperational phase, it could be necessary to perform maintenance that would require excavation and dewatering at offsite facilities (e.g., transmission lines, reclaimed and potable water pipelines, access roads). The dewatering activity could create temporary drawdown of the water table. However, the water table and flow would return to normal once dewatering ceased. No hydrologic monitoring of these offsite facilities is required during preoperation.

6.3.4 OPERATIONAL HYDROLOGICAL MONITORING

This phase of the monitoring would document observable effects from Units 6 & 7 operation. The operational hydrologic monitoring program would be designed to document the effects of the operation of the units and detect any unexpected effects that arise from facility operation. The operational hydrological monitoring program is anticipated to extend preoperational monitoring for the duration of the Units 6 & 7 operation. Modifications to the monitoring program (for example, changes in monitoring stations or collection procedures) would be regularly assessed over the duration of the operational hydrological monitoring program.

6.3.4.1 Surface Water

As addressed in Section 5.2, the FDEP has delegated authority of the NPDES permitting program for the state of Florida. Florida adopted the federal storm water general permit for industrial activities as specified in Rule 62-621.300(5) (a), F.A.C., and operates the permit as the *State of Florida Multi-Sector Generic Permit for Stormwater Discharge Associated with Industrial Activity*. Stormwater from Units 6 & 7 would be released to the industrial wastewater facility under a requested modification of the site's non-discharge IWWF permit.

It is anticipated that surface water monitoring of the existing cooling canals would continue to be performed similar to the preoperational monitoring activities.

Since the radial collector wells would be a secondary cooling water source for Units 6 & 7, the monitoring frequency would be dependent upon their operation. Surface water stages would be measured within the return canal of the industrial wastewater facility and in Biscayne Bay in the area of the equipment barge unloading area.

6.3.4.2 Groundwater

Specifics related to the operational monitoring are anticipated to be similar to the specifics for the preoperational hydrological monitoring program. An operational plan for hydrologic monitoring may be implemented to identify changes in groundwater hydrology from the pumping of water from the radial collector wells. The groundwater level monitoring program would consist of extending preoperational monitoring for the duration of the Units 6 & 7 operation. The need for modifications to the monitoring program (for example, changes in monitoring stations or frequency of collection) would be regularly assessed over the duration of the operational hydrological monitoring program.

As presented in Section 5.2, wastewater and cooling tower blowdown would be discharged to the Boulder Zone of the Lower Floridan aquifer via deep injection wells. Twelve deep injection wells and six dual-zone monitoring wells would be operated. It is anticipated that the hydraulic

monitoring program would be similar to the exploratory well monitoring program and is summarized in Table 6.3-1.

During operation, the volume of water pumped by the radial collector wells would be monitored. Groundwater could be also monitored at monitoring wells adjacent to the collector wells and along the shoreline to collect field measurements of water elevation.

During the operational phase, it could be necessary to perform routine maintenance on the offsite facilities (e.g., transmission lines, reclaimed and potable water pipelines, access roads). Any disturbances to surface water flow as a result of the activities would be temporary and would not require hydrologic monitoring.

Table 6.3-1
Hydrological Monitoring of the Deep Injection Wells

Monitoring Station	Parameter	Frequency
Deep Injection Wells	Flow Rate	Continuous
Dual Zone Monitoring Wells	Water Level	Continuous

6.4 METEOROLOGICAL MONITORING

The meteorological monitoring program is the same throughout the pre-application, preconstruction, construction, and operational phases. The monitoring program is a continuation of the ongoing meteorological monitoring program for Units 3 & 4.

The purpose of this section is to establish that the onsite meteorological measurements program used by Units 6 & 7 would be adequate to: (1) describe local and regional atmospheric transport and diffusion characteristics, (2) ensure environmental protection, and (3) provide an adequate meteorological database for evaluation of the effects of plant operation. This description includes an analysis of the meteorological monitoring system that provides an evaluation of:

- Tower location and instrument siting
- Meteorological parameters measured
- Meteorological sensors
- Data recording and transmission
- Instrument surveillance
- Data acquisition and reduction
- Data validation and screening
- Data display and archiving
- System accuracy
- Data recovery rate and annual and joint frequency distribution of data
- Need for additional data sources for airflow trajectories

This evaluation demonstrates that the meteorological monitoring program meets the requirements of 10 CFR Part 50, Appendix I and 10 CFR 51.45(c), 51.50, and 100.20(c)(2) and the guidance in Section C of RG 1.23, Revision 1, with the exception of humidity measurements; Section C.4 of RG 1.111, Revision 1; RG 1.21, Revision 1 and ANSI/ANS 3.11, Dec 2005.

6.4.1 GENERAL DESCRIPTION — ONSITE METEOROLOGICAL MEASUREMENTS PROGRAM

The location at which meteorological measurements would be necessary in order to characterize the dispersion conditions depends largely on the complexity of the terrain in the vicinity of the site. The following briefly describes the topographic features of the Turkey Point vicinity. This description, together with the description in Section 2.7 regarding the topographic features and the dispersion characteristics of the Turkey Point plant property, forms the basis for assessing the adequacy of the meteorological monitoring program for Units 6 & 7.

As a peninsula, Florida receives sea breezes from both the Gulf of Mexico and the Atlantic Ocean. The major local influence on onsite meteorology is the presence of the Atlantic Ocean. Units 6 & 7 would be located less than 0.4 miles west from the shore of Biscayne Bay. Figures 2.7-1 and 2.7-15 provide 50-mile and 5-mile radius maps, respectively. As shown in Figure 2.7-1, terrain within 50 miles is generally flat and rises gently from sea level at the shore to approximately 86 feet MSL northeast of the site and 8 to 10 miles west of the site. Additional images presenting terrain variations by downwind sector are shown in Figure 2.7-14.

6.4.2 PREOPERATION MONITORING PROGRAM

Unit 3 began operation in 1972 and Unit 4 in 1973. Renewed operating licenses for both units were issued by the NRC in 2002 (NUREG-1437). The onsite meteorological measurement program includes the South Dade 60-meter guyed meteorological tower that serves as the primary data collection system and the land utilization (LU) 10-meter tower with engineered guy wires that serves as a backup to the primary system. The 10-meter tower is used for emergency situations at Turkey Point. The South Dade tower was rebuilt in 1994. Meteorological data from the South Dade tower was used for pre-application analysis. The backup meteorological system is an independent system installed and maintained for the purpose of providing redundant site-specific meteorological information (10-meter wind speed, wind direction, and sigma theta), representative of the local environment.

The onsite meteorological measurement program for both the primary and backup towers was upgraded in 2007 to support the new Units 3 & 4 Distributed Control System (DCS) installation. Existing data loggers and radio communication equipment were replaced with improved instrumentation to enhance the maintainability and reliability of the system. The upgraded system included meteorological tower communication hardware and computer software.

The monitoring system is equipped with lightning protection and redundant power supplies.

For preparation of the COL Application, the adequacy and accuracy of the meteorological collection system were assessed based on the recommendations contained in NUREG-1555. The areas assessed include tower locations, siting of sensors, sensor performance

specifications, methods and equipment for recording sensor output, data acquisition and reduction procedures, and the quality assurance program for sensors, recorders, and data reduction. The findings, as summarized in Tables 6.4-1 through 6.4-4 conclude that the instrument heights, location of the South Dade tower, relocation of the LU tower, system accuracies, methodologies for data acquisition and reduction, and procedures for instrumentation surveillance conform to RG 1.23 Revision 1 (except for humidity measurements as previously noted) and industry standard ANS/ANSI 3.11 (Dec 2005). Data collected by the South Dade tower for Units 3 & 4 provides a suitable data set for Units 6 & 7.

Because the South Dade tower and instrument siting conform to RG 1.23, Revision 1, data collected by the tower is representative of the overall site meteorology. Instrumentation surveillance and data validation in accordance with the applicable regulatory and industry guidance has routinely been performed to ensure data quality as well as to achieve the acceptable annualized data recovery rate of 90 percent.

Data collected from the South Dade tower has been used for Units 6 & 7 to:

- Describe local and regional atmospheric transport and diffusion characteristics
- Calculate the dispersion estimates for both postulated accidental and expected routine airborne releases of effluents
- Evaluate environmental risk from the radiological consequences of a spectrum of accidents
- Provide an adequate meteorological database for evaluation of the effects of construction and operation, including radiological and nonradiological impacts and real-time predictions of atmospheric effluent transport and diffusion.

6.4.2.1 Location, Elevation, and Exposure of Instruments

Factors that were considered in determining how well the measurement instrument locations would represent the conditions for Units 6 & 7 include the prevailing wind direction, topography, and location of man-made and vegetation obstructions.

Findings, as presented below, indicate that the data collected from the South Dade tower is suitable for use in characterizing atmospheric dispersion conditions for Units 6 & 7.

6.4.2.2 Tower Siting and Instrument Conformance

The geographic coordinates for the South Dade tower are: 25º 21' 05.74120" north latitude and 80º 22' 45.54962" west longitude. The geographical coordinates for the LU tower are: 25º 25' 35.072" north latitude and 80º 20' 15.536" west longitude.

As shown in Figure 2.7-15, the area within five miles of Units 6 & 7 is generally flat with terrain variation of approximately seven feet. The locations of the South Dade and LU meteorological towers with respect to the existing and new units are shown in Figure 6.4-1 and 6.4-2, respectively. The South Dade tower is approximately 5.8 miles southwest of Units 6 & 7, at elevation 0.8 feet MSL, while the LU tower is currently approximately 0.30 miles northwest of Units 6 & 7, at elevation 3 feet MSL. The finished grade at the Units 6 & 7 power blocks would be approximately 25.5 feet MSL.

Although the base of the South Dade tower is approximately 25 feet below the elevation of the finished plant grade of Units 6 & 7, there would be minimal terrain variations between the Units 6 & 7 plant area and the South Dade tower. The locations of the South Dade meteorological tower and Units 6 & 7 have similar meteorological exposures.

The base of the LU tower would be approximately 22 feet below the finished plant grade of Units 6 & 7. Based on the relatively close distance (0.30 miles) of the LU tower to Units 6 & 7, the LU tower would have different meteorological exposures than Units 6 & 7 and would require relocation.

6.4.2.3 Obstructions

The wind sensors should be located over level, open terrain at a distance of at least 10 times the height of any nearby natural and man-made obstructions (e.g., terrain, trees, and buildings), if the height of the obstruction exceeds one-half the height of the wind measurements (RG 1.23, Revision 1). Therefore, an assessment regarding whether the wind measurements made at locations and heights on the South Dade and LU towers would avoid airflow modifications by obstructions was made and the findings are described below.

Equipment shelters, housing the data acquisition system for tower measurements and a backup diesel generator, are located adjacent to both the South Dade and LU towers. The shelters are located on raised mounds to protect them from tidal surges and hurricanes.

The South Dade equipment shelter mound (the built up area on which the shelter rests) is approximately 21.5 feet north of the South Dade tower and the equipment shelter building is approximately 36.8 feet north of the tower. The roof height of the shelter (relative to 60-meter tower base elevation) was measured; the shelter mound at approximately 9.6 feet above ground level north of the tower and the shelter roof at approximately 10.8 feet above the base, for a total height of approximately 20.4 feet.

Possible obstruction interference on the South Dade meteorological measurement was evaluated. The azimuth angles of each side of the shelter were sighted and measured from the tower base. These form the basis of defining a sector of possible influence. This sector extends from approximately 353 degrees to 28 degrees in the 360-degree tower wind measurement field.

A frequency of occurrence analysis of wind direction for one year (January–December 2003) of wind data from the 10-meter level from the sector of possible influence occurred 6.8 percent of the time during 2003. It was concluded that the effects of the building mound/shelter at the 10-meter wind measurement were minimal.

There have been no changes to obstructions in relation to the South Dade tower. As previously stated, potential wake effects are not considered to have influenced wind measurements from the South Dade tower during the period of record used to support preparation of this COL Application.

The surrounding terrain, nearby trees, and plant structures (existing and planned) were also evaluated to determine whether they could affect the meteorological measurements. As shown in Figure 6.4-1, surrounding terrain of the South Dade tower, located in an open field, is generally flat with low profile plants. No terrain-induced airflow influence on the meteorological measurement would result. The tallest existing and planned buildings (both Units 3 & 4 and Units 6 & 7) would be approximately 5.8 miles northeast from the South Dade tower. No building-induced obstructions to airflow would result from Units 6 & 7.

Finally, wind sensors are mounted on a boom extending six feet outward on the upwind side of the tower to minimize tower structure influence.

The LU meteorological tower equipment shelter is currently located approximately 35 feet (10.7 meters) west of the 10-meter LU tower. With an obstruction height of approximately 20 feet, according to the 10 times the height of the obstruction convention, the tower should be 200 feet away. Since tower separation from the obstruction is approximately 35 feet, the site does not meet conventional specifications for the measurement of an obstruction. A utility pole is located northwest of the LU tower. It should be noted however, that similar to the South Dade tower, the obstructions are not in the path of prevailing east wind direction flow.

Due to increased traffic during Units 6 & 7 construction and the raised elevation of the finished plant grade (25.5 feet MSL) and associated structures, the LU tower would need to be relocated to an appropriate location on the plant property to ensure tower/instrument operation is in conformance with relevant regulations and guidance documents.

6.4.2.4 Heat and Moisture Sources

Based on the structure layout as shown in Figure 6.4-3, the ambient temperature measurements on the South Dade tower were assessed to determine whether they avoid air modification by any heat and moisture sources (e.g., ventilation sources, cooling towers, water bodies, large parking lots). A brief description is also included for the LU tower.

The South Dade tower is in a field with grassy surfaces. There are no large concrete or asphalt parking lots or temporary land disturbances such as plowed fields or storage areas nearby. The closest large concrete or asphalt parking lots and ventilation sources are at Units 3 & 4, which is approximately 6.5 miles from the South Dade tower.

The cooling system for Units 6 & 7 would include six mechanical draft cooling towers. As shown in Figure 6.4-1, the cooling canals of the industrial wastewater facility are approximately 4500 feet northeast of the South Dade tower at their closest point, while the Units 6 & 7 cooling towers would be located approximately 5.5 miles northeast of the South Dade tower. The location of the South Dade tower is not directly downwind of the cooling canals or the Units 6 & 7 cooling towers under the prevailing downwind wind direction (i.e., easterly). Therefore, there would be no influence on the South Dade heat sensors. In addition, the tower temperature sensors are mounted in fan-aspirated radiation shields, which are horizontal to minimize the impact of thermal radiation and precipitation. The monitoring functions on the South Dade tower would be maintained.

The LU tower is located immediately adjacent to the main return canal in the industrial wastewater facility (Figure 6.4-2). Although the proximity to the canals could impact temperature measurements, temperature is not measured at the LU tower. The LU tower is used for emergency situations only (short-term) and not for normal data collection/reporting. The LU tower is located near an asphalt road, however the road has very little traffic and again, temperature is not measured at the LU tower. The potential effects from temperature would not be a factor for tower relocation.

No parameters related to atmospheric moisture are currently measured on the Turkey Point plant property.

6.4.2.5 Wind Loss

Both precipitation gauges are equipped with funnel screens, but not equipped with wind shields to prevent wind-caused under-recording of precipitation. However, wind effects on precipitation catch losses are known to be much greater during snowfall than rainfall, and snowfall is not a factor at the Turkey Point plant property.

6.4.2.6 Meteorological Parameters Measured

Meteorological instrumentation includes two levels of measurements on the South Dade tower, and a single level on the LU tower. The meteorological data collected for NRC reporting take all of their data from the South Dade tower. The LU 10-meter data would be used as backup, if needed. The meteorological instrumentation on these towers is summarized in Table 6.4-3.

The actual height of the sensors for wind direction and speed at the 10-meter elevation of the South Dade tower (height from bottom of concrete pad base is 11.58 meters (38.0 feet). The Units 6 & 7 reactor buildings would have no stacks. Power block accident atmospheric release points for the AP1000 are at ground level, 25.5 feet above sea level, below the upper wind measurement height (i.e., 60 meters). Ground level releases include all release points or areas that are lower than two and one-half times the height of adjacent solid structures. Because the ground level release scenario provides a bounding case, and none of the release heights is higher than 2.5 times the height of the associated reactor containment shield building, elevated releases were not considered. Meteorological parameters measured for these releases are consistent with RG 1.23, Revision 1, Section 2.

Ambient temperature is monitored both at the 10- and the 60-meter levels. The actual height of temperature sensors A and B at the 10-meter elevation of the South Dade tower (height from bottom of concrete pad base is 10.36 meters (34 feet) above ground level. Vertical differential temperature (i.e., ΔT) is calculated as the difference between the temperatures measured at the 10-meter and 60-meter levels. Precipitation is measured using a tipping bucket precipitation gauge mounted at ground level but away from the tower shelter to prevent any interference in precipitation capture. The precipitation gauge is located 24.5 feet (7.5 meters) southeast from the base of the 60-meter tower. Solar radiation is measured approximately 23 feet (7 meters) southeast from the base of the 60-meter tower at 4 feet (1.2 meters) above ground, but the data collected was not used in preparing this COL Application.

On the LU tower, wind speed, wind direction, and wind direction standard deviation (i.e., sigma theta for atmospheric stability class determination), are obtained at the 10-meter level.

6.4.2.6.1 Meteorological Sensors

A description of the meteorological sensors including sensor type, manufacturer model, sensor specifications (including sensor starting threshold, range, and measurement resolution), and system accuracy for the Units 3 & 4 data collection system during the preoperational monitoring period for the current configuration are provided in Table 6.4-4.

As presented in Subsection 6.4.2, the existing meteorological data collection system was upgraded in 2007 to support the new DCS system installation, which included upgrading data logger and radio communication equipment in the control buildings for both the primary and backup towers to enhance maintainability and reliability of the system. Climatronics cup sets and bi-vane are used for wind measurements. Climatronics temperature sensors are used for ambient temperature and ΔT calculations. Campbell Scientific added bridge circuits to the thermistor to provide a voltage input directly to the data loggers. A Climatronics 8-inch rain gauge (tipping bucket) is located approximately 24.5 feet southeast from base of the South Dade tower.

Meteorological sensors used on both the primary and backup meteorological towers are designed to operate in the environmental conditions found at Turkey Point. Specifically, these instruments are capable of withstanding the following environmental conditions as provided in the specification of the upgraded meteorological monitoring system:

- Ambient temperature range of –40.0°F (–40°C) to +120.0°F (49°C).
- Wind load up to 100 mph (45 meters per second) (The wind sensors were damaged at 100 mph when tested by Hurricane Andrew).

The instruments on the towers, past and present, are off-the-shelf components that are used universally throughout the nuclear industry and other industries for meteorological measurement. Based on operating experience, the only adverse operational effects that have been noted were the susceptibility of the rotating cup and weather vane instruments to bearing wear and degradation as a result of the site environmental conditions that required the instruments to be replaced approximately every six months.

6.4.2.6.2 Instrumentation Surveillance

Calibration and maintenance of the onsite meteorological monitoring system is in accordance with RG 1.23, Revision 1, Section C.5, Regulatory Position, Instrument Maintenance and Servicing Schedules, and ANS/ANSI 3.11, Section 7, System Performance (ANS/ANSI Dec 2005).

The meteorological equipment is kept in proper operating condition by staff that are trained and qualified for the necessary tasks. The existing meteorological monitoring system is calibrated semiannually at both the primary and backup towers, and channel checks are performed daily in order to achieve maximum data recovery. System operability is also checked by using the system's three radio frequencies, one which is exclusive to the land utilization building. Two other radio frequencies are exclusive to the Units 3 & 4 plant computers to remotely monitor the system status. More frequent calibrations and/or replacement intervals for individual components may be conducted, on the basis of the operational history of the component type.

Detailed instrument calibration procedures and acceptance criteria are followed during system calibration. Calibrations verify and, if necessary, reestablish accuracies of sensors, associated signal processing equipment, and displays. Routine calibrations include obtaining both as-found (before maintenance) and as-left (final configuration for operation) results. The end-to-end results are compared with expected values. Any observed anomalies that may affect equipment performance or reliability are reported for corrective action. If any acceptance criteria are not met during performance of calibration procedures, timely corrective measures (e.g., adjusting

response to conform to desired results by qualified personnel on site or returning the sensor to vendor for calibration) are initiated.

Inspection, service, and maintenance, including preventive and/or corrective maintenance on system components for transmitting, manipulating, and/or processing meteorological data for computer display or storage, are performed according to the instrument manuals and plant surveillance program procedures to maintain at least 90 percent data recovery.

6.4.2.7 Meteorological Data Processing

The data processing procedure for Units 6 & 7 meteorological data involves three basic steps:

- Data acquisition
- Data processing
- Data analysis

6.4.2.7.1 Data Acquisition

Following an upgrade of the meteorological program in 2007 to accommodate the DCS installation, data has been collected and electronically transmitted to various plant computers for display. The LU computer is used for QC checks, but reports are done only from manual data collection from the towers directly. Archives of this data are held in hard copy in document control and digitally on the network drive.

The recorders were removed when the DCS system was installed. A modbus radio modem to a data logger transmits across fiber optic link to the plant computer.

Running 15-minute averages are performed at the towers and are transmitted to the plant. This is because of the risk of reconstruction error in the VHF radio modems; however, data from the meteorological tower is transmitted to a computer at the LU office, capable of reading the meteorological tower data real time. Refer to Figures 6.4-3 and 6.4-4 for the system block diagrams for the current configuration.

6.4.2.7.2 Data Processing

The processing equipment is housed in environmentally controlled (air conditioned) shelters. A direct readout capability from these microprocessors during routine system inspection is included.

The microprocessors sample the meteorological processor modules once per second for each parameter measured. Rainfall is monitored for pulse counts and calculated to a 15 minute total

and hourly total. Water collected by the rain gauge is automatically drained and counted each time an internal bucket fills with 0.01 inch of rainfall.

The microprocessors provide current sampling values as well as the 15- and 60-minute averages. Sigma theta is computed for each wind direction channel in the microprocessor. These calculated averages are output to the data logger. Data can be stored to a diskette by plugging in a laptop and downloading it for subsequent system monitoring, data verification, and processing uses.

6.4.2.7.3 Data Analysis

Meteorological data is generally reviewed every workday to identify possible data problems and notify appropriate personnel. Meteorological data is validated before it is placed into permanent archival storage to verify that the amount of valid data in the master record meets regulatory requirements for minimum data collection.

Meteorological validations are performed to ensure accurate data transmission from the sensors and include checks such as minimum wind speed, minimum wind direction, wind speed, and wind direction comparisons between the 10- and 60-meter levels, temperature ranges, and hourly ΔT limits.

Computer software is used in the screening process to identify recurring types of data errors, including the following items:

- Missing data (out-of-range values) and unchanging data for the 10-meter wind speed, wind direction, and ΔT for the primary tower.
- The daily average difference between the primary and backup tower wind speeds and wind directions measured at 10 meters.
- Periods of daytime stable and nighttime unstable conditions.
- The parameter and the date(s) and time(s) requiring adjustment or correction are accurately identified. The reasons that the data is to be edited (missing or questionable) are indicated as well as the basis for the corrections or adjustments. Methods for data substitution include using the following:
    - — Alternate monitor (e.g., backup tower instrument or sigma theta to estimate atmospheric stability)
    - — Extrapolation for short durations if the observations before and after the missing/ questionable data is consistent (persistence)

— Seasonal average data

The quality of the adjusted data is reviewed, and suspected data is flagged. Any data adjustments or corrections are documented and archived. In addition, visual scanning of the 10-meter wind speed and direction data will be routinely performed for abnormal values or inconsistency.

Routine hourly average data would be downloaded and formatted monthly for review and editing. Acceptable data editing methods have been established and implemented. Typically, missing or invalid primary tower 10-meter wind speed, wind direction, and ΔT data are manually replaced with backup tower data. Upon completion of the validation and editing, the meteorological data constitute quality records.

6.4.2.7.4 Data Display and Archiving

In order to identify rapidly changing meteorological conditions for use in performing emergency response dose consequence assessments, 15-minute average values would be compiled for real-time display in the Units 6 & 7 control rooms, technical support center, and emergency operations facility. The meteorological channels required for input to the dose consequence assessment models are available and presented in a format compatible for input to these dose assessment models in RG 1.97.

An additional feature of the data acquisition system is the storage of the 15- and 60-minute averaged meteorological data. At a minimum, the latest 12 months of averaged data resides on the system hard-drive. The historical data can be retrieved, archived, displayed, or printed.

6.4.2.7.5 System Accuracy

Sources of error for time-averaging digital systems include sensors, cables, signal conditioners, temperature environments for signal conditioning and recording, equipment, recorders, processors, data displays, and data reduction process.

The system accuracies of the meteorological data collection system are compared to the regulatory requirements and the findings are summarized in Table 6.4-4. As shown in Table 6.4-4, the system accuracies meet the regulatory guidance in RG 1.23, Revision 1 and ANS/ANSI 3.11 (ANS/ANSI Dec 2005).

6.4.2.7.6 Meteorological Instrumentation

Currently, meteorological parameter data signals from the primary and backup towers are read directly by the dataloggers and transmit across serial links to the radio modems. The data logger converts, tracks, trends, and transmits the data via wireless antenna to the DCS, where the data

is available to DCS workstations in Units 3 & 4 and emergency facilities. Each meteorological tower has its own dedicated communication link to the DCS of Units 3 & 4 and, therefore, the backup tower is the duplicate communication link for the primary tower.

The meteorological monitoring system block diagrams for Units 6 & 7 are provided in Figures 6.4-3 and 6.4-4 for the primary and backup towers, respectively.

6.4.2.8 Meteorological Data Used for Application

6.4.2.8.1 Data Recovery Rate and Annual Joint Frequency Distribution of Data

As described in RG 1.23, the minimum amount of onsite meteorological data to be provided at the time of application is a consecutive 24-month period of data that is defendable, representative, and complete, but not older than 10 years from the date of the application. However, 3 or more years of data are preferable and, if available, should be submitted with the application. Based on review of 10 years of data from Units 3 & 4, the 2005–2006 dataset was determined to be the best available (using validated data with the least data substitution), representative (tower and sensor siting in accordance with RG 1.23, Revision 1), and complete. However, as a result of data recovery issues at the 60-meter level, a third year of data was used (2002) to ensure a composite recover of at least 90 percent.

The annualized data recovery rates for 2002, 2005, and 2006 are presented in Table 6.4-5 for the individual parameters (i.e., wind speed, wind direction, ambient temperature, and temperature difference) and the composite parameters. As shown in the table, composite data recovery rates meet the RG 1.23, Revision 1 requirement of at least 90 percent.

The required joint frequency distributions are presented in Tables 2.7-10 and 2.7-11 in the format described in RG 1.23, Revision 1 for wind speed and wind direction by stability class and by all stability classes combined for the 10- and 60-meter level measurements. It should be noted that no calms were reported during the 2002, 2005, and 2006 annual periods. Wind speeds greater than 0.5 mph (starting threshold of sensor) are considered non-calm winds. Forty two hours of calm winds (less than 0.5 mph) were recorded. These hours, however, were not considered valid and not included in the dataset.

6.4.2.8.2 Need for Additional Data Sources for Airflow Trajectories

Because the Turkey Point area is generally flat with airflow dominated mostly by large-scale weather patterns as concluded in Section 2.7, data collected by the Units 3 & 4 collection system can be used for the description of atmospheric transport and diffusion characteristics within 50 miles of Units 6 & 7.

The modeling methodology used to calculate dispersion estimates out to 50 miles, XOQDOQ, does not use offsite data. The XOQDOQ model, an NRC-sponsored computational model based on RG 1.111, is a constant mean wind direction model using meteorological data from a single station. In the model, application of the terrain-induced airflow recirculation factor options are provided to account for the effects of airflow recirculation phenomenon occurring within the area of interest when the meteorological data from a single station is used to represent the entire modeling domain. However, application of the airflow recirculation factor for sites located within open terrain is not required. This methodology implies that the meteorological data from an onsite station is reasonably representative of the entire modeling domain and adjustment to the dispersion estimates calculated by the model out to 50 miles of a site located within open terrain is not required.

For coastal sites in open terrain such as Turkey Point, an airflow recirculation factor provided in the XOQDOQ model is used to account for potential airflow recirculation as a result of sea breeze and land breeze effects and during the infrequent stagnation conditions that could lead to more restrictive dispersion estimates. With application of the appropriate airflow recirculation factor, data collected from an onsite meteorological monitoring station for making dispersion estimates out to 50 miles is adequate. Therefore, no offsite data collection systems were used to determine the dispersion characteristics of the Turkey Point area.

6.4.2.8.3 Supplemental Data for Environmental Impact Evaluation

Supplemental data from the NWS, Miami International Airport, Florida, is suitable for making impact predictions resulting from operation of the Units 6 & 7 cooling towers, regarding visible plume, drift deposits, fogging, and icing. In particular, the AERMOD and CALPUFF models used for predicting cooling tower salt deposits and fogging impacts, respectively, require such data as twice daily mixing height, cloud ceiling, cloud cover, dry bulb, wet bulb, wind speed, and wind direction that are routinely measured at Miami but not at Turkey Point for all parameters. Furthermore, long-term meteorological data at Miami is available that allowed for the year-to-year variation in meteorological data to be factored into the cooling tower plume impact predictions. The 2001–2005 Miami meteorological data was used for this modeling.

6.4.3 OPERATIONAL MONITORING

The Units 3 & 4 meteorological monitoring program is conducted in accordance with the applicable regulatory guidance and the existing system would be used during Units 6 & 7 operation.

Although the current system, including both the tower and meteorological sensors, may be upgraded periodically or replaced before Units 6 & 7 operation, the functional requirements of the operational program for Units 6 & 7 are described based on the current system.

The LU tower would need to be relocated because of potential construction impacts. The relocated LU tower would be equipped with instrumentation that satisfies applicable regulations and regulatory guidance.

6.4.4 EMERGENCY PREPAREDNESS SUPPORT

The 10-meter wind speed/direction data from the LU 10-meter tower would be the primary data used in emergencies. The data from the South Dade tower would be used as backup during an actual plant emergency if required.

The Units 6 & 7 onsite data collection system would provide representative meteorological data for use in real-time atmospheric dispersion modeling for dose assessments during and following any accidental atmospheric radiological releases. The data would be also used to represent meteorological conditions within the 10-mile emergency planning zone radius (NUREG-0696, NUREG-0737, and NUREG-0654).

Similar to the Units 3 & 4 meteorological monitoring program, the microprocessors would sample the meteorological processor modules once per second for wind speed, wind direction, and ambient temperature for calculations of vertical temperature difference in order to provide near real-time meteorological data for use in atmospheric dispersion modeling. Dose assessment calculations would be performed using the most recent 15-minute average of data, in accordance with RG 1.97.

To identify rapidly changing meteorological conditions for use in performing emergency response, 15-minute average values would be compiled for real-time display in the Units 6 & 7 control rooms, technical support center, and emergency operations facility. The meteorological channels required for input to the dose assessment models would be available and presented in a format compatible for input to these dose assessment models, in accordance with the requirements in RG 1.97.

Provisions are currently in place to obtain representative regional meteorological data from the National Weather Service in Miami during an emergency if the existing meteorological system is unavailable. The current (or similar) emergency plan procedures and the monitoring system arrangement would be used for Units 6 & 7.

Table 6.4-1
Meteorological Tower Siting Conformance Status

RG 1.23, Revision 1 Criteria	Conformance Status	Remarks
Tower Siting		
The meteorological tower sites and the Units 6 & 7 location have similar meteorological exposure.	Yes	The Turkey Point plant property is generally flat land.
The base of the tower is at approximately the same elevation as the finished plant grade of Units 6 & 7.	No No	The South Dade tower is below the approximately 25.5 feet finished plant grade. However, due to the similarity of the landscape, there would be minimal effects. The finished plant grade of Units 6 & 7 and associated buildings would produce different meteorological exposures than at the current LU tower location. The LU tower would need to be relocated.
Location of the tower is not directly downwind of the plant cooling systems (i.e., cooling canals in the industrial wastewater facility and mechanical draft cooling towers) under the prevailing downwind wind direction.	Yes No	The South Dade tower is not located near preexisting or planned cooling systems. The LU tower is located near existing cooling canals on both the east and west sides; however, the majority of the cooling canals are located west of the LU tower, while the path of the prevailing downwind wind direction is from the east. The LU tower would need to be relocated because of construction impacts and operational concerns (i.e., height of the Units 6 & 7 finished plant grade and structures).
Tower is not located on or near permanent man-made surface.	Yes No	There are no large concrete or asphalt parking lot or temporary land disturbance, such as plowed fields or storage areas nearby the South Dade tower. The closest large concrete or asphalt parking lots are at Units 3 & 4, which is approximately 6.5 miles from the South Dade tower. The LU tower is located near an asphalt roadway and temperature is not measured. Temperature concerns would not be an issue in the siting of the LU tower at a new location.

Table 6.4-2
Meteorological Sensor Siting Conformance Status

RG 1.23, Revision 1 Criteria	Conformance Status	Remarks
Sensor Siting		
Wind sensors should be located away from nearby obstructions to airflow (e.g., plant buildings, other structures, trees, nearby terrain) by a distance of at least 10 times the height of any such obstruction that exceeds one-half the height of the wind measurement level to avoid any modifications to airflow (i.e., turbulent wake effects).	Yes No	The South Dade tower is located near a raised mound/equipment shelter. However, the effects were found to be minimal on the South Dade tower. The LU tower would need to be relocated because of construction impacts and operational concerns (i.e., height of the finished plant grade and buildings).
Wind sensors are located at heights that avoid airflow modifications by nearby obstructions with heights exceeding one-half of the wind measurement.	Yes	See remark above.
Wind sensors are located extended outward on a boom to reduce airflow modification and turbulence induced by the supporting structure itself. Wind sensors on the side of a tower should be mounted at a distance equal to at least twice the longest horizontal dimension of the tower (e.g., the side of a triangular tower).	Yes	Tower booms (6 feet long) are oriented into the prevailing winds to reduce tower effects on the measurements. The wind sensors are boom-mounted more than approximately 6.5 feet from the tower (more than twice the tower's width of 3 feet).
The sensors should be on the upwind side of the mounting object in areas with a dominant prevailing wind direction.	Yes	The wind speed/direction boom is pointed southeast into the dominant wind direction.
Air temperature and dew point sensors are located in such a way to avoid modification by the existing and proposed heat and moisture sources, such as ventilation systems, water bodies, or the influence of large parking lots or other paved surfaces.	Yes (see remark) No	The South Dade tower is not located near any heat or moisture sources. The LU tower is located near the cooling canals. Dew point is not measured at either the South Dade or LU towers.
Temperature sensors should be mounted in fan-aspirated radiation shields to minimize adverse influences of thermal radiation and precipitation. Aspirated temperature shields should either be pointed downward or laterally towards the north. The shield inlet should be at least 1.5 times the tower horizontal width away from the nearest point on the tower.	Yes	Temperature is measured only on the South Dade Tower. Temperature sensors are mounted in fan-aspirated radiation shields. Aspirated temperature shields are horizontal. The shield inlet is situated approximately 2.5 feet from the tower (slightly less than 1.5 times the tower's width of 3 feet).
Precipitation measured at ground level near the base of the tower. Precipitation gages should be equipped with wind shields to minimize wind-caused loss of precipitation and, where appropriate, equipped with heaters to melt frozen precipitation.	Yes (see remark)	Precipitation is measured at ground level near the base of each of the towers, but the gauge is located away from the tower shelter to prevent any interference in precipitation capture. Neither precipitation gauge is equipped with wind shields to minimize the wind-caused loss of precipitation, but each gauge has a funnel screen.

6.5 ECOLOGICAL MONITORING

Ecological monitoring programs are typically implemented to address the elements of the ecosystem for which a causal relationship between new unit construction and/or operational activities and adverse change is established or strongly suspected. The following is a description of ecological monitoring for terrestrial resources (Subsection 6.5.1) and aquatic resources (Subsection 6.5.2) associated with Units 6 & 7. The results of the monitoring are described in Section 2.4.

6.5.1 TERRESTRIAL ECOLOGY AND LAND USE

6.5.1.1 Pre-Application Terrestrial Ecological Monitoring

Ecological monitoring includes the determination of the occurrence and relative abundance of terrestrial fauna, including “important” (NUREG-1555) species.

Wildlife presence and habitat occurrence were determined during a series of pre-application surveys documenting the amphibians, birds, mammals, and reptiles on site. Seasonal surveys for birds on the Turkey Point plant property were conducted in March 2009 and June 2009. The avian monitoring consisted of timed, pedestrian surveys of the various habitats within the Turkey Point plant property (Figure 2.4-3a) to determine their seasonal species composition and relative abundance. Approximately 90 species of birds have been documented during these and earlier surveys.

Surveys for small mammals, reptiles, and amphibians on the Units 6 & 7 plant area and other project construction areas, were conducted in April 2009. These one-time surveys were conducted during the peak period of activity of these species to document presence and relative abundance. Three, nine, and six species of amphibians, reptiles and mammals were documented during these surveys, respectively (see Table 2.4-2).

As reported in Subsection 2.4.1, several important species (as defined in NUREG-1555) exist or have been observed within the Turkey Point plant property including the American crocodile, American alligator, wood stork, Florida manatee, eastern indigo snake, little blue heron, snowy egret, reddish egret, tricolored heron, white ibis, white-crowned pigeon, roseate spoonbill, least tern, Florida burrowing owl, and game species such as deer, rabbits, waterfowl, and dove. Many other species are also listed as occurring in Miami-Dade County by federal and/or state agencies, but their habitats typically do not occur within the Turkey Point plant property and thus they have not been observed onsite. The monitoring programs were proposed for the crocodile, stork, and manatee because (1) they are federally listed, (2) construction activities could result in loss of critical habitat (crocodile), disturbance near breeding colonies (stork), or possible endangerment of individuals due to increases in vehicle/boat traffic (crocodile/manatee). Other important species generally do not require monitoring programs due to a less-threatened status

(e.g., species of special concern rather than endangered), abundance of nearby habitats for them to utilize, or generally low numbers on plant property (e.g. upland game species).

Construction-related areas associated with Units 6 & 7 within the Turkey Point plant property have been surveyed for threatened and endangered species. Portions of the transmission, reclaimed and potable water pipeline corridors, and improved access roads, were surveyed for terrestrial threatened and endangered species during the pre-application phase.

The construction period will generally be the most sensitive period for all important species due to increased disturbance (e.g., noise, vibrations, traffic, human presence) and thus is the period in need of most monitoring. Given that crocodiles breed in the industrial wastewater facility adjacent to construction areas and the importance of this population to overall population recovery, regulatory agencies will likely suggest continuation of existing FPL crocodile monitoring and may require additional monitoring in support of the proposed action. Much of the Turkey Point plant property has been designated as critical habitat for the American crocodile (Figure 2.4-4). FPL has maintained a program to manage crocodile habitat since 1978 in response to the colonization of the industrial wastewater facility by this species in the late 1970s. A monitoring component was added to the program in subsequent years. The program activities are addressed in detail in Subsection 2.4.1.2, and include creation and enhancement of nesting habitat, nest monitoring, relocation of hatchlings to freshwater sanctuaries, managing vegetation in the nesting areas (cooling canals), and the education of site personnel and onsite workers on the occurrence of the species on site and their protection and conservation. Given that crocodiles are still federally listed (threatened), the Turkey Point crocodile population has grown over the last three decades and the industrial wastewater facility is classified as critical habitat for the crocodiles. The existing FPL crocodile monitoring program will be continued within the Turkey Point plant property through the pre-application period. Protected avian species, primarily wading birds, have been documented foraging and roosting within the Turkey Point plant property (Subsection 2.4.1). However, no nests for these species have been observed within the plant boundary. If these species are impacted during construction, their foraging and/or roosting activities would likely shift to other areas within the plant property or other nearby shallow water sites. Therefore, monitoring beyond the aforementioned seasonal avian surveys would not be necessary. Similarly, a few rare waterbirds have been observed along the proposed transmission and reclaimed and potable water pipeline corridors during recent reconnaissance, as described in Subsection 2.4.1. Additional pre-application surveys would not be necessary.

No rare plants have been observed during most surveys of construction-related areas within the Turkey Point plant property. However, recent surveys (2008-2009) of transmission corridors associated with Units 6 & 7 documented approximately 30 existing or proposed state and federally listed plant species, including three species within the segment of Clear Sky-to-Levee corridor within the plant property boundary. These three species are typically found on or near disturbed soils, such as spoil piles (see Subsection 2.4.1.2).

FPL has initiated discussions with the appropriate federal and state agencies regarding endangered and threatened species. Jurisdictional and non-jurisdictional wetland habitats would be impacted by construction activities, although the extent of this impact within the transmission and the reclaimed water pipeline corridors is pending finalization of those routes and wetland delineation projects within those corridors.

White-tailed deer, rabbits, waterfowl, and doves are game species that exist on the Turkey Point plant property and are classified as important species. There are no site-specific management activities for these species and they are not hunted on site. The construction and operation of Units 6 & 7 would not alter the conditions for these game species on the Turkey Point plant property. No hunting or management would occur, and no monitoring of these species is warranted.

Although specific monitoring of other important species is not performed, site personnel and onsite workers are trained on the protection and conservation of wildlife species.

6.5.1.2 Construction, Preoperational, and Operational Monitoring

Given the harsh environment (e.g., hypersaline mudflats) being altered and the limited flora and fauna inhabiting the Turkey Point plant property, general terrestrial ecology surveys (amphibians, birds, mammals, reptiles) are not planned for the Units 6 & 7 plant area and other impacted construction areas during the construction, preoperational, and operational stages. Possible exceptions include monitoring pertaining to American crocodiles and manatees. FPL's ongoing crocodile monitoring and management will continue, but may need to be expanded to examine for potential construction-related impacts to crocodiles nesting in the northern portion of the return canals and potential construction traffic-related impacts on crossing crocodiles throughout the industrial wastewater facility. The presence of manatees would be monitored during barge turning basin and equipment barge unloading area modifications and barge deliveries of components and equipment.

Important species other than the crocodile and manatee will likely shift to other areas when disturbed and thus would not require monitoring during the construction, preoperational, and operational stages.

Offsite areas include the reclaimed and potable water pipelines and transmission corridors to the Davis, Levee, Miami, and Pennsuco substations (Figure 2.2-5). As presented in Subsection 2.4.1, construction of the new corridors and potential modifications (expansion, new towers, etc.) to existing transmission corridors would not impact most protected wildlife species or critical habitats. However, wood storks nest near a segment of the Clear Sky-to-Levee transmission corridor; construction of these lines could potentially disturb these birds and affect their nesting. Similarly, this same segment of the corridor contains habitats used by both Florida panthers and

Everglade snail kites. Habitat impacts would be avoided to the extent practicable and potential impacts of the new lines on wood storks, Florida panthers, and/or Everglade snail kites would be monitored. Rare plants within the transmission corridors would be avoided to the extent practicable during construction and should not require additional monitoring.

6.5.2 AQUATIC ECOLOGICAL MONITORING

The aquatic communities within and adjacent to the areas proposed for development, as well as important offsite aquatic resources, are described in Subsection 2.4.2. Existing and proposed monitoring of aquatic resources are described in this section.

6.5.2.1 Pre-Application Aquatic Ecological Monitoring

Surveys of the Units 6 & 7 plant area were conducted in August and November 2007. The onsite surface water habitats that may be affected by construction and operation of Units 6 & 7 include hypersaline mudflats, remnant canals, channels, dwarf mangrove wetlands, and open water. All of these habitats support only a limited number of aquatic species because of the harsh conditions of water level fluctuations, high water temperatures, and high salinities. Other than the American crocodile, described in Subsection 6.5.1, no listed aquatic or semi-aquatic species exist within the Units 6 & 7 plant area.

Fish were surveyed during summer 2009 in seven areas that would be potentially impacted by construction of Units 6 & 7. These sample areas included the two remnant canals on the plant area, the dead-end canal (laydown area), pools within the mangrove areas (nuclear administration building, training building, and parking area), an area adjacent to SW 344th Street/ Palm Drive (in the area of the FPL reclaimed water treatment facility), a portion of the return canal, shallow flats in the east-central part of the nuclear island, and two locations along the cooling canals of the industrial wastewater facility.

Fish were collected using (8-foot diameter) cast nets, a 20-foot-long minnow seine, and standard “Gee” type minnow traps. All fish collected were hardy species common in estuarine habitats in south Florida. No rare, unusual, sensitive, or protected species were collected. One additional species, the Atlantic needlefish (*Strongylura marina*), was observed in the return canal but not captured. The Atlantic needlefish is a common inhabitant of coastal waters from New England to the Florida Keys and west to Mexico.

The primary open water habitat found on the Turkey Point plant property is the industrial wastewater facility, which supports a variety of aquatic species typical of a shallow, subtropical, hypersaline environment, including phytoplankton, zooplankton, marine algae, rooted plants, crabs, and estuarine fish. Historically, the most abundant fish in the industrial wastewater facility have been killifish (Family Cyprinodontidae) and live-bearers. Some game species, such as the common snook *(Centropomus undecimalis)* and tarpon *(Megalops atlanticus),* have been

observed in the cooling canals, but the presence of self-sustaining populations has not been documented.

In summer 2008, a survey for the presence of seagrasses in the barge turning basin was performed in anticipation of the need to modify the equipment barge unloading area to accommodate delivery of modules and components for Units 6 & 7. Sparse patches of seagrass occur along the northern shore of the turning basin, in the vicinity of the existing boat slip and equipment barge unloading area. Several small areas with 5 percent to 20 percent coverage of turtlegrass (*Thalassia testudinum*) and shoal grass (*Halodule wrightii*) were observed, comprising a total of approximately 170 ft^2 (0.004 acres).

A one-year baseline aquatic biological characterization study was completed in March 2009. Five sampling stations were selected to characterize aquatic biota in Card Sound Canal and Card Sound. Sampling was conducted every other week for a total of 26 sampling events. Each sampling event consisted of three components: trawling for juvenile and adult fish and shellfish, towing nets for ichthyoplankton and meroplankton, and monitoring for water quality. Each station was sampled for each component once during the daytime and once at night for a total of 10 collections per sampling event (two sampling events per 24 hours at each of five stations). Sampling both daytime and nighttime photoperiods provided information on potential diel movements and changes in species composition and aggregations within the sampling area.

A baseline aquatic biological characterization of Card Sound was completed in March 2009. Plankton samples collected in Card Sound during the study may reasonably be assumed to represent plankton present in nearshore habitats of Biscayne Bay in the general area of the radial collector wells. Plankton were sorted and specimens assigned to one of four categories: fish eggs, fish larvae (ichthyoplankton), commercially important meroplankton, and non-commercially important meroplankton). The commercially important meroplankton are represented primarily by decapod crustaceans with commercial value, such as edible shrimps (penaeid species), lobster, blue crabs, and stone crabs, but also include some mollusks (e.g., clams, oysters, squid) and several other organisms used as bait or in medical research (e.g., mole crabs, horseshoe crabs, and mantis shrimps). The non-commercially important taxa represent a variety of other decapod crustaceans, such as grass shrimp, hermit crabs, and mud crabs (Xanthidae).

Benthic macroinvertebrates were sampled and seagrasses were surveyed from Biscayne Bay near the Turkey Point peninsula in March 2009. Sediment samples collected from 250 to 750 feet offshore in 3 feet of water were passed through a 0.5 mm sieve to collect macroinvertebrates. The majority of the 123 taxa identified from the Biscayne Bay samples were polychaetes and crustaceans. Abundance, species richness, and diversity were greatest at the station nearest to the shore.

Seagrasses were surveyed in approximately 49-hectares around the Turkey Point peninsula. Essentially the entire survey area was found to contain turtle grass or shoal grass. Turtle grass coverage was densest immediately surrounding the peninsula, but densities were variable. Shoal grass was less widespread, occurring most often in shallow waters along or near the peninsula shoreline. The two species often co-occurred, but shoal grass was absent at many sampling locations.

6.5.2.2 Construction, Preoperational and Operational Monitoring

Important aquatic habitats include Lower Biscayne Bay, Card Sound, Biscayne National Park, Biscayne Bay Park Aquatic Preserve, and Everglades National Park. A number of federally-listed and state-listed plants and animals are associated or potentially associated with these areas including two fish: the mangrove rivulus and the smalltooth sawfish (Subsection 2.4.2). Radial collector wells would be constructed as a source of makeup water to the circulating water system cooling towers. Because the radial collector well laterals would be advanced a lateral distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay, construction and operation of the radial collector wells would not adversely impact these important aquatic habitats. Therefore, no preoperational or operational monitoring of fish or other aquatic species is warranted.

Aquatic species in the regional canals along the roads and transmission and reclaimed and potable water pipeline corridors include common freshwater forage fishes native to south Florida, such as mosquitofish (*Gambusia holbrooki*), sailfin molly (*Poecilia latipinna*), least killifish (*Heterandria formosa*), sunfish (*Lepomis* spp.), and gar (*Lepisosteus* spp.). Nonindigenous fish commonly inhabiting canals of Miami-Dade County include peacock bass (*Cichla ocellaris*), spotted tilapia (*Tilapia mariae*), blue tilapia (*Oreochromis aureus*), Mayan cichlid (*Cichlasoma urophthalmus*), jaguar guapote (*Cichlasoma managuense*), and oscar (*Astronotus ocellatus*).

Cooling water would be discharged via deep injection wells to the Boulder Zone of the Lower Floridan aquifer. No aquatic species would be exposed to the discharged water; therefore no pre-operational or operational monitoring is warranted.

Because no rare or sensitive aquatic species are expected to occur in the construction areas, and because construction activities would be conducted under stormwater permits that require the use of environmental best management practices, additional monitoring is not warranted.

6.6 CHEMICAL MONITORING

6.6.1 PRE-APPLICATION CHEMICAL MONITORING

The objective of the pre-application chemical monitoring program is to establish existing (baseline) water chemistry conditions to further support descriptions presented primarily in Subsection 2.3.1 and to assist in the determination of potential impacts during construction and operation in Chapters 4 and 5, respectively. Data was obtained for surface water and groundwater as explained below.

6.6.1.1 Surface Water

Water quality monitoring was performed at five locations in conjunction with the ecological characterization effort on a bi-weekly basis for one year. The sampling stations are located at the Card Sound Canal and Card Sound. Table 6.6-1 summarizes the analytical parameters included in the surface water quality monitoring. Figure 2.4-3a depicts the sampling locations.

6.6.1.2 Groundwater

Table 6.6-1 summarizes the analytical parameters included in the groundwater chemical monitoring program. The wells monitored and analytical/field results are summarized in Tables 2.3-22 and 2.3-23. Remote monitoring was also conducted at several monitoring wells for conductivity using transducers.

6.6.2 CONSTRUCTION AND PREOPERATIONAL MONITORING

The chemical monitoring of surface water and groundwater would be conducted to provide data necessary to evaluate changes in water quality that might result from construction of Units 6 & 7 up to initial operations. This evaluation would be completed using the pre-application baseline dataset and the results documented for periodic evaluation of operations impacts.

6.6.2.1 Surface Water

Surface water monitoring would be established at surface water monitoring points most likely to be potentially impacted by construction activities.

Table 6.6-2 summarizes the current surface water quality monitoring required by the IWWF permit before release into the cooling canals of the industrial wastewater facility. No changes to this monitoring are planned.

In addition, chemical monitoring of surface water would be established at other surface water monitoring points most likely to be potentially impacted by construction activities. These locations

could include the barge turning basin and Biscayne Bay and would be monitored for applicable chemical parameters to ensure no adverse impacts to surface water.

Specific monitoring would be developed as part of the NPDES permit process for construction activities that would occur offsite (e.g., roadway improvements, transmission substation expansion, and linear facilities such as transmission line rights-of-way, reclaimed water pipelines, and potable water pipelines). The need for modifications to the monitoring program would be regularly assessed and implemented as necessary over the duration of the construction chemical monitoring program to ensure no adverse impacts.

6.6.2.2 Groundwater

The deep injection well and its associated dual zone monitoring well would be sampled and analyzed for the parameters and frequencies summarized in Table 6.6-3.

Pre-application monitoring wells located within the Units 6 & 7 plant area would be abandoned in accordance with applicable regulatory requirements during construction. Chemical measurements would be collected from newly installed monitoring wells to monitor the effects of construction, particularly dewatering, on groundwater. These newly installed wells may be temporary and would be later abandoned.

Initial startup and monitoring plans would be developed and executed as necessary to demonstrate the operational effectiveness of the radial collector wells and the effects on the local groundwater flow regime and surface water bodies such as the industrial wastewater facility and Biscayne Bay.

Any dewatering activities related to construction activities that would occur offsite (e.g., roadway improvements, transmission substation expansion, and linear facilities such as transmission line rights-of-way, reclaimed water pipelines, and potable water pipelines) would be localized and temporary, therefore, no chemical monitoring of groundwater in these areas would be required.

6.6.3 OPERATIONAL MONITORING

The operational chemical monitoring program would be designed to document effects from the operation of the Units 6 & 7 and detect any unexpected effects that arise from facility operation. The operational chemical monitoring program is anticipated to be an extension of the preoperational monitoring program. Modifications to the monitoring program (for example, changes in monitoring stations or collection procedures) would be assessed regularly over the duration of the operational hydrological monitoring program. Adjustments to the program would be made in consultation with FDEP.

6.6.3.1 Surface Water

The specific procedures of the operational monitoring requirements for the industrial wastewater facility are anticipated to be similar to the existing chemical monitoring program. The program may be modified in response to data collected and consultations with the FDEP. The current sampling requirements and frequencies for the IWWF permit are summarized in Table 6.6-2.

In addition, chemical monitoring of surface water could be established at other surface water monitoring points most likely to be potentially impacted by maintenance activities during operation. These locations could include the barge turning basin and Biscayne Bay and would be monitored for applicable chemical parameters to ensure no adverse impacts to surface water.

Since the radial collector wells would be a secondary cooling water source for Units 6 & 7, the monitoring frequency would be dependent upon operation. During operation, the radial collector well water would be monitored for conductivity, salinity, and total dissolved solids (TDS). Surface water locations located at the return canal of the industrial wastewater facility and in Biscayne Bay in the area of the equipment barge unloading area would be measured for conductivity and salinity.

During the operational phase, it could be necessary to perform routine maintenance on the offsite facilities (e.g., transmission lines, reclaimed and potable water pipelines, access roads). Any disturbances to surface water flow as a result of the activities would be temporary and would not require chemical monitoring.

6.6.3.2 Groundwater

The operational monitoring program for the deep injection wells, both at the injectate discharge and six dual-zone monitoring wells, would be similar to that described in Table 6.6-3.

Groundwater could be monitored at monitoring wells adjacent to the radial collector wells and along the shoreline for field measurements of conductivity and salinity.

During the operational phase, it could be necessary to perform maintenance that would require excavation and dewatering at offsite facilities (e.g., transmission lines, reclaimed and potable water pipelines, access roads). The dewatering activity could create temporary drawdown of the water table. However, the water table and flow would return to normal once dewatering ceased. No chemical monitoring of these offsite facilities is required during operation.

Table 6.6-1
Pre-Application Chemical Monitoring of Surface Water and Groundwater at the Units 6 & 7 Plant Area

Parameter	Units
Surface Water	
Dissolved Oxygen	mg/L
Specific Conductance	milliSiemens per centimeter

6.7 SUMMARY OF MONITORING PROGRAMS

The Units 6 & 7 monitoring programs are described in detail in Sections 6.1 through 6.6 and are summarized in the following subsections. Table 6.7-1 identifies key elements of the monitoring programs to be implemented during the pre-application, construction, preoperational, and operational phases.

6.7.1 PRE-APPLICATION MONITORING

The current Units 3 & 4 ecological, radiological, chemical, hydrological, and meteorological monitoring programs have been used as a baseline to characterize the conditions for new Units 6 & 7. No additional pre-application radiological monitoring was performed.

Thermal monitoring was performed in the upper portion of the Upper Floridan and the Biscayne aquifers in the Units 6 & 7 plant area, as described in Sections 2.3 and 6.1.

Ecological surveys were performed during the pre-application phase at the Units 6 & 7 plant area, other impacted areas on the Turkey Point plant property, along the transmission corridors, along the route for the reclaimed and potable water pipelines, including both terrestrial and aquatic surveys, Card Sound, Biscayne Bay and Card Sound Canal. The results of these surveys were used to characterize environmental conditions. These surveys were described in Section 2.4 and 6.5.

Hydrological studies included the initiation of a groundwater investigation program described in Subsection 2.3.1, Section 6.3, and Section 6.6 at the Units 6 & 7 plant area. Monitoring also occurred during pumping tests at the Units 6 & 7 plant area.

Pre-application meteorological monitoring consisted of the continuation of the existing Units 3 & 4 program. Data from this program and a description of its use are provided in Sections 2.7 and 6.4.

Baseline water quality studies for chemical monitoring were conducted in the Biscayne aquifer and Card Sound. The results and monitoring are described in Subsections 2.3.2, 2.3.3 and Section 6.6.

6.7.2 PRECONSTRUCTION/CONSTRUCTION MONITORING

Historical information and current data formed the basis from which to assess the impacts of Units 6 & 7 preconstruction and construction activities.

The radiological monitoring currently being performed for Units 3 & 4 would be continued and enhanced to include Units 6 & 7 during construction and would overlap with the more comprehensive preoperational and operational monitoring programs (see Section 6.2). Additional

thermoluminescent dosimeters would be installed for Units 6 & 7 before construction and the existing radiological monitoring program expanded to include these dosimeters.

Hydrological surface water monitoring would be performed as required by the NPDES permit. Groundwater elevation monitoring would be performed to measure the effects of dewatering during construction of the power blocks. Hydrologic and chemical monitoring would be performed in the dual zone monitoring wells designed to monitor potential impacts from operation of the deep injection wells. Planned environmental hydrological monitoring is described in Section 6.3. Chemical monitoring is outlined in Section 6.6.

Meteorological monitoring during plant construction is not planned because no significant air quality and meteorological-related construction impacts have been identified that would warrant site-specific onsite monitoring. However, the existing meteorological monitoring program would continue through this phase.

Ecological monitoring would be performed during the modification of the barge turning basin and equipment barge unloading area. Monitoring would also be conducted during barge deliveries.

Crocodile monitoring would continue to be performed during this phase of the project and may be increased due to the increased construction vehicular traffic in the Units 6 & 7 plant area.

Although sampling frequency would be dictated by site conditions, it is expected that surface water and groundwater would be monitored during portions of the construction phase to provide data for assessing potential changes in surface water or groundwater quality. This potential monitoring is described in Section 6.6.

6.7.3 PREOPERATIONAL MONITORING

Thermal monitoring of water would continue as outlined in Table 6.7-1. Areas to be monitored would include the Units 6 & 7 plant area, the radial collector well area, dual zone monitoring wells in the Upper Floridan aquifer, and potential areas of stormwater releases.

Radiological monitoring that would be expanded over the preconstruction/construction monitoring to include the features listed in Table 6.2-2 would continue. The preoperational radiological monitoring program would begin up to 2 years before operation of Unit 6, as identified in Table 6.2-1.

Hydrological preoperational monitoring would be a continuation of construction-phase monitoring.

Preoperational meteorological monitoring would be a continuation of the preexisting monitoring program.

Preoperational ecological monitoring would be a continuation of the preexisting ecological monitoring at Turkey Point.

Chemical monitoring would be a continuation of preconstruction/construction groundwater and surface water monitoring, as applicable. These activities would include characterization monitoring of the wells in the Upper Floridan aquifer to monitor the potential hydrologic, thermal, and chemical impacts from the deep injection wells. Preliminary frequency and chemical criteria are outlined Section 6.3 and 6.6.

6.7.4 OPERATIONAL MONITORING

Thermal, chemical, and hydrologic monitoring would be required for the dual zone monitoring wells associated with the deep injection wells. Thermal monitoring would continue to be performed on wells in the vicinity of the power blocks and would also be performed on wells associated with monitoring the potential impact of the radial collector wells on the industrial wastewater facility. The existing Units 3 & 4 radiological monitoring program would be expanded to include Units 6 & 7. Monitoring during this phase would be the same as for preoperational monitoring in accordance with the revised radiological monitoring program. Hydrological monitoring would include continued collection of groundwater elevation measurements during the course of implementing the radiological monitoring program. Monitoring would potentially include that of the deep injection dual zone monitoring wells in the Upper Floridan aquifer and wells associated with the radial collector wells, as well as those in the vicinity of the power blocks.

Meteorological monitoring would be a continuation of the preoperational monitoring program described in Section 6.4. No new specific ecological monitoring associated with operation of the new units is proposed. The existing crocodile monitoring program would continue. The chemical monitoring program would be that specified in the underground injection control permit and any permit requirements associated with operational permits issued by FDEP, including storm water permits and National Pollutant Discharge Elimination System (NPDES) permits, as well as any sampling required to monitor the operation of the radial collector wells. Currently, FPL does not release water under stormwater or NPDES permits. All current site water releases are to the industrial wastewater facility.

Table 6.7-1 (Sheet 1 of 4)
Summary of Monitoring Programs

Resource	Program	Scope/Content	Status
PRE-APPLICATION			
Ecology	Ecological Monitoring	Bird surveys	Complete
		One-time surveys for small mammals, reptiles, and amphibians	Complete
		Use of existing crocodile monitoring program through pre-application	Existing
		Performance of a seagrass survey in the equipment barge unloading area. Visual survey of dead-end canal northeast of Units 6 & 7 plant area.	Complete
		Performance of a 1-year baseline aquatic biological characterization	Complete
		Performance of a benthic invertebrate survey and seagrass survey in the area of the radial collector wells	Complete
Human Health	Radiological Monitoring	No additional radiological monitoring was performed	N/A
Water	Hydrological Monitoring	Monitoring was conducted during groundwater pumping tests in the Units 6 & 7 plant area to establish design level criteria.	Complete
		Groundwater monitoring was conducted to provide groundwater level data for baseline analyses	Ongoing[1]
	Thermal Monitoring	Thermal monitoring was performed as part of baseline groundwater and surface water monitoring	Complete
	Chemical Monitoring	Chemical monitoring was performed as part of baseline groundwater and surface water monitoring	Complete
Air Quality and Meteorology	Meteorological Monitoring	The existing meteorological monitoring program for Units 3 & 4 was used for pre-application analyses	Existing
PRECONSTRUCTION/CONSTRUCTION			
Ecology	Ecological Monitoring	Expansion of crocodile monitoring through this phase due to increased traffic	Existing
		Monitoring of manatees during construction activities in the barge turning basin, equipment unloading area modifications, and during barge deliveries	Complete
Human Health	Radiological Monitoring	Radiological monitoring program for Units 6 & 7 is planned to monitor for construction worker dose	To be developed
Water	Hydrological Monitoring	Surface water monitoring at the barge turning basin and Biscayne Bay for applicable hydrologic parameters including turbidity, as required	To be developed
		Groundwater flow/level monitoring during deep injection well pilot testing and use for construction discharges and full well installation	To be developed

Table 6.7-1 (Sheet 2 of 4)
Summary of Monitoring Programs

Resource	Program	Scope/Content	Status
Water (cont.)	Hydrological Monitoring (cont.)	Specific monitoring as part of the NPDES permit process for construction activities that would occur offsite (e.g., roadway improvements, transmission substation expansion, and linear facilities such as transmission line rights-of-way, reclaimed water pipelines, and potable water pipelines).	To be developed
		Groundwater and surface water level monitoring during dewatering activities at the power block	To be developed
		Surface water level monitoring during radial collector well installation	To be developed
	Thermal Monitoring	Stormwater discharges would continue to be monitored in accordance with an FDEP permit, as required	To be updated
		Groundwater thermal monitoring during deep injection well pilot testing and use for construction discharges and full well installation	To be developed
PRECONSTRUCTION/CONSTRUCTION			
Water	Chemical Monitoring	Monitoring at stormwater outfall and/or release points would be performed in accordance with permit requirements, as applicable	To be updated
		Groundwater monitoring would continue during portions of construction and preoperation to ascertain the chemical effects of construction and/or dewatering on local groundwater	To be developed
		Chemical monitoring would be performed for the deep injection well as part of the deep injection well permit requirements	To be developed
Air Quality and Meteorology	Meteorological Monitoring	The existing meteorological monitoring program for Units 3 & 4 would be used to monitor during these project phases	Existing
PREOPERATIONAL			
Ecology	Ecological Monitoring	Expand crocodile monitoring through this phase due to increased traffic	Existing
		Monitor for manatees during construction activities in turning basin, equipment unloading area modifications, and during barge deliveries	To be developed
Human Health	Radiological Monitoring	Radiological monitoring program for Units 6 & 7 would be incorporated into existing program	Update to existing
Water	Hydrological Monitoring	Existing surface water monitoring for the cooling canals of the industrial wastewater facility during the preoperational phase will suffice as the preoperational hydrologic baseline	To be developed
		Monitor groundwater in the vicinity of the deep injection wells	To be developed

Table 6.7-1 (Sheet 3 of 4)
Summary of Monitoring Programs

Resource	Program	Scope/Content	Status
Water (cont.)	Thermal Monitoring	Monitoring of groundwater in the Upper Floridan aquifer in the vicinity of the deep injection wells	To be developed
	Chemical Monitoring	Ongoing surface water monitoring could continue to identify potential impacts of site construction, if warranted by site conditions	Ongoing
		Monitoring at stormwater outfall and/or discharge points would be performed in accordance with permit requirements, as applicable	To be developed
		Groundwater monitoring would continue during portions of preoperation to ascertain the chemical effects on local groundwater during this period	Ongoing
		Chemical monitoring would be performed if required by FDEP wastewater deep injection well permit to discharge cooling water to the Boulder Zone of the Lower Floridan aquifer	To be developed
		Surface water monitoring at the barge turning basin and Biscayne Bay for applicable chemical parameters, as required	To be developed
Air Quality and Meteorology	Meteorological Monitoring	The existing meteorological monitoring program for Units 3&4 would be used to monitor during those project phases.	Existing/modified
OPERATIONAL			
Ecology	Ecological Monitoring	Expanding current monitoring through this phase due to increased traffic	Existing
		Monitoring manatees during maintenance activities in barge turning basin, equipment unloading area modifications, and during barge deliveries	To be developed
Human Health	Radiological Monitoring	The monitoring program specified in Section 6.2 would be conducted	Existing/modified
Water	Hydrological Monitoring	Existing surface water monitoring for the cooling canals of the industrial wastewater facility during the preoperational phase will suffice as the preoperational hydrologic baseline	To be developed
		Potential monitoring of groundwater in radial collector wells	To be developed
		Monitoring groundwater in vicinity of FDEP deep injection wells	To be developed

CHAPTER 7 ENVIRONMENTAL IMPACTS OF POSTULATED ACCIDENTS INVOLVING RADIOACTIVE MATERIALS

This chapter assesses the environmental impacts of postulated accidents involving radioactive materials. Section 7.1 evaluates design basis accidents. Section 7.2 considers the impact of severe accidents, Section 7.3 addresses severe accident mitigation alternatives, and Section 7.4 addresses transportation accidents.

7.1 DESIGN BASIS ACCIDENTS

This section evaluates the radiological consequences of design basis accidents. Subsection 7.1.1 lists the accidents considered, Subsection 7.1.2 outlines the evaluation methodology, Subsection 7.1.3 describes the source terms, and Subsection 7.1.4 presents the resulting consequences.

7.1.1 SELECTION OF ACCIDENTS

The design basis accidents considered in this section are from the DCD (WEC 2011). Table 7.1-1 lists the design basis accidents having the potential for releases to the environment, and shows the NUREG-0800 Standard Review Plan (SRP) section numbers and accident descriptions as well as the corresponding accidents as defined in the DCD. The radiological consequences of the accidents listed in Table 7.1-1 are assessed to demonstrate that new units can be sited at Turkey Point without undue risk to the health and safety of the public.

7.1.2 EVALUATION METHODOLOGY

The DCD presents the radiological consequences of the accidents identified in Table 7.1-1. The DCD design basis analyses are updated with site data to demonstrate that the DCD analyses are bounding for the Turkey Point site. The basic scenario for each accident is that some quantity of activity is released at the accident location inside a building and this activity is eventually released to the environment. The transport of activity within the plant is independent of the site and specific to the AP1000 design. Details about the methodologies and assumptions pertaining to each of the accidents, such as activity release pathways and credited mitigation features, are provided in the DCD.

The dose to an individual located at the exclusion area boundary (EAB) or the low population zone (LPZ) is calculated based on the amount of activity released to the environment, the atmospheric dispersion of the activity during the transport from the release point to the offsite location, the breathing rate of the individual at the offsite location, and activity-to-dose conversion factors. The only variable parameter is atmospheric dispersion. Site-specific doses were obtained by adjusting the DCD doses to reflect site-specific atmospheric dispersion factors (X/Q) values. Since the site-specific X/Q values are bounded by the DCD X/Q values, this approach demonstrates that the site-specific doses are within those calculated in the DCD.

The DCD uses conservative assumptions to perform bounding safety analyses that substantially overstate the environmental impact of the identified accidents. Among the conservative assumptions in the DCD is the use of time-dependent X/Q values corresponding to the top 5th percentile meteorology during the 2-hour accident period that yields the maximum dose, meaning that conditions would be more favorable for dispersion 95 percent of the time. In this

environmental report, the maximum 2-hour dose is calculated based on the 50th percentile site-specific X/Q values, reflecting more realistic meteorological conditions.

The X/Q values were calculated using the methodology of RG 1.145, *Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants,* (Rev. 1, Nov. 1982) with site-specific meteorological data. As described in Subsection 2.7.5, the methodology of RG 1.145 is implemented in the NRC-sponsored PAVAN computer program. This program computes X/Q values at the EAB and the LPZ for each combination of wind speed and atmospheric stability for each of the 16 downwind direction sectors and then calculates overall (nondirection-specific) X/Q values. For a given location, either the EAB or the LPZ, the initial maximum X/Q value is the 50th percentile overall value calculated by PAVAN. For the LPZ, the X/Q values for all subsequent times were calculated by logarithmic interpolation between the 50th percentile X/Q value and the annual average X/Q value. Releases were assumed to be at ground level, and the shortest distances between the power block and the offsite locations were selected to conservatively maximize the X/Q values.

The accident doses are expressed as total effective dose equivalent (TEDE), consistent with 10 CFR 50.34. The TEDE consists of the sum of the committed effective dose equivalent (CEDE) from inhalation and the effective dose equivalent from external exposure. The CEDE is determined using the dose conversion factors in Federal Guidance Report 11 (U.S. EPA 1988), while the effective dose equivalent is based on the dose conversion factors in Federal Guidance Report 12 (U.S. EPA 1993). Appendix 15A of the DCD provides information on the methodologies used to calculate CEDE and effective dose equivalent values. As described in RG 1.183, *Alternative Radiological Source Terms for Evaluating Design Basis Accidents at Nuclear Power Reactors* (Rev. 0, Jul 2000) the dose conversion factors in Federal Guidance Reports 11 and 12 are acceptable to the NRC Staff.

7.1.3 SOURCE TERMS

The design basis accident source terms in the DCD were calculated in accordance with RG 1.183, based on 102 percent of the rated core thermal power of 3400 MW (WEC 2011). The time-dependent isotopic activities released to the environment from each of the evaluated accidents are presented in Tables 7.1-2 to 7.1-10.

7.1.4 RADIOLOGICAL CONSEQUENCES

For each of the accidents identified in Table 7.1-1, the site-specific dose for a given time interval was calculated by multiplying the DCD dose by the ratio of the site X/Q value from Subsection 2.7.5.2 to the DCD X/Q value. The time-dependent DCD X/Q values and the time-dependent site X/Q values and their ratios are shown in Table 7.1-11. As all site X/Q values are bounded by DCD X/Q values, site-specific doses for all accidents are also bounded by DCD

doses. The total doses are summarized in Table 7.1-12, based on individual accident doses presented in Tables 7.1-13 to 7.1-22. For each accident, the EAB dose shown is for the 2-hour period that yields the maximum dose, in accordance with RG 1.183.

The results of the site analysis contained in the referenced tables demonstrate that all accident doses meet the site acceptance criteria of 10 CFR 50.34. The acceptance criteria in 10 CFR 50.34 apply to accidents of exceedingly low probability of occurrence and low risk of public exposure to radiation. For events with a higher probability of occurrence, more restrictive dose limits are specified in RG 1.183. Where applied, the more restrictive dose limit is either 10 percent or 25 percent of the 10 CFR 50.34 limit of 25 rem TEDE. Although conformance to these more restrictive dose limits is not required for an environmental report, they are included in the tables for comparison purposes, and shown to result in doses that meet the more restrictive limits.

The TEDE dose limits shown in Tables 7.1-12 to 7.1-22 are from RG 1.183, Table 6, for all accidents except reactor coolant pump shaft break (NUREG-0800 SRP Section 15.3.4, Rev. 3, Mar 2007) and failure of small lines carrying primary coolant outside containment (NUREG-0800 SRP Section 15.6.2, Rev. 2, Jul 1981). Although RG 1.183 does not address these two accidents, NUREG-0800 identified a dose limit of 2.5 rem for these accidents. All doses are within the acceptance criteria. Because the dose criteria of 10 CFR 50.34 are intended to provide assurance of low risk to the public under postulated accidents, any health effects resulting from the design basis accidents are negligible.

Table 7.1-1
Selection of Accidents

SRP/DCD Section	SRP Description	DCD Description	Identified in NUREG-1555[(a)] Section 7.1 Appendix A	Comment
15.1.5A	Radiological Consequences of Main Steam Line Failures Outside Containment of a PWR	Steam System Piping Failure	Yes	Addressed in DCD Section 15.1.5
15.2.8	Feedwater System Pipe Breaks Inside and Outside Containment (PWR)	Feedwater System Pipe Break	Yes	In the DCD, this is bounded by Section 15.1.5 accident
15.3.3	Reactor Coolant Pump Rotor Seizure	Reactor Coolant Pump Shaft Seizure (Locked Rotor)	Yes	
15.3.4	Reactor Coolant Pump Shaft Break	Reactor Coolant Pump Shaft Break	Yes	In the DCD, this is bounded by Section 15.3.3 accident
15.4.8	Spectrum of Rod Ejection Accidents (PWR)	Spectrum of Rod Cluster Control Assembly Ejection Accidents	No	Evaluated for completeness
15.6.2	Radiological Consequences of the Failure of Small Lines Carrying Primary Coolant Outside Containment	Failure of Small Lines Carrying Primary Coolant Outside Containment	Yes	
15.6.3	Radiological Consequences of Steam Generator Tube Failure (PWR)	Steam Generator Tube Rupture	Yes	
15.6.5A	Radiological Consequences of a Design Basis Loss of Coolant Accident Including Containment Leakage Contribution	Loss-of-Coolant Accident Resulting from a Spectrum of Postulated Piping Breaks Within the Reactor Coolant Pressure Boundary	Yes	Addressed in DCD Section 15.6.5
15.6.5B	Radiological Consequences of a Design Basis Loss of Coolant Accident: Leakage From Engineered Safety Feature Components Outside Containment	Loss-of-Coolant Accident Resulting from a Spectrum of Postulated Piping Breaks Within the Reactor Coolant Pressure Boundary	Yes	Addressed in DCD Section 15.6.5
15.7.4	Radiological Consequences of Fuel Handling Accidents	Fuel Handling Accident	Yes	

(a) Oct 1999

Summary of Design Basis Accident Doses

DCD/SRP Section	Accident	Site Dose (rem TEDE)		Limit[a] (rem TEDE)	Dose Table
		EAB	LPZ		
15.1.5A	Steam System Piping Failure				
	Preexisting Iodine Spike	1.9E-01	8.8E-03	25	7.1-13
	Accident-Initiated Iodine Spike	2.2E-01	2.4E-02	2.5	7.1-14
15.2.8	Feedwater System Pipe Break[b]				
15.3.3	Reactor Coolant Pump Shaft Seizure				
	No Feedwater	1.9E-01	4.3E-03	2.5	7.1-15
	Feedwater Available	1.5E-01	9.1E-03	2.5	7.1-16
15.3.4	Reactor Coolant Pump Shaft Break[c]				
15.4.8	Spectrum of Rod Cluster Control Assembly Ejection Accidents	6.7E-01	6.0E-02	6.3	7.1-17
15.6.2	Failure of Small Lines Carrying Primary Coolant Outside Containment	4.1E-01	1.1E-02	2.5	7.1-18
15.6.3	Steam Generator Tube Rupture				
	Preexisting Iodine Spike	5.2E-01	1.6E-02	25	7.1-19
	Accident-Initiated Iodine Spike	2.2E-01	1.0E-02	2.5	7.1-20
15.6.5A,B	Loss-of-Coolant Accident Resulting from a Spectrum of Postulated Piping Breaks within the Reactor Coolant Pressure Boundary	9.1E+00	5.6E-01	25	7.1-21
15.7.4	Fuel Handling Accident	1.0E+00	2.6E-02	6.3	7.1-22

(a) NUREG-1555 specifies a dose limit of 25 rem TEDE for all design basis accidents. The more restrictive limits shown in the table apply to safety analysis report doses, but are shown here to demonstrate that even these more restrictive limits are met.
(b) Feedwater System Pipe Break is bounded by Steam System Piping Failure, as indicated in the DCD.
(c) Reactor Coolant Pump Shaft Break is bounded by Reactor Coolant Pump Shaft Seizure, as indicated in the DCD.

7.2 SEVERE ACCIDENTS

Severe accidents are defined as accidents with substantial damage to the reactor core and degradation of containment systems. Because the probability of a severe accident is very low for the AP1000, such accidents are not part of the design basis for the plant. However, the NRC requires, in its *Policy Statement on Severe Reactor Accidents Regarding Future Designs and Existing Plants* (50 FR 32138), the completion of a probabilistic risk assessment for severe accidents for new reactor designs. This requirement is codified in 10 CFR 52.47, *Contents of Applications*.

Westinghouse completed a probabilistic risk assessment for the AP1000 design (WEC 2004) as part of their application for design certification. The AP1000 design was reviewed by the NRC, and the review was documented in NUREG-1793, *Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design*. Subsequently, the NRC certified the design, concluding that this advanced design meets the NRC's safety goals and represents an improvement in safety over currently operating reactors in the United States.

The Westinghouse analysis used generic, but conservative, meteorology and regional characteristics. FPL presents in this section an update of the generic probabilistic risk assessment analysis of severe accidents to include Turkey Point site-specific characteristics and impacts over the entire life cycle of a severe accident. The purpose of this section is to show the complete impacts of a severe accident, demonstrate that the impacts are less than NRC safety goals, and support the severe accident mitigation alternatives analyses in Section 7.3.

7.2.1 WESTINGHOUSE METHODOLOGY

The Westinghouse probabilistic risk assessment for the AP1000 established an event tree that defined the possible functional end states of the containment following a severe accident initiated by internal events. These end states are grouped into three categories: (1) an intact containment with normal leakage or a larger leak with a containment isolation failure, (2) a containment breach, possibly a result of high containment pressure or a hydrogen detonation, and (3) containment bypass such as a steam generator tube rupture. Using the EPRI code Modular Accident Analysis Program, Westinghouse determined that six source term categories would represent the entire suite of potential severe accidents from these three end state categories. An accident frequency was assigned to each of the six categories (Table 7.2-1).

The six source term categories or accident categories are:

1. Intact Containment — Containment integrity is maintained throughout the accident. The release of radioactivity to the environment is a result of nominal design leakage.

2. Containment Bypass — Radioactivity is released from the reactor coolant system to the environment via the secondary system or other interfacing system bypass. Containment failure occurs before the onset of core damage. This accident category contributes to the large, early release frequency.

3. Containment Isolation Failure — Radioactivity is released through a failure of the valves that close the penetrations between containment and the environment. Containment failure occurs before the onset of core damage. This accident category contributes to the large, early release frequency.

4. Early Containment Failure — Radioactivity release occurs through a containment failure caused by some dynamic severe accident phenomenon after the onset of core damage but before core relocation. Such phenomena could include hydrogen detonation, hydrogen diffusion flame, steam explosions, or vessel failures. This accident category contributes to the large, early release frequency.

5. Intermediate Containment Failure — Radioactivity release occurs through a containment failure caused by some dynamic severe accident phenomenon after core relocation but before 24 hours have passed since initiation of the accident. Such phenomena could include hydrogen detonation and hydrogen deflagration. This accident category contributes to large releases but does not occur early in the accident life cycle.

6. Late Containment Failure — Radioactivity release occurs through a containment failure caused by some dynamic severe accident phenomenon more than 24 hours after initiation of the accident. Such phenomena could include the failure of containment heat removal. This accident category contributes to large releases but does not occur early in the accident life cycle.

Westinghouse then used the NRC code MACCS2 (Chanin and Young May 1997) to model the environmental consequences of the severe accidents described above. The MELCOR Accident Consequence Code System (MACCS) and its successor MACCS2 were developed specifically for the NRC to evaluate severe accidents at nuclear power plants. The meteorology Westinghouse used to represent a generic AP1000 site is specified in EPRI's Utility Requirements Document (EPRI Mar 1999). The meteorology is from a database selected because it is expected to result in calculated impacts greater than those that would be expected at 80 to 90 percent of U.S. operating plants. The population considered also was selected to provide impacts greater than those that would be expected at 80 to 90 percent of the plants. The Westinghouse analysis focused on 24 hours following core damage as a measure of the consequences from a large release and, therefore, did not address the chronic exposure pathways such as ingestion, inhalation of resuspended material, or groundshine subsequent to plume passage.

Additional details on the Westinghouse analysis are found in (WEC 2004) and reported in the DCD (WEC 2011).

7.2.2 FPL METHODOLOGY

FPL also used the MACCS2 computer code to evaluate consequences of severe accidents. The exposure pathways modeled include external exposure to the passing plume, external exposure to material deposited on the ground, inhalation of material in the passing plume or resuspended from the ground, and ingestion of contaminated food and surface water. The MACCS2 code primarily addresses dose from the air exposure pathway, but also calculates dose from surface runoff and deposits on surface water. The code also evaluates the extent of contamination. A difference between the Westinghouse generic analysis and the Turkey Point site-specific analysis is that FPL used site-specific meteorology and population data and extended the analysis to include long-term exposure pathways, such as ingestion, over the life cycle of the accident. Ingestion exposure was determined using the COMIDA2 food model option of MACCS2.

To assess human health impacts, FPL determined the collective dose to the 50-mile population, number of latent cancer fatalities, and number of early fatalities associated with each severe accident category. Economic costs were also determined, including the costs associated with short-term relocation of people, decontamination of property and equipment, interdiction of food supplies, and indirect costs resulting from loss of use of the property and incomes derived as a result of the accident.

Five files provide input to a MACCS2 analysis. One file provides data to calculate the amount of material released to the atmosphere that is dispersed and deposited. The calculation uses a Gaussian plume model. Important inputs in this file include the core inventory, release fractions, and geometry of the reactor and associated buildings. A second file provides inputs to calculations regarding exposure in the time period immediately following the release. Important site-specific information includes emergency response information such as evacuation time. A third input file provides data for calculating long-term impacts and economic costs and includes region-specific data on agriculture and economic factors. These three files access both a meteorological file, which uses actual Turkey Point meteorological monitoring data and a site characteristics file which is built using SECPOP2000 (NUREG/CR-6525) as a template.

Three years of meteorological data (2002, 2005, and 2006) from the existing Units 3 and 4 60-meter meteorological tower were analyzed. MACCS2 requires an entire calendar year of meteorological data. The year 2002 meteorology data was selected for subsequent analyses because it resulted in the largest consequences of the years analyzed, and, therefore, is the most conservative meteorological dataset of the 3 years.

For this analysis, the census data were modified to include transient populations and projected to the year 2080, as described in Subsection 2.5.1. MACCS2 also requires the spatial distribution of certain agriculture and economic data (fraction of land devoted to farming, annual farm sales, fraction of farm sales resulting from dairy production, and property value of farm and nonfarm land) in the same manner as the population. Agricultural production and economic parameters were taken from the 2007 National Census of Agriculture. Nonfarm land property values were taken from 2010 Florida property tax records for the portion of the counties within 50 miles of Turkey Point.

The resultant MACCS2 calculations and accident frequency information was used to determine risk. The consequence risk is the product of frequency of an accident times the consequences of the accident. The consequence can be either radiation dose or economic cost. Dose-risk is the product of the collective dose times the accident frequency. Because the AP1000's severe accident analysis addressed a suite of accidents, the individual risks were summed to provide a total risk. Similarly, cost-risk is the product of economic cost times the accident frequency, and the individual risks were summed to provide a total cost-risk. Therefore, risk can be reported as person-rem per reactor year or dollars per reactor year.

A ground-level release height and no release heat for each accident release hypothesized was assumed. A sensitivity analysis was performed on each of those assumptions; release heights of middle and top of containment and release heat of 1 and 10 megawatt per release segment were considered. The dose-risk varied by less than 3.3 percent for each of the sensitivity calculations.

An evacuation time estimate for the population surrounding the Turkey Point site which assumed evacuation to a 10-mile radius was also performed. The evacuation time estimate was used in the MACCS2 analysis to estimate the evacuation of transient and resident populations within the 10-mile radius.

As described above, the resulting MACCS2 calculations include only internally initiated events, consistent with the Westinghouse analysis. The external event core damage frequencies are slightly greater than the internal event core damage frequencies. An approach to qualitatively estimate the total event core damage frequency (internal and external events) could be to double the internal event core damage frequency, which would double the resulting dose-risk or cost-risk.

7.2.3 CONSEQUENCES TO POPULATION GROUPS

The exposure pathway consequences to population groups including air exposure pathways, surface water exposure pathways, and groundwater exposure pathways are addressed in the following sections.

7.2.3.1 Air Exposure Pathways

Each of the six accident categories was analyzed with MACCS2 to estimate population dose, number of early and latent cancer fatalities, cost, and farmland requiring decontamination. The analysis assumed that 95 percent of the population was evacuated following declaration of a general emergency. For each accident category, FPL calculated the risk for each analytical endpoint (population dose, fatalities, cost, and contaminated land) by multiplying it by the accident category frequency. The results are provided in Table 7.2-1.

7.2.3.2 Surface Water Exposure Pathways

People can be exposed to radiation when deposited airborne radioactivity runs off into or is deposited onto surface water. The exposure pathway can be from drinking the water, external radiation from submersion in the water, external radiation from human activities near the shoreline, or ingestion of fish or shellfish. MACCS2 only calculates the dose from drinking the water. The MACCS2 severe accident dose-risk to the 50-mile population from drinking water is 0.0079 person-rem per year of AP1000 operation. This value is included with the air exposure pathways dose and is the sum of all six accident category risks.

Surface water exposure pathways involving swimming, fishing, boating, and performing activities near the shoreline are not modeled by MACCS2. Surface water bodies within the 50-mile region of Turkey Point include the Biscayne Bay, Atlantic Ocean, Card Sound, the Everglades, canals, ponds, and other smaller water bodies. NUREG-1437 does not provide specific data on submersion and shoreline activities; however, it does indicate that these contributors to dose are much less than for drinking water and consuming aquatic foods, especially at estuary sites. NUREG-1437 evaluated doses from the aquatic food exposure pathway (fishing) for the existing licensed power reactors. For sites near large water bodies, the NRC evaluation estimated the uninterdicted aquatic food exposure pathway dose risk which ranged from 270 person-rem per reactor year (Hope Creek on the Delaware Bay) to 5500 person-rem per reactor year (Calvert Cliffs on the Chesapeake Bay). The Units 6 & 7 site would more likely be similar to Calvert Cliffs on the Chesapeake Bay. Actual dose-risk values would be expected to be much less (by a factor of 2 to 10) due to interdiction of contaminated foods (NUREG-1437). Furthermore, because the AP1000 atmospheric exposure pathway doses are lower than those of the existing licensed power reactors, it is reasonable to conclude that the doses from surface water sources would be considerably lower than those reported above for the surface water exposure pathway.

7.2.3.3 Groundwater Exposure Pathways

Radioactivity released during an accident can directly and indirectly enter groundwater that serves as a source of drinking water or irrigation, or can move through an aquifer that eventually discharges to surface water. NUREG-1437 evaluated the groundwater exposure pathway dose, based on the analysis in NUREG-0440, *Liquid Pathway Generic Study*. NUREG-0440 analyzed a

core meltdown that contaminated groundwater which subsequently contaminated surface water. However, NUREG-0440 did not analyze direct drinking of groundwater because of the limited number of potable groundwater wells and limited accessibility.

The *Liquid Pathway Generic Study* results provide conservative, uninterdicted population dose estimates for six generic categories of plants. These dose estimates were one or more orders-of-magnitude less than those attributed to the atmospheric exposure pathway. The Units 6 & 7 site is represented by one of these categories and would be bounded by this analysis. Therefore, the doses from the Units 6 & 7 site groundwater exposure pathway would be much less than the doses from the atmospheric exposure pathway.

7.2.4 COMPARISON TO NRC SAFETY GOALS

FPL compared the severe accident risks from Units 6 & 7 against two risk goals identified by the NRC (51 FR 30028) as described below. The results are presented in Table 7.2-2.

7.2.4.1 Individual Risk Goal

The risk of prompt fatalities that might result from reactor accidents to an average individual in the vicinity of a nuclear power plant should not exceed 0.1 percent of the sum of “prompt fatality risks” resulting from other accidents to which members of the U.S. population are generally exposed. As noted in the Safety Goals Policy statement (51 FR 30028), “vicinity” is defined as the area within 1 mile of the plant site boundary. “Prompt Fatality Risks” are defined as those risks to which the average individual residing in the vicinity of the plant is exposed to as a result of normal daily activities. Such risks are the sum of risks that result in fatalities from such activities as driving, household chores, occupational activities, etc. For this evaluation, the sum of prompt fatality risks was taken as the U.S. accidental death risk value of 39.1 deaths per 100,000 people per year for 2005 (CDC Apr 2008).

7.2.4.2 Societal Risk Goal

The risk of cancer fatalities that might result from nuclear power plant operations to the population in the area near a nuclear power plant should not exceed 0.1 percent of the sum of the cancer fatality risks resulting from all other causes. As noted in the Safety Goal Policy Statement (51 FR 30028), “near” is defined as within 10 miles of the plant. The cancer fatality risk from all other sources was taken as 186.6 deaths per 100,000 people per year for 2003 to 2005 (CDC Apr 2008).

7.2.5 CONCLUSIONS

The total calculated dose-risk to the 50-mile population from airborne releases from an AP1000 reactor at Turkey Point would be 0.27 person-rem per reactor year (Table 7.2-1). This value is

greater than the 0.043 person-rem per reactor year reported by Westinghouse in the DCD (WEC 2011). The FPL analysis included long-term (chronic) exposure pathways in the dose-risk. The equivalent short-term exposure pathway dose from a single AP1000 reactor at Turkey Point would be 0.083 person-rem per reactor year. This value is also greater than the dose-risk reported in the DCD. This is a result of the large population within 50 miles surrounding Units 6 & 7.

The AP1000 dose-risk at the Units 6 & 7 site is less than the population risk for all current reactors that have performed severe accident mitigation alternatives (SAMA) analysis through 2008 as part of license renewal, and less than that for the five reactors analyzed in NUREG-1150, *Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants*.

Comparisons with the existing licensed power reactors indicate that risk from the surface water exposure pathway is small. Under the severe accident scenarios, surface water is primarily contaminated by atmospheric deposition. The AP1000 atmospheric exposure pathway doses are significantly lower than those of the existing licensed power reactors. Therefore, it is reasonable to conclude that the doses from the surface water exposure pathway at the Units 6 & 7 site would be consistently lower than those for the currently licensed power reactors.

The risks of groundwater contamination from a severe AP1000 accident (see Subsection 7.2.3.3) would be much less than the risk from currently licensed power reactors. Additionally, interdiction could substantially reduce the groundwater exposure pathway risks.

For comparison, as reported in Section 5.4, the total collective dose from Units 6 & 7 normal operations is expected to be 4.0 person-rem per year. As previously described, dose-risk is dose times frequency. Normal operations have a frequency no greater than one. Therefore, the dose-risk for normal operations is 4.0 person-rem per reactor year. Comparing this value to the severe accident dose-risk of 0.27 person-rem per reactor year indicates that the dose-risk from severe accidents is approximately 7 percent of the dose-risk from normal operations.

The risk of cancer fatalities from a severe accident for the Units 6 & 7 site is reported in Table 7.2-2 as 2.1E-10 for early fatality risk per reactor year and 2.6E-12 late (cancer) fatalities per year per reactor year. Comparing these values to the NRC safety goals indicates that the risk is less than 0.1 percent of the NRC safety goals.

The impacts from an AP1000 reactor at the Units 6 & 7 site would be SMALL because the probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are small and because the early and late fatality risks meet the NRC safety goals.

7.3 SEVERE ACCIDENT MITIGATION ALTERNATIVES

As described in Section 7.2, Westinghouse performed a generic severe accident analysis for the AP1000 as part of the design certification process (WEC 2011). The Westinghouse analysis determined that severe accident impacts are small and that no potential mitigating design alternatives are cost-effective, that is, appropriate mitigating measures are already incorporated into the plant design. Section 7.2 extends the Westinghouse generic severe accident analysis to examine the proposed new nuclear units at Turkey Point and determined that the generic conclusions remain valid for the Units 6 & 7 site. The analysis in this section provides assurance that there are no cost-beneficial design alternatives that would need to be implemented at the Units 6 & 7 site to mitigate these small impacts.

7.3.1 THE SEVERE ACCIDENT MITIGATION ALTERNATIVE ANALYSIS PROCESS

Design or procedural modifications that could mitigate the consequences of a severe accident are known as severe accident mitigation alternatives (SAMAs). In the past, SAMAs were known as severe accident mitigation design alternatives (SAMDAs) that primarily focused on design changes and did not consider procedural modification SAMAs. The Westinghouse DCD analysis is an SAMDA analysis. For an existing plant with a well-defined design and established procedural controls, the normal evaluation process for identifying potential SAMAs includes four steps:

1. Define the base case — The base case is the dose-risk and cost-risk of a severe accident before implementation of any SAMAs. A plant's probabilistic risk assessment is a primary source of data in calculating the base case. The base case risks are converted to a monetary value to use for screening SAMAs. Section 7.2 presents the base case for a single AP1000 unit at the Units 6 & 7 site, without the monetization step.

2. Identify and screen potential SAMAs — Potential SAMAs can be identified from the plant's individual plant examination, the plant's probabilistic risk assessment, and the results of other plants' SAMA analyses. This list of potential SAMAs is assigned a conservatively low implementation cost based on historical costs, similar design changes, and/or engineering judgment, then compared to the base case screening value. SAMAs with higher implementation cost than the base case are not evaluated further.

3. Determine the cost and net value of each SAMA — Each SAMA remaining after Step 2 has a detailed engineering cost evaluation developed using current plant engineering processes. If the SAMA continues to pass the screening value, Step 4 is performed.

4. Determine the benefit associated with each screened SAMA — Each SAMA that passes the screening in Step 3 is evaluated using the probabilistic risk assessment model to

determine the reduction in risk associated with implementation of the proposed SAMA. The reduction in risk benefit is then monetized and compared to the detailed cost estimate. Those SAMAs with reasonable cost-benefit ratios are considered for implementation.

The base case benefit value is calculated by assuming the current dose-risk of the unit could be reduced to zero and assigning a defined dollar value for this change in risk. Any design or procedural change cost that exceeded the benefit value would not be considered cost-effective. The dose-risk and cost-risk results (Section 7.2 analyses) are monetized in accordance with methods established in NUREG/BR-0184, *Regulatory Analysis Technical Evaluation Handbook*. NUREG/BR-0184 presents methods for determining the value of decreases in risk using four types of attributes: public health, occupational health, offsite property, and onsite property. Any SAMAs in which the conservatively low implementation cost exceeds the base case monetization would not be expected to pass the screening in Step 2. If the FPL baseline analysis produces a value that is below that expected for implementing any reasonable SAMA, no matter how inexpensive, the remaining steps of the SAMA analysis are not necessary.

7.3.2 THE AP1000 SAMDA ANALYSIS

The Westinghouse SAMDA analysis is presented in Appendix 1B of the DCD. Westinghouse compiled a list of potential SAMDAs based on the AP600 analysis and other plant designs and suggestions from the AP600/AP1000 design staff. Some SAMDAs were then screened out based on their inapplicability to the AP1000 or the fact that they were already included in the AP1000 design. Rough implementation costs that far exceeded any reasonable benefit were also excluded. The 13 SAMDAs that passed the screening process are as follows and are described more fully in the DCD.

- Chemical volume and control system upgrade to mitigate small loss-of-coolant accidents
- Filtered containment vent
- Self-actuating containment isolation valves
- Passive containment spray
- Steam generator shell-side passive heat removal system
- Steam generator safety valve flow directed to in-containment refueling water storage tank
- Increased steam generator secondary side pressure capacity
- Secondary containment filtered ventilation

- Diverse in-containment refueling water storage tank injection valves
- Diverse containment recirculation valves
- Ex-vessel core catcher
- High-pressure containment design
- Improved reliability of diverse actuation system

These remaining SAMDAs were quantified by the probabilistic risk assessment model to determine the reduction in risk for implementing the SAMDA. Each SAMDA was assumed to reduce the risk of the accident sequences that they address to zero, a conservative assumption. Using the cost-benefit methodology of NUREG/BR-0184, the maximum averted cost risk was calculated for each SAMDA. The maximum averted cost risk calculation used the dose-risks and cost-risks calculated for the severe accidents described in Subsection 7.2.1. Westinghouse calculated the base case maximum averted cost risk to be $21,000 (2007 dollars) using a 7 percent discount rate.

Westinghouse next compared the implementation costs for each SAMDA to the $21,000 value and found that none of the SAMDAs would be cost-effective. The least costly SAMDA, self-actuating containment isolation valves, had an implementation cost of approximately $30,000, with the others having costs at least an order of magnitude greater. The one potential SAMDA was further evaluated but not found to be cost-effective.

In its *Finding of No Significant Impact* relating to the certification of the AP1000 design, the NRC (U.S. NRC Jan 2005) concluded, "none of the potential design modifications evaluated are justified on the basis of cost-benefit considerations. The NRC further concludes that it is unlikely that any other design changes would be justified in the future on the basis of person-rem exposure because the estimated core damage frequencies are very low on an absolute scale."

Pursuant to 10 CFR 51.55(b), it was confirmed that the design changes that are incorporated into the referenced DCD, as defined in Section 1.1, did not change the SAMDA screening or evaluation results or conclusions. Specifically, the SAMDAs assessed as being rejected for the certified AP1000 design, as documented in DCD Revision 19, Appendix 1B, have not become cost-beneficial for Units 6 & 7, nor have any new SAMDAs been identified for Units 6 & 7.

7.3.3 MONETIZATION OF THE UNITS 6 & 7 BASE CASE

The principal inputs to the calculations are the core damage frequency (reported in Section 7.2), dose-risk and cost-risk (reported in Table 7.2-1), dollars per person-rem ($2000 as provided by NRC in NUREG/BR-0184), plant operating life (60 years), and economic discount rate (7 percent

and 3 percent are NRC precedents). Both the Westinghouse and FPL severe accident analyses described in Section 7.2 calculate risks from internal events. For this SAMDA analysis, the base-case core damage frequency, dose-risk, and cost-risk for internal events were escalated to account for external events, both at power and at shutdown. As explained in the DCD, dose-risk and cost-risk were scaled up by the ratio of the total (internal and external events) frequency divided by the internal events frequency (5.0E-07/2.4E-07 per reactor year). With these inputs, the monetized value of reducing the base case core damage frequency to zero is presented in Table 7.3-1. The monetized value, known as the maximum averted cost-risk, is conservative because no SAMA can reduce the core damage frequency to zero.

The maximum averted cost risk of $55,513 for a single proposed AP1000 at Turkey Point is so low that FPL does not believe there are any design changes, over those already incorporated into the advanced reactor design, that could be determined to be cost-effective. With a 3 percent discount rate, the valuation of the averted risk is $123,602. The least costly SAMDA, the self-actuating containment isolation valves, had an implementation cost of approximately $30,000. The maximum averted cost risk of $55,513 is the total cost risk benefit from the implementation of every SAMDA, and the benefit from implementation of the least costly SAMDA is only a portion of the total (maximum) cost risk benefit. The cost risk benefit from the implementation of the least costly SAMDA is only $994. Each of the remaining SAMDA implementation costs are much greater than the maximum averted cost risk of $55,513.

As demonstrated in WEC 2011, and confirmed for Turkey Point, the benefit of any SAMDA is much less than its implementation cost. The Turkey Point analysis resulted in slightly higher values than the Westinghouse generic analysis results of $21,000 for the 7 percent discount rate and $43,000 for the 3 percent discount rate. This is a result of the larger population and higher property values surrounding the Units 6 & 7 site.

Accordingly, further evaluation of design-related SAMAs is not warranted. FPL does not believe that administrative SAMAs, such as those relating to procedures or training, are appropriate for evaluation at this time because the procedures and training have not been developed. The purpose of this analysis is to demonstrate that the maximum averted cost risk for an AP1000 at the Units 6 & 7 site are not cost-beneficial. Evaluation of administrative SAMAs would not be appropriate until a plant design is finalized and plant administrative processes and procedures are being developed. At that time, appropriate administrative controls on plant operations would be incorporated into the plants' management systems as part of the baseline.

7.4 TRANSPORTATION ACCIDENTS

Subsection 5.7.2.1 addresses the conditions in subparagraphs 10 CFR 51.52(a)(1) through (5) regarding use of Table S-4 to characterize the impacts of radioactive materials transportation in this environmental report. Because the AP1000 does not meet all of the conditions set forth in 10 CFR 51.52(a), a further analysis of the transportation effects was required. Subsection 5.7.2.2 describes the methodology used to analyze the impacts of transporting radioactive materials and addresses the incident-free transport of radioactive materials to and from Units 6 & 7. Subsection 7.4.1 describes the radiological impacts of transportation accidents. The nonradiological impacts of transportation accidents are addressed in Subsection 7.4.2.

7.4.1 RADIOLOGICAL IMPACTS OF TRANSPORTATION ACCIDENTS

7.4.1.1 Transporting Unirradiated Fuel

Accidents involving unirradiated fuel shipments are addressed in Table S-4 of 10 CFR 51.52. Unirradiated fuel would be transported to the site via truck. Accident risks are calculated as frequency multiplied by consequence. Accident frequencies for transporting fuel to future reactors are expected to be lower than those used in the analysis in WASH-1238 (AEC Dec 1972), which forms the basis for Table S-4 of 10 CFR 51.52, because of improvements in highway safety and security. Traffic accident, injury, and fatality rates have decreased over the past 30 years. Because fuel form, cladding, and packaging for the AP1000 are similar to those of current generation light water reactors (LWRs), the consequences of accidents that are severe enough to result in a release of radioactivity to the environment would also be similar. Accordingly, the risks of accidents during transporting unirradiated fuel to Units 6 & 7 would be expected to be smaller than the reference LWR consequences listed in Table S-4.

7.4.1.2 Transporting Spent Fuel

The RADTRAN 5 computer code was used to estimate impacts of transportation accidents involving spent fuel shipments. RADTRAN 5 considers a spectrum of potential transportation accidents, ranging from those with high frequencies and low consequences (i.e., fender benders) to those with low frequencies and high consequences (i.e., accidents in which the shipping container is exposed to severe mechanical and thermal conditions).

The radionuclide inventory of AP1000 spent fuel after 5 years of decay was estimated using the ORIGEN code (Version 2.1). A screening analysis was performed to select the dominant contributors to accident risks and to simplify the RADTRAN 5 calculations. This screening identified the radionuclides that would collectively contribute more than 99.999 percent of the dose from inhalation of radionuclides released following a transportation accident (NUREG-1811). The spent fuel inventory used in this analysis for the AP1000 is presented in Table 7.4-1. The specific quantities and characteristics of the crud deposited on AP1000 spent

fuel from corrosion products generated elsewhere in the reactor coolant system are unknown at this time because of insufficient operating experience. The spent fuel transportation accident risks were calculated assuming the entire Co-60 inventory (Table 7.4-1) is in the form of crud. Assuming a minimum decay period of 5 years, the expected Co-60 activity is approximately 4.09 Ci/metric tons uranium (MTU). Sb-125 was also included in the crud analysis. However, the total activity of Sb-125 reported as crud was less than 0.003 percent of the total Sb-125 inventory in the fuel. These crud values were included as a separate group in the RADTRAN 5 calculations. The total activity of the crud components is roughly five orders of magnitude lower than the fission and activation products of the fuel. Therefore, from a radiological dose standpoint, the crud contribution is negligible.

Massive shipping casks are used to transport spent fuel because of the radiation shielding and accident resistance features required by 10 CFR Part 71, *Packaging and Transportation of Radioactive Material*. Spent fuel shipping casks must be certified Type B packaging systems, meaning they must withstand a series of severe hypothetical accident conditions with essentially no loss of containment or shielding capability.[1] As stated in NUREG/CR-6672 (Sprung et al. Mar 2000), the probability of encountering accident conditions that would lead to shipping cask failure is less than 0.01 percent (i.e., more than 99.99 percent of all accidents would result in no release of radioactive material from the shipping cask). The analysis presented in this ER assumed that shipping casks for AP1000 spent fuel would provide equivalent mechanical and thermal protection of the spent fuel cargo, in accordance with the requirements of 10 CFR Part 71.

For the spent fuel from the AP1000, the RADTRAN 5 accident risk calculations were performed using an assumption of 0.5 MTU per shipment for radionuclide inventories. The resulting risk estimates were multiplied by the expected annual spent fuel shipment amounts (in MTU per year) to derive estimates of the annual accident risks associated with spent fuel shipments from the AP1000. The amount of spent fuel shipped per year was assumed to be equivalent to the annual discharge quantity: 23 MTU per year for the AP1000. (This discharge quantity has not been normalized to the reference LWR. The normalized value is presented in Table 7.4-2.) The release fractions for current generation LWR fuels were used to approximate the impacts from the advanced LWR spent fuel shipments. This assumes that the fuel materials and containment systems (i.e., cladding and fuel coatings) behave similarly to current LWR fuel under applied mechanical and thermal conditions.

Using RADTRAN 5, the population dose from the released radioactive material was calculated for four possible exposure pathways:

- External dose from exposure to the passing cloud of radioactive material.

1. Requirements for Type B packaging are set forth in 49 CFR 173.413 and 10 CFR 71.41 through 51.

- External dose from the radionuclides deposited on the ground by the passing plume (the radiation exposure from this pathway was included even though the area surrounding a potential accidental release would be evacuated and decontaminated, thus preventing long-term exposures from this pathway).

- Internal dose from inhalation of airborne radioactive contaminants.

- Internal dose from resuspension of radioactive materials that were deposited on the ground (the radiation exposures from this pathway were included even though evacuation and decontamination of the area surrounding a potential accidental release would prevent long-term exposures).

External doses from increased radiation fields surrounding a shipping cask with damaged shielding were also considered. It is possible that shielding materials incorporated into the cask structures could become damaged because of an accident; however, the loss of shielding events was not included in the analysis because their contribution to spent fuel transportation risk is much smaller than the dispersal accident risks from the pathways listed above.

Calculations were performed to assess the environmental consequences of transportation accidents when shipping spent fuel from Units 6 & 7 to a spent fuel repository assumed to be at Yucca Mountain, Nevada. The shipping distances and population distribution information for the route were the same as those used for the incident-free transportation impacts analysis described in Subsection 5.7.2.2. Table 7.4-2 presents accident risks associated with transporting spent fuel from Units 6 & 7 to the proposed Yucca Mountain repository. The accident risks are provided in the form of a collective population dose (i.e., person-rem per year over the shipping campaign). The table also presents estimates of accident risk per reactor year normalized to the reference reactor analyzed in WASH-1238. The transportation accident impacts were also calculated for the alternative sites (St. Lucie, Glades, Martin, and Okeechobee 2) in the region of interest.

The risk to the public from radiation exposure was estimated using the nominal probability coefficient for total detrimental health effects (730 fatal cancers, nonfatal cancers, and severe hereditary effects per 1E+06 person-rem) per reference reactor year from the International Commission on Radiological Protection Publication 60 (ICRP 1991). These values are presented in Table 7.4-2. These estimated risks are quite small compared to the fatal cancers, nonfatal cancers, and severe hereditary effects that would be expected to occur annually in the same population from exposure to natural sources of radiation. Therefore, negligible increases in environmental risk effects are expected from accidents that may result during shipping spent fuel from the site to a spent fuel disposal repository. The risks of accidents during transporting spent fuel from Units 6 & 7 or an alternate site would be consistent with the environmental impacts presented in Table S-4.

7.4.1.3 Transporting Radioactive Waste

As shown in Table 5.7-4, transporting radioactive waste meets the applicable conditions in 10 CFR 51.52(a) and no further analysis is required.

7.4.2 NONRADIOLOGICAL IMPACTS OF TRANSPORTATION ACCIDENTS

Nonradiological impacts would include the projected number of accidents, injuries, and fatalities that could result from shipments of radioactive materials to or from the Units 6 & 7 site and return of empty containers. Nonradiological impacts were estimated using accident, injury, and fatality rates from Table 4 of *State-Level Accident Rates for Surface Freight Transportation: A Reexamination* (Saricks and Tompkins Apr 1999). This data is representative of the traffic accident, injury, and fatality rates for heavy truck shipments similar to those that would be used to transport radioactive materials to and from the site. These rates (measured in impacts per vehicle-mile traveled) are multiplied by the annual numbers of shipments and estimated travel distances for the shipments to estimate annual impacts. These estimates include the human health impacts projected to result from traffic accidents involving shipments of radioactive materials; they do not consider the radiological or hazardous characteristics of the cargo.

7.4.2.1 Transporting Unirradiated Fuel

The nonradiological accident impacts that could result from shipments of unirradiated fuel to Units 6 & 7 and return of empty containers from the site are presented in Table 7.4-3. The nonradiological impacts for the reference LWR analyzed in WASH-1238 are also shown for comparison. Nationwide median rates for interstate highway transportation from Saricks and Tompkins (1999) were used to estimate the annual impacts. Consistent with the incident-free transportation analysis described in Subsection 5.7.2, an average round-trip shipping distance of 4000 miles was used to evaluate the unirradiated fuel shipments. The differences between the reference LWR and AP1000 results are because of the lower number of shipments per year (when normalized for electrical output) projected for the AP1000 units at Units 6 & 7. The values presented in Table 7.4-3 would be doubled for a two-unit plant.

7.4.2.2 Transporting Spent Fuel

The general approach to calculating the nonradiological impacts for spent fuel shipments is similar to that for other radioactive materials shipments. The primary difference is the spent fuel shipping route characteristics and are better defined allowing the state-specific accident statistics in Saricks and Tompkins (1999) to be used in the analysis. State-by-state shipping distances and road types were obtained from the TRAGIS output file (see Subsection 5.7.2.2.2 for a description of the TRAGIS routing model). The shipping distances were doubled to allow for return shipments of empty containers to Units 6 & 7. This information, the annual number of shipments, and state-

specific accident statistics were used to estimate the nonradiological impacts presented in Table 7.4-4.

7.4.2.3 Transporting Radioactive Waste

Nonradiological impacts of radioactive waste shipments were calculated using the same general approach as the unirradiated fuel shipments. A shipping distance of 500 miles was assumed consistent with the analysis in WASH-1238. Because the destination of the waste shipments is not known, the national median accident, injury, and fatality rates from Saricks and Tompkins (1999) were used to calculate the values presented in Table 7.4-5. The nonradiological impacts for the reference LWR analyzed in WASH-1238 are also shown for comparison. The differences between the reference LWR and AP1000 are because of the lower number of radioactive waste shipments projected for the AP1000. The values presented in Table 7.4-5 would be doubled for a two-unit plant.

7.4.3 CONCLUSION

The transportation accident risk results for the AP1000 for unirradiated and spent fuel and radioactive waste are less than the nonradiological effects of accidents in transportation (one fatal injury in 100 reactor years and one nonfatal injury per ten reactor years) indicated in Table S-4. Based on this analysis, the overall transportation accident risks associated with unirradiated fuel, spent fuel, and radioactive waste shipments from the proposed AP1000 units at Units 6 & 7 are consistent with the risks associated with transporting the radioactive materials from current generation reactors presented in Table S-4 of 10 CFR 51.52 (reproduced in Table 5.7-2) and thus would be SMALL.

CHAPTER 8 NEED FOR POWER

The environmental report should include consideration of the benefits of the proposed action [10 CFR 51.45(c)]. To accurately characterize the benefits associated with the proposed action, the NRC must assess the need for power (NRC 2003). NRC guidance NUREG-1555 provides detailed instructions for NRC to use in reviewing the need for power. However, the guidance also identifies the NRC expectation that states may perform an evaluation of the need for power. NUREG-1555 indicates that if the state's evaluation is (1) systematic, (2) comprehensive, (3) subject to confirmation, and (4) responsive to forecasting uncertainty, no additional independent review by NRC is needed. This chapter describes the state of Florida process for determining need for power, the evaluation that it performed for Turkey Point Units 6 & 7, and how the evaluation meets the NRC criteria for not performing an additional review.

8.1 STATE OF FLORIDA PROCESS FOR DETERMINING NEED FOR POWER

Florida has a traditional system for regulating electric service in which utilities have a defined service territory and customers within a service territory purchase their electricity from the local utility. The state regulates rates and services of the utilities, electric grid reliability, and planning for and meeting electric needs. FPL is a regulated Florida electric utility and Figure 8.1-1 shows FPL's service territory. Descriptions of the FPL service territory, FPL's power system and resources, and the role of Florida Reliability Coordinating Council (FRCC) are provided in Subsections 8.1.3, 8.1.4, and 8.1.5, respectively.

The state has charged the Florida Public Service Commission (FPSC) with the responsibility of regulating electric utilities (FS 2007a, FS 2007b). In addition, the state has established the Florida Office of Public Counsel (FOPC) to advocate for utility customers before regulatory agencies such as the FPSC. Both state agencies have roles in the process of determining need for power. Finally, the FRCC, one of the North American Electric Reliability Corporation (NERC) regional councils, plays a role.[1]

The FPSC is the sole forum for determination of the need for power within Florida. By statute and by its own regulations, there are two key components to FPSC's evaluation of need for power:

- Ten-year site plans
- Determinations of need

The following sections describe each component and how each has addressed the need for power from Turkey Point Units 6 & 7.

1. There is no independent system operator or regional transmission organization within Florida.

8.1.1 TEN-YEAR SITE PLANS

Florida 10-year site plans are comparable to what other states call integrated resource plans. Florida requires the following:

(1) Each electric utility shall submit a 10-year site plan which shall estimate its power-generating needs and the general location of its proposed power plant sites [FS 186.801(1)]. The FPSC has made this an annual submittal requirement for utilities having generating capacity of 250 megawatts or greater and requires addressing fuel requirements [FAC 25-22.071(1)(a)].

(2) The FPSC must make a preliminary study of the plan and classify it as “suitable” or “unsuitable.” The FPSC study must review:

a. The need, including the need as determined by the Commission, for electrical power in the area to be served

b. The effect on fuel diversity with the State

c. Anticipated environmental impact of each proposed site

d. Possible alternatives to the proposed plan

e. Views of appropriate local, state, and federal agencies

f. The extent to which the plan is consistent with the state comprehensive plan

g. State information on energy availability and consumption [FS 186.801(2)]

(3) Utilities shall compile and submit to the FPSC aggregate data derived from individual plans. The FRCC prepares and submits these data for the utilities to the state of Florida and NERC.

As an example, in 2008 11 utilities submitted 10-year site plans. The FPSC held a public workshop to facilitate discussion of the plans. The FPSC made supplemental requests of reporting utilities and reviewed data from other sources, including the following documents prepared by the FRCC:

The 2008 *Regional Load and Resource Plan* contains aggregate data on demand and energy, capacity and reserves, and proposed new generating unit and transmission line additions for Peninsular Florida as well as statewide (FPSC 2008a).

The 2008 *Reliability Assessment* is an aggregate study of generating unit availability, forced outage rates, load forecast methodologies, and gas pipeline availability (FPSC 2008a).

The *Long Range Transmission Reliability Study* is an assessment of the adequacy of Peninsular Florida's bulk power and transmission system. The study includes both short-term (2009–2012) detailed analysis and long-term (2013–2017) evaluation of developing trends that would require transmission additions or other corrective action (FPSC 2008a).

The FPSC found the plans to be suitable and, in reporting on its annual review, addressed energy demand; energy generation; fuel price, supply, and transportation; transmission plans; and state, regional, and local comments. The FPSC uses the annual review report to meet its statutory requirement for reporting to the Florida legislature and for providing electricity forecasts to the Florida Energy and Climate Commission (FPSC 2008a).

FPL annually submits 10-year plans to the FPSC. The FPL plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites.

Chapter I of the FPL 10-year plan provides an overview of FPL's current generating facilities and other resources including purchased power, demand side management (DSM), and FPL's transmission system. Chapter II presents FPL's load forecasting methodology and its forecast of seasonal peaks and annual energy usage. Chapter III discusses FPL's integrated resource planning process and outlines FPL's projected resource additions based on FPL's integrated resource planning work. Chapter IV discusses environmental information as well as preferred and potential site locations for additional electric generation facilities. Chapter V addresses 12 "discussion items" which pertain to additional information that is to be included in a site-plan filing. Table 8.1-2 presents excerpts from the table of contents of the 2010 plan.

Site plans are long-term planning documents and should be reviewed in this context. A site plan contains tentative information, especially for the latter years of the 10-year time horizon, and is subject to change at the discretion of the utility. Detailed evaluation of the need for power takes place during the second of the Florida three-component system, determination of need. Although not specifically presented in the FPL 2010 10-year plan because the reporting period ends in 2019, the plan notes that FPL had petitioned the FPSC for a determination of need for two new nuclear units at its existing Turkey Point power plant site. Subsection 8.1.2 addresses the FPL petition and the FPSC determination of need in detail.

8.1.2 DETERMINATION OF NEED

In 1973, the Florida Legislature enacted the Power Plant Siting Act (PPSA). The PPSA provides clear timelines and regulatory requirements for utilities seeking to build new power plants and directly associated facilities (such as transmission lines) in the State. Pursuant to the requirements of Chapter 25-22.080 (F.A.C. 1997) and contained within the Florida PPSA, an applicant for a new plant that exceeds 75 MW of steam generating capacity must file a petition for

a Determination of Need with the FPSC. As provided in F.S. Section 403.519, the FPSC is the sole forum for determining the need for construction of an electrical power plant in the state. This section of the statute further provides that in making its determination, the FPSC should take into account the need for electric system reliability and integrity, the need for adequate electricity at a reasonable cost, the need for fuel diversity and supply reliability, whether the proposed plant is the most cost-effective alternative available, and whether renewable energy sources and technologies as well as conservation measures are used to the extent reasonably available (FS 2007b).

In October 2007, FPL submitted to the Florida Public Service Commission (FPSC) its Petition to Determine Need for Units 6 & 7 (FPL 2007a) and the supporting documents, including the Need Study for Electrical Power (FPL 2007b) and the testimony of 15 witnesses. Table 8.1-1 presents the table of contents of the FPL Petition to Determine Need.

In the Petition to Determine Need for Units 6 & 7, FPL, proposed to add two new units, Units 6 & 7, at its existing Turkey Point generating plant site. These proposed units would collectively add between 2200 and 3040 MW (approximately 2234 MW with selection of two AP1000 reactors) baseload generating capacity to FPL's service area.

Several interested parties intervened in the need determination proceeding, including the FOPC, the independent ratepayer advocate appointed by the Legislature; five utilities, Florida Municipal Electric Association (FMEA), Florida Municipal Power Agency (FMPA), JEA, Orlando Utilities Commission (OUC), and Seminole Electric Cooperative, Inc.; and a private citizen.

In addition to the pre-filed testimony, the public was provided the opportunity to provide testimony at two public hearings. Topics of interest voiced in the public testimony portion of the hearings included system reliability and integrity; fuel diversity; environmental compliance costs; conservation, DSM and renewables; and cost-effectiveness.

FPSC Staff reviewed the information provided by FPL, the intervening parties, and public testimony, and performed an independent analysis of the information presented in FPL’s petition, which concluded that the FPSC should determine that there was a need for FPL’s proposed new nuclear units at Turkey Point. After conducting several days of hearings and upon a full review of an extensive administrative record, the FPSC determined that there was a need for FPL’s proposed new nuclear units at Turkey Point and granted FPL’s petition by a final order in April 2008 (FPSC 2008b). In its final order, the FPSC found:

Need for Electric System Reliability and Integrity

> “FPL has a need for 8350 MW of additional capacity beginning in the 2011 through 2020 period. Turkey Point 6 and 7 will provide only a portion of FPL’s need for capacity. … If FPL’s load forecast dramatically declines or the amount of DSM or renewable generation available

substantially increases, the most likely result will be the cancellation of some gas-fired combined cycle plants that have not yet been certified. Based on this record, FPL has shown that it has a reliability need for either the 1100 MW or 1520 MW units (referring to the AP1000 or ESBWR designs respectively considered) in 2018 and 2020."

Need for Fuel Diversity

"…[T]he addition of nuclear generation will maintain FPL's fuel diversity and security. In 2006, FPL generated approximately 50% of its power from natural gas, approximately 21% from nuclear power, and 18% from coal. Without the addition of Turkey Point 6 and 7, FPL's fuel mix is projected to climb to approximately 75% from natural gas while the amount of nuclear generation would drop to approximately 16%. The addition of 2200 to 3040 MW of capacity (referring to the 2 - AP1000 or 2 - ESBWR designs respectively considered) associated with Turkey Point 6 and 7 would increase nuclear generation to approximately 26% and natural gas to 65% by the year 2021, the first full year of operation for both units."

Need for Baseload Generating Capacity

"…[B]y 2010 FPL will have approximately 15,235 MW of existing or certified base-load generation capacity which consists of coal (902 MW), gas-fired combined cycle (10,979 MW), and nuclear generation facilities (3354 MW). As mentioned previously, FPL's peak load is expected to increase by over 6000 MW by the year 2020. FPL's base-load needs are also projected to increase by approximately the same amount. Even with the addition of Turkey Point 6 and 7, FPL's base-load needs will continue to be met primarily with natural gas-fired combined cycle generators."

Need for Adequate Electricity at a Reasonable Cost

"…[W]e believe the cost estimate information presented in the record is appropriate. Accordingly, we find that construction of Turkey Point 6 and 7 will not only provide adequate electricity, but also ensure the most reasonable costs to ratepayers."

No Mitigating Renewable Energy Sources and Technologies or Conservation Measures

"…[W]e find that there are no additional cost-effective conservation measures available that might mitigate FPL's need for Turkey Point 6 and 7. FPL has identified an incremental increase of 1899 MW of DSM summer peak demand reduction by the year 2020, as well as over 280 MW of renewable energy from purchased power contracts. As previously discussed, FPL has demonstrated a reliability need in excess of these values for the years 2018 through 2020. A reduction in peak demand or an increase in renewable generation would likely result in the deferral of uncertified natural gas units. In addition, it is unrealistic to assume that FPL could achieve the amount of energy savings through DSM in ten years, that took 26 years to

accomplish. As such, we find that there are no additional renewable energy sources or conservation measures which could effectively mitigate FPL's need for Turkey Point 6 and 7."

Most Cost-Effective Source of Power

"Turkey Point 6 and 7 will provide the most cost-effective source of power…. The results of FPL's break-even analysis indicate that Turkey Point 6 and 7 are projected to produce savings in 17 of the 18 scenarios considered. Such results indicate a high likelihood of FPL's ratepayers realizing net benefits over the life of the project. Turkey Point 6 and 7 are projected to produce annual fuel savings of over $1 billion dollars starting in 2021 and about $94 billion over the life of the units when compared to a combined cycle alternative. As environmental compliance costs increase, so do the benefits associated with Turkey Point 6 and 7 because nuclear generation is considered a "non-emitting" technology for GHG (Greenhouse Gas) emissions. Nuclear power plants have an initial licensed operating life of 40 years with the potential to renew the operating license for another 20 years. Therefore, the fuel and environmental benefits of Turkey Point 6 and 7 could continue beyond the analysis presented in this proceeding."

Regarding the information provided by FPL and its forecasting methodologies, the FPSC stated in its order granting FPL's Petition to Determine Need for Turkey Point Units 6 & 7 Electrical Power Plant:

"We reviewed FPL's forecast assumptions, regression models, and the projected system peaks demands, and find that they are appropriate for use in this docket. The forecast assumptions were drawn from independent sources which we have relied upon in prior cases. The regression models used to calculate the projected peak demands conform to accepted economic and statistical practices. Finally, the projected peak demands produced by the models appear to be a reasonable extension of historical trends" (FPSC 2008b).

The Florida Public Service Commission approval of the Petition for Need Determination can be found at their website (FPSC 2008b).

8.1.3 DESCRIPTION OF SERVICE AREA

As provided in its Ten Year Power Plant Site Plan, FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.7 million people. FPL served an average of 4,499,067 customer accounts in 35 counties during 2009 (FPL Apr 2010). FPL's service area is shown in Figure 8.1-1. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, nonutility-owned generation, DSM, and interchange/purchased power (FPL Apr 2010). FPL's customer categories include:

- Residential

- Commercial
- Industrial
- Railroad and railways, and street and highway lighting
- Other public authorities
- Sales for resale (wholesale)

8.1.4 FPL-OWNED RESOURCES

The existing FPL generating resources are located at 16 generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units in Jacksonville, Florida (Figure 8.1-1). The current FPL-owned generating facilities consist of 4 nuclear units, 3 coal units, 14 combined-cycle units, 17 fossil steam units, 48 combustion gas turbines, 1 simple-cycle combustion turbine, and 1 photovoltaic facility (FPL Apr 2010).

FPL's bulk transmission system comprises 6727 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 585 substations in Florida (FPL Apr 2010).

The existing FPL power system, including generating plants, major transmission stations, and transmission lines, is shown in Figure 8.1-2. Figure 8.1-3 shows FPL's interconnection ties with other utilities.

8.1.5 FLORIDA RELIABILITY COORDINATING COUNCIL

FPL is a member of the Florida Reliability Coordinating Council (FRCC). The FRCC is one of the (NERC) regional councils and has approximately 25 members. These members include investor-owned utilities, such as FPL, cooperative systems, municipal utilities, power marketers, and independent power producers (FRCC 2007). There are no Independent System Operators or Regional Transmission Organizations operating in Florida (FERC 2009). The FRCC annually produces an annual Load and Resource Plan, which is a compilation of operating entities' 10-year site plans projecting the next 10 years, addressing, among other subject matter, regional firm peak demand, available capacity, and reserve margin. This information is provided to the FPSC each July, and a Commission workshop is held in August for a more intensive review by the Commission.

8.2 POWER DEMAND

This section describes the NRC requirements and how the Florida Statutes along with the approved Petition to Determine Need for Units 6 & 7 Electrical Power Plant fulfills those requirements that are provided in NUREG-1555, Sections 8.2 through 8.4.

8.2.1 ENVIRONMENTAL STANDARD REVIEW PLANS (ESRPS)

The ESRP 8.2.1 (Power and Energy Requirements), ESRP 8.2.2 (Factors Affecting Growth of Demand), ESRP 8.3 (Power Supply) and ESRP 8.4 (Assessment of Need for Power) data and informational needs are fulfilled by the state processes required by Florida Statutes (F.S.) Chapter 186 with Rules 25-22.070, 25 22.071, and 25-22.072, Florida Administrative Code (F.A.C.) along with F.S. Section 403.519 and the Petition to Determine Need for Turkey Point Units 6 & 7 Electrical Power Plant, all of which are described below.

8.2.2 POWER AND ENERGY REQUIREMENTS

As described in FPL's Ten Year Power Plant Site Plan (FPL Apr 2010), there are four fundamental steps to FPL's resource planning process. These are summarized as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and develop competing resource plans)

Step 3: Evaluate the competing options and resource plans regarding system economics and non-economic factors

Step 4: Select a resource plan and commit, as needed, to near-term options

The first step, often referred to as a reliability or resource adequacy assessment for the utility system, is essentially a determination of the amount of capacity or megawatts of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed and when. This step starts with an updated load forecast. Several databases are also updated with the new information regarding forecasted loads, delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions, among other information. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

These key assumptions, plus other updated information, are applied in determining the magnitude and the timing of FPL's resource needs. These determinations are accomplished by

system reliability analyses that are typically based on a dual planning criteria of a minimum peak period reserve margin of 20 percent (FPL applies this to both summer and winter peaks) and a maximum loss-of-load probability of 0.1 day per year. Both of these criteria are commonly used throughout the regulated utility industry.

The result of this first fundamental step of the resource planning process is a projection of how many new megawatts of resources are needed to meet both reserve margin and loss-of-load probability criteria and, thus, maintain system reliability, and when the megawatts are needed. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

During Step 2, feasibility analyses of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. In similar analyses, feasibility evaluations of new DSM options and/or continued growth in existing DSM options are typically conducted. Resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet, dynamic programming, and/or linear and non-linear programming techniques. At the conclusion of this second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

In Step 3, FPL performs, among other evaluations, economic analyses of the competing resource plans focusing on total system economics. These analyses are performed using the following:

- Various spreadsheets/models such as the P-M Area model, which is used by FPL to develop the fuel cost budget and to conduct other production cost-related analyses

- FPL's DSM cost-effectiveness spreadsheet model for analyzing the cost-effectiveness of individual DSM measures/programs, and then utilizes its linear programming model to develop DSM portfolios

- FPL's nonlinear programming model for analyzing the potential for lowering system peak loads through additional load management capacity

The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology).

The results of the above three steps are used to develop the future generation plan, which would include incremental resource additions/changes.

Key inputs to these planning steps are discussed below.

Load Forecast

Long-term (20-year) forecasts of sales, net energy for load (NEL)[1], and peak loads are typically developed on an annual basis for resource planning work at FPL, and new forecasts were developed by FPL every year for use in the Ten Year Power Plant Site Plan for FPL's ongoing analyses. These forecasts are a key input to the models used in FPL's integrated resource planning process. The primary drivers to typically develop these forecasts are economic conditions and weather.

The projections for the national and Florida economies are obtained from IHS Global Insight. Global Insight is a privately held company that provides comprehensive economic data to entities such as FPL for application and in-depth analysis. Population projections are obtained from the Bureau of Economic and Business Research of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Two sets of weather variables are developed and used in FPL's forecasting models:

- Cooling and Heating Degree-Hours are used to forecast energy sales
- Temperature data is used to forecast summer and winter peaks

The Cooling and Heating Degree-Hours are used to capture the changes in the electric usage of weather-sensitive electric appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory. Miami, Fort Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Hours which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, composite temperatures and hourly profiles of temperatures are used for the summer and winter peak models.

1. NEL is determined as the sum of all energy sales plus utility use and losses.

Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each of the six revenue classes for the most recent forecasting period of 2011–2026. The first five classes represent retail sales and the sixth represents wholesale sales. These six revenue classes, based on customer categories listed in Subsection 8.1.3, are:

- Residential
- Commercial
- Industrial
- Railroad and railways, and street and highway lighting
- Other public authorities
- Sales for resale (wholesale)

These forecasts were adjusted to match the NEL forecast. The results of these sales forecasts for the years 2011–2026, along with historical data, are presented in Table 8.2-1.

Energy Sales Forecasts

Rural and Residential Sales

Residential electric usage per customer is estimated by using an econometric model. The model contains Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, lagged Heating Degree-Hours, real price of electricity (a 12-month moving average), Florida real household disposable income, a variable designed to reflect the impact of empty homes, and a dummy variable for the specific month of November 2005. The price of electricity plays a role in explaining electric usage because electricity, like all other goods and services, will be used in greater or lesser quantities depending on its price. To capture economic conditions, the model includes Florida's real personal disposable income. The degree of economic prosperity can, and does, affects residential electricity sales. The impact of weather is captured by the Heating and Cooling Degree-Hours. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted. A dummy variable for November 2005 was included because an analysis of residuals identified that data point as an outlier.

Commercial Sales

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida real household disposable income, commercial real price of electricity (a 12-month moving average), Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, a variable designed to reflect the impact of empty homes, seasonal dummy variables for the months of February and December, a dummy variable for the specific month of January 2007, and an autoregressive term. Cooling degree-hours are used to capture weather-sensitive load in the commercial sector.

Industrial Sales

The industrial category is comprised of two groups; very small accounts (those with less than 20 kW of demand) and large, traditionally industrial customers. The forecast is developed using a separate econometric model for each group of industrial customer. The small industrial sales model utilizes the following variables: Florida Housing Starts, Cooling Degree-Hours, lagged Cooling Degree-Hours, industrial real price of electricity, and an autoregressive and seasonal autoregressive terms. The large industrial sales model utilizes the following variables: Florida Housing Starts, industrial real price of electricity, dummy variables for October and November 2004, and an autoregressive term.

Railroad and Railways Sales and Street and Highway Lighting Sales

The projections for railroad and railways sales are based on historical average use per customer because the number of customers is projected to remain the same. This class consists solely of Miami-Dade County’s Metrorail system.

The forecast for street and highway lighting sales is developed using historical usage patterns and multiplying these usage levels by the number of forecasted customers.

Other Public Authority Sales

Other public authority sales are developed using historical usage characteristics.

Sales for Resale (Wholesale)

Resale (wholesale) customers are municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City of Key West, Florida Metro- Miami-Dade County, and Lee County Electric

Cooperative. Starting in June 2014, Seminole Electric Cooperative will also be a customer in this category.

Net Energy for Load

An econometric model is developed to produce an NEL forecast. The key inputs to the model are the real price of electricity, heating and cooling degree-hours, and Florida real household disposable income. In addition, the model also includes variables for mandated energy efficiency and a variable designed to capture the impact of empty homes, along with seasonal dummies.

The NEL forecast is developed by multiplying the NEL per customer forecast by the total number of customers forecasted. Once the NEL forecast is obtained, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecast previously discussed are then adjusted to match the total billed sales. The forecasted NEL values 2011–2026, along with historical peak loads, are presented in Table 8.2-1.

8.2.3 FACTORS AFFECTING GROWTH OF DEMAND

As previously addressed, both FPL's Ten Year Power Plant Site Plan (FPL 2008), and the Need Study for Electrical Power (FPL 2007b) were based on FPL's integrated resource planning process. This process was used to determine the timing and magnitude of need for construction and operation of Turkey Point Units 6 & 7. The Need Study for Electrical Power was also part of FPL's filing with the FPSC for approval of Turkey Point Units 6 & 7 (which was approved by the FPSC). Consideration and application of basic factors affecting growth and demand for power, as detailed in the Site Plan and Need Study, are summarized in this section.

System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of a growing customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the peak forecast models to capture these behavioral relationships. The forecasting methodology of summer, winter, and monthly system peaks is presented below. The forecasted values for summer and winter peak loads for the years 2011–2026, along with historical summer and winter peak loads, are presented in Table 8.2-2.

System Summer Peak

The summer peak forecast is developed using an econometric regression model. This econometric model uses the following explanatory variables: total average customers, the real price of electricity, Florida real personal income, average temperature on peak day, and a heat

buildup weather factor consisting of the sum of the cooling degree-hours during the peak day and 3 days before.

System Winter Peak

The winter peak forecast is developed using the same econometric regression methodology as is used for summer peak forecasts. The winter peak model is a per customer model that contains the following explanatory variables: the square of the minimum temperature on the peak day and heating degree-hours for the day before as well as for the morning of the winter peak day. The model also includes an economic variable—Florida real personal income.

FPL forecasts continued growth of customers in its service territory. At the time that FPL filed for FPSC approval of Units 6 & 7, they were projecting an annual average increase of approximately 85,000 new customers for the next 14 years. Annualized retail customer growth was projected to be 2.1 percent for 2008 and an average of 1.7 percent for the next 12 years. In addition to significant projected customer growth, significant increases in per customer electrical load and energy were also forecast. Energy use per customer was forecast to increase 1.7 percent in 2008, with a compound annual average growth rate of 1.2 percent thereafter. Combining the growth in customers and the growth in energy use per customer yields a growth in energy sales estimated at 3.8 percent in 2008, and then an average of 2.9 percent for the next 13 years.

FPL also projected that summer peak demand would grow from approximately 21,700 MW in 2011 to approximately 30,200 MW in 2026. Similarly, the winter peak was forecast to grow from approximately 21,400 MW in 2011 to approximately 26,300 MW in 2026.

As stated in Subsection 8.1.2, in the FPSC's order approving FPL's Petition to Determine Need, it found:

> "We reviewed FPL's forecast assumptions, regression models, and the projected system peaks demands, and find that they are appropriate for use in this docket. The forecast assumptions were drawn from independent sources which we have relied upon in prior cases. The regression models used to calculate the projected peak demands conform to accepted economic and statistical practices. Finally, the projected peak demands produced by the models appear to be a reasonable extension of historical trends" (FPSC 2008b)

In the May 3, 2010 filing for the Nuclear Power Plant Cost Recovery Clause, FPL informed the FPSC of a revised in-service date for Turkey Point Units 6 & 7. The revised in-service dates of 2022 for Unit 6 and 2023 for Unit 7 were derived from sequencing the preparation and construction phase activities. In addition, although FPL's demand growth rate has slowed from the time of the need filing, FPL currently projects that it will have a need for new resources beginning in 2016 and increasing every year thereafter.

Demand Side Management

As described in FPL's Ten Year Power Plant Site Plan (FPL Apr 2010), FPL has required and implemented cost-effective DSM programs since 1978. These programs include both conservation/energy efficiency and load management programs. FPL's DSM efforts through 2009 have resulted in a cumulative summer peak reduction of approximately 4257 MW at the generator and an estimated cumulative energy saving of approximately 51,055 gigawatt hour at the generator. Accounting for reserve margin requirements, FPL's DSM efforts through 2009 have eliminated the need to construct the equivalent of approximately 13 new 400 MW generating units. FPL offers a wide variety of DSM programs and a DSM-based renewable energy option to its customers. In addition, FPL is actively engaged in DSM research and development.

DSM Programs

The DSM programs include residential and business programs. At the time FPL filed for FPSC approval of the determination of need for Turkey Point Units 6 & 7, residential DSM programs included:

- Residential Building Envelope: Offers incentives to customers to install energy efficient roof and ceiling insulation measures.
- Duct System Testing and Repair: Provides reduced cost air-conditioning duct system testing to identify leaks, and encourages the repair of those leaks by qualified contractors.
- Residential Air-Conditioning: Offers incentives to customers to purchase higher efficiency heating, ventilating, and air-conditioning equipment.
- Residential Load Management (On Call Program): Offers load control of major appliances/ household equipment to residential customers in exchange for monthly electric bill credits.
- Residential New Construction (BuildSmart): Encourages the design and construction of energy-efficient homes by offering education to contractors on energy efficiency measures, and providing construction design reviews and home inspections.
- Residential Low-Income Weatherization: Combines energy audits and incentives to encourage low-income housing administrators to retrofit homes with energy efficiency measures.
- Residential Conservation Service: Offers a walkthrough energy audit, a computer generated Class A audit, and a customer-assisted energy audit.

Business DSM programs at that time included:

- Business HVAC: Offers business customers financial incentives to upgrade to higher efficiency HVAC equipment that exceed the minimum efficiencies mandated by the DOE.

- Business Efficient Lighting: Offers business customers financial incentives to install high-efficiency lighting measures at the time of replacement.

- Business Building Envelope: Offers financial incentives to business customers to install high-efficiency building envelope measures such as roof/ceiling insulation and reflective roof coatings.

- Business Custom Incentive: Serves as a “catch-all” program for cost-effective business efficiency measures that are not included in other FPL programs.

- Business On Call: Offers load control of central air-conditioning units to both small nondemand-billed and medium demand-billed business customers in exchange for monthly electric bill credits.

- Commercial Industrial Demand Reduction: Reduces peak demand by allowing the direct control of customer loads of 200 kW or greater during periods of extreme demand or capacity shortages.

- Business Energy Evaluation: Offers free standard level energy evaluations onsite and online, as well as more detailed shared costs evaluations.

- Commercial/Industrial Load Control: Reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program was closed to new participants in 2000.)

- Business Water Heating: Encourages the installation of energy-efficient heat recovery units or heat pump water heaters.

- Business Refrigeration: Encourages the installation of controls and equipment to reduce the usage of electric strip heat for defrosting purposes.

- Cogeneration and Small Power Production: Facilitates FPL compliance with regulatory requirements concerning qualifying facilities and small power producers. One role of the program is to assist customers in the evaluation of potential cogeneration projects, including self-generation.

DSM goals were first set for FPL by an FPSC Order in 1994 (FPSC Oct 1994). The latest DSM goals were set for FPL by an FPSC Order in 2009 (FPL Apr 2010). In this latest order, the Commission established an FPL goal significantly higher (approximately 225 percent) than the amount of DSM that was projected in 2009 to meet 100 percent of FPL's remaining resource needs through 2019. The FPSC ordered FPL to have a cumulative summer MW DSM goal of 1498 by 2019. FPL expects to provide a description of its approved DSM programs in its 2011 Site Plan (FPL Apr 2010). FPL assumed a continuation of DSM signups at currently projected trends (see Table 8.2-2). In determining its future capacity, FPL forecasts that it will achieve its DSM plan through the above DSM programs.

Greater DSM would not eliminate the need for baseload power from Units 6 & 7. As stated in Subsection 8.1.2, in the FPSC's order approving FPL's Petition to Determine Need, it found:

> "…[W]e find that there are no additional cost-effective conservation measures available that might mitigate FPL's need for Turkey Point 6 and 7. FPL has identified an incremental increase of 1899 MW of DSM summer peak demand reduction by the year 2020, as well as over 280 MW of renewable energy from purchased power contracts. As previously discussed, FPL has demonstrated a reliability need in excess of these values for the years 2018 through 2020. A reduction in peak demand or an increase in renewable generation would likely result in the deferral of uncertified natural gas units. In addition, it is unrealistic to assume that FPL could achieve the amount of energy savings through DSM in ten years, that took 26 years to accomplish. As such, we find that there are no additional renewable energy sources or conservation measures which could effectively mitigate FPL's need for Turkey Point 6 and 7."

DSM Research and Development Programs

FPL's research and development programs include the Conservation Research and Development (CRD) Program and the Residential Thermostat Load Control Pilot Project. The CRD Program is an umbrella research project under which new DSM technologies are analyzed. Several FPL DSM programs have emerged from the CRD Program which has also resulted in the addition of cost-effective measures to existing programs. FPL operates the CRD Program based on DSM plan approval, or for 6 years, whichever occurs first, with a spending cap of $2,500,000 for the period.

In June 2007, FPL filed a petition with the FPSC for the Residential Thermostat Load Control Pilot Project. Under the project, FPL is proposing to evaluate whether the benefits of the existing On-Call Program can be expanded through use of a new generation of communication and control technologies that put residential customers in charge of decisions that could lower energy costs, while allowing customers to override FPL control of their heating and air-conditioning appliances. The FPSC approved FPL's request in August 2007.

Table 8.2-1
FPL History and Forecast of Energy Consumption, Capacity, and Peak Demand

Year	Energy Consumption (gigawatt-hours)									
	Residential	Commercial	Industrial	Railroads and Railways	Street and Highway Lighting	Other Public Authorities	Total Sales	Sales For Resale	Utility Use and Losses	Net Energy for Load
Historical										
2001	47,588	37,960	4,091	86	419	67	90,212	970	7,222	98,404
2002	50,865	40,029	4,057	89	420	63	95,523	1,233	7,443	104,199
2003	53,485	41,425	4,004	93	425	64	99,496	1,511	7,386	108,393
2004	52,502	42,064	3,964	93	413	58	99.095	1.531	7,467	108,093

(a) Assumes no new generation capacity additions after the following FPSC-approved projects: West County 3 (2011 in-service date), Cape Canaveral modernization (2013), and Riviera modernization (2014). These projections are consistent with information filed with the Florida Public Service Commission on April 1, 2011 in FPL's 2011 Ten-Year Site Plan, and on May 2, 2011 in FPL's 2011 NCRC filing.

(b) FPL has resource needs beginning in the Summer of 2016 and increasing every year thereafter. (FPL's resource needs are driven by its Summer reserve margin criterion of 20% which is projected to be violated years earlier than its Winter reserve margin criterion of 20% would be as shown above. Through the year 2026, FPL's projected resource need is approximately 6,900 MW driven by the Summer reserve margin criterion.

8.3 SATISFACTION OF NRC CRITERIA

The following analysis describes how the state and regional evaluations satisfy the NRC criteria for Units 6 & 7 that the evaluation of the need for power was: (1) systematic, (2) comprehensive, (3) subject to confirmation, and (4) responsive to forecasting uncertainty (NUREG-1555).

8.3.1 SYSTEMATIC

The state of Florida and the FRCC approaches to determining need for power include processes that are systematic. The state of Florida has established its processes by statute, creating the FPSC to oversee need-for-power planning by public utilities such as FPL and the Office of Public Counsel to serve as a public interest advocate before the FPSC. The need-for-power planning must be reflected in annually updated Ten Year Power Plant Site Plans and, for Units 6 & 7 specifically, is subjected to a further detailed analysis at the Petition for a Determination of Need stage before the FPSC. These processes, created through statutes and implemented by regulations, provide for a transparent, systematic means by which interested parties may participate in a legal process that assures the state of Florida adequately addresses the expected electricity demands within the state.

The FRCC process is a national one, set up by the NERC to comply with the Energy Information Administration (EIA) data-gathering requirements. The FRCC gathers the data on an annual basis, compiles it, and submits it to the NERC as a region-specific composite. The NERC submits the data to the EIA as a national composite together with region-specific information. The statutory, regulatory, and administrative requirements that make up the Florida and FRCC processes comprise methodical state and regional processes for systematically reviewing the need for power that FPL is responsible for satisfying.

8.3.2 COMPREHENSIVE

Florida imposes requirements on FPL for annual comprehensive integrated resource planning and Petition for a Determination of Need that includes:

- Demand and energy forecast for at least a 10-year period
- Supplier's or producer's program for meeting the requirements shown in its forecast in an economic and reliable manner, including demand-side and supply-side options
- Brief description and summary of cost-benefit analysis, if available, of each option that was considered, including those not selected

- Supplier's or producer's assumptions and conclusions with respect to the effect of the plan on the cost and reliability of energy services, and a description of the external environmental and economic consequences of the plan to the extent practicable

FPL follows industry practices in performing its integrated resource planning, breaking its analyses down by types of customers, identifying economic inputs to modeling, performing more detailed analyses for short-term forecasts, and accounting for supply and demand uncertainties. This is further described in Subsection 8.2.3.

FRCC regional planning includes:

- Historical and projected peak demand and energy
- Existing capacity
- Historical and projected demand and capacity
- Historical and projected capacity purchases, sales, and transfers
- Bulk electric transmission system description
- Projected changes to bulk electric transmission system

The Florida and FRCC need-for-power planning processes comprise comprehensive state and regional processes that encompass all of the components that the NRC would cover if the NRC had to perform a detailed review, covering the subject completely. These processes take into account a vast amount of data from varied sources and are subject to judicial review and challenge.

8.3.3 SUBJECT TO CONFIRMATION

FPL need-for-power planning is subject to FPSC, FOPC, and public and other stakeholder review, particularly regarding its petition for need for Units 6 & 7. These processes each result in publicly reviewable data and forecasts in the Ten Year Power Plant Site Plans and Petition for a Determination of Need. The Florida need-for-power planning processes are also confirmable by comparing FPL forecasts to FRCC composite forecasts.

The Florida and FRCC need-for-power analyses are subject to corroboration at the level of the generator or supplier (e.g., FPL) and, by way of comparison, to overall regional data.

8.3.4 RESPONSIVE TO FORECASTING UNCERTAINTY

As described previously, FPL's integrated resource planning incorporates a number of steps to select a resource plan to address forecasted capacity needs. FPL incorporates key assumptions in the reliability assessment of its system and, in developing long-term load forecasts, uses statistical modeling to quantify and qualify data inputs, such as economic projections and population trends in terms of their impact on the future demand for electricity. FPL uses econometric modeling that enables it to perform analyses of the sensitivity of results to changes in model inputs and to create high- and low-range forecasts. This econometric modeling is described in Subsection 8.2.3. Uncertainty analysis is also used in establishing planning reserve margins, themselves an acknowledgement of uncertainty.

The results of FPL's most recent planning effort are represented in FPL's Ten Year Power Plant Site Plan (FPL Apr 2010) and Need Study for Electrical Power (FPL 2007a) that have been approved by the FPSC. Importantly, the Florida Statutes require that FPL submit a Ten Year Power Plant Site Plan annually. This requires FPL to annually review its forecasted power needs and data inputs to its resource planning. Consequently, under this robust requirement, forecasting uncertainty is addressed on an annual basis by FPL, with adjustment forecasts made annually, as required, based on the most recent and up-to-date historical data.

It should be noted that despite the downturn in the economy, and negative growth in Florida's population during 2009, FPL experienced a near record Summer peak of 22,351 MW, and an all-time peak of 24,339 MW during the 2009-2010 Winter peak period. These peaks were driven by extreme weather. (FPL Apr 2010)

8.3.5 CONCLUSION

NRC guidance identified the expectation that if the states perform an evaluation of need for power and the evaluation is (1) systematic, (2) comprehensive, (3) subject to confirmation, and (4) responsive to forecasting uncertainty, no additional NRC review is needed. This chapter demonstrates that the state of Florida process meets these criteria. Therefore, no additional review by the NRC is needed.

9.0 ALTERNATIVES TO THE PROPOSED ACTION

The proposed action is for the NRC to issue a COL to authorize construction and operation of two approximately 1200 gross MWe nuclear power units to address future baseload generation needs.

Chapter 9 describes the alternatives to construction and operation of new nuclear units at the Turkey Point plant property, as well as alternative plant and transmission systems. The descriptions provide sufficient detail to assess the impacts of the alternative generation options or plant and transmission systems relative to those of the proposed action. The chapter includes four subsections:

- No-Action Alternative (Section 9.1)
- Energy Alternatives (Section 9.2)
- Site Selection Process (Section 9.3)
- Alternative Plant and Transmission Systems (Section 9.4)

The Florida Reliability Coordinating Council is a not-for-profit company incorporated in the state of Florida whose purpose is to ensure and enhance the reliability and adequacy of bulk electricity supply in Florida.

As described in Chapter 8, FPL's service territory is located within the Florida Reliability Coordinating Council region.

9.1 NO-ACTION ALTERNATIVE

The no-action alternative is the decision not to proceed with construction and operation of Units 6 & 7 due to such factors as: the denial of the necessary federal, state, regional, and/or local permits; financing; or some other factor unrelated to the need for power. Under the no-action alternative, Units 6 & 7 would not be constructed or operated at Turkey Point, the environmental impacts and benefits from construction and operation of Units 6 & 7 would not occur, and the benefits, including electricity and economic benefits, associated with construction and operation of Units 6 & 7 would be lost.

The no-action alternative also presupposes that no additional conservation measures (e.g., demand side management, renewable energies such as solar energy, etc.) would be enacted to decrease the amount of electrical capacity that would otherwise be required in the FRCC Region.

As described in Chapter 8, there is a demonstrated need for additional baseload generation capacity in the FRCC Region to meet future energy demands. As such, the Florida Public Service Commission (FPSC) granted FPL's Petition to Determine Need for Units 6 & 7 by a final order in April 2008 (FPSC Apr 2008). The FPSC considered the following factors prior to issuance of the order: (1) the need for electric system reliability and integrity; (2) the need for adequate electricity at a reasonable cost; (3) the need for fuel diversity and supply reliability; (4) whether the proposed plant is the most cost effective alternative available; and (5) whether renewable energy sources and technologies as well as conservation measures are used to the extent reasonably available.

The addition of nuclear generation capacity would address these needs and would also support national and international goals to reduce the generation of greenhouse gases as outlined in the Energy Policy Act of 2005 (Public Law 109-58) and the state of Florida’s Executive Orders regarding climate change (Executive Order Nos. 7-126, -127, and -128).

Other benefits associated with the operation of Units 6 & 7 would include the direct employment of 403 people. The creation of 403 permanent Units 6 & 7 operations jobs would inject $9,489,828 to $94,898,279 per year into the regional economy. Additionally, for every new operations job, an estimated additional 2.1696 indirect jobs would be created, which means that the 403 direct jobs would result in an additional 874 jobs in the region, for a total of 1277 new jobs.

The environmental impacts of Units 6 & 7 would not occur if the new units were not constructed and operated. However, there would be substantial financial and environmental benefits to the local community, state of Florida, and the nation from the construction and operation of Units 6 & 7. Thus, the no-action alternative is not preferable to the construction and operation of Units 6 & 7, which would provide a net output of approximately 2200 MW of baseload generation.

9.2 ENERGY ALTERNATIVES

This section provides an analysis of several energy alternatives relating to the proposed project to determine whether any of these options are competitive. A competitive alternative is defined as one that is feasible, is capable of supplying baseload power, and compares favorably with the proposed project in terms of environmental and health impacts.

Subsection 9.2.1 provides an assessment of alternatives that do not require new generation capacity. This assessment includes the economic and technical feasibility of (1) supplying electrical energy from the proposed units without constructing new generating capacity, or (2) initiating energy conservation measures that would avoid the need for the units.

Subsection 9.2.2 provides an analysis of alternative energy sources that provide new generation capacity which could reasonably be expected to meet the demand from both a load and economic standpoint for additional generating capacity determined for the proposed project. Some of the alternatives that require new generation capacity in Subsection 9.2.2 were eliminated from further consideration and discussion based on their availability in the region, overall feasibility, or ability to supply baseload power.

In Subsection 9.2.3, the alternatives that were not previously eliminated, those determined to be potentially competitive, are investigated in further detail relative to specific criteria regarding environmental and health impacts. If any alternative is deemed to be environmentally preferable to the proposed project, an economic cost comparison is provided.

9.2.1 ALTERNATIVES THAT DO NOT REQUIRE NEW GENERATION CAPACITY

In accordance with NUREG-1555, this subsection is intended to provide an assessment of the economic and technical feasibility to meet the demand for energy without constructing new generation capacity. Potential options are to:

- Purchase power from other utilities or power generators
- Reactivate or extend the service life of existing plants within the power system, or extend the capacity through power uprates or other efficiency improvements
- Implement demand side management actions (including conservation measures)
- Use an existing peaking facility to provide baseload power

Further, as presented in Chapter 8, the structure of the current generating supply system in the relevant region of the proposed project is as follows:

- The Florida Public Service Commission has the power and jurisdiction to supervise and regulate rates and services of Florida's public utilities, including establishing service territories (FS 2007a and FS 2007b).

- FPL is an investor-owned electric utility that generates, transmits, and distributes electric power. FPL is subject to Florida Public Service Commission regulation as a traditional utility (FS 2007b).

- FPL has a state-designated service territory. Customers have no choice of alternative electric service providers, and the state would have approval authority for the need for the electric power to be generated. FPL provides electric service to more than 4.5 million customer accounts in 35 of Florida's counties along the eastern seaboard and the southern and southwestern portions of Florida (FPL Apr 2010).

Florida statutes require that each electric utility in the state of Florida with a minimum existing generating capacity of 250 MW annually submit a ten-year power plant site plan to the Florida Public Service Commission (FS 2007c). Part of the development of this plan includes an integrated resource planning process to determine the need for power.

As part of FPL's efforts to meet its projected resource needs, FPL considered and documented in its 2010 Ten-Year Plan:

- Purchase of power from other utilities

- Existing resources—upgrading and possibly repowering existing units

- Demand side management programs

- New generation sources—these sources are expected to meet objectives outlined in FPL's 2010 Ten-Year Plan, that include, in part:

    — Providing a diverse fuel mix

    — Lowering greenhouse gas emissions to comply with the 2017 carbon dioxide emission targets outlined in the Governor's 2007 Executive Order 07-127

    — Increasing renewable energy contribution

9.2.1.1 Purchase Power from Other Utilities or Power Generators

In formulating plans to meet the determined capacity needs, FPL accounted for purchases from other utilities or power generators. Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities to purchase firm capacity and energy. FPL has a unit power sales contract to purchase 931 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company (Southern) through May 2010. An additional contract with Southern will result in FPL receiving 930 MW from June 2010 through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units. In addition, FPL has contracts with the Jacksonville Electric Authority for the purchase of 381 MW (summer) and 375 MW (winter) of coal-fired generation from the St. John's River Power Park. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in the first half of 2016.

FPL has other firm capacity purchase contracts with a variety of non-qualifying facility suppliers. FPL currently purchases non-firm (as available) energy from several cogeneration and small power production facilities. (FPL Apr 2010)

These capacity purchase amounts are incorporated in FPL's integrated resource planning work. While purchase power will remain a source of power for FPL, it is not adequate to provide the projected baseload capacity required to maintain its summer reserve margin criterion of 20 percent throughout the ten year period. Therefore, purchasing power from other generators is not considered a competitive option to the proposed baseload generation capacity of this project.

9.2.1.2 Reactivate or Extend Service Life of Existing Plants, or Extend the Capacity

The existing FPL generating resources consist of 88 generating units located at 16 generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, Florida. The current generating facilities consist of four nuclear units, three coal units, 14 combined cycle units, 17 fossil steam units, 48 combustion gas turbines, one simple cycle combustion turbine, and one photovoltaic facility (FPL Apr 2010).

Reactivating or extending the service life of existing plants or extending the capacity through power uprates or other efficiency improvements could theoretically reduce the need for a new nuclear power station. FPL has plans to provide power uprates at FPL's four existing nuclear units (Turkey Point Units 3 & 4 and St. Lucie Units 1 & 2). (FPL Apr 2010) The proposed capacity uprates will add approximately 450 MW of capacity to FPL's system in the 2011–2012 time frame. (FPSC May 2010) FPL has committed to extending the capacity of all four of its current nuclear units prior to the in-service dates of 2022 for Turkey Point Unit 6 and 2023 for Turkey Point Unit 7.

Thus, there exists no further opportunity for FPL to extend the capacity of its existing nuclear fleet.

Another potential strategy is repowering one or more of FPL' s existing generating plants. FPL's repowering plan consists, in part, of replacing an existing steam plant with a heat rate of approximately 10,000 Btu/kWh, with a new state-of-the-art advanced combined cycle unit that uses natural gas as the primary fuel, with a heat rate of less than 6600 Btu/kWh. FPL plans to repower two existing generating plants, Cape Canaveral and Riviera Beach, each consists of two older fossil fired steam generating units which will be converted into new highly efficient combined cycle units. The existing two-unit plant at FPL's Cape Canaveral site will be replaced by a new combined cycle unit with a projected output of approximately 1210 MW in 2013. This new unit will be called the Cape Canaveral Next Generation Clean Energy Center. The existing two-unit plant at FPL's Riviera site will also be replaced by a new combined cycle unit with a projected output of approximately 1210 MW in 2014. This new unit will be called the Riviera Beach Next Generation Clean Energy Center. These conversions were approved by the FPSC in September 2008 and were incorporated in FPL's recent integrated resource plan. (FPL Apr 2010) Any repowering of FPL's existing fossil fired generating plants would likely be fossil fueled; i.e., natural gas. As determined in Subsection 9.2.2, the environmental impact and feasibility of fossil fuel generation is not environmentally preferable to Turkey Point Units 6 & 7. In addition, additional natural gas-fired capacity will further increase FPL's dependence on natural gas. Conversely, Turkey Point Units 6 & 7 will significantly lower FPL's dependence on natural gas.

An evaluation of placing/removing existing facilities from inactive reserve was also included in FPL's 2010 Ten-Year Plan. When FPL developed its integrated resource plan as part of their 2010 Ten-Year Plan, relatively recent developments influenced FPL's resource planning efforts. One of these is the Executive Orders directive issued in 2007 calling for reduction in greenhouse gas emissions and greater contribution from renewable energy sources. The lower resource need projection allowed FPL to include in its resource plan the temporary removal of a number of its existing, older, less efficient generating units from active service starting in 2010. Inactive Reserve units continue to be maintained so that they can be returned to service as needed. The following older, less efficient units will be placed on Inactive Reserve status in 2010: Cutler Units 5 & 6, Port Everglades Units 1 & 2, Sanford Unit 3, and Turkey Point Unit 2. In 2011, Port Everglades Units 3 & 4 are also projected to be placed on Inactive Reserve. FPL's 2010 Ten-Year Plan resource planning indicates that those plants on Inactive Reserve status will begin to be returned to operation starting in 2018. While FPL's 2010 Ten-Year Plan allows for the “temporary retirement” of some of its older, less efficient generating units, these units will begin to be brought back into service in order for FPL to meet its 20 percent summer reserve margin criteria. (FPL Apr 2010) Thus, the return to active service of these existing facilities has been included in FPL's resource plan and along with other measures will still not be adequate to meet its 20 percent reserve margin criteria.

Therefore, reactivating or extending the service life of existing plants or extending the capacity is not considered a potentially competitive option to the proposed baseload non-fossil-fueled generation capacity of the proposed project.

9.2.1.3 Demand Side Management

Demand side management is the practice of reducing customers' demand for energy through programs such as energy conservation, efficiency, and load management so that the need for additional generation capacity is eliminated or reduced. Demand side management can minimize environmental effects by avoiding the construction and operation of new generating facilities.

As described in FPL's 2010 Ten-Year Plan, FPL has sought out and implemented cost-effective demand side management programs since 1978 (FPL Apr 2010). These programs include both conservation/energy-efficiency and load management.

FPL's demand side management efforts through 2009 have resulted in a cumulative summer peak reduction of approximately 4257 MW at the generator and an estimated cumulative energy saving of approximately 51,055 gigawatt hours at the generator. Accounting for reserve margin requirements, FPL's demand side management efforts through 2009 have eliminated the need to construct the approximate equivalent of 13 new 400 MW generating units (FPL Apr 2010).

Representative examples of residential demand side management programs that FPL had implemented to achieve such reductions include:

- Residential building envelope: offers incentives to residential customers to install energy efficient reflective roof and ceiling insulation measures.

- Residential air conditioning: offers incentives to customers to purchase higher efficiency heating, ventilating, and air conditioning equipment.

- Residential load management (On-Call Program): offers load control of major appliances/ household equipment to residential customers in exchange for monthly electric bill credits.

- Residential new construction (BuildSmart): encourages the design and construction of energy efficient homes by offering education to contractors.

- Residential low income weatherization: combines energy audits and incentives to encourage low income housing administrators to retrofit homes with energy efficiency measures.

- Residential conservation service: offers a walk-through energy audit, a computer generated Class A audit, and a customer-assisted energy audit.

Representative examples of business demand side management programs that FPL had implemented include:

- Business heating, ventilation, and air conditioning: offers business customers financial incentives to upgrade to higher efficiency equipment.

- Business efficient lighting: offers business customers financial incentives to install high efficiency lighting measures at the time of replacement.

- Business building envelope: offers incentives to business customers to install high efficiency building envelope measures such as roof/ceiling insulation, reflective roof coatings, and window treatments.

- Business On Call: offers load control of central air conditioning units to both small and non-demand-billed, and medium demand-billed, business customers in exchange for monthly electric bill credits.

- Business energy evaluation: offers free standard level energy evaluations on-site and on-line.

- Business water heating: provides financial incentives to encourage the installation of energy-efficient heat recovery units or heat pump water heaters. (FPL Apr 2009)

FPL has consistently been among the leading utilities nationally in demand side management achievement. For example, according to the U.S. Department of Energy's 2007 data (the last year for which the Department of Energy's data was available), FPL ranked number 1 nationally in energy efficiency demand reduction and number 2 nationally in load management demand reduction. Notwithstanding this effective program, in late 2009, the Florida Public Service Commission imposed new goals for demand side management for the period 2010 through 2019. The Florida Public Service Commission-imposed demand side management goals for FPL were significantly higher (approximately 225 percent) than the amount of demand side management that was projected in 2009. In addition, the Florida Public Service Commission ordered FPL to spend $15.5 million per year to promote demand side management-based applications of solar water heating and photovoltaics. Thus, a rigorous demand side management effort will be in place many years prior to the in-service dates of 2022 for Unit 6 and 2023 for Unit 7. It is not expected that a further increase in demand side management goals would be practicable or cost-effective. Therefore, implementing further demand side management programs is not considered a potentially competitive option to the baseload generation capacity of the proposed project.

9.2.1.4 Use an Existing Peaking Facility to Provide Baseload Power

Baseload facilities are normally used to satisfy all or part of the baseload of the system and, as a consequence, operate at full power continuously throughout the year. Peaking facilities usually

run for short periods when demand on the grid exceeds baseload generation capacity in the region. Continuously running a peaking facility to provide baseload power would not reduce the need for a new nuclear power station. Peaking facilities are small facilities, generally fueled by oil or natural gas, that quickly can be turned on and off according to swings in demand. Because they have a relatively low installed capital cost, simple cycle combustion turbines and diesel generators are the most prevalent peaking technologies. Peaking technologies are generally less fuel efficient and release more air pollutants than baseload technologies using similar fuels. Consequently, peaking technologies are more expensive to operate, and their impact on the environment per unit of generation is greater than the impact from baseload technologies using similar fuels. Therefore, using existing peaking facilities to provide baseload power is not considered a potentially competitive alternative for the proposed project.

9.2.1.5 Conclusion

Based on the analysis, there are no potentially competitive alternatives that do not require new generation. That is, in each of the above analyses, there are no alternatives or combinations of alternatives which include purchased power, the reactivation, and extended service life of plants within the regional system that have the potential to supply the required baseload capacity that are feasible, and have the potential to compare favorably with the proposed project.

9.2.2 ALTERNATIVES THAT REQUIRE NEW GENERATION CAPACITY

9.2.2.1 Introduction

In accordance with NUREG-1555, this subsection provides an analysis of alternative energy sources that could reasonably be expected to meet the demand from both a load and economic standpoint for additional generating capacity determined for the proposed nuclear project. This COL Application is premised on the construction and operation of Units 6 & 7 that would serve as large baseload generators. Therefore, as defined in NUREG-1555, any potentially competitive alternative would also need to be able to provide baseload power.

To generate a set of alternative energy sources for analysis, NUREG-1437, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, provides a starting point. The NRC analysis of alternative energy sources in NUREG-1437 includes commonly known generation technologies and various state energy plans were consulted to identify alternative generation sources typically being considered by state authorities across the country. Although NUREG-1437 is specific to license renewal, the alternatives analysis contained there can be applied to the proposed nuclear project applying for a COL to determine if an alternative technology represents a reasonable or potentially competitive alternative to the proposed project. Accordingly, the following energy sources were identified as alternatives to the proposed project:

- Wind (Subsection 9.2.2.2)

- Solar — photovoltaic cells (Subsection 9.2.2.3.1)
- Solar — solar thermal systems (Subsection 9.2.2.3.2)
- Hydroelectric power (Subsection 9.2.2.4)
- Geothermal (Subsection 9.2.2.5)
- Fuel cells (Subsection 9.2.2.6)
- Biomass (Subsection 9.2.2.7)
- Municipal solid wastes/landfill gas (Subsection 9.2.2.8)
- Coal (Subsection 9.2.2.9)
- Natural gas (Subsection 9.2.2.10)
- Petroleum (Subsection 9.2.2.11)
- Integrated gasification combined cycle (Subsection 9.2.2.12)
- Combination of alternatives (Subsection 9.2.3.3)

The alternative technologies considered in this analysis have been determined to be consistent with national policy goals for energy use, and are not prohibited by federal, state, or local regulations.

To be considered competitive, an alternative energy source must satisfy the following criteria:

- The alternative energy conversion technology is developed, proven, and available in the relevant region in the life of the proposed nuclear project.
- The alternative energy source provides baseload generating capacity equivalent to the capacity of the proposed nuclear project.
- The alternative energy source does not result in environmental or health impacts in excess of a nuclear plant.

As mentioned, this subsection identifies whether the selected alternative sources of energy could reasonably be expected to meet the demand from a load and economic standpoint in accordance with NUREG-1555. Although environmental and health impacts are assessed in Subsection 9.2.3 for those alternatives deemed potentially competitive, a brief summary of potential environmental

impacts is presented in this subsection in accordance with the data needs described in NUREG-1555. Based on the inability to meet one or more of these criteria, several of the alternative energy sources were determined to be noncompetitive and were not considered further. Alternatives that were considered to be potentially competitive are assessed in greater detail with respect to environmental and health impacts in Subsection 9.2.3.

9.2.2.2 Wind

9.2.2.2.1 Overview

The terms *wind energy* or *wind power* describe the process by which wind is used to generate mechanical power or electricity. Wind turbines convert the kinetic energy in wind into mechanical power. A generator can convert this mechanical power into electricity. Wind turbines work in the following fashion: the wind turns the blades, which spin a shaft, which connects to a generator, and makes electricity (U.S. DOE Nov 2006).

The amount of power generated by this process depends on the average wind speed and the area swept by the turbine blades. Areas are classified across the country in reference to their potential to supply wind energy. The energy potential of wind is expressed by wind generation classes that range from one (least energetic) to seven (most energetic). In a Class 1 region, at a height of 164 feet (50 meters), the average wind speed is less than 12.5 mph and offers a wind power of less than 200 watts per square meter. A Class 7 region has an average wind speed of more than 19.7 mph and offers a wind power of more than 800 watts per square meter at a height of 164 feet (AWEA 2008b).

9.2.2.2.2 Current Technology Status

Onshore wind power is a fully commercialized technology. According to the DOE, wind-powered capacity in the United States increased 46 percent in 2007, and had the fastest growing wind-power capacity in the world in 2005, 2006, and 2007. Despite this rapid growth, wind energy only makes up approximately 0.72 percent of the nation’s electricity consumption and 0.77 percent of the net electricity generation (U.S. DOE May 2008).

Wind power systems produce power intermittently because they can only be fully operational when the wind blows at sufficient velocity and duration. Although advances in technology have improved wind turbine reliability to 98 percent, modern utility-scale wind turbines typically operate 65 to 90 percent of the time and often run at less than full capacity (AWEA 2008a and NRRI Feb 2007). Therefore, the capacity factors for wind power systems generally range from 25 to 40 percent (AWEA 2008a). This low capacity factor, resulting from wind’s intermittent ability to produce electricity, prevents wind power from providing baseload power.

For wind energy to supply baseload power, wind power would need to provide continuous power. Wind power systems that combine wind turbine generation with energy storage may overcome these obstacles and provide a source of power that is functionally equivalent to a conventional baseload electric power plant. By storing the power produced from wind power systems and releasing it when the wind facilities are not generating power, energy storage in combination with the wind facilities would be able to generate electricity continuously. Energy storage technologies include batteries, flywheel storage, superconducting magnetic energy storage, compressed air, pumped hydropower, and supercapacitors. However, large-scale energy storage is either not available or not economically viable (Schainker Dec 2006).

Until recently, the offshore wind energy potential in the United States was ignored because vast onshore wind resources have the potential to fulfill the electrical energy needs for the entire country. However, development of onshore wind resources has mainly focused on remote areas of the western United States with Class 6 or greater wind regimes and on a few ridgelines in the eastern United States. The challenge of transmitting the electricity from these remote areas to large load centers may limit wind grid penetration for land-based turbines. Offshore wind turbines can generate power closer to large coastal load centers than land-based turbines. Reduced transmission constraints, steadier and more energetic winds, and European success have made offshore wind energy more attractive for the United States. However, U.S. waters are generally deeper than those on European coasts and will require new technology to use those resources (NREL Jun 2004).

Environmental conditions at sea are more severe than on land, and the sea poses saltwater corrosion concerns and additional loads from waves. In the past, turbine manufacturers have taken conventional land-based turbine designs, upgraded their electrical and corrosion-control systems to facilitate a marine service environment, and placed them on concrete bases or steel monopiles to anchor them to the seabed. This type of approach is only acceptable in water depths of 15 to 40 feet. Experience with offshore wind power development in Europe indicates that the use of conventional land-based turbine designs in a marine environment leads to reliability issues and increased maintenance costs. New turbine designs would be needed to withstand harsh offshore conditions (NREL Jun 2004).

9.2.2.2.3 Ability to Serve Regional Needs

According to the DOE, National Renewable Energy Laboratory, while there are no Class 3 or greater wind energy classes located inland in Florida, Florida has a resource wind energy potential (Class 3) along its coastline (U.S. DOE Jan 2008). Areas designated Class 3 or greater are suitable for most wind turbine applications, whereas Class 2 areas are marginal. Currently, wind regimes of Class 4 or higher are potentially economical for the advanced utility-scale wind turbine technology currently under development.

FPL's strong commitment to renewable energy includes building a new 13.8 MW capacity wind generation facility at FPL's St. Lucie nuclear power plant site on Hutchinson Island, located along Florida's coastline. Hutchinson Island's average annual wind speeds of 13.8 mph are strong enough for FPL's proposed wind farm to generate electricity (FPL Apr 2008b). Florida is not an ideal location for mass wind energy production and sites such as the St. Lucie site are limited in Florida and are not capable of producing the same baseload as the proposed project.

9.2.2.2.4 Potential Environmental Impacts

Wind energy is a renewable energy source that produces electricity without releasing air or water pollutants; however, there are some disadvantages relating to environmental impacts such as aesthetic and noise concerns, large land requirements, potential harm to birds and bats, and radar interference (AWEA 2008c).

NUREG-1437 identifies the large land requirements for wind energy as a potential environmental impact. The land use requirement for utility-scale wind plants in open and flat terrain is approximately 60 acres per MW of installed capacity. Approximately 5 percent (3 acres) of this area is occupied by turbines, access roads, and other equipment. The remaining land area can be used for compatible activities such as farming or ranching (AWEA 2008c).

Another potential environmental impact relating to wind power is its impact on birds. Wind energy production may affect birds in three ways:

- The most widely noted are fatalities resulting from collisions with rotors, towers, power lines, or with other related structures. Electrocution on power lines is also possible.
- Birds may avoid wind turbines and the habitat surrounding them.
- The direct impacts on bird habitat from the footprint of turbines, roads, power lines, and auxiliary buildings.

Measures, such as monitoring, eliminating guy wires, and minimizing lighting, can be taken to prevent/minimize avian and other wildlife impacts at each wind energy project (AWEA May 2004).

There are two potential sources of noise associated with wind plants: the turbine blades passing through the air as the hub rotates and the gearbox and generator. Standing next to the turbine, it is usually possible to hear a swishing sound as the blades rotate and the whir of the gearbox and generator may also be audible. However, as distance from the turbine increases, these effects are reduced. Well-designed wind turbines are generally quiet in operation and, compared to the noise of road traffic, trains, aircraft, and construction activities, the noise from wind turbines is very low. At 130 feet, the noise level from a wind turbine is 50 dBA to 60 dBA or about as noisy as

a conversational speech or a busy office. A wind farm at 1640 feet would have a noise level of 35 dBA to 45 dBA (the level of a quiet bedroom) (BWEA 2008).

Experience has shown that wind turbines can degrade performance of air traffic control or air defense radar. The phenomenon can include sudden or intermittent appearance of radar contacts at the location of the wind turbine caused by blade motion or rotation of the turbine to face the wind. Air traffic control radar interference is generally limited to wind turbines that are in the radar line of sight. Studies indicate that this problem may be minimal for turbines more than 5 nautical miles (5.75 miles) from the radar. In September 2006, the Department of Defense report titled *The Effect of Windmill Farms on Military Readiness* identified similar conflicts with air defense radar. According to this report, these conflicts can extend for tens of miles from the radar facility as a result of atmospheric refraction (MTC 2008a).

9.2.2.2.5 Conclusions

Based on this analysis, offshore wind technology has not matured sufficiently to support production for a baseload facility. Although land-based wind energy is developed and proven, it would only be available along Florida's coastline where siting issues exist. Additionally, the capacity factor for wind energy is inadequate to provide baseload power. Because wind power alone cannot generate baseload power, it cannot serve the purpose of the proposed project and therefore is not a potentially competitive alternative. However, land-based wind power could be included in a combination of alternatives to the proposed nuclear project. However, it is questionable how much, if any, of the capacity of wind facilities in Florida would be considered firm capacity due to the intermittent nature of wind resources in Florida. Therefore, wind facility capacity in Florida may contribute little, or not at all, to meeting FPL's reserve margin requirements. Therefore, wind technology is retained for further consideration. Combinations of alternatives, including wind, are described in Subsection 9.2.3.3.

9.2.2.3 Solar Technologies

There are two basic types of solar technologies that produce electrical power: photovoltaics and solar thermal systems, evaluated in Subsections 9.2.2.3.1 and 9.2.2.3.2, respectively.

9.2.2.3.1 Photovoltaic Cells

Overview

Photovoltaic cell technology involves converting sunlight directly into electricity. Photovoltaic cells are primarily made of the semiconductor material silicon. Light particles from the sunlight called photons penetrate the solar cell and knock electrons free from a semiconductor material, usually silicon, to create an electric current. As long as an adequate amount of light flows into the cell, electrons flow out of the cell. The cell does not consume its electrons and lose power like a

battery. Instead, it operates as a converter that turns one kind of energy (sunlight) into another (electrical current). Individual photovoltaic cells are typically combined into modules that hold approximately 40 cells, and modules are then mounted into photovoltaic arrays. A large number of arrays can be combined to create a power generation plant (U.S. DOS Apr 2005).

Current Technology Status

Electric power generation from photovoltaic cells has been commercially demonstrated. However, only sunlight of certain energies will work efficiently to create electricity, and much of it is reflected or absorbed by the material that makes up the cell. Consequently, a typical commercial solar cell has an energy conversion efficiency of 15 percent. Low efficiencies mean that larger arrays are required, resulting in higher capital costs (NREL Jul 2008b). Additional research is needed in semiconductor materials, device properties, and fabrication processes to improve the efficiency, stability, and cost of photovoltaic solar energy conversion (NREL Jul 2008a).

Because photovoltaic cells rely on a fuel source that is intermittent, capacity factors are relatively low. The average annual capacity factor for photovoltaic systems is 24 percent, much lower than the 90 percent or better for a baseload plant, such as a nuclear plant (NREL Jul 2002).

Ability to Serve Regional Needs

When sunlight passes through the earth’s atmosphere, a portion of the light is scattered or absorbed by haze, particles, or clouds (NREL Jan 2003). Sunlight can, therefore, be categorized as either direct or diffused. Photovoltaic cells can use any form of sunlight, direct or diffused, to generate power. Photovoltaic systems typically use flat-plate collectors fixed in a tilted position correlated to the latitude of the location. This allows the collector to best capture the available sunlight. The average solar radiation for a flat-plate collector in Florida ranges from 5000 watt-hour to 5500 watt-hour of solar radiation per square meter per day (EERE Feb 2008). Therefore, Florida has a good available resource throughout the state. In fact, FPL has completed construction of the nation's largest photovoltaic power generation facility in the country, the 25 MW DeSoto Next Generation Solar Energy Center. In addition a second photovoltaic power generation facility is also in operation in Brevard County. It is named the Space Coast Next Generation Solar Energy Center and has a nameplate rating of 10 MW. These two facilities are in addition to the Rothenbach Park Solar Array in Sarasota. This photovoltaic facility was commissioned in October 2007 as the first large-scale photovoltaic facility with a nameplate rating of 250 kW. (FPL Apr 2009). However, because of the intermittent nature of the solar resource, FPL currently considers photovoltaic output as non-firm capacity and energy. Therefore, photovoltaic facilities do not contribute to meeting FPL’s reserve margin as do firm capacity resources such as nuclear units, i.e., Turkey Point Units 6 & 7.

Potential Environmental Impacts

The environmental advantages of photovoltaic cells are that they have near-zero emissions and have an unlimited supply of free fuel. Water use is much less than other technologies that require cooling water and is reduced to minimal amounts used to wash dust from panel faces. Environmental disadvantages of photovoltaic cells are sizeable land use requirements, aesthetic intrusion, and potential use of hazardous materials (lead) to store energy.

The amount of land required depends on the available solar insolation and ranges from approximately 3.8 to 7.6 acres per MW for photovoltaic systems (NREL Jul 2002). Assuming an average capacity factor of 24 percent, a photovoltaic facility generating a net output equivalent to the proposed nuclear project of approximately 2200 MW is estimated to require at least 34,599 acres (approximately 54.1 square miles). Because of the relatively large land area requirements, a large photovoltaic facility would pose aesthetic concerns. In addition, retired system components (e.g., batteries) would likely require disposal as hazardous waste.

Conclusions

Based on this analysis, photovoltaic technology is developed and proven, and viable sites with adequate insolation levels are available in Florida at the start of commercial operation of the proposed nuclear project. However, as a result of its intermittent nature, the capacity factor for photovoltaic technology is inadequate to provide firm capacity. Because photovoltaics alone cannot provide firm baseload capacity, it cannot serve the purpose of the proposed project and, therefore, is not a potentially competitive alternative.

9.2.2.3.2 Solar Thermal

Overview

Solar thermal systems capture the sun's heat and transform it into electricity or steam. Solar thermal systems include lenses or mirrors that concentrate the thermal power of sunlight into a fluid system to induce motion. The fluid is then routed through a turbine to generate electricity (NREL Jul 2002). This is basically the same type of system that is used to generate electricity from combustion of coal, except the thermal energy comes from the sun instead of from coal combustion. For this reason, solar thermal systems provide easy integration into the transmission grid. Solar thermal systems can also be equipped with a thermal storage tank to store the energy in the heat transfer fluid. This allows a solar thermal plant to provide dispatchable electric power. These plants can be hybridized with fossil fuels because it is heat, not light as in photovoltaic, that powers the plant, and that heat can come from any source of power allowing these plants to operate during periods of peak demand, even when the sun is not shining (NREL Jul 2002).

Current Technology Status

There are three types of solar thermal systems: parabolic trough, dish-Stirling, and power tower. Parabolic trough systems have been deployed in major commercial installations. The other solar thermal technologies have less commercial experience, but all have seen significant pre-commercial development in the past two decades. Parabolic trough plants 30 MW to 80 MW in size are in commercial operation, with a total of 354 MW in the California Mojave Desert demonstrating reliable operation and excellent performance since 1985, which is operated and partially owned by FPL's parent company, NextEra Energy, Inc. (which previously operated as FPL Group, Inc.). Additional trough systems are under development in Arizona, Nevada, and Spain. Dish-Stirling systems are currently in an aggressive commercialization program by industry centered on a 25 kW dish system unit for modular production of over 100 MW plants. Recently, two California utilities signed power purchase agreements for dish-Stirling projects that could provide as much as 1750 MW capacity by 2014. A prototype 10 MW power tower that was successfully operated in California demonstrated efficient thermal energy storage and 24-hour-per-day electric production (WGA Jan 2006).

Generating capacity factors for solar thermal are too low to meet baseload requirements. Current solar thermal systems are as large as 200 MW, with capacity factors that range from 30 to 50 percent (NRRI Feb 2007). This range is relatively low compared to capacity factors of 90 percent or better for a baseload plant, such as a nuclear plant. Furthermore, the intermittent nature of the solar resource in Florida results in solar thermal systems, located in Florida, providing non-firm capacity and energy. Consequently, such systems contribute little, if any, to meeting FPL's reserve margin requirements.

Ability to Serve Regional Needs

Solar thermal plants can only use the direct component of the sunlight but focus the energy to achieve higher temperatures. Solar thermal technologies produce more electricity on clear, sunny days with more intense sunlight and when the sunlight is at a more direct angle (i.e., when the sun is perpendicular to the collector). To work effectively, solar thermal installations require consistent levels of sunlight (solar insolation).

The average amount of solar energy reaching the ground needs to be at least 6 kWh per square meter per day for solar thermal systems (NREL Jul 2002). Solar thermal systems use tracking, concentrating collectors so they always face the sun. For concentrating collectors, Florida could pursue some types of technologies, but large-scale thermal utility systems are not effective with this immature technology because the solar resource map for concentrating collectors shows a maximum of 4.5 kWh per square meter per day for Florida (EERE Feb 2008). Even with the immaturity of the technology, FPL has decided to pursue and has completed construction of a new solar thermal facility located at the Martin plant site. This facility is a "hybrid" energy center,

coupling solar thermal technology with an existing combined cycle generation unit and produces steam that replaces steam that would have otherwise have been produced by burning natural gas in one of the existing combined cycle units at the site, Martin Unit 8. This solar thermal facility, named the Martin Next Generation Solar Energy Center, is projected to produce up to 75 MW of steam capability, thus allowing reduced use of fossil fuels by FPL when the solar thermal facility is producing steam. (FPL Apr 2010) As previously mentioned, this solar thermal facility adds no additional firm capacity to FPL's system.

Potential Environmental Impacts

The environmental advantages of solar thermal technology are that it has near-zero emissions and it uses free fuel. Cooling water requirements for solar thermal systems that use wet cooling towers are similar to that of conventional boiler power technology. Parabolic trough plants and power towers use approximately 740 gallons of water per megawatt hour (MWh). Dish-Stirling plants are air-cooled and do not use any water for cooling. All solar thermal technologies require a minimal amount of water, approximately 37 gallons per MWh, to wash dust from mirror surfaces (NREL Apr 2006).

Environmental disadvantages of solar thermal technologies are sizeable land use requirements and the associated aesthetic intrusion. The land area required for solar thermal technologies is around four acres per megawatt for dish-stirling, 5 acres per MW for parabolic trough, and 8 acres per MW for power tower systems (NREL Jul 2002).

Conclusions

Based on this analysis, solar thermal technology is developed and proven (EERE Feb 2008). However, because of its intermittent nature, the capacity factor for solar thermal technology is inadequate to provide firm capacity. Therefore, it cannot serve the purpose of the proposed project and, therefore, is not a potentially competitive alternative.

9.2.2.4 Hydroelectric Power

9.2.2.4.1 Overview

Hydroelectric power plants (also called hydropower plants) use the kinetic energy of falling water to produce electricity. The flowing water turns a turbine that is connected to a generator. The amount of power generated by this process depends on several variables: the volume of water, the flow rate, and the distance the water is falling. Hydropower is a proven energy source that can be used to provide baseload power, but its use is limited to locations that have both a large volume of flowing water and a change in elevation.

9.2.2.4.2 Current Technology Status

Hydropower is a fully commercialized technology that has provided baseload power for more than a century. Hydropower is currently the leading renewable energy source used by electric utilities to generate electric power (EIA Jul 2008b). In 2007, hydroelectric power plants accounted for 7.8 percent of the nation's power net summer capacity and 6.0 percent of the power generated (EIA Apr 2009). However, hydropower's estimated capacity factor of 40 to 50 percent is below the nominal nuclear power facilities' capacity factors of 90 percent or better, and the National Hydropower Association forecasts a decline in large-scale hydropower use through 2020 as a result of increased environmental regulation (INL Jul 2005 and U.S. DOE Sep 2005).

There are two types of hydropower facilities: impoundment and diversion. The most common type is an impoundment facility, where river water is contained behind a dam to form a reservoir. The water can be released to meet changing demands for electricity or to maintain the reservoir level. These systems can be very efficient with as much as 90 percent of the energy being converted to electrical power (MDNR Jul 2007). In some cases, impoundment systems are used specifically to store energy. This is done at pumped storage facilities with two separate reservoirs, one positioned at a much higher elevation than the other. Water is released from the upper reservoir to flow through a turbine to produce electricity during peak demand. During off-peak periods, the water is pumped back to the upper reservoir using a different source of power. Pumped storage serves as a load management tool by lowering the amount of power that other generation units must provide during the periods of highest demand (and highest cost) for electricity (NRRI Feb 2007).

Diversion facilities use the flow of a fast-moving river, often near waterfalls, and do not require a dam. A portion of the water is diverted through a canal or set of pipes to a turbine positioned in or to the side of the river. Electricity generation, therefore, varies depending on the flow of the river. These systems cannot store power in the way a dam does and are best applied for smaller-scale local power applications or in remote locations away from main utility power grids (MDNR Jul 2007).

9.2.2.4.3 Ability to Serve Regional Needs

Though Florida is bordered on three sides by water, it is classified as a low-hydropower resource (EIA Aug 2006). A study conducted by the DOE estimates that there are 13 undeveloped potential hydropower sites in Florida. The results for individual site capacities range from 200 kW to 18 MW. The majority (69 percent) of the hydropower sites in Florida are greater than 1 MW, and less than 10 MW. The 13 identified sites are located within one major river basin (Appalachicola River Basin) and several minor river basins (U.S. DOE Dec 1998b). Thus, the available hydropower in the entire state of Florida is well below the approximate 2200 MWe net capacity of the proposed nuclear project.

9.2.2.4.4 Potential Environmental Impacts

Land use impacts for a large-scale hydropower facility using impoundments is likely to be substantial. NUREG-1437 estimates land use of 1 million acres per 1000 MWe generated by hydropower. Based on this estimate, an approximate 2200 MW hydroelectric plant would require approximately 2.2 million acres, 3459 square miles, to be flooded. Associated with this large land loss would be some erosion, sedimentation, dust, potential loss of cultural artifacts, aesthetic impacts, and equipment exhaust from land clearing and excavation. Alterations to terrestrial habitats could increase the risks to threatened and endangered species. The original land uses would be replaced by electricity generation and recreation, and perhaps, residential and business developments that take advantage of the lake environment.

Hydropower facilities can have a substantial effect on the surrounding environment's ecology. Diverting water out of the stream channel (or storing water for future electrical generation) can dry out streamside vegetation. Insufficient stream flow degrades habitat for fish and other aquatic organisms in the affected river reach below the dam. Water in the reservoir is stagnant compared to a free-flowing river, so waterborne sediments and nutrients can be trapped, resulting in the undesirable growth and spread of algae and aquatic weeds. In some cases, water spilled from high dams may become supersaturated with nitrogen gas and cause gas-bubble disease in aquatic organisms inhabiting the tailwaters below the hydropower plant (U.S. DOE Aug 2005a).

Additionally, changes in water temperature, currents, and amount of sedimentation produce a different aquatic environment above and below the dam. Alterations to aquatic habitats could change the risks to threatened and endangered species (NUREG-1437). The dam can block upstream movements of migratory fish. Downstream-moving fish may be drawn into the power plant intake flow and pass through the turbine. These fish are exposed to physical stresses (pressure changes, shear, turbulence, strike) that may cause disorientation, physiological stress, injury, or death (U.S. DOE Aug 2005a).

9.2.2.4.5 Conclusions

Based on this analysis, although hydropower is a developed and proven technology for baseload power, the potential for future hydropower development in Florida is inadequate to supply the amount of power to be provided by the proposed nuclear project. Because hydropower in Florida is not available in sufficient quantities to supply the power to be provided by the proposed project, it cannot serve the purpose of the proposed project and, therefore, is not a potentially competitive alternative.

9.2.2.5 Geothermal

9.2.2.5.1 Overview

Geothermal power plants use naturally heated fluids in underground reservoirs as an energy source for electricity production. Electricity production using geothermal energy is based on conventional steam turbine and generator equipment, in which expanding steam powers the turbine generator to produce electricity. Geothermal energy is tapped by drilling wells into the reservoirs and piping the hot water or steam into a power plant for electricity production.

9.2.2.5.2 Current Technology Status

Geothermal energy has provided commercial baseload power around the world for more than a century (MIT 2006). Geothermal plants have high availabilities and can achieve capacity factors of 97 percent (GEA 2008). The United States is the world leader in online capacity of geothermal energy and the generation of electric power from geothermal energy, with 30 percent of the world total. As of August 2008, the United States had approximately 2958 MW of geothermal generating capacity with seven states generating power from geothermal plants (GEA Aug 2008).

There are four types of geothermal resources: hydrothermal (hot water or steam at moderate depths of 330 feet to 14,800 feet), geopressured (hot water aquifers containing dissolved methane under high pressure in sedimentary formations at depths of 9800 feet to 19,700 feet), hot dry rock (abnormally hot geologic formations with little or no water), and magma (molten rock at temperatures of 1200ºF to 2370ºF) (USGS Mar 2003 and RISE 2008).

At present, only high-grade (shallow, hot, and permeable) hydrothermal reservoirs are used for the generation of electricity. However, recent research indicates that it may be feasible to extract geothermal electric power from hot dry rock systems and geopressured reservoirs using enhanced geothermal systems. Enhanced geothermal systems is a process where geothermal aquifers with low permeability can be stimulated to create a conductive fracture network where the reservoir operates similar to a conventional hydrothermal reservoir (MIT 2006). Enhanced geothermal systems are currently in the early stages of development. The DOE Geothermal Technologies Program is conducting research on enhanced geothermal systems with the goals of demonstrating the feasibility of creating enhanced geothermal system reservoirs capable of producing hot fluids at the high rates needed for commercial development by 2011 and demonstrating the economic feasibility of enhanced geothermal systems by 2018 (U.S. DOE Aug 2005b).

Another emerging technology is hydrocarbon/geothermal coproduction. There is growing interest in producing electricity from the thermal fluid that flows from oil and gas wells. Geothermal coproduction has been predicted to be capable of providing 1000 to 5000 MW to the seven states in the Texas Gulf Coast Plain alone (GEA Aug 2008).

Commercially available geothermal generating technologies include dry steam, flash steam, and binary-cycle power plants. The type of power plant depends on the temperature and pressure of the geothermal reservoir (U.S. DOE Nov 2004).

Dry steam power plants draw from underground reservoirs of steam. The steam is piped directly from wells to the power plant, where it enters a turbine. The steam turns the turbine, which turns a generator. The steam is then condensed and injected back into the reservoir via another well. The geysers in northern California, the world's largest source of geothermal power, use dry steam (U.S. DOE Nov 2004).

Flash steam power plants tap into reservoirs with temperatures of 360°F or higher. This very hot water flows up through the wells under its own pressure. As it flows to the surface, the fluid pressure decreases and some of the hot water boils or "flashes" into steam. The steam is then separated from the water and used to power a turbine generator unit. The remaining water and condensed steam are injected through a well back into the reservoir (U.S. DOE Nov 2004).

Binary-cycle power plants operate with water at lower temperatures of approximately 225°F to 360°F. These plants use heat from the geothermal water to boil a working fluid, usually an organic compound with a lower boiling point. The working fluid is vaporized in a heat exchanger and the vapor turns a turbine. The water is then injected back into the ground to be reheated. The water and the working fluid are confined in separate closed loops during the process, so there are little or no air emissions (U.S. DOE Nov 2004).

9.2.2.5.3 Ability to Serve Regional Needs

Use of geothermal resources for the generation of electricity is currently limited to shallow, high-temperature convective hydrothermal reservoirs. A lower temperature type of geothermal energy is found in parts of the eastern United States. The University of Florida Geophysical Laboratory has investigated heat flow values for the Gulf coastal plain and north-central Florida. Thermal gradients found in the majority of the wells drilled in Florida were below average to average, indicating little promise of a significant geothermal resource (OSTI Nov 1984). A heat flow map of the United States shows Florida with heat flows generally in the 25 to 39 MW-per-square-meter range with a small portion in the 40 to 44 MW-per-square-meter range and an even smaller portion located in the panhandle in the 55 to 59 MW per square meter range (MIT 2006). However, a new geothermal demonstration project is under development in Florida. The Jay Oilfield demonstration project is set to begin in 2008 and will use thermal fluids commonly coproduced from oil and gas wells. The expected capacity of the project is 200 kW but has potential for 1 MW, much less than the proposed project (GEA Aug 2008).

9.2.2.5.4 Potential Environmental Impacts

Land use impacts from geothermal power are potentially substantial. Estimates found in NUREG-1437 estimate that geothermal power generation facilities require between 1 and 8 acres per MW (U.S. DOE Nov 2004). Based on a 95-percent capacity factor, a geothermal power plant with a net output of approximately 2200 MW would require at least 2300 acres (3.64 square miles). Other major environmental concerns associated with geothermal development are the release of small quantities of carbon dioxide and hydrogen sulfide, and disposal of sludge and spent geothermal fluids. Subsidence and reservoir depletion is also a concern when withdrawal of geothermal fluids exceeds natural recharge or injection. Induced seismicity can be a concern when large amounts of geothermal fluids are injected back into the hydrothermal reservoir (U.S. DOE Nov 2004).

9.2.2.5.5 Conclusions

Based on this analysis, geothermal power using high-grade (shallow, hot, and permeable) hydrothermal reservoirs is developed and proven. However, because there are no known shallow, high-temperature hydrothermal resources in Florida, the potential for future geothermal power using currently available technology is inadequate to supply the equivalent power of the proposed nuclear facility. Therefore, geothermal power is not a potentially competitive alternative for baseload power in Florida.

9.2.2.6 Fuel Cells

9.2.2.6.1 Overview

Fuel cells are similar to common batteries. Both have a positive and a negative terminal, rely on chemical reaction, and produce electricity when the circuit is closed. In hydrogen fuel cells, hydrogen passes through an anode catalyst where it is ionized into a positively charged hydrogen ion and a negatively charged electron. The hydrogen ions then pass through a conductive medium and combine with oxygen to form water. The electrons formed by the ionization process create an electrical current (NRRI Feb 2007). Hydrogen fuel can come from a variety of hydrocarbon resources that are gasified by subjecting them to steam under pressure. Natural gas is typically used as the source of hydrogen.

9.2.2.6.2 Current Technology Status

Fuel cell power plants are in the initial stages of commercialization and are still an immature technology. Fuel cells are classified by the type of electrolyte used. There are currently five types: (1) alkaline fuel cells, (2) phosphoric acid fuel cells, (3) proton exchange membrane fuel cells, (4) molten carbonate fuel cells, and (5) solid oxide fuel cells. Electric output for proton exchange membrane fuel cells and solid oxide fuel cells range from 5 kW to 250 kW. Phosphoric acid fuel

cells are capable of producing 200 kW, and molten carbonate fuel cells can produce anywhere from 250 kW to 2 MW of power (NRRI Feb 2007).

9.2.2.6.3 Ability to Serve Regional Needs

According to the Fuel Cells 2000 Worldwide Stationary Fuel Cell Installation database, nine fuel cell power plants have been installed in Florida and one system is planned by the state of Florida for an undisclosed university (FC2000 2008). These are all stationary fuel cell installations. That is, they generally provide supplemental power and/or backup assurance for critical areas, or they may be installed as a grid-independent generator for onsite service in areas that are inaccessible by powerlines. FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of proton exchange membrane fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the proton exchange membrane technology (FPL Apr 2010). Currently, the technology is still too immature to provide baseload capacity on a utility scale.

9.2.2.6.4 Potential Environmental Impacts

Fuel cells work without combustion and, therefore, do not produce the environmental side effects associated with combustion. The only by-products of the fuel cell generation process are heat, water, and carbon dioxide (MTC 2008b). The impacts of the end-of-life phase of fuel cells are small, in part, because of the large motivation to recover precious metals components. However, one must also consider the life cycle impacts of fuel cells. A life cycle assessment which considered the manufacturing of fuel cells was conducted by EPA’s National Risk Management Research Laboratory and NASA’s Jet Propulsion Laboratory. As detailed in this report, the fabrication of fuel cells is an energy-intensive, high-temperature process and the fuel cell also uses heavy metals such as nickel, chromium, and manganese in the catalysts, electrodes, and interconnects (U.S. EPA 2009). Further, the fuel, hydrogen, in hydrogen fuel cells requires the manufacturing of hydrogen. Significant challenge must be overcome. Hydrogen production is capital intensive and developers have not established standard designs (U.S. DOE Dec 2005).

9.2.2.6.5 Conclusions

This technology has not matured sufficiently for a baseload facility on a utility scale. Therefore, fuel cell technology is not a potentially competitive alternative for the proposed project.

9.2.2.7 Biomass

9.2.2.7.1 Overview

Biopower refers to electric power generated from converted vegetation (i.e., biomass). The most common biomass resources today are waste wood and agricultural crop residues from growing such crops as corn and sugar cane. Research is underway to explore the production of switch grass and other crops for the specific purpose of biomass conversion for electricity production (NRRI Feb 2007).

Biopower generation is a two-step process. The first step is to convert biomass feedstock into biofuel. The second step is to convert biofuel into electricity via combustion. Most biopower today is produced in direct combustion gas turbines, but it can also be used in combined-cycle turbines, diesel engines, or serve as a substitute in existing coal-fired burners (NRRI Feb 2007). Power from biomass is a proven commercial electricity generation option in the United States (EERE Jun 2000).

9.2.2.7.2 Current Technology Status

Biomass-fired facilities generate electricity using commercially available equipment and well-established technology (EERE Jun 2000). Biomass is the largest source of renewable electricity generation among the non-hydropower renewable fuels (EIA Mar 2009). There are four primary classes of utility-scale biomass power systems: direct-fired, co-fired, gasification, and modular systems. A brief description of each class is provided as follows:

- Nearly all of the biomass-energy-using electricity generation facilities in the United States use direct-fired steam turbine conversion technology. This technology is relatively simple to operate and it can accept a wide variety of biomass fuels. Biomass power boilers are typically in the 20 MW to 50 MW range and the technology is inefficient (U.S. DOE Sep 2006).

- Co-firing involves substituting biomass for a portion of coal in an existing power plant furnace. It is the most economic near-term option for introducing new biomass power generation. Because much of the existing power plant equipment can be used without major modifications, co-firing is far less expensive than building a new biopower plant. Compared to the coal it replaces, biomass reduces sulfur dioxide, nitrogen oxides, and other air emissions. After tuning the boiler for peak performance, there is little or no loss in efficiency from adding biomass (U.S. DOE Sep 2006). While biomass can be successfully co-fired with coal, it is not without technical challenges. Biomass is much less dense than coal, requiring a large volume of fuel to be handled. Larger areas of biomass storage and additional handling are required to accommodate the lower-density materials. Moreover, the ash residue left from combusting biomass contains alkali and alkaline earth elements, such as sodium, potassium, and calcium. These compounds bind irreversibly with the catalysts used in selective catalytic

reduction reactors that have been installed on coal-fired generating plants. These compounds can lead to increased catalyst plugging and cause deactivation of selective catalytic reduction catalysts, thus reducing or eliminating the ability of this technology to reduce nitrogen oxide emissions (Bowers Mar 2005).

- Biomass can be used in integrated gasification combined-cycle (IGCC) systems in which gasifiers heat the biomass in an environment where the solid biomass breaks down to form a flammable gas. The biogas is then cleaned and filtered to remove problem chemical compounds before being burned in a combined-cycle unit (U.S. DOE Sep 2006). IGCC systems are described in Subsection 9.2.2.12.

- Modular systems employ some of the same technologies mentioned above, but on a smaller scale that is more applicable to villages, farms, and small industries (U.S. DOE Sep 2006).

9.2.2.7.3 Ability to Serve Regional Needs

Florida ranks 16th in the nation in agriculture. According to the U.S. Department of Agriculture 2002 Census, there are 10.41 million acres of farmland equaling 30.2 percent of the state's total land area (USDA Jul 2008). The Department of Agriculture and Consumer Services believes that Florida can be a leader in the effort of producing energy from crops and timber because of the vast amount of farm acreage in the state and its mild climate, which permits crops to be grown virtually year round (FDACS 2008).

In 2006, the Farm-to-Fuel Initiative was statutorily created to enhance the market for and promote the production and distribution of renewable energy from Florida-grown crops, agricultural waste and residues, and other biomass (FDACS 2008). In 2006, wood/wood waste and other biomass accounted for 1.1 percent of Florida's 2 percent total renewable net generation or 202 MW of summer electricity capacity (EIA May 2008).

A study on biomass feedstock availability (Walsh et al. 2000) reports that there are 9,757,000 tons of forest residues available annually in Florida. Because mill residues are clean, concentrated at one source, and relatively homogeneous, nearly 98 percent of all residues generated in the United States are currently used as fuel or to produce other fiber products. There are 2,678,000 tons of mill residues available annually in the state (Walsh et al. Jan 2000).

9.2.2.7.4 Potential Environmental Impacts

As addressed in NUREG-1437, the overall level of construction of a biomass-fired power facility would be approximately the same as that for a similar sized coal-fired plant. Like coal-fired facilities, biomass plants require large areas for fuel storage and processing and involve the same type of combustion equipment. Fuel processing, in most cases involving some type of grinding operation, produces emissions of dust and particulates (NREL Nov 1999).

Conversion of large tracts of land for production of energy crops would pose potentially adverse environmental impacts on wildlife habitat and biodiversity, reduce soil fertility, increase erosion, and reduce water quality. The net environmental impacts would depend on previous land use, the particular energy crop, and how the crop is managed. If the land has not previously been developed for farming or other purposes, displacement of natural land cover such as forests and wetlands with energy crops would likely have negative environmental impacts. In addition, conversion of food crops into energy crops results in a reduction in food production that may need to be replaced elsewhere.

Air emissions and water consumption are usually the principal sources of environmental concern related to biomass facilities. Combustion of biomass fuels in modern power plants leads to many of the same kinds of emissions as the combustion of fossil fuels, including criteria air pollutants, greenhouse gases, and production of ash. While the air emissions would likely be less than a coal-fired facility, they would be substantially greater than the proposed nuclear project. The controls for limiting these emissions are similar to those used in coal-fired plants (NREL Nov 1999). Water consumption impacts would be similar to other boiler power technology.

9.2.2.7.5 Conclusions

Based on this analysis, biomass-fired technology is developed, proven, and available in Florida at the start of commercial operation of the proposed nuclear project. However, as a result of adverse environmental impacts, the small scale of existing plants, and the large amount of fuel preparation, burning biomass to generate electricity is not considered to be a potentially competitive alternative.

9.2.2.8 Municipal Solid Waste/Landfill Gas

9.2.2.8.1 Overview

Municipal solid waste refers to the stream of garbage collected through community sanitation services. Municipal solid waste includes everyday items such as grass clippings, household garbage, newspapers, food scraps, clothing, bottles, paint, batteries, etc. Municipal solid waste can be directly combusted in waste-to-energy facilities to generate electricity (U.S. EPA Dec 2007c).

Landfill gas is created when organic waste in a landfill naturally decomposes. This gas consists of approximately 50 percent methane, approximately 50 percent carbon dioxide, and a small amount of non-methane organic compounds. Instead of allowing landfill gas to escape into the air, it can be captured, converted, and used as an energy source (U.S. EPA Jun 2008).

9.2.2.8.2 Current Technology Status

Municipal solid waste-fired and landfill gas facilities generate electricity using commercially available equipment and well-established technology. Conventional direct combustion is presently the most common technology used in the United States for municipal solid waste-to-energy power generation. At the power plant, municipal solid waste is unloaded from collection trucks and shredded or processed to ease handling. Very large items such as refrigerators or stoves, recyclable materials, and hazardous waste materials such as batteries are removed before combustion. Noncombustible materials such as metals can be removed before or after combustion, but are usually separated from the ash with magnetic separators. After separation, the remaining waste is fed into a combustion chamber to be burned. The heat released from burning the municipal solid waste is used to produce steam, which turns a steam turbine to generate electricity (U.S. EPA Dec 2007c).

At the end of 2007, the DOE reported 107 municipal solid waste generation facilities in operation in the United States. Nameplate capacities of these plants range from 0.1 MW to 90 MW, and more than half are less than 20 MW. The combined power capacity of the nation's municipal solid waste facilities is approximately 2829 MW (EIA 2007). These power facilities are much smaller than the proposed nuclear project.

Another option of converting landfill waste into electricity is using landfill gas in internal-combustion turbines that are connected to generators. The amount of gas that a particular landfill will produce depends on its age and size. Although gas is produced as soon as anaerobic conditions are established in the landfill, it may be several years before there is enough gas to fuel an electric generator. Later, as the site ages, gas production (as well as the quality of the gas) declines to the point at which power generation is no longer economical. In the case of a typical well-engineered and well-operated landfill, gas may be produced for as long as 50 to 100 years, but using this to fuel generators may be economically feasible for only 10 to 15 years (Santee Cooper 2008).

The EPA reports that the United States has at least 450 operational projects in 43 states supplying 11 billion kilowatt hours of electricity and 77 billion cubic feet of landfill gas to direct-use applications annually. The power capacity of these power plants ranges between 30 kW and 10.5 MW. There are an additional 540 candidate landfills with a total gas generation potential of 240 billion cubic feet per year or electric potential of 1280 MW—much less than the proposed project (U.S. EPA Jun 2008).

9.2.2.8.3 Ability to Serve Regional Needs

In Florida, there are 12 municipal solid waste-to-energy facilities (FLDEP 2007). Currently, there are 82 landfills in Florida, and the EPA regards only 21 of them as candidates for landfill gas-to-

energy development and an additional 30 others as potential candidate sites (U.S. EPA Aug 2008). Assuming the landfills identified by the EPA as candidates or potential candidates produce enough gas to generate 20 MW each annually, the energy production is still less than half of the proposed nuclear project's power capacity. In 2006, municipal solid waste-landfill gas accounted for 0.8 percent of Florida's 2 percent total renewable net generation or 447 MW of summer electricity capacity (EIA May 2008). Additionally, as landfill gas generators can only be economically used for 10 to 15 years, even if future landfills are constructed that provide additional candidate sites, the fuel source will likely be depleted before the end of the proposed nuclear project's operating life.

9.2.2.8.4 Environmental Impacts

The decision to burn municipal solid waste to generate energy is usually driven by the need for an alternative to landfills rather than by energy considerations (NUREG-1437). Combusting waste usually reduces its volume by approximately 90 percent and the remaining ash is buried in landfills (FPSC & FDEP Jan 2003). However, it is unlikely that many landfills will begin converting waste to energy due to the factors that may limit the growth in municipal solid waste power generation. Chief among these reasons are environmental regulations and public opposition to siting municipal solid waste facilities near feedstock supplies.

The overall level of land use impacts from construction of a municipal solid waste-fired plant would be approximately the same as that for a conventional coal-fired plant (NUREG-1437). The air emission profile and other operational impacts (including impacts on the aquatic environment, air, and waste disposal) for a municipal solid waste plant would also be similar to a conventional fossil fuel unit.

Burning landfill gas is beneficial to the environment by preventing methane, a greenhouse gas, from entering the atmosphere directly (Santee Cooper 2008). The air emission profile and other operational impacts (including impacts on the aquatic environment, air, and waste disposal) for a landfill gas plant would also be similar to a conventional fossil fuel unit. The overall level of land use impacts from construction of a landfill gas-fired plant should be approximately the same as for similar sized conventional gas-fired plant.

9.2.2.8.5 Conclusions

Based on this analysis, municipal solid waste- and landfill gas-fired technology is developed, proven, and would be available in Florida at the start of commercial operation of the proposed nuclear project. However, the small scale of existing plants, the large amount of fuel preparation required in the case of municipal solid waste-fired plants, the relatively short operating life in the case of landfill gas-fired plants, and because the full potential of municipal solid waste and landfill

gas in Florida is less than the proposed project, burning municipal solid waste and landfill gas to generate electricity is not a potentially competitive alternative.

9.2.2.9 Coal

9.2.2.9.1 Overview

Coal-fired electric plants provide the greatest percentage of the electricity generated in the United States, accounting for approximately 48.5 percent of the electricity generated and approximately 31.4 percent of the available net summer electric power capacity in 2007 (EIA Apr 2009). To generate electricity from coal, coal is initially extracted from surface or underground mines. The coal is often cleaned or washed at the coal mine to remove impurities before it is transported to the power plant—usually by train, barge, or truck. At the power plant, coal is burned in a boiler to produce steam. The steam is run through a turbine to generate electricity (U.S. EPA Dec 2007).

The United States has abundant coal reserves, and the price of coal per million Btu is projected to be roughly the same price in 2030 as in 2007 (EIA Mar 2009). Coal-fired plants are likely to continue to be a reliable energy source well into the future, assuming environmental constraints do not cause the gradual substitution of other fuels.

9.2.2.9.2 Current Technology Status

There are two primary technologies identified for generating electrical energy from coal: pulverized coal boiler and circulating fluidized bed boiler.

9.2.2.9.3 Pulverized Coal Boiler

In pulverized coal boilers, coal is ground up finely and blown into the combustion chamber of a boiler where it is combusted. The hot gases and heat energy from the incineration process convert water into high-pressure steam. The steam is then passed through a turbine to produce electricity. Flue gases are usually routed through a selective catalytic reduction scrubber for nitrogen oxide reduction, and into a heat exchanger to salvage any residual heat. After this, the flue gas flows to a particulate removal system and a sulfur dioxide scrubber system.

The steam systems used in the current generation of pulverized coal boilers are generally designated as subcritical (or conventional), supercritical, or ultra-supercritical. This designation is based on the pressure and temperature of the steam. Subcritical units operate at a nominal pressure of 2400 psi and a peak temperature of 1050°F. Supercritical units would operate at a similar peak temperature but at a nominal pressure of 3500 psi. Ultra-supercritical units operate at a nominal pressure of 4500 psi and a minimum temperature of 1100°F. As the temperature and pressure of the steam at the turbine inlet increases, so does the efficiency of the power steam cycle. As the efficiency of the steam cycle is increased, the amount of fuel necessary to produce

the same amount of energy is reduced, in turn reducing plant emissions (NRRI Feb 2007). Therefore, ultra-supercritical units are the most effective steam systems available and have efficiencies as high as 46 to 48 percent. This is compared to subcritical and supercritical net efficiencies of 36 to 37.5 percent and 40 to 42 percent, respectively (EPRI May 2007).

The subcritical pulverized coal technologies are commercially mature and widely used throughout the world. In 2005, 346 of the operating coal plants in the United States had been in operation for more than 50 years. Supercritical pulverized coal plants are a highly proven and reliable technology with installations dating back to 1957. Ultra-supercritical units are still undergoing development in the United States (NRRI Feb 2007).

9.2.2.9.4 Fluidized Bed Boiler Technologies

The fluidized bed boiler is an advanced electric power generation process that minimizes the formation of gaseous pollutants by controlling coal combustion parameters and by injecting a sorbent (such as crushed limestone) into the combustion chamber along with the fuel. Crushed fuel mixed with the sorbent is fluidized on jets of air in the combustion chamber to enhance combustion and heat transfer. Sulfur released from the fuel as sulfur dioxides is captured by the sorbent in the bed to form a solid compound that is removed with the ash. The resultant by-product is a dry, benign solid that is potentially a marketable by-product for agricultural and construction applications. More than 90 percent of the sulfur in the fuel is captured in this process. Nitrogen oxide formation in fluidized bed power plants is approximately 70 to 80 percent lower than that for conventional pulverized coal boilers because the operating temperature range of 1500ºF to 1700ºF is below the temperature at which thermal nitrogen oxide is formed. However, due to this lower operating temperature, fluidized bed systems do not achieve the higher efficiency levels achieved by conventional pulverized coal boilers (U.S. DOE Mar 2003).

Circulating fluidized bed combustion boilers use a relatively high fluidization velocity that entrains the bed material, in conjunction with hot cyclones, to separate and recirculate the bed material from the flue gas before it passes to a heat exchanger (U.S. DOE Mar 2003). This improves operating characteristics and performance and simplifies design, making it easier to scale up (Ghosh Sep 2005). In terms of environmental performance, circulating beds have better sulfur capture, carbon burnout, and nitrogen oxide control characteristics than noncirculating beds (Ghosh Sep 2005).

To improve the thermal efficiency of the fluidized bed technology, a new type of fluidized bed boiler has been proposed that encases the entire boiler inside a large pressure vessel pressurized 6 to 16 times greater than atmospheric pressure. Combustion of coal in a pressurized fluidized bed boiler results in a high-pressure stream of combustion gases that can spin a gas turbine to make electricity and boil water for a steam turbine. It is estimated that pressurized fluidized bed plants could generate 50 percent more electricity from coal than a

regular power plant from the same amount of coal. The pressurized fluidized bed technology is currently in the demonstration phase and is not a feasible alternative for the proposed nuclear project (U.S. DOE Mar 2003).

The atmospheric fluidized bed combustion technology is a commercially mature technology that has been used for more than 50 years and has more than 600 units operating worldwide in the size range of 20 MW to 300 MW (Ghosh Sep 2005). Designs are being developed for units as large as 600 MW. The technology's total capacity represents approximately 2 percent of the overall coal-fired generation capacity in the world. In the United States, there are 185 atmospheric fluidized bed combustion boilers with a total capacity of 6000 MW (Ghosh Sep 2005).

9.2.2.9.5 Ability to Serve Regional Needs

The United States has abundant low-cost coal reserves, and the price of coal for electric generation is projected to remain steady for the next 20 years (EIA Mar 2009). Coal is one of the leading fuels for electricity production in Florida, accounting for over one-third of the net generation. There are no coal mines in Florida and coal-fired plants rely on supplies delivered by railroad and barge, mainly from Kentucky, Illinois, and West Virginia (EIA Aug 2008). However, Executive Orders issued by Florida's Governor in July 2007 requiring a significant reduction in greenhouse gas emissions in Florida, may hinder the approval to build a new advanced coal technology plant in Florida (FPL Apr 2010).

9.2.2.9.6 Potential Environmental Impacts

The environmental impacts of construction of a typical pulverized coal-fired steam plant are well known because coal-fired steam plants represent approximately half of the electrical generation in the United States (EIA Apr 2009). The combustion of coal creates several by-products that are damaging to the air quality of the environment, including sulfur dioxides, nitrogen oxides, carbon dioxide, mercury and other trace metals, ash, and volatile organic compounds (NRRI Feb 2007).

Coal-fired power plants use large quantities of water for producing steam and for cooling (U.S. EPA Dec 2007). A coal-fired plant uses approximately 600 gallons of water per megawatt-hour of generation (EPRI Mar 2002). When the water used in the power plant is discharged to a lake or river, the pollutants in the water can harm fish and plants (U.S. EPA Dec 2007). This water may contain trace levels of metals or chemicals and may be at a higher temperature than the source water into which it is discharged (NRRI Feb 2007). Life cycle impacts are also associated with the mining and transportation of coal. Coal mining impacts include air quality impacts from fugitive dust, water quality impacts from acidic runoff, and aesthetic and cultural resource impacts (NUREG-1437). While impacts from the transportation of coal include air quality impacts from the

emissions produced during transport, environmental impacts from the transportation of coal by barge would also include aquatic ecology and water impacts.

9.2.2.9.7 Conclusions

Based on the analysis, pulverized coal boiler technology is a potentially competitive alternative to the proposed nuclear project. Based on ample fuel availability, generally understood environmental impacts associated with constructing and operating a coal-fired power generation plant, and good plant efficiencies, a pulverized coal-fired power plant is considered a potentially competitive alternative and is, therefore, examined further in Subsection 9.2.3.

However, because of the lower operating temperature of the fluidized bed system—thus its lower efficiency levels in relation to the conventional pulverized coal boilers—and the limited size of available units, fluidized bed is not a potentially competitive alternative for the proposed nuclear project.

9.2.2.10 Natural Gas

9.2.2.10.1 Overview

There are several commercially mature generation technologies that use natural gas as fuel, as described below:

- Gas-fired steam generator technology uses combustion to heat water to produce pressurized steam, which rotates a generator to produce electricity. Because of the much lower energy efficiencies of steam gas facilities, this technology is being replaced, in particular with combined cycle technology.

- In simple-cycle combustion turbine technology, fuel is burned in a combustion turbine and the resulting hot gases rotate the turbine to generate electricity before being emitted to the air. Simple combustion gas turbine systems are not efficient enough to be economically viable for baseload applications.

- Combined-cycle technology uses a combination of combustion turbine technology and steam generator technology. In the combined-cycle unit, hot combustion gases in the turbine rotate the turbine to generate electricity, and waste combustion heat from the turbine is routed through a heat recovery steam generator. There, water is turned to steam that rotates a steam turbine to generate additional electricity. Combining two cycles in the generation of electricity improves the overall thermal efficiency by as much as 50 percent over simpler, straight combustion gas turbines (NRRI Feb 2007).

9.2.2.10.2 Current Technology Status

Since the early 1990s, gas-fired power plants have comprised more than 90 percent of new generation capacity in the United States (NRRI Feb 2007). Natural gas-fired electric plants now account for the largest percentage of the U.S. electric power net summer capacity at 39.5 percent, but generated only 21.6 percent of the nation's electricity in 2006 (EIA Apr 2009). This low use is caused by the high prices for natural gas in recent years, making it more economical to produce electricity using other fuels and using gas-fired plants during periods of high demand. Recent studies indicate that when natural gas prices exceed $6 per thousand cubic feet, gas-fired combined cycle units lose their competitiveness with other technologies, particularly pulverized coal units (NRRI Feb 2007). In 2007, the average annual price of natural gas used for electric power generation was $7.30 per thousand cubic feet (EIA Jul 2008a).

9.2.2.10.3 Ability to Serve Regional Needs

Natural gas accounts for approximately 27 percent of Florida's net power generation (EIA Aug 2008). Florida receives most of its natural gas supply from other Gulf Coast States via two major interstate pipelines: the Florida Gas Transmission line, which runs from Texas through the Florida panhandle to Miami, and the Gulfstream pipeline, an underwater link from Mississippi and Alabama to central Florida. With the completion of the Cypress pipeline in May 2007, the Jacksonville area has also begun receiving supplies from the liquefied natural gas import terminal at Elba Island, Georgia. Because Florida's natural gas supply is vulnerable to disruption from hurricanes and tropical storms, to safeguard against these threats and meet energy demand, FPL is considering the option of constructing a third natural gas pipeline along the eastern portion of the state.

Florida's natural gas consumption is high and has grown rapidly in recent years, due primarily to increasing demand from the electric power sector. To help meet Florida's growing demand for natural gas, companies have proposed building new liquefied natural gas import terminals in the federal waters off of Florida's Atlantic and Gulf Coasts, and on the nearby islands of the Bahamas (EIA Aug 2008). There is an extensive infrastructure for distribution and abundant resources available for a large baseload combined cycle gas-fired power plant. However, Executive Orders issued by Florida's Governor in July 2007 requiring a significant reduction in greenhouse gas emissions in Florida, may hinder the approval to build a gas-fired power plant in Florida (FPL Apr 2010).

9.2.2.10.4 Potential Environmental Impacts

Combustion of natural gas produces nitrogen oxides and carbon dioxide, but in lower quantities than burning coal or oil (U.S. EPA Dec 2007b). The burning of natural gas in combustion turbines requires very little water and does not produce any water discharges. However, pollutants and

heat build up in natural gas boilers and combined cycle systems. When these pollutants and heat reach certain levels, the water is often discharged into lakes or rivers (U.S. EPA Dec 2007b).

Gas-fired plants occupy approximately one-tenth the space of nuclear and pulverized coal plants. This partially explains the relatively low level of public opposition to combined cycle gas turbine plants relative to other baseload technologies (NRRI Feb 2007).

9.2.2.10.5 Conclusions

Because gas-fired generation, using combined-cycle turbines, is based on the use of well-known technology and generally has well-understood environmental impacts associated with construction and operation, it is a potentially competitive alternative to the proposed nuclear project. Gas-fired generation is examined further in Subsection 9.2.3.

9.2.2.11 Petroleum

9.2.2.11.1 Overview

Petroleum (oil) consumption in the electric power sector uses three main types of oil derivatives: distillate fuel oil, residual fuel oil, and petroleum coke. To produce electricity from oil, crude oil is initially removed from the ground by drilling deep wells and pumping it to the surface. The crude oil is then transported to a refinery where it is refined into a number of fuel products and where a number of the impurities such as sulfur, nitrogen, and metals are removed. From the refinery, oil is transported to power plants by barge, pipelines, trucks, or trains. At the power plants, several methods can be used to generate electricity from oil. One method is to burn the oil in boilers to produce steam that is used by a steam turbine to generate electricity. Alternatively, a more common method is to burn the petroleum in combustion turbines, similar to simple combustion gas turbine systems. Another technology is to burn the oil in a combustion turbine and use the hot exhaust to make steam to drive a steam turbine—called combined-cycle technology (U.S. EPA Sep 2008).

9.2.2.11.2 Current Technology Status

Petroleum-fired power plants are a commercially mature generation technology. Petroleum-fired power plants provided 1.6 percent of electricity generated in the United States in 2006 and accounted for approximately 5.6 percent of the electric power capacity (EIA Apr 2009). The high cost of petroleum has prompted a steady decline in its use for electricity generation in recent decades. Reliance on foreign sources of petroleum, future increases in petroleum prices, and competition for petroleum resources by the transportation and petrochemical industry are expected to make petroleum-fired generation less attractive than other power alternatives.

9.2.2.11.3 Ability to Serve Regional Needs

Most of Florida's crude oil production comes from fields in the northwestern panhandle, but the state also produces some crude oil from smaller fields in the south. Although companies have explored for oil and gas in the federal outer continental shelf south of Panama City, exploration activity has been dormant since 1995, when a litigation settlement returned 73 oil and gas leases in this area to the federal government. Florida has no oil refineries and relies on petroleum products delivered by tanker and barge to marine terminals near the state's major coastal cities. Due in part to Florida's tourist industry, demand for petroleum-based transportation fuels (i.e., motor gasoline and jet fuel) is among the highest in the United States (EIA Aug 2008). Though Florida petroleum reserves are approximately 0.3 percent of U.S. reserves, Florida ranks third among states in petroleum use, and approximately 73 percent of Florida petroleum consumption is for transportation. Florida production of electrical power from oil fluctuates between 12 and 17 percent (Mulkey Sep 2007).

9.2.2.11.4 Environmental Impacts

Construction and operation of a petroleum-fired plant would have environmental impacts. For example, NUREG-1437 estimates that construction of a 1000 MWe petroleum-fired plant would require approximately 120 acres. Construction and operation of a petroleum-fired plant would have comparable impacts on regional air quality and the aquatic environment as would a similar sized coal-fired plant.

9.2.2.11.5 Conclusions

Based on this analysis, petroleum energy technology is developed, proven, and would be available in Florida at the start of commercial operation of the proposed nuclear project. Although the land use requirements are relatively small, concerns related to fuel availability, along with the national policy to reduce foreign oil dependence, and the adverse environmental impacts to air and water quality led to the conclusion that petroleum energy technology is not a potentially competitive alternative.

9.2.2.12 Integrated Gasification Combined Cycle

9.2.2.12.1 Overview

Integrated Gasification Combined Cycle (IGCC) is an electric power generation process that combines modern gasification technology with both gas turbine and steam turbine power generation (combined-cycle). IGCC plants can be powered by many carbon-based fuels such as coal, petroleum coke, and biomass. Gasification uses steam and oxygen to convert the fuel into synthesis gas (syngas) in a high-temperature, high-pressure chamber. Syngas is a mixture of carbon dioxide, carbon monoxide, and hydrogen, of which the last two are the primary

combustible components. The syngas is burned in a combustion turbine and the hot exhaust gas from the turbine is routed to a heat recovery steam generator, where it produces steam to power a steam turbine. Electricity is produced in both cycles via generators, powered by the gas turbine and the steam turbine, thus the term combined cycle. IGCC plants are suitable for baseload operation because they combine low cost fuels and high output (NRRI Feb 2007).

9.2.2.12.2 Current Technology Status

IGCC power plants are in the early stages of commercialization. There are currently two commercial-size, coal-based IGCC plants in the United States. Both were supported initially under the DOE Clean Coal Technology demonstration program, but now operate commercially without DOE support (CEUS Jul 2006). The nameplate capacity of existing and planned units typically ranges from 250 MW to 630 MW (NRRI Feb 2007).

Experience has been gained with the chemical processes of gasification, fuel properties, and their impact on the IGCC design, efficiency, and economics. However, system reliability is still relatively lower than conventional coal-fired power plants, and the major reliability problem is related to the gasification section. There are also problems with the combination of gasification and power production systems. For example, if the gases are not adequately cleaned, they can cause damage to the gas turbine (PERMG Jun 2005).

9.2.2.12.3 Ability to Serve Regional Needs

As mentioned in Subsection 9.2.2.9, the United States has abundant low-cost coal reserves, and the price of coal for electric generation is projected to remain steady for the next 20 years (EIA Mar 2009). As described in Subsection 9.2.2.7, there is insufficient biomass feedstock available in the Florida to power a large baseload facility. Subsection 9.2.2.11 describes that petroleum coke sources are likely to be available economically in Florida. Further, IGCC technology has the ability to economically capture the sulfur in the carbon-based fuels; therefore, the process can be used to burn cheaper high-sulfur coal and petroleum-coke with less environmental impacts.

9.2.2.12.4 Environmental Impacts

IGCC technology is cleaner than any other coal-based fuel combustion technology because major pollutants can be removed from the gas stream before combustion (NRRI Feb 2007 and Ghosh Sep 2005). For example, the sulfur in the fuel is captured and removed as hydrogen sulfide in the gasifier via a conventional acid-gas removal system. The concentrated hydrogen sulfide can be recovered as elemental sulfur or sulfuric acid and sold as commercial by-product. The largest solid waste stream produced by IGCC installations is slag, a black, glassy, sand-like material that is potentially a marketable byproduct. Slag production is a function of the fuel's ash content. In this way, IGCC units do not produce ash or scrubber wastes. As much as 50 percent of the mercury in a feedstock is removed in IGCC systems, much of it bound in the slag and

sulfur byproducts (NCC May 2001 and Ghosh Sep 2005). Land use concerns would be similar to conventional pulverized coal-fired power plants of the same capacity.

9.2.2.12.5 Conclusions

Based upon the analysis, IGCC technology has not matured sufficiently to support production for a large baseload facility. Both of the IGCC facilities that presently operate in the United States were supported with federal funds that would be unavailable for this IGCC alternative. Additionally, the system reliability associated with IGCC technology is considerably less than other carbon-based fuel-fired technologies. Thus, IGCC is not considered to be a potentially competitive alternative.

9.2.2.13 Conclusion

Based on the analysis of alternatives that require new generation, there are two potentially competitive alternatives identified—the pulverized coal-fired alternative and the combined cycle natural gas fired alternative—each is, therefore, retained for further analysis in Subsection 9.2.3. The remaining alternatives were eliminated either because they could not reasonably meet the demand as a baseload source, the technology was immature, or the technology was not viable in the region of interest.

9.2.3 ASSESSMENT OF COMPETITIVE ALTERNATIVE ENERGY SOURCES AND SYSTEMS

This subsection provides an analysis of the potentially competitive alternatives identified in Subsections 9.2.1 and 9.2.2 for comparison with the associated proposed nuclear project. The analysis of the potentially competitive alternatives is a two-step process:

1. The first step provides a comparison of the environmental and health impacts of the potentially competitive alternatives to the proposed action to determine if one or more of the identified potentially competitive alternatives can be expected to provide an appreciable reduction in overall environmental and health impacts, and/or offer solutions to potential adverse impacts predicted for the proposed project for which no mitigation procedure could be identified.

2. The second step includes a comparison of the economic costs of any potentially competitive alternatives found to be environmentally preferable to the proposed action to determine if an alternative is preferred/superior to the proposed project.

The alternatives assessed in Subsections 9.2.1 and 9.2.2 that were considered to be competitive and were identified for further analysis are: (1) pulverized coal-fired generation, (2) combined cycle gas-fired generation, and (3) a combination of alternatives. Completion of the first step of

the analysis involves a determining or categorizing the environmental impacts associated with the potentially competitive alternative. This categorization of the environmental impacts associated with the identified alternatives and the proposed action was completed in accordance with the NRC established regulations for quantifying environmental impacts based on the Council on Environmental Quality Guidance, 40 CFR 1508.27, and those identified in 10 CFR Part 51, and in NUREG-1555. These regulations and guidance establish three significance levels for characterizing environmental impacts: SMALL, MODERATE, or LARGE. The definitions of the significance levels are as follows:

- SMALL — Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

- MODERATE — Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

- LARGE — Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

Consideration is given to ongoing and potential additional mitigation in proportion to the significance of the impact to be addressed (i.e., impacts that are SMALL receive less mitigative consideration than impacts that are LARGE).

9.2.3.1 Pulverized Coal-Fired Generation

Subsection 9.2.2.9 identified pulverized coal boiler technology as a potentially competitive alternative to the proposed nuclear project. The comparative pulverized coal-fired alternative consists of three boiler units, each with a net capacity of 728.4 MW. This configuration was chosen to equate to the proposed nuclear project net capacity and the natural gas-fired alternative described in Subsection 9.2.3.2, allowing for a valid comparison amongst the alternatives chosen and the proposed project. Table 9.2-1 details basic attributes chosen to complete a reasonable analysis of the pulverized coal-fired units. The boiler and emission control technology were chosen to yield the lowest emission factor for the pollutants of concern provided by the EPA AP-42 document, yielding a more favorable comparison for the alternative (U.S. EPA Jan 1995). For the purposes of this analysis, coal and limestone were assumed to be delivered by barge to the Turkey Point plant property.

9.2.3.1.1 Environmental Impacts

In accordance with NUREG-1555, the first step in the analysis is to make a determination as to whether the potentially competitive alternative is environmentally preferable. The results of this analysis are presented in this subsection. In conformance with NUREG-1555, an analysis of the following environmental impact categories is included for comparison with the proposed project:

air quality, waste management, land use, ecology, water use and quality, aesthetics, socioeconomics, historic and cultural resources, and environmental justice.

The NRC provides an overview of these environmental impact categories associated with the construction and operation of a coal-fired alternative in NUREG-1437. In summary, the NRC concludes that construction impacts could be substantial, due in part to the large land area required (which can result in natural habitat loss) and the large workforce needed; however, the installation of a new coal-fired plant where an existing nuclear plant is located would reduce many of these construction impacts. The analysis presented in NUREG-1437 also concludes that there are major adverse impacts from operations of a coal-fired plant such as human health concerns associated with air emissions, waste generation, and losses of aquatic biota as a result of cooling water withdrawals and discharges. NUREG-1437 also identifies socioeconomic benefits for the surrounding communities in the form of several hundred jobs, substantial tax revenues, and plant spending. In order to characterize the environmental impacts of the comparison pulverized coal-fired plant, a more detailed evaluation of the particular comparison plant, taking into account the conclusions presented in NUREG-1437, is provided below.

Air Quality

Air quality impacts of coal-fired generation are considerably different from those of nuclear power and can potentially be significant, as depicted in NUREG-1437. A coal-fired plant would emit:

- Acid rain precursors—(sulfur dioxides, as sulfur oxide surrogate) and nitrogen oxides
- Criteria (health based) air pollutants—particulate matter, carbon monoxide, sulfur dioxides, and an ozone precursor, nitrogen oxide
- Hazardous air pollutants—mercury (Hg), and the naturally occurring radionuclides—uranium-238 and thorium-232
- Greenhouse gases —mainly CO_2 which has been linked to global climate change

As Table 9.2-1 indicates, and for the purpose of this analysis, it is assumed a plant design would minimize air emissions through a combination of boiler technology and post-combustion pollutant removal. The analysis indicates that the comparison pulverized coal-fired alternative would burn an estimated 5.72 million tons of coal per year and produce the following emissions:

Pollutant	Emissions
Nitrogen Oxide	1387 tons per year
Sulfur Dioxides	7499 tons per year
Carbon Monoxide	1430 tons per year
PM_{10}[(a)]	58 tons per year
$PM_{2.5}$[(b)]	15 tons per year
Carbon Dioxide	14 million tons per year
Mercury	0.24 tons per year

(a) Particulates with an aerodynamic diameter of less than 10 microns
(b) Particulates with an aerodynamic diameter of less than 2.5 microns

These emission totals for the potentially competitive alternative are calculated based on the parameters and assumptions identified in Table 9.2-1 and emission factors published in AP-42 (U.S. EPA Jan 1995).

Thus, the pulverized coal-fired comparison plant would emit several of the regulated criteria air pollutants. Criteria air pollutants are regulated in the Clean Air Act. The Clean Air Act required the EPA to set national ambient air quality standards (NAAQS) for six common air pollutants known as criteria pollutants: particle pollution, or particulate matter, ground-level ozone, carbon monoxide, sulfur oxides, nitrogen oxides, and lead. For each of these six criteria air pollutants, the EPA has set primary (health-based) standards and/or secondary (environmental and property damage) standards. Areas of the country in violation of NAAQS primary standards are designated as non-attainment areas, and new sources to be located in or near these areas may be subject to more stringent air permitting requirements. Florida does not have regions that are designated as non-attainment with respect to the NAAQS for one or more criteria pollutants. New sources of criteria air pollutants would need to be considered to prevent significant deterioration or increases above the air quality baseline before permitting a pulverized coal-fired plant (U.S. EPA Apr 2008).

The pulverized coal-fired comparison plant would also emit significant sulfur dioxides and nitrogen oxide emissions, both acid rain precursors, and would be subject to the requirements in Title IV of the Clean Air Act. Title IV of the Clean Air Act was enacted to reduce emissions of sulfur dioxides and nitrogen oxide, the two principal precursors of acid rain. The acid rain requirements of the Clean Air Act amendments established a cap on the allowable sulfur dioxides emissions from power plants. Each company with fossil fuel-fired units was allocated sulfur dioxide allowances. To be in compliance with the Act, companies must hold enough allowances to cover their annual sulfur dioxides emissions. The Clean Air Act amendments also implemented a technology-based emission reduction program for nitrogen oxide aimed at achieving emission reductions through compliance with emission limitations (U.S. EPA Apr 2008). In 2007, emissions from generators in Florida ranked third nationally (in thousand metric tons) and 28th nationally (in lbs/MWh—for nitrogen oxide emissions). While for sulfur dioxide emissions, Florida ranked 11th

highest nationally (in thousand metric tons) and 31st nationally (in lbs/MWh) for sulfur dioxide emissions (EIA Apr 2009). Both sulfur dioxides and nitrogen oxide emissions would increase if a new coal-fired plant were operated at Turkey Point. To operate a fossil-fuel generation plant, FPL would have to purchase sulfur dioxide allowances from the open market or shut down existing fossil-fired capacity from one of its other plants and apply the credits from that plant to the new one. Additionally, technology based nitrogen oxide limitations would have to be met.

The emission of nitrogen oxide, sulfur dioxides, and mercury from the pulverized coal-fired comparison plant may potentially be impacted by additional pieces of legislation. In March 2005, the EPA promulgated two rules as part of the Clear Skies initiative—the Clean Air Interstate Rule (CAIR) and the Clean Air Mercury Rule (CAMR). Although both CAIR and CAMR have been vacated, consideration of the possible impacts of potentially similar regulations is warranted. The CAIR rule addressed power plant nitrogen oxide and sulfur dioxide emissions that contribute to non-attainment of the 8-hour ozone and fine particulate matter standards in downwind states. Twenty-eight states, including Florida, would have been subject to the requirements of the rule. On July 11, 2008, the D.C. Court issued an opinion vacating and remanding these rules; however, parties to the litigation requested rehearing of aspects of the Court's decision, including the vacatur of the rules. On December 23, 2008, the Court granted rehearing only to the extent that it remanded the rules to EPA without vacating them. It is anticipated that promulgation of a rule similar to the CAIR would yield the following analogous emission reduction requirements—emission reductions of nitrogen oxide by over 60 percent and sulfur dioxide emissions by over 70 percent would be required. These reductions would be accomplished by the installation of additional emission controls at existing coal-fired facilities or by the purchase of emission allowances from a cap-and-trade program (U.S. EPA Mar 2009).

The second rule of legislation the U.S. EPA issued, the CAMR, addressed mercury emissions, a regulated hazardous air pollutant—also potentially emitted by the pulverized coal-fired comparison plant. CAMR would have set emissions limits on mercury to be met in two phases beginning in 2010 and 2018, and encouraged a cap and trade approach to achieve the target emission limits. On February 8, 2008, the D.C. circuit court vacated the EPA’s CAMR. On February 6, 2009, the Department of Justice, on behalf of EPA, asked the Supreme Court to dismiss EPA's request that the Court review the D.C. Circuit Court's vacatur of the CAMR. Promulgation of a rule similar to CAMR would yield the following analogous emission reduction requirements to the March 2005 rule—during the first phase cap in 2010, mercury will be reduced by taking advantage of “co-benefit” reductions required in CAIR— nitrogen oxide and sulfur dioxide controls indirectly help to reduce mercury emissions. The second phase cap in 2018 would reflect a level of mercury emission reductions that exceed the level that would be achieved solely as a co-benefit of controlling nitrogen oxides and sulfur dioxides under CAIR. Each new coal-fired electrical generation unit in Florida would be required to acquire enough mercury allowances to cover its annual mercury emissions (U.S. EPA Mar 2009b).

The pulverized coal-fired comparison plant would also emit large quantities of greenhouse gases, particularly carbon dioxide. Recent concern over the emissions of greenhouse gases and their effect on climate change is leading to legislation requiring the reduction of greenhouse gas emissions. In fact, Executive Orders issued by Florida's Governor in July 2007 require a significant reduction in greenhouse gas emissions in Florida. These orders include a goal of providing 20 percent of the energy produced by electric utilities from renewable, non-emitting sources and requiring a significant reduction in greenhouse gas emissions by 2017. Therefore, new advanced coal technology power plants may no longer be seen as viable options in Florida (FPL Apr 2010).

NUREG-1437 identified that air quality from a coal-fired alternative would be impacted by releases of radionuclides. Radionuclides are among the hazardous air pollutants included in section 112 (b) of the Clean Air Act amendments. The three major fossil fuels—coal, oil, and natural gas—contain varying quantities of the naturally occurring radionuclides of the uranium-238 and thorium-232 series and potassium-40. When these fuels are burned to produce steam in the production of electricity, radionuclides are entrained in the combustion gases and may be emitted into the environment. The decay series of uranium and thorium constitute the major radionuclides contained in coal. A national database of nearly 7000 coal samples was analyzed with regard to the uranium and thorium content of the major ranks of coal used by utilities. Bituminous coal, the coal assumed to be used in the comparison plant, had an average content of 1.24 ppm uranium and 2.18 ppm thorium, with a corresponding activity of 0.41 picoCuries per gram (pCi/g) for each member of the U-238 series and 0.24 pCi/g for each member of the Th-232 series. The EPA assessed the exposure and risks as a result of radionuclide emissions from utilities and decided not to regulate radionuclide emissions from coal-fired boilers. The radionuclide content of coal is not unique when compared to other natural materials. In fact, it is generally assumed that the average radioactivity of the earth's crust (i.e., soil and rocks) is approximately twice that of coal (U.S. EPA Feb 1998).

NUREG-1437 also identified that temporary fugitive dust would be generated during construction of a coal-fired plant. Exhaust emissions would come from vehicles and equipment used during the construction process. In addition, during operations, coal-handling equipment would introduce fugitive particulate emissions.

Thus, air impacts from a coal-fired generation facility would be substantial. Adverse human health effects from coal combustion have led to important federal legislation in recent years because public health risks, such as cancer and emphysema, have been associated with coal combustion. Global warming and acid rain are also potential impacts. Recent changes in air quality regulations indicate that the EPA and the federal government recognize the importance of stability for air resources. However, a new pulverized coal-fired generating plant would need to obtain a New Source Review and Prevention of Significant Deterioration construction permit and the plant would need an operating permit issued under Title V of the Clean Air Act. These permits

would establish limits to prevent substantial air quality impacts from the pulverized coal-fired alternative.

Thus, the coal-fired alternative would have MODERATE impacts on air quality. The impacts may be noticeable, but would not destabilize air quality in the area as a result of the use of mitigation technologies and compliance with issued permits.

Waste Management

The pulverized coal-fired alternative would generate substantial solid waste in the form of ash from coal combustion and scrubber sludge from air pollution controls. Based on the assumed plant parameters, the potentially competitive coal comparison plant would annually consume approximately 5.72 million tons of coal with an ash content of 8.94 percent. Particulate control equipment would collect most (99.9 percent) of this ash (approximately 510,906 tons per year). According to the EPA, approximately 30 percent of the ash produced by coal-fired power plants is recycled (U.S. EPA Jul 2008). Assuming this amount of waste mitigation, a new pulverized coal-fired plant at Turkey Point would recycle approximately 153,272 tons of coal ash per year and an annual total of approximately 357,634 tons of ash would require disposal.

For comparison purposes, it was assumed that the potentially competitive pulverized coal plant would be equipped with a wet flue gas desulfurization system with forced air oxidation using limestone as a reagent. (The wet flue gas desulfurization system would be located after the particulate matter control equipment [filter baghouse].) The wet flue gas desulfurization control removal technology with a forced-air oxidation system generates a large amount of gypsum waste that would need to be recycled or disposed of in a landfill (Buecker Aug 2006). Forced-oxidized systems produce gypsum (calcium sulfate dihydrate, whereas unoxidized systems will produce a wet material that is comprised of calcium sulfite with varying levels of calcium sulfate (EERC Dec 2007). The American Coal Ash Association reported that over 79 percent of the flue gas desulfurization gypsum was beneficially used in 2006. The major beneficial use of gypsum is wallboard. In addition to building materials, gypsum can be used for a variety of civil engineering applications from road construction to agricultural applications such as soil conditioners, nutritional sulfur, and fertilizer absorption enhancers (ACAA Aug 2006 and U.S. EPA Mar 2008). The comparison plant flue gas desulfurization control equipment would require approximately 234,107 tons of limestone a year to mitigate sulfur oxide emissions and would generate 402,708 tons per year of waste in the form of gypsum. Assuming 79 percent of the waste is recycled as a mitigation measure, Turkey Point would recycle approximately 318,140 tons of gypsum under the pulverized coal-fired alternative and an annual total of 84,569 tons of gypsum would require disposal. Ash and gypsum waste disposal over a 60-year plant life would require approximately 380 acres, primarily for ash disposal—assuming a landfill height of 30 feet (U.S. EPA Jul 2008).

With proper facility placement, along with current waste management and monitoring practices, waste disposal would not destabilize any resources. After closure of the waste site and revegetation, the land would be available for other uses. Waste disposal for the coal-fired alternative would have MODERATE impacts. The impacts of increased waste disposal would be clearly noticeable, but would not destabilize any important resource and further mitigation of the impact would be unwarranted.

Land Use

NUREG-1437 estimates that approximately 1700 acres and the associated terrestrial habitat would be impacted during the construction of a 1000 MW coal-fired power plant and an additional 22,000 acres for mining the coal and disposing of the waste could be committed to supporting a coal plant during its operational life. Because most of this construction would be in previously disturbed areas, impacts would be minimal. As with any large construction project, some erosion, sedimentation, and fugitive dust emissions could be anticipated, but would be minimized through application of best management practices that minimize soil loss and restore vegetation after construction (NUREG-1437).

Thus, land use impacts from construction and operation of the pulverized coal-fired alternative would be MODERATE.

Ecology

During construction of the pulverized coal-fired alternative, construction impacts would alter the ecology. Ecological impacts to a plant site could include impacts on threatened or endangered species, wildlife habitat loss, reduced wildlife reproduction, habitat fragmentation, and a local reduction in biodiversity. There could be impacts to terrestrial ecology from cooling tower drift. There would also be aquatic ecology impacts from the transport of coal by barge to the site. It is estimated that approximately 272 barge deliveries to the site per year would be required, assuming the capacity of each coal barge is 21,000 tons (NREL Jun 1999). Most of the construction impacts would be avoided if a previously disturbed site such as Turkey Point is used (NUREG-1437).

Thus, the ecological impacts and impacts to threatened and endangered species would be SMALL to MODERATE, similar to the proposed project.

Water Use and Quality

Construction activities would disturb the land surface, which may temporarily affect surface water quality. Potential water quality impacts would consist of suspended solids from disturbed soils, biochemical oxygen demand, nutrient loading from disturbed vegetation, and oil and grease from construction equipment. Construction activities that disturb one acre or more would require a

National Pollutant Discharge Elimination System (NPDES) permit for stormwater discharges from the site. Provisions of the NPDES permit would ensure that best management practices are implemented to minimize impacts to surface waters during construction. A spill prevention, control, and countermeasures plan would be implemented to minimize water quality impacts from minor spills of fuel, hydraulic fluid, lubricants, paint, and other liquids. Construction would cause no appreciable consumption of surface water resources.

During operation of the pulverized coal-fired alternative, based on EPRI estimates, cooling tower water makeup water withdrawal would be approximately 18,450 gpm to 22,140 gpm and consumptive use through evaporation would be approximately 17,712 gpm (EPRI Mar 2002). This amount of water consumption would be taken from a combination of sources, reclaimed water and radial collector wells. Reclaimed water would come from a Miami-Dade County wastewater treatment plant that could potentially supply the required makeup water for the comparison pulverized coal-fired plant along with radial collector wells. Radial collector wells would be designed and sited to induce recharge from Biscayne Bay. The quality of the supply water from these sources would meet the regulatory requirement for use in industry.

The Boulder Zone within the lower Floridian aquifer could be used for discharge of blowdown effluents originally sourced from either saline or fresh water. The Boulder Zone has been used since 1977 to store vast quantities of treated sewage injected into it by Miami, Fort Lauderdale, and West Palm Beach. Currently, over 90 Class I injection wells are used to dispose over 400 million gallons/day of secondary wastewater in southeast Florida. The extremely high permeability associated with its cavernous nature prevents pressure buildup in injection wells, and its high salinity, make it an ideal zone for receiving injected wastes.

An underground injection control permit would be required for disposal of effluent through an underground injection well. This permit would establish conditions for discharging wastewater to the Boulder Zone. Stormwater runoff streams from the coal storage area, fly ash and bottom ash piles, and the gypsum storage area would be collected in a lined recycle basin for reuse with no direct discharge to the surface water. A spill prevention, control, and countermeasures plan would be implemented to minimize water quality impacts from minor spills.

Thus, water use and quality impacts would be SMALL.

Aesthetics

The pulverized coal-fired power block would be as high as 200 feet tall and the exhaust stack could be as high as 650 feet. The stack and associated plume would likely be visible in daylight hours for distances greater than 10 miles. The Federal Aviation Administration generally requires that structures exceeding an overall height of 200 feet above ground level have markings and/or lighting so as not to impair aviation safety. Visual effects of a new coal-fired plant at Turkey Point

would be consistent with the industrial nature of the current site—located onsite are two nuclear units along with three oil and gas units.

Coal-fired generation introduces mechanical sources of noise that could be audible offsite. Sources contributing to total noise produced by plant operation are classified as continuous or intermittent. Continuous sources include the mechanical equipment associated with normal plant operations. Intermittent sources include the equipment related to coal handling, solid waste disposal, transportation related to coal and limestone delivery, use of outside loudspeakers, and the commuting of plant employees. Noise associated with barge transportation of coal and limestone would be minimal for the pulverized coal-fired alternative comparison plant. Noise and light from the pulverized coal-fired comparison plant may be detectable offsite, but these effects would be mitigated by the location of the comparison pulverized coal-fired plant in a relatively unpopulated area.

Thus, the aesthetic impacts associated with the pulverized coal-fired alternative would be SMALL.

Socioeconomics

Short-term socioeconomic impacts would result from the estimated 2500 peak construction workers to build the facilities, and long-term impacts would result from the estimated 250 full-time workers to operate the coal-fired facility (NUREG-1437).

During construction, the communities immediately surrounding the plant site would experience demands on housing and public services that could have noticeable impacts. NUREG-1437 states that socioeconomic impacts at a rural site would be greater than at an urban site, because more of the peak construction workforce would need to move to the area to work. New construction could have a negative impact on availability and cost of housing and after construction, the communities would be affected by the loss of jobs (NUREG-1437). Transportation impacts would be temporary, noticeable, but not destabilizing during plant construction and small during plant operation.

Miami-Dade County would benefit from tax payments for the new pulverized coal-fired comparison plant and, depending on how these are distributed, this could help address socioeconomic impacts.

Thus, socioeconomic impacts associated with constructing and operating the pulverized coal-fired alternative would be MODERATE (adverse) to LARGE (beneficial).

Historic and Cultural Resources

The potential impacts of new plant construction on historic and archaeological resources have been described and evaluated for the proposed project, Units 6 & 7 in Subsection 2.5.3 and 4.4.3. Cultural resource impacts would be unlikely because of the previously disturbed nature of the site and could be, if needed, minimized by survey and recovery techniques.

Thus, cultural resource impacts associated with constructing and operating the pulverized coal-fired alternative at Turkey Point and associated transmission corridors would be SMALL.

Environmental Justice

Environmental justice impacts would depend on the nearby population distribution. Environmental justice impacts have been described and evaluated for the proposed project in Subsections 2.5.3 and 4.4.3.

Thus, environmental justice impacts associated with constructing and operating the pulverized coal-fired alternative at Turkey Point and associated transmission corridors would be SMALL.

9.2.3.1.2 Human Health Effects

As NUREG-1437 states, human health effects associated with coal combustion include public health risks such as cancer and emphysema. Concerns over adverse human health effects from coal combustion have led to federal legislation in recent years. The principal pollutants generated by coal combustion that can cause health problems are particulates, sulfur oxide, and nitrogen oxide, mercury, trace elements (including arsenic, fluorine, selenium, and the radionuclides uranium and thorium), and organic compounds generated by incomplete coal combustion.

Nitrogen oxide emissions contribute to ozone formation, which in turn contributes to health risks. Ozone can irritate respiratory systems, reduce lung function, aggravate asthma, inflame and damage cells that line the lungs, and may cause permanent lung damage (U.S. EPA Sep 2008b). Additionally, exposure to fine particulates, $PM_{2.5}$ —sulfur dioxides are a precursor to fine particulates—has been associated with reduced lung function and chronic bronchitis; and, in people with heart disease, short-term exposure has been linked to heart attacks and arrhythmias (U.S. EPA Sep 2008c).

Recently, the EPA conducted a detailed study of possible health impacts from exposure to emissions of approximately 20 potentially toxic substances from coal-burning electric utilities. The EPA used U.S. Geological Survey (USGS) information on U.S. coal quality to assess the potential health impacts of approximately 14 potentially toxic trace elements that may be mobilized by coal combustion. The EPA concluded that, with the possible exception of mercury,

there is no compelling evidence to indicate that emissions from U.S. coal-burning electric utilities cause human health problems in relation to toxic pollutants of concern (USGS Jul 2000).

Regulatory agencies, including the EPA and state agencies, set air emission standards and requirements based on human health and environmental impacts for the criteria air pollutants. These agencies also impose site-specific emission limits as needed to meet the health standards.

Thus, with the limits imposed for the regulated constituents of air emissions, human health impacts from burning coal at a newly constructed coal-fired plant would be SMALL.

9.2.3.1.3 Design Alternatives

The location of Turkey Point lends itself to coal delivery by barge. Subsection 9.4.1 analyzes alternative designs for the Units 6 & 7 heat dissipation systems. Based on this analysis, a cooling tower was assumed to be used for the pulverized coal-fired alternative.

9.2.3.1.4 Conclusion

The impacts of the pulverized coal-fired alternative are compared to the proposed nuclear project in Table 9.2-3. As the comparison in these tables demonstrates, the pulverized coal-fired alternative is not environmentally preferable to the proposed nuclear project. Therefore, an economic cost comparison is not warranted.

9.2.3.2 Natural Gas Generation

As identified in Subsection 9.2.2.10, gas-fired generation using combined-cycle turbines has been identified as a potentially competitive alternative to the proposed project. The gas-fired alternative would be located at the site for the proposed nuclear project. It would be comprised of three 728.4 MW net capacity natural gas combined cycle units for comparison with the proposed project. Table 9.2-2 details basic attributes chosen to complete a reasonable analysis of the natural gas-fired units. The emission control technology selected was chosen to yield the lowest emission factor for the pollutants of concern provided by the EPA AP-42 document, yielding a more favorable comparison for the alternative. The gas-fired alternative defined in Subsection 9.2.2.10 would be located on land adjacent to an 1100 MW unit, Unit 5, natural gas combined-cycle unit exists along with the associated pipeline (U.S. EPA Jan 1995).

9.2.3.2.1 Environmental Impacts

The NRC provides an overview of the environmental impacts associated with natural gas-fired plants. Land use impacts from gas-fired units would be less than those of the coal-fired alternative. Reduced land requirements as a result of construction on the existing site and a smaller facility footprint would reduce impacts to ecological, aesthetic, and cultural resources. As

described, an incremental increase in the workforce could have socioeconomic impacts. Human health effects associated with air emissions would be of concern, but the effect would be less than those of coal-fired generation (NUREG-1437). An evaluation of the environmental impacts related to the potentially competitive combined-cycle gas-fired plant is presented below.

Air Quality

As indicated in NUREG-1437, natural gas combustion is relatively clean compared to other fossil fuel combustion. Also, because the heat recovery steam generator does not receive supplemental fuel, the combined-cycle operation is highly efficient versus the coal-fired alternative. Therefore, the gas-fired alternative would release similar types of emissions, but generally in quantities less than the coal-fired alternative (NUREG-1437). Control technology for gas-fired turbines focuses on the reduction of nitrogen oxide emissions. The comparative gas-fired alternative would use approximately 104 billion standard cubic feet of natural gas per year and would generate these emissions:

Pollutant	Emissions
Nitrogen Oxide	584 tons per year
Sulfur Dioxides	35 tons per year
Carbon Monoxide	121 tons per year
$PM_{2.5}$[(a)]	101 tons per year
Carbon Dioxide	5.9 million tons per year

(a) Particulates with an aerodynamic diameter of less than 2.5 microns—all particulates are $PM_{2.5}$

These emission totals for the competitive alternative are calculated based on the parameters and assumptions identified in Table 9.2-2 and emission factors published in AP-42 (U.S. EPA Jan 1995).

As described in Subsection 9.2.3.2, the potentially competitive natural gas combined-cycle plant would also have to meet requirements of the Clean Air Act regarding both the criteria air pollutants and acid rain requirements. The emission reductions required in potentially new legislation would also apply to the competitive combined-cycle gas-fired generation plant—analogous to the CAIR. Additionally, similar to the pulverized coal-fired alternative, the combined-cycle gas-fired alternative would also need to obtain and meet New Source Review and Prevention of Significant Deterioration requirements and operational requirements in a Title V operating permit.

Similar to the pulverized coal-fired comparison plant, the combined cycle gas-fired alternative would also emit large quantities of greenhouse gases, although in much less quantities than the coal-fired alternative. As described in Subsection 9.2.3.1, Executive Orders issued by Florida's

Governor in July 2007 require a significant reduction in greenhouse gas emissions in Florida. These orders include a goal of providing 20 percent of the energy produced by electric utilities from renewable, non-emitting sources and requiring a significant reduction in greenhouse gas emissions by 2017. Therefore, approval for a new combined cycle gas-fired power plants may prove challenging in Florida (FPL Apr 2010).

Thus, the combined cycle gas-fired alternative would have MODERATE impacts on air quality. The impacts may be noticeable, but would not destabilize air quality in the area due the use of mitigation technologies and compliance with permits.

Waste Management

In NUREG-1437, an analysis of environmental impacts from waste generation from gas-fired plants concludes that the impact would be minimal. The only significant solid waste generated at a new gas-fired plant would be spent selective catalytic reduction catalyst used to control nitrogen oxide emissions, portions of which could be regenerated or recycled. Other then spent selective catalytic reduction catalyst, waste generation at an operating natural gas-fired plant would largely be limited to construction debris during construction and typical office wastes. These impacts would be so minor that they would not noticeably alter any important resource attribute.

Thus, the solid waste impacts associated with a combined cycle natural gas-fired alternative would be SMALL.

Land Use

Similar to the coal-fired alternative, the ability to construct the gas-fired alternative on land adjacent to Turkey Point would reduce construction-related impacts relative to construction on a greenfield site. NUREG-1437 estimates that the gas-fired alternative would impact approximately 110 acres of land and associated terrestrial habitat for plant requirements and approximately 3600 acres of additional land would be required for gas wells, collection stations, and pipelines. A new pipeline corridor would not need to be constructed. An existing 24-inch transmission pipeline located at Turkey Point, which serves Unit 5, is present and utilization of the existing corridor would minimize additional land use impacts. Construction impacts would be minimized through the application of best management practices that minimize soil loss and restores vegetation immediately after the excavation is backfilled.

Thus, land use impacts for construction and operation of the combined cycle gas-fired alternative would be SMALL.

Ecology

The gas-fired alternative would introduce construction impacts and new incremental operational impacts, which may alter the ecology of the surrounding environment. Ecological impacts to a plant site could include impacts on threatened or endangered species, wildlife habitat loss, reduced wildlife reproduction, habitat fragmentation, and a local reduction in biological diversity. Most of these impacts would be avoided, however, due to the disturbed nature of Turkey Point (NUREG-1437).

Thus, the ecological impacts and impacts to threatened and endangered species would be SMALL.

Water Use and Quality

Construction activities would disturb land surface, which may temporarily affect surface water quality. Potential water quality impacts would consist of suspended solids from disturbed soils, biochemical oxygen demand, nutrient loading from disturbed vegetation, and oil and grease from construction equipment. Construction would require an NPDES permit for stormwater discharges from the site. Provisions of the NPDES permit would ensure implementation of best management practices to minimize impacts to surface waters during construction. Runoff detention ponds would be designed to detain runoff within the containment areas to allow for settling and to reduce peak discharges. A spill prevention, control, and countermeasures plan would be implemented to minimize water quality impacts from minor spills of fuel, hydraulic fluid, lubricants, paint, and other liquids. Although the spill prevention control and countermeasures plan would be primarily intended to prevent spills from reaching navigable waters, it would also mitigate impacts on local groundwater because any spills would be quickly responded to and not permitted to penetrate to groundwater. Construction would cause no appreciable consumption of surface water resources.

During operation of the gas-fired alternative, based on the EPRI estimates, cooling tower makeup water withdrawal would be approximately 8487 gpm and consumptive use through evaporation would be approximately 6642 gpm (EPRI Mar 2002). This amount of water consumption would be taken from a combination of sources, reclaimed water and radial collector wells. Reclaimed water would come from a Miami-Dade County wastewater treatment plant that could potentially supply the required makeup water for the comparison gas-fired plant along with radial collector wells that would be designed and sited to induce recharge from Biscayne Bay. The quality of the supply water from these sources would meet the regulatory requirement for use in the industry.

The Boulder Zone within the lower Floridian aquifer could be used for discharge of blowdown effluents originally sourced from either saline or fresh water. The Boulder Zone has been used since 1977 to store vast quantities of treated sewage injected into it by Miami, Fort Lauderdale,

and West Palm Beach. Currently, over 90 Class I injection wells are used to dispose over 400 million gallons/day of secondary wastewater in southeast Florida. The extremely high permeability associated with its cavernous nature prevents pressure buildup in injection wells, and its high salinity makes it an ideal zone for receiving injected wastes.

An underground injection control permit would be required for disposal of effluent through an underground injection well. This permit would establish conditions for discharging wastewater to the Boulder Zone. A spill prevention control and countermeasures plan would be implemented to minimize water quality impacts from minor spills.

Thus, water use and quality impacts would be SMALL.

Aesthetics

Aesthetic impacts would be similar to the pulverized coal-fired alternative, but smaller because of the reduced site size. The gas-fired units' steam turbine building would be approximately 100 feet high. The tallest structure would be the 150-foot-high auxiliary boilers and heat recovery steam generator stacks. These structures would not alter the visual effects of existing two nuclear units along with three oil and gas units located at Turkey Point.

Thus, the aesthetic impacts associated with the gas-fired alternative would be SMALL.

Socioeconomics

Short-term socioeconomic impacts would result from the estimated 1200 peak construction workers to build the facilities, and long-term impacts would result from the estimated 150 full-time workers to operate the gas-fired facility (NUREG-1437).

Similar to the pulverized coal-fired alternative, during construction, the communities immediately surrounding the plant site would experience demands on housing and public services that could have noticeable impacts. New construction could have a negative impact on availability and cost of housing and after construction, and the communities would be affected by the loss of jobs (NUREG-1437).

Miami-Dade County would benefit from tax payments for the new gas-fired comparison plant and, depending on how these tax payments are distributed, this could help address socioeconomic impacts.

Transportation impacts would be temporary, noticeable, and destabilizing for brief periods during plant construction and small during plant operation.

Thus, socioeconomic impacts associated with constructing and operating the gas-fired alternative would be MODERATE (adverse) to MODERATE (beneficial).

Historic and Cultural Resources

The potential impacts of new plant construction on historic and archaeological resources have been described and evaluated for the proposed project in Subsections 2.5.3 and 4.4.3. Cultural resource impacts would be unlikely due to the previously disturbed nature of the site and could be, if needed, minimized by survey and recovery techniques.

Thus, cultural resource impacts associated with constructing and operating the gas-fired alternative at Turkey Point and associated transmission corridors would be SMALL.

Environmental Justice

Environmental justice impacts would depend on the nearby population distribution. Environmental justice impacts have been described and evaluated for the proposed project in Subsections 2.5.3 and 4.4.3.

Thus, environmental justice impacts associated with constructing and operating the gas-fired alternative at Turkey Point and associated transmission corridors would be SMALL.

9.2.3.2.2 Human Health Effects

In NUREG-1437, the NRC identified cancer and emphysema as potential health risks from gas-fired plants. Nitrogen oxide emissions contribute to ozone formation, which in turn contributes to health risks. Ozone can irritate respiratory systems, reduce lung function, aggravate asthma, inflame and damage cells that line the lungs, and may cause permanent lung damage (U.S. EPA Sep 2008b). Nitrogen oxide emissions from any plant would be regulated by the state or EPA. Exposure to fine particulates, $PM_{2.5}$, has been associated with reduced lung function and chronic bronchitis; and, in people with heart disease, short-term exposure has been linked to heart attacks and arrhythmias (U.S. EPA Sep 2008c).

Regulatory agencies, including the EPA and state agencies, set air emission standards and requirements based on human health and environmental impacts for the criteria air pollutants. These agencies also impose site-specific emission limits as needed to meet the health standards.

Thus, with the limits imposed for the regulated constituents of air emissions, human health impacts from a newly constructed gas-fired plant would be SMALL.

9.2.3.2.3 Design Alternatives

Combined-cycle plants use a combination of combustion turbine and heat recovery steam generators to generate power. Therefore, their heat rejection rates are substantially lower than

comparably sized nuclear- and coal-fired steam generators. Consequently, combined-cycle plants with recirculated cooling systems generally use cooling towers rather than ponds.

9.2.3.2.4 Conclusion

The impacts of the potentially competitive combined-cycle gas-fired generation are compared to the proposed nuclear project in Table 9.2-3. As the comparison in this table demonstrates, the gas-fired alternative is not environmentally preferable to proposed nuclear project. As such, an economic cost comparison is not warranted.

9.2.3.3 Combination of Alternatives

As identified in NUREG-1555, consideration of combinations of individual alternatives available to the applicant should be analyzed with respect to environmental and health impacts for comparison with the proposed project to determine if any of the available combinations are environmentally preferable. This subsection reviews possible combinations of alternatives that could generate replacement baseload power instead of the proposed nuclear project. As previously stated, the nuclear project has a net capacity of approximately 2200 MW of electrical generation and is expected to supply baseload power to the Florida Public Service Commission region.

9.2.3.3.1 Determination of Alternatives

The selected combinations of alternatives were developed as potentially competitive alternatives to the proposed project, based on technological maturity, ability to serve regional needs, and suitability of the technology in the region of interest. As detailed in Subsection 9.2.2, individually, many of the alternatives would not be able to provide the baseload capacity required; however, a combination of these alternatives may be sufficient to provide the required baseload capacity equivalent to the proposed project.

When determining a plausible combination of alternatives, consideration was given to either a technology's capability of supplying baseload power, or its ability to provide smaller environmental impacts. Because the proposed nuclear project would provide baseload capacity in a predictable, consistent manner, the alternative combination would need to provide the consistent baseload supply, and if coupled with a renewable energy source, environmental impacts may be reduced. Therefore, when determining a combination of alternative sources that includes a variable renewable source of energy, the alternative must be combined with an alternative capable of supplying baseload capacity, a fossil fuel-fired source. This allows the fossil fuel-fired portion to provide the entire load during times when the output of the renewable source of energy is reduced or unavailable. When available, the output of the renewable source may displace a portion of the baseload supply, and the output of the fossil fuel-fired portion can be reduced to accommodate the increase in renewable generation.

Of the renewable energy alternatives evaluated, only wind and solar are viable technologies in the region of interest. The remaining technologies were eliminated from further consideration because they were either not viable in the region of interest, the technology was not mature, and/or the environmental impacts would not be preferable to the proposed project. The two remaining renewable energy technologies, evaluated in Subsection 9.2.2, wind energy (Subsection 9.2.2.2) and solar energy (Subsection 9.2.2.3), individually were not considered potentially competitive alternatives as stand-alone technologies primarily because of each alternative's lack of ability to provide the required baseload capacity because of their intermittent capacity. However, as noted in the evaluation provided in Subsection 9.2.2, each technology is viable in the region of interest. In fact, FPL plans to pursue both wind and solar projects in the FPL service area. Therefore, for this portion of this analysis, wind and solar are considered as renewable power sources that can supplement a baseload capable source.

Of the fossil fuel alternatives evaluated, only coal (Subsection 9.2.2.9) and natural gas (Subsection 9.2.2.10) were technologically viable and could provide the required baseload capacity and, thus, were deemed potentially competitive alternatives. However, as the evaluations presented in Subsections 9.2.3.1 and 9.2.3.2 indicate, the coal and natural gas alternatives did not produce smaller environmental impact levels in comparison with the proposed project. Of the two technologies, natural gas has a smaller environmental impact. For this reason, in the environmental comparison portion of this combination alternative study, natural gas is used as the fossil fuel for baseload capacity.

Thus, this analysis examines the reduction in environmental impacts from a combined-cycle natural gas-fired facility when generation from the facility is displaced by a renewable resource—either wind or solar. The impacts of natural gas considered are those shown in Subsection 9.2.3.2. Also, the renewable part of the alternative combination is any combination of renewable technologies that could produce power equal to or less than the proposed nuclear project, when that resource is available.

9.2.3.3.2 Environmental Impacts

The overall environmental impacts associated with the construction and operation of the combined-cycle gas-fired alternative is addressed in Subsection 9.2.3.2 and summarized in Table 9.2-3. Depending on the amount of renewable output included in the combination alternative, the level of environmental impacts of the combined-cycle gas-fired alternative portion would be comparatively lower. If 100 percent of the power level of the proposed project was not available from the renewable alternative, some level of environmental impact associated with the combined-cycle gas-fired alternative remains. Alternatively, when 100 percent of the load is carried by the renewable portion, the environmental impact of the operation of the combined-cycle gas-fired alternative is eliminated.

A determination of the environmental impacts that a combination of these alternatives would have can be made from the previous evaluations provided in Subsections 9.2.2 and 9.2.3.2. The environmental impacts associated with a combined-cycle gas-fired facility and equivalent renewable wind and solar facilities are summarized in Table 9.2-3. Individually, the combined-cycle gas-fired facility has impacts that are greater than the proposed project. Some of the environmental impacts of the renewable energy sources are equal to or greater than those of the proposed nuclear project. Therefore, the combination of a gas-fired plant and wind or solar facilities would have environmental impacts that are equal to or greater than those of a nuclear facility.

Impacts from wind and solar facilities are described in Subsections 9.2.2.2 and 9.2.2.3, respectively. Land use impacts from wind and/or solar facilities could be SMALL to LARGE, and the aesthetic impacts of wind could be SMALL to LARGE, depending on the size of the facilities. Similarly, impacts of wind/solar facilities on ecological resources and threatened and endangered species could be SMALL to MODERATE, depending on facility sizes and locations. The environmental impacts from the operation of wind and/or solar facilities in combination with a combined-cycle gas-fired facility would be SMALL, except for land use and aesthetic impacts from wind and solar facilities which would range from SMALL to LARGE, the ecological resource and threatened and endangered species impacts from wind and solar facilities which would range from SMALL to MODERATE, and the air quality impacts from the combined cycle gas-fired facility which would be MODERATE. In comparison, the environmental impacts of a new nuclear plant for the proposed nuclear project would be SMALL except for ecological resources (SMALL to MODERATE). Therefore, a combination of alternatives would not be environmentally preferable to the proposed nuclear project and are not evaluated further.

9.2.3.3.3 Summary

Although other combinations of the various alternatives are not presented, the lower capacity factors, greater potential environmental impacts, and immature technologies would not provide a viable, potentially competitive alternative that is either environmentally equivalent or preferable. Wind and solar generation in combination with a combined-cycle natural gas-fired facility could be used to generate baseload power and would serve the equivalent purpose of the proposed project. However, wind and solar generation in combination with a combined-cycle natural gas-fired alternative would have equivalent or greater environmental impacts when compared to a new nuclear units at Turkey Point. Therefore, wind and solar generation in combination with a natural gas-fired alternative is not competitive with the proposed project.

9.2.4 CONCLUSION

Based on the environmental impacts evaluated, neither a pulverized coal-fired nor a combined-cycle natural gas-fired alternative would result in fewer environmental impacts than the proposed

nuclear project. In fact, both types of plants would result in substantially greater environmental impacts on air quality relative to the proposed nuclear project. This conclusion is shown in detail in Table 9.2-3. In addition, a combination of the combined-cycle natural gas-fired alternative with a renewable source of energy—wind or solar—could achieve a smaller impact on the air quality but only with an accompanying moderate to large impact on land use. Therefore, the pulverized coal-fired alternative, combined-cycle natural gas-fired alternative, and combination of alternatives would not be environmentally preferable to the proposed nuclear project.

Table 9.2-1
Coal-Fired Alternative

Attribute	Basis
Unit size = 728.4 MWe net	Will provide equivalent comparison to the AP1000 units at Turkey Point
Number of units = 3	Provides equivalent comparison to two AP1000 units at Turkey Point
Boiler type = PC, dry bottom, tangentially fired, bituminous	Minimizes nitrogen oxide emissions (U.S. EPA Jan 1995)
Capacity factor = 0.85	Typical for large coal-fired units (U.S. DOE Dec 1998)
Heat rate = 8,568 Btu/kWh	Assumed based on DOE data (U.S. DOE Dec 1998)
Fuel type = Bituminous coal	Typical coal used by Florida electric utilities in 2005 and 2006 (EIA Oct 2007) and (USGS 1996)
Fuel heat value = 12,185 Btu/lb	Average heat value of coal used in Florida electric utilities in 2005 and 2006 (EIA Oct 2007)
Fuel ash content by weight = 8.94%	Average percent ash content of coal by weight used in Florida electric utilities in 2005 and 2006 (EIA Oct 2007)
Fuel sulfur content by weight = 1.38%	Average sulfur content of coal used in Florida electric utilities in 2005 and 2006 (EIA Oct 2007)
Uncontrolled nitrogen oxide emission factor = 9.7 lb/ton	AP-42 emission factor for PC, bituminous, tangentially fired, dry-bottom, with low nitrogen oxide burner (U.S. EPA Jan 1995)
Nitrogen oxide control = low nitrogen oxide burners, overfire air and selective catalytic reduction (95% reduction)	Best available and widely demonstrated to minimize nitrogen oxide emissions (U.S. EPA Jan 1995)
Uncontrolled sulfur oxide emission factor = 38S, where S= the weight percent sulfur content of coal; therefore, the emission factor for the comparison plant = 52.44 lbs/ton	AP-42 emission factor for PC, bituminous, tangentially fired, dry-bottom, with low nitrogen oxide burner (U.S. EPA Jan 1995)
Sulfur oxide control = post combustion flue gas desulfurization wet scrubber system - limestone (95% removal efficiency)	Best available for minimizing sulfur oxide emissions (U.S. EPA Jan 1995)
Uncontrolled PM filterable (PM_{10}) emission factor = 2.3A, where A is the percent ash content of the coal; therefore, the emission factor for the comparison plant = 20.56 lbs/ton	AP-42 uncontrolled emission factor for PM_{10} (U.S. EPA Jan 1995)
Uncontrolled $PM_{2.5}$ emission factor = 0.6A, where A is the percent ash content of the coal; therefore, the emission factor for the comparison plant = 5.36 lbs/ton	AP-42 uncontrolled emission factor for $PM_{2.5}$ (U.S. EPA Jan 1995)
PM control = fabric filters (baghouse-99.9% removal efficiency)	Best available for minimizing particulate emissions (U.S. EPA Jan 1995)
Uncontrolled carbon monoxide emission factor = 0.5 lb/ton	AP-42 emission factor for PC, bituminous, tangentially fired, dry-bottom, (U.S. EPA Jan 1995)
Mercury (Hg) emission factor = 8.3E-05 lbs/ton	AP-42 emission factor for controlled coal combustion—wet limestone scrubber with a fabric filter (U.S. EPA Jan 1995)
Uncontrolled carbon dioxide emission factor = 204.33 lbs/MMBtu	DOE emission factor based upon typical coal used by Florida electric utilities in 2005 and 2006 (EIA Aug 1994) and (EIA Oct 2007)

Btu = British thermal unit
kWh = kilowatt hour
MWe = megawatt electrical output
MM= million
PM= Particulate Matter
$PM_{2.5}$ = particulates with a diameter of 2.5 microns or less

Table 9.2-2
Gas-Fired Alternative

Attribute	Basis
Unit size = 728.4 MWe net	Will provide equivalent comparison to the AP1000 units at Turkey Point
Number of units = 3	Provides equivalent comparison to two AP1000 units at Turkey Point
Comparison Plant Type = combined cycle natural gas	Assumed
Capacity factor = 0.8	Assumed based on performance of modern plants (Baxter Sep 2004)
Heat rate = 7,000 Btu/kWh	Assumed based on comparison data for new gas-fired combined cycle developed for Interstate Natural Gas Association of America (INGAA 2000)
Fuel heat value = 1,028 Btu/cubic feet	Approximate heat value of natural gas for the years 2005–2008 as listed by the Energy Information Administration (EIA Jul 2008c)
Fuel Sulfur content = 0.0007%	Sulfur content of natural gas in pipelines (INGAA 2000)
Nitrogen oxide control = selective catalytic reduction with steam/ water injection	Best available to minimize nitrogen oxide emissions (U.S. EPA Jan 1995)
Nitrogen oxide emission factor = 0.0109 lb/MMBtu	AP-42 emission factor for selective catalytic reduction -controlled gas fired units with water injection (U.S. EPA Jan 1995)
Uncontrolled sulfur dioxide emission factor = 0.94S, where S= the weight percent sulfur content of coal; therefore, the emission factor for the comparison plant = 0.000658 lbs/MMBtu	AP-42 emission factor for natural gas fired turbines (U.S. EPA Jan 1995)
Carbon monoxide emission factor = 0.00226 lb/MMBtu	AP-42 emission factor for selective catalytic reduction -controlled gas fired units (U.S. EPA Jan 1995)
Uncontrolled $PM_{2.5}$ emission factor[(a)] = 0.0019 lb/MMBtu	AP-42 emission factor for stationary gas turbines using water-steam injection

(a) All particulate matter is $PM_{2.5}$

Btu = British thermal unit
kWh = kilowatt hour
MWe = megawatt electrical output
MM= million
PM= Particulate Matter
$PM_{2.5}$ = particulates with a diameter of 2.5 microns or less

Table 9.2-3
Impacts Comparison Summary

Impact Category	Proposed Project (Turkey Point COL)	Coal-Fired Generation	Gas-Fired Generation	Combinations of Alternatives
Land Use	SMALL	MODERATE	SMALL	SMALL to LARGE
Water Use and Quality	SMALL	SMALL	SMALL	SMALL
Air Quality	SMALL	MODERATE	MODERATE	SMALL to MODERATE
Ecological Resources	SMALL to MODERATE	SMALL to MODERATE	SMALL	SMALL to MODERATE
Human Health	SMALL	SMALL	SMALL	SMALL
Socioeconomics	SMALL[(a)]	SMALL[(a)]	SMALL[(b)]	SMALL
Waste Management	SMALL	MODERATE	SMALL	SMALL
Aesthetics	SMALL	SMALL	SMALL	SMALL to LARGE
Historic and Cultural Resources	SMALL	SMALL	SMALL	SMALL
Environmental Justice	SMALL	SMALL	SMALL	SMALL

(a) SMALL (adverse) to LARGE (beneficial).
(b) SMALL (adverse) to MODERATE (beneficial).
Note: To allow for a valid comparison, only adverse impacts are listed in the table.

9.3 SITE SELECTION PROCESS

As required by 10 CFR 51.45(b)(3), this section provides an analysis of alternative sites for the proposed Turkey Point site for the construction and operation of two nuclear power reactors (the proposed project). The National Environmental Policy Act (NEPA) mandates that reasonable alternatives to a proposed action be evaluated. Consistent with this requirement, the site selection process is focused on other sites that could be considered to be reasonable alternatives to the proposed project. The analysis described in this section addresses alternative sites to determine if there is an "environmentally preferable" site in terms of environmental impacts and other factors when compared to the proposed site (U.S. NRC April 2011).

This section provides a description of the process for evaluating alternative sites that includes identification of the Region of Interest (ROI); selection of candidate areas, potential sites, primary sites, and candidate sites; factors considered at each level of the selection process; criteria used to screen sites; and methodologies used in the alternative site comparison process. Subsection 9.3.1 provides an overview of the site selection process. Subsection 9.3.2 details how the alternative sites were selected. Subsection 9.3.3 compares these alternatives with the proposed site.

9.3.1 OVERVIEW OF THE SITE SELECTION PROCESS

FPL currently operates a two-unit nuclear power plant at its Turkey Point site near Homestead, Florida (Turkey Point Units 3 & 4). Including the two nuclear power units, FPL operates five power-generating units at the Turkey Point site. Nuclear Units 3 and 4 and associated structures and features occupy approximately 8000 acres, including the cooling canal system. The proposed site for Turkey Point 6 & 7 was previously found acceptable on the basis of a NEPA review and has been demonstrated to be environmentally satisfactory on the basis of nearly 40 years of operating experience (Units 3 and 4 began operation in 1972 and 1973). The area to be occupied by the proposed new units was included in the original license application and site analysis for Turkey Point Units 3 & 4. Under these circumstances, NUREG-1555 allows consideration of the proposed site as a "special case" enabling it to be compared to other alternative sites within the ROI, as follows:

> *"…there will be special cases in which the proposed site was not selected on the basis of a systematic site-selection process. Examples include plants proposed to be constructed on the site of an existing nuclear power plant previously found acceptable on the basis of a NEPA review and/or demonstrated to be environmentally satisfactory on the basis of operating experience, and sites assigned or allocated to an applicant by a State government from a list of State-approved power-plant sites. For such cases, the reviewer should analyze the applicant's site-selection process only as it applies to candidate sites*

other than the proposed site, and the site comparison process may be restricted to a site-by-site comparison of these candidates with the proposed site."

"As a corollary, all nuclear power plants sites within the identified region of interest having an operating nuclear power plant or a construction permit issued by the NRC should be compared with the applicant's proposed site."

The review process outlined in this section is consistent with the special case postulation recognized in NUREG-1555 and considers the advantages already present at existing nuclear facilities that have been previously reviewed by the NRC and found to be suitable for construction and operation of a nuclear power plant.

In 2006, FPL commissioned a team of industry and environmental experts to initiate a site selection study to identify and evaluate possible sites for construction and operation of two new nuclear power units. Site selection was conducted consistent with the process outlined in the *EPRI Siting Guide: Site Selection and Evaluation Criteria for an Early Site Permit Application*, dated March 2002 (EPRI 2002). The site selection study led to selection of Turkey Point as the site for its Combined License application (COLA) for new nuclear units. Decision processes and results of the site selection study were reported in Florida Power & Light Company, *Project Bluegrass New Nuclear Power Generation Final Site Selection Study Report*, October 2006. The overall objective of that process was to identify a nuclear power plant site that 1) meets FPL's business objectives for the COL project, 2) satisfies applicable NRC site suitability requirements, and 3) is compliant with NEPA requirements regarding the consideration of alternative sites.

The 2006 Siting Study was augmented in 2011 to:

- Address FPL's additional understanding of NRC guidance (NUREG-1555, Section 9.3) for the consideration of alternative sites subsequent to publication of the original 2006 Siting Report, and

- Provide additional technical basis and rationale in response to questions raised by the NRC during the environmental audit in June 2010 and formal Requests for Additional Information (RAI) issued by the NRC in its review of the Turkey Point Units 6 & 7 COLA.

Specifically, the augmentation adds:

- Explicit steps for regional screening and candidate area identification,

- Canvassing candidate areas to identify additional greenfield potential sites, and

- Evaluation of additional potential sites in accordance with criteria and processes used in the 2006 Siting Study.

Results of the augmentation analysis have been documented in Florida Power & Light Company, Turkey Point 6 & 7, *New Nuclear Power Generation (formerly Project Bluegrass) Augmented Site Selection Study Report,* August 2011 (FPL Aug 2011). The Augmentation Report does not supersede or replace analyses in the original Siting Report. The original site selection methodologies are preserved, and augmented with the regional screening, candidate area identification, and additional potential site evaluations noted above. The Augmentation Report was written to provide an integrated decision document describing how FPL made its decision to select Turkey Point as the proposed site while meeting the current NRC review requirements. It provides the basis on which FPL addresses requirements for the consideration of alternative sites for the Turkey Point 6 & 7 COLA.

FPL divided its analysis into two general steps:

- Identify the alternative sites (Subsection 9.3.2). This step includes identification of the ROI, and explains the process for identifying candidate areas, potential sites, primary sites, and candidate sites. From these candidate sites, Turkey Point 6 & 7 was selected as the proposed site and the remaining sites were designated as alternative sites.

- Compare the alternative sites with the proposed site (Subsection 9.3.3). This step is a site-by-site comparison of the alternative sites with the proposed site to see if any of the alternatives might be “environmentally preferable” to the proposed site. The objective of this step is to determine whether the impacts at the alternative sites are greater than or equal to the impacts at the proposed site. During this step, FPL considered various topics consistent with those identified in NUREG 1555. These topics provided the environmental and health impact information that enabled FPL to determine the environmental impacts of the proposed plant at the alternative sites. Once the comparison was completed, FPL determined if any of the alternative sites were environmentally preferable.

Because the findings in Subsection 9.3.3 identified no alternative site that was environmentally preferable to the proposed site, a subsequent analysis, consistent with NUREG-1555, to determine whether the proposed site was “obviously superior” to the alternative sites was not required.

9.3.2 SITE SELECTION PROCESS

The following subsections describe the process used to identify and evaluate potential locations, including the existing Turkey Point site, for construction and operation of the two proposed reactor units. The site selection process proceeded through the following steps that successively

reduced the number of sites down to a final proposed site and four alternative sites (section numbers in parentheses).

- Identify the ROI (Subsection 9.3.2.1)
- Identify candidate areas of more favorable site suitability within the ROI, as part of the augmentation analysis in 2011 (Subsection 9.3.2.2)
- Identify potential sites within the ROI, via two parallel processes (Subsection 9.3.2.3), including:
    - — Identify a spectrum of existing and available sites for initial consideration, as identified by FPL team of experts in 2006; and
    - — Canvass candidate areas to identify additional potential greenfield sites, as part of the augmentation analysis in 2011
- Screen the potential sites to identify primary sites, using nine screening criteria (Subsection 9.3.2.4)
- Screen the primary sites to identify candidate sites, using 34 general siting criteria (Subsection 9.3.2.5)
- Select the proposed site (Turkey Point Units 6 & 7) from the candidate sites (Subsection 9.3.2.6)

9.3.2.1 Identification of Region of Interest

For the purpose of alternative site analysis, NUREG-1555 defines the ROI as the geographic area considered in the search for potential and candidate sites, and the relevant service area is defined as the region to be served by the proposed project (U.S. NRC April 2011). For this COL application, the ROI is the area within (or immediately adjacent to) the FPL service territory. The FPL service territory is shown in Figure 9.3-1.

The FPL service territory spans the state of Florida (north-south) and is concentrated mainly along the eastern coast. The general topography of the territory is relatively flat, and land classifications include residential, industrial, and agricultural. Florida has abundant surface water resources that include the Atlantic Ocean, the Gulf of Mexico, lakes, rivers, and canals, as well as abundant groundwater resources. Florida does not have significant seismic activity; however, karst formations and sinkholes are common in parts of Florida.

Power generated by the proposed project would be used within the FPL service territory, with particular emphasis on the load centers for the greater Miami area (Palm Beach, Broward, and Miami-Dade Counties). The need for power is described in Chapter 8. Figure 9.3-2 depicts the existing transmission system in the FPL service territory.

9.3.2.2 Identify Candidate Areas within the ROI

The ROI was screened to eliminate those areas that are either unsuitable or are significantly less suitable than other potential siting areas. Exclusionary and avoidance criteria identified in the EPRI Siting Guide (EPRI 2002) were reviewed to identify those regional screening criteria and related physical features that provide insights into site suitability on an areal basis within the FPL ROI. Regional screening criteria applied to the ROI are listed in Table 9.3-1.

Information defined for each of the ROI screening criteria listed in Table 9.3-1 was mapped and displayed on separate maps of the ROI. These maps were then combined using a simple overlaying technique to produce a composite screening map (FPL Aug 2011).

Figures 9.3-3 and 9.3-4 depict the results of the regional screening process, identifying areas of higher suitability for siting a new nuclear power plant. After applying all regional screening criteria, the following 16 candidate areas were identified:

- CA-1, Caloosahatchee River/West Lake Okeechobee
- CA-2, Various Canals/South Lake Okeechobee
- CA-3, St. Lucie Canal and River/East Lake Okeechobee
- CA-4, Kissimmee River/North Lake Okeechobee
- CA-5, Peace River
- CA-6, St. Johns River South
- CA-7, St. Johns River Central
- CA-8, St. Johns River North
- CA-9, St. Mary’s River
- CA-10, St. Johns River/Reclaimed
- CA-11, West Palm Beach Canal/Reclaimed (North)

- CA-12, West Palm Beach Canal/Reclaimed (South)
- CA-13, South Miami Reclaimed (South) (Turkey Point)
- CA-14, South Miami Reclaimed (North)
- CA-15, Coastal Existing Plant (St. Lucie)
- CA-16, South Gulf Coast

9.3.2.3 Identify and Screen Potential Sites

In order to obtain a set of potential sites that spans the nuclear power plant siting options within the region of interest, two independent processes for potential site identification were implemented. In the first, FPL convened a team of internal experts to identify the full spectrum of existing and available sites that could be initially considered. In the second, the candidate areas identified in Section 3.0 of the Augmentation Report (FPL Aug 2011) were canvassed to identify additional potential greenfield sites.

Cumulatively, a total of 21 potential sites (Figure 9.3-5) were identified:

Existing and Available Sites (15)	Additional Greenfield Sites (6)
Charlotte	Collier A
Desoto	DeSoto A
Ft. Myers	Glades A
Glades	Hendry A
Hardee	Martin A
Hendry (2 locations)	Palm Beach A
Highlands	
Manatee	
Martin	
Okeechobee (2 locations)	
St. Lucie	
Turkey Point	
West County	

9.3.2.3.1 Identify Existing and Available Sites

FPL established a site selection team to identify potential sites for consideration in the site selection study. Internal FPL members of the team were identified such that they represented the full span of FPL business units and their associated specialized knowledge of existing and available sites that could be initially considered. Business units represented included:

- Resource Assessment and Planning
- Nuclear Division
- Environmental Services
- Transmission Planning
- External and Governmental Affairs
- Corporate Real Estate
- Legal
- Development

Thus, in representing their business units, the team collectively provided access to the full knowledge and capability of the Company with respect to sites in the FPL service territory and nearby regions.

Functionally, the canvassing was conducted at an August 2006 meeting during which each FPL business unit representative was asked to bring to the meeting all site-related knowledge available within their units. The committee was polled to identify the full spectrum of known existing and available sites (e.g., undeveloped land already owned by FPL or an interested seller) within or near the FPL service territory. Once all site alternatives available within the region of interest had been identified, the committee – again representing the knowledge and insights inherent in their business units – determined the feasibility of developing a new nuclear power plant at the identified sites.

Within the ROI, 23 sites were identified by FPL as locations that could be evaluated for the COL project and, potentially, a new nuclear power plant. These sites, which included existing power plant sites and greenfield sites previously identified by FPL, represented the full suite of siting trade-offs available within the ROI and therefore provided an initial basis for evaluation of a reasonable set of alternative locations.

FPL team personnel reviewed this set of sites in a joint meeting on August 1, 2006, to identify the final set of potential sites for this study. The following groups of sites were reviewed.

FPL Existing Sites

Twelve existing FPL power-generating sites were considered. Two of the sites have existing nuclear power generating plants.

- Canaveral
- Cutler
- Ft. Myers
- Lauderdale
- Manatee
- Martin
- Port Everglades
- Putnam
- Riviera
- Sanford
- St. Lucie (existing nuclear)
- Turkey Point (existing nuclear)

Additionally, three FPL-owned greenfield sites were considered:

- Andytown
- DeSoto
- West County

Finally, eight non-FPL-owned greenfield sites were considered; these sites were identified by the FPL corporate real estate department as being potentially available and feasible sites for new power generation projects:

- Charlotte
- Glades
- Hardee
- Hendry (2 locations)

- Highlands
- Okeechobee (2 locations)

Each of the sites was evaluated qualitatively with respect to the following considerations:

- Sufficient land[1] currently exists for new nuclear power plant construction;
- Sufficient land can be obtained for new nuclear power plant construction;
- Adequate sources of water; and
- Transmission feasibility.

Using this process, the following 15 potential sites were identified for further consideration; these sites are depicted in Figure 9.3-5:

- Charlotte
- DeSoto
- Ft. Myers
- Glades
- Hardee
- Hendry (2 locations)
- Highlands
- Manatee
- Martin
- Okeechobee (2 locations)

1. 3000 acres was used as a general guideline in determining land sufficiency for sites other than existing nuclear power plant sites, based on the lower bound of the Desired Owner Buffer Area for two nuclear power units, as identified by FPL - where the Desired Owner Buffer Area includes the plant components/protected area and the owner controlled/buffer area. Land sufficiency at existing nuclear power plant sites (St. Lucie and Turkey Point) is known, based on detailed licensing and operational knowledge of these sites.

- St. Lucie
- Turkey Point
- West County

Sites in the northern part of the ROI (Putnam, Sanford, Canaveral), as well as the Cutler site, were eliminated due to transmission feasibility; these sites are located far from the FPL load centers identified in Subsection 9.3.2.1, and would not achieve the project objective of balancing loads in South Florida. Additionally, right-of-way acquisition would be difficult, and/or transmission connections at these sites would have to be coordinated with other utilities. In addition, the Cutler, Sanford and Canaveral sites do not have adequate land area, and additional land could not feasibly be acquired.

The Andytown, Lauderdale, Port Everglades, and Riviera sites were eliminated from further consideration because these sites do not include enough land for a new nuclear power plant and additional land cannot be feasibly acquired in the time-frame required to support the FPL COLA schedule.

9.3.2.3.2 Candidate Area Canvassing

Canvassing of the candidate areas identified in Subsection 9.3.2.2 was conducted to search for additional greenfield potential sites. The objective of this step was to identify a second set of potential sites – not necessarily associated with existing or known properties – that could be suitable for a nuclear power plant. These additional sites allowed for more comprehensive characterization of siting trade-offs within the ROI, as well as provided further assurance that the process identified the best environmental sites that could reasonably be identified in the ROI. The process for conducting this canvassing is described below.

The sixteen candidate areas identified in the ROI screening (Subsection 9.3.2.2) were canvassed to identify potential greenfield sites that would be feasible for a new nuclear power plant, using the following process:

1. Satellite imagery of the areas was viewed using Google Earth® (http://earth.google.com/). Potential sites of approximately 5000 acres were identified by applying the considerations described below.[2]

2. 1:100,000- and 1:24,000-scale topographic maps (USGS) were examined to identify areas for potential sites and to clarify and optimize locations identified from satellite photography. Information on identified sites was supplemented using state maps and atlases.

3. The latitude and longitude of the approximate center point of each potential site was noted.

Specific considerations applied in selecting these potential sites were:

- Avoidance of high-population areas.
- Avoidance of ecologically sensitive and special designation areas.
- Avoidance of special dedicated land uses (e.g., national parks).
- Proximity to target transmission/load centers.

Siting suitability characteristics of the candidate areas, as identified during the canvassing process, are provided in Table 9.3-2.

For each of the potential sites identified, aerial photographs and other available geographic information were compiled and nominal site locations were identified. Potential sites were defined to be approximately 5000 acres[2] in size. In addition to reflecting major siting trade-offs, the objective of this phase was to optimize potential sites within each area with respect to additional environmental considerations (e.g., wetlands) and engineering feasibility.

Additional factors taken into account in this process, as feasible, included:

- Flexibility to optimize site layout and design for cost minimization.
- Flexibility to optimize site layout and design for avoidance or mitigation of environmental impacts.
- Optimization of site engineering factors (e.g., topography, foundation conditions, grading requirements).

Using this additional process, the following 6 potential greenfield sites were identified for further consideration; these sites are also depicted in Figure 9.3-5:

- Collier A

---

2. The nominal 5000-acre area is consistent with the upper bound of the desired owner buffer area, as identified by FPL for the site selection study, and provided a consistent basis for comparison of potential sites while providing flexibility for ultimately locating plant components within the evaluated area. This flexibility allows for the refinement of detailed plant locations as more information (e.g., environmental and geotechnical considerations, land availability) is developed regarding the site in subsequent steps in the siting process, while avoiding the need to reevaluate the site as locational refinements are made.

- DeSoto A
- Glades A
- Hendry A
- Martin A
- Palm Beach A

9.3.2.4 Identification of Primary Sites

The potential sites identified in Subsection 9.3.2.3 were evaluated to identify a smaller set of primary sites for more detailed evaluation (FPL Aug 2011).

The overall process for the evaluation of potential sites was composed of three elements; each element is described in the following paragraphs.

- Develop criterion ratings for each site;
- Develop weight factors reflecting the relative importance of each criterion; and
- Develop composite site-suitability ratings.

Criterion Ratings – Each potential site was assigned a rating of 1 to 5 (1 = least suitable, 5 = most suitable) for each of the nine screening criteria, using the rationale listed in Table 9.3-3. Information sources for these evaluations included publicly available data, data available from FPL files and personnel, and large-scale satellite photographs.

Weight Factors – Weight factors reflecting the relative importance of these criteria were developed by a multi-disciplinary committee in the areas of nuclear power plant site suitability that was convened at FPL offices on August 29, 2006; this committee was comprised of subject matter experts in water use and availability, engineering, real estate, ecology, transmission, land use, health & safety, socioeconomics and public relations. The weight factors were derived using methodology consistent with the modified Delphi process specified in the Siting Guide (EPRI 2002). Weight factors used (1 = least important, 10 = most important) are listed in the table below.

Criterion Number	Criterion	Weight Factor
P1	Cooling Water Supply	9.5
P2	Flooding	3.9
P3	Population	7.6
P4	Hazardous Land Uses	5.0
P5	Ecology	6.1
P6	Wetlands	6.4
P7	Railroad Access	5.6
P8	Transmission Access	8.5
P9	Land Acquisition	6.5

Composite Suitability Ratings – Ratings reflecting the overall suitability of each site were developed by multiplying criterion ratings by the criterion weight factors and summing over all criteria for each site.

Criteria used in this evaluation were derived from the larger set of more detailed criteria listed in Chapter 3 of the EPRI Siting Guide (EPRI 2002). These criteria provide insights into the overall site suitability trade-offs inherent in the available sites within the ROI and were designed to take advantage of data available at this stage of the site selection process.

Results of applying these screening criteria and weight factors are summarized in Table 9.3-4 and Figure 9.3-6 (FPL Aug 2011).

The top eight ranked sites were initially selected as primary sites. This set includes a variety of site characteristics and includes sites that were rated favorably (in the screening criteria evaluations) in comparison with lesser ranked sites from an environmental perspective.

In addition, the St. Lucie and Turkey Point sites were brought forward and included as primary sites based on the fact that they are existing, operating nuclear power plant sites within the ROI. Inclusion of these sites in the set of primary sites allows a detailed evaluation of their unique advantages, including confidence in site characteristics, existing infrastructure, and public acceptance. These sites are retained for further analysis as falling with the special case (described above) for licensed nuclear power plant sites.

The ten primary sites identified for further evaluation are:

- DeSoto
- Glades
- Glades A
- Hendry 1

- Martin
- Martin A
- Okeechobee 1
- Okeechobee 2
- St. Lucie
- Turkey Point

9.3.2.5 Identification of Candidate Sites

To narrow the ten primary sites even further, a more extensive set of 34 general siting criteria, also derived from the EPRI Siting Guide (EPRI 2002), were applied. The list of criteria is shown in Table 9.3-5. The overall process for applying the general site criteria was analogous to that described for the potential sites and involved the same three elements; a different set of weights were developed for the 34 general siting criteria by the same multi-disciplinary committee. Information sources for the primary site evaluations included publicly available data, information available from FPL files, personnel, and large scale satellite photographs.

Composite suitability ratings reflecting the overall suitability of each primary site were developed by multiplying criterion ratings by the criterion weight factors and summing over all criteria for each site (FPL Aug 2011). Results of applying these screening criteria and weight factors to the ten primary sites are summarized in Table 9.3-5 and Figure 9.3-7.

The Okeechobee 1, DeSoto, and Hendry 1 sites rated lowest in the general siting criteria evaluations, and were deferred from further analysis. The remaining seven top-ranked sites included:

- Glades
- Glades A
- Martin
- Martin A
- Okeechobee 2
- St. Lucie

- Turkey Point

Examination of evaluation results indicated that neither Glades A nor Martin A provided significant advantages over the other sites identified in their respective counties (i.e. Glades and Martin). Glades A is farther from the proposed water source, leading to the expectation that it would encounter more cost and regulatory difficulties in water supply compared to Glades. The Martin A site is expected to be questionable with regard to the regulatory feasibility of developing a water supply from the C-44 Canal due to its close geographic proximity to the C-44 Reservoir and Stormwater Treatment Area component of the Indian River Lagoon-South Everglades restoration project. Accordingly, Glades A and Martin A were not carried forward for further consideration as they were capably represented by the existing Glades and Martin sites, respectively. The following five candidate sites were identified:

- Glades
- Martin
- Okeechobee 2
- St. Lucie
- Turkey Point

9.3.2.6 Selection of Proposed Site

As discussed in Subsection 9.3.2.5, the Glades, Martin, Okeechobee 2, St. Lucie, and Turkey Point sites were selected as candidate sites for the FPL COLA. Based on the comprehensive evaluations conducted to this point, all of these sites appear to be feasible locations for a new nuclear power plant.

To select a proposed site for the COLA from this set of candidate sites, additional considerations were evaluated in 2006 to provide further insight on their relative suitability to support FPL's objectives for the COL project and a future nuclear plant.

The objective of these additional considerations for the five candidate site studies was to provide further insight into site conditions and/or to provide further confidence on specific issues that were viewed as important to the COLA site decision. Specific factors considered in this evaluation were as follows:

- Environmental impact – Existence of ecological or environmental permitting issues
- Transmission – Availability of existing right-of-way and cost of upgrades

- Land acquisition – Existing land ownership and expected difficulty of acquiring site (if applicable)
- Reliability (transmission) – Analysis of reliability from a power-transmission perspective
- Reliability (generation) – Qualitative analysis of risk factors for reliable power production and supply
- Public acceptance – Ability to obtain public acceptance to support siting activities
- Political (local) – Governmental/organizational support at the local level
- Political (state) – Governmental and regulatory support at the state and Federal level
- Transmission takeaway – Feasibility of constructing the necessary upgrades to deliver power to the system
- Schedule compatibility – Level of confidence that site will support commencement of COLA activities in January 2007
- Site layout feasibility – Ability of site to accommodate plant layout

Evaluation of these factors was conducted in 2006 by a multi-disciplinary team of FPL professionals with specific expertise, experience, and ongoing involvement in the areas being evaluated; for example, personnel involved in environmental permitting throughout the FPL service territory provided input on environmental matters, and public relations staff provided judgments on public acceptance and political factors.

Results of these evaluations were reported by assigning ratings for each candidate site that ranged from 1 to 3 (1 = more favorable, 3 = less favorable), based on experience and best professional judgment. Each of the ratings was discussed in 2006 by the FPL siting team. The resulting ratings are summarized in Table 9.3-6; information on the basis for these ratings, along with results of the General Siting Criteria evaluations (Subsection 9.3.2.5), are provided in the following paragraphs.

Environmental Impact

The St. Lucie site was rated least favorable because much of the land proposed for development contains red and black mangrove habitat and would incur significant environmental impact. Turkey Point was rated average with respect to environmental impact. Some of the land proposed for development at the Turkey Point site is designated as critical crocodile habitat. Some mitigation may be implemented because the entire cooling canal system is designated as

critical habitat and the proposed area of development is small in relation to the whole canal system. The Glades, Martin, and Okeechobee 2 sites were rated as more favorable because environmental impacts can be mitigated more effectively than at the St. Lucie or Turkey Point sites.[3]

Transmission

Transmission access was originally evaluated in terms of distance to the load center in the greater Miami area and the amount of new right-of-way that would have to be acquired; these factors are described in the screening criteria rating description in Section 5.0 of the Augmentation Report. Based on those evaluations the following ratings were applied to the candidate sites:

- Glades – 2
- Martin – 1
- Okeechobee 2 – 2
- St. Lucie – 3
- Turkey Point – 1

Land Acquisition

The Turkey Point, St. Lucie, and Martin sites are all rated more favorable as these sites are FPL owned properties. The Glades site is rated average because while the property is not owned by FPL, options to purchase exist. The Okeechobee 2 site is rated less favorable because the property is not owned by FPL and purchasing options have not been developed.

3. The assumptions regarding the relative environmental impacts of the sites evaluated included the assumption that there is the potential for crocodile habitat to be impacted at Turkey Point, requiring species-specific mitigation, and that the other candidate sites had more common aquatic resources to be mitigated.

Reliability (Transmission)

The Turkey Point and Martin sites are rated more favorable with respect to transmission reliability. Power generation from a new power plant at Turkey Point could be routed on a geographically diverse corridor, thereby minimizing reliability risks. Transmission from all other sites would be co-located with existing transmission lines with varying degrees of congestion and crossings. Transmission from the St. Lucie site is less favorable as co-location within one heavily used right-of-way would be required.

Reliability (Generation)

The Glades site is rated more favorable due to a lower hurricane frequency and resulting site evacuation and shutdown requirements. The Turkey Point site is rated less favorable due to the slightly higher frequency of hurricanes.

Public Acceptance

The Turkey Point site is rated more favorable because the existing nuclear plant's license renewal received strong local community support. The Glades site also is rated favorable due to demonstrated local government support. The Okeechobee 2 site is rated average because local political leaders have indicated they would support a nuclear power generation project. The Martin and St. Lucie sites do not appear to have a similarly strong supportive base and are rated less favorable.

Political Acceptance (Local)

The Glades and Okeechobee 2 sites are rated more favorable because no rezoning or comprehensive plan amendments would be required for a new nuclear power plant. The Turkey Point site was rated average because no comprehensive plan amendments would be necessary, but some level of rezoning or land use definition appears to be required. The Martin and St. Lucie sites are rated less favorable because both sites would require significant effort with local planning issues.

Political Acceptance (State/Federal)

With respect to regulatory requirements, there is no significant distinction between the candidate sites. The Florida State government has shown strong support for new nuclear power generation. The Martin site could present some resistance due to previously observed political perception surrounding water use issues and Lake Okeechobee water levels. As such, all sites have been rated more favorable, with the exception of the Martin site, which has been rated less favorable.

Transmission Takeaway Feasibility

The Turkey Point and St. Lucie sites are rated more favorable because neither site would require significant acquisition of new transmission right-of-way. The Glades site would require a significant acquisition of new right-of-way, but was rated average because a coal-fired power plant was proposed in the vicinity of the Glades location (at the time the Siting Study was conducted), and a nuclear plant at the site would benefit from earlier work to obtain some portion of the necessary right-of-way. The Martin site also was rated average because existing right-of-way could be utilized, although they are congested in areas. The Okeechobee 2 site is rated less favorable because significant amounts of right-of-way acquisition and new line construction would be required.

Schedule Compatibility

The ability to meet schedule requirements at a site closely parallels the land-acquisition evaluation above. The Turkey Point, St. Lucie, and Martin sites were rated more favorable because they are located on FPL-owned property. The Glades site was rated average as the property is not owned by FPL, but options to purchase exist. The Okeechobee 2 site was rated less favorable because the property is not owned by FPL and purchasing options have not been developed.

Site Layout

The Glades and Okeechobee 2 sites were rated more favorable. Both sites are greenfield sites and would allow the greatest flexibility in developing layouts for a new nuclear power plant. The Martin site was also rated more favorable because a considerable amount of FPL-owned property exists that would provide a similar amount of flexibility. Both existing nuclear power plant sites were rated lower than the greenfield sites because layout flexibility is reduced at each site due to the existing facilities. The Turkey Point site was rated average because there are several potential locations that can be developed. St. Lucie was rated less favorable because the restrictions to available land and surrounding natural features would significantly limit the ability to site new nuclear facilities.

Results of the 11 additional site selection considerations above, combined with the results of the general criteria evaluations (Subsection 9.3.2.5), were used to identify a proposed site as described below.

Results of the evaluations as described above confirm that all of the five candidate sites are viable locations for a nuclear power plant. However, these evaluations do serve to further distinguish among the five candidate sites and identify the most favorable site. The Turkey Point site rates more favorable in 8 of the 12 considerations. With respect to the criteria described above, Turkey Point ranked least favorable in only one (Transmission Reliability), whereas

Martin, Okeechobee and St. Lucie each ranked least favorable in at least three. Glades ranked least favorable in none of these considerations, but its composite score (from the technical analysis reported in Subsection 9.3.2.5) was lowest of all the candidate sites.

Based on these results, the overall ranking of the five candidate sites is as follows:

1. Turkey Point

2. Glades

3. Martin

4. Okeechobee 2

5. St. Lucie

Thus, taking into consideration the results of each evaluation conducted (including satisfying the overall business objectives for the FPL COL project), the Turkey Point site was selected as the proposed site for FPL's new nuclear power generation project.

9.3.3 ALTERNATIVE SITE REVIEW

This subsection reviews the four alternative sites based on the selection criteria suggested in NUREG-1555 to determine whether any of the alternative sites are environmentally preferable or obviously superior to the proposed Turkey Point site.

RG 4.2, *Preparation of Environmental Reports for Nuclear Power Stations* notes: "The applicant is not expected to conduct detailed environmental studies at alternative sites; only preliminary reconnaissance-type investigations need be conducted" (U.S. NRC Jul 1976). The site alternatives described here are compared based on recent information about existing facilities in the surrounding area and existing environmental studies.

Potential impacts from construction and operation of the proposed project at candidate sites other than the proposed site are analyzed, and a single significance level of potential impact (i.e., SMALL, MODERATE, or LARGE) is assigned to each analysis consistent with the criteria that NRC established in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, Footnote 3 as follows:

- SMALL – Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

- MODERATE – Environmental effects are sufficient to alter noticeably, but not to destabilize, any important attribute of the resource.

- LARGE – Environmental effects are clearly noticeable and are sufficient to destabilize any important attributes of the resource.

For some analyses, FPL determined the criteria used by the NRC in NUREG-1437, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, to be appropriate for the analyses presented here, and those criteria were reviewed to assign a significance level in impacts. Impact categories (e.g., land use, socioeconomics) for the alternative sites are the same as those described in Chapter 4 for construction and Chapter 5 for operation of Units 6 & 7 at the Turkey Point site.

For the purpose of alternative site analysis, FPL assumed the same type of power units would be placed at each of the four sites (two Westinghouse AP1000 nuclear power units). However, other design parameters would not necessarily be the same at each of the sites. For example, cooling water storage reservoirs are assumed to be necessary at some but not all alternative sites.

Based on conceptual site layouts developed for each alterative site, FPL estimated that approximately 3360 acres of land acquisition would be required at both the Glades and Okeechobee greenfield sites for the onsite plant components (facility and cooling water storage reservoir). With respect to the 11,300-acre Martin site, which is owned by FPL, the existing 6500-acre reservoir would not be available for two new nuclear units, and a new 3000-acre reservoir would need to be constructed, such that total onsite land requirements at the Martin site would be similar to that required at the two greenfield sites (approximately 3360 acres). Taking into account existing uses on the Martin site – including the existing power plant, cooling pond, the recently constructed solar thermal plant, and other protected areas that are unavailable for development, the amount of remaining land available for development is approximately 568 acres. As a result, FPL would need to acquire approximately 2800 acres of land to develop two nuclear units at this site. Land acquisition would not be required to site the facility at the St. Lucie site because sufficient land (over 900 acres available for development) is already owned by FPL and is designated for power plant activities.

FPL assumed that freshwater sources (primarily surface water) would supply the cooling water needs for the Glades, Martin, and Okeechobee 2 sites. Surface water sources include Lake Okeechobee, a river, or a water canal, and the water would be transferred to the site via underground pipelines. FPL assumed the St. Lucie site would employ the same type of water intake and canal transfer system used for St. Lucie Units 1 & 2 (ocean water). For heat rejection, FPL assumed a closed-loop system with mechanical draft cooling towers for each alternative site.

9.3.3.1 Evaluation of the Glades Site

During the site selection process, the Glades site was originally identified as a nominal 3000-acre undeveloped area in the southeastern region of Glades County approximately 1 mile south of U.S. Highway 27. Nearby towns include Moore Haven (2 miles east), Clewiston (15 miles southeast), La Belle (18 miles west), and Okeechobee (35 miles northeast). The Miami load center is approximately 75 miles southeast of the Glades site. Lake Okeechobee is approximately 5 miles to the northeast. The site is not owned by FPL but is considered potentially available and feasible for a power generation project. Portions of the site are within the 100-year floodplain. The location of the Glades site is shown in Figure 9.3-8.

9.3.3.1.1 Land Use Including Site and Transmission Line Rights-of-Way

Based on the conceptual site layout developed for the Glades greenfield site, the following land requirement assumptions were made which form the basis of the environmental comparison of alternative sites:

- The assumed facility footprint would require approximately 362 acres and the assumed cooling water storage reservoir would require approximately 3000 acres. New facilities at the plant site would include the nuclear power units, support buildings, a switchyard, storage areas, stormwater retention ponds, and deep injection wells for subsurface water disposal.

- The assumed extent of non-transmission linear features, including access road corridors, pipeline corridors and rail access, is as follows:

    — Access road: 23.1 acres – assuming a corridor length of approximately 1.9 miles and a corridor width of 100 feet. Based on conceptual site layouts developed for the Glades site, site access would be from SR 78. A portion of SR 78 would be widened from two lanes to four lanes to accommodate anticipated traffic levels attributable to construction.

    — Rail: 74.8 acres – based on an assumed length of approximately 6.2 miles and corridor width of 100 feet, to provide access to the nearest railway northeast of the site.

    — Intake/makeup pipeline corridors: 3.4 acres, including intake pipeline connecting the reservoir to the nearby C-43 Canal (assumed cooling water source).

- The assumed extent of conceptual transmission corridor routing is approximately 5824 acres based on an assumed length of 121 miles and a corridor width that varies from approximately 200 to 500 feet, connecting the new nuclear units to the existing FPL transmission system at the Andytown Substation in Broward County.

- Based on the sub-totals above for both onsite and offsite plant components, the total area potentially affected at the Glades alternative site is estimated at approximately 9287 acres. With respect to the transmission line corridor included within this total, the estimated acreage requirements assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. However, these estimates provide the basis for an updated and consistent environmental comparison of alternative sites.

- Additional acreage (up to several hundred acres) may be required to support construction activities (e.g., additional laydown areas, batch plant, fill/spoil areas). However, cleared land would be used to the greatest extent possible. The impact on this acreage would be temporary, and it would also be reclaimed to the extent possible following construction.

The majority of the Glades site area is currently in agricultural and farm use. A topographic survey of the nearby, formerly proposed FPL Glades Power Park site, was performed. In general, the topographic survey indicates that there is very little natural slope to the ground surface. The site is surrounded primarily by sugarcane fields.

Based on land use data for year 2002, approximately 82.4 percent of the land in Glades County is farmland (USDA Jun 2004). Glades County is currently the second largest producer of sugar in the state. Like most of the land area in the county, the Glades site is used for agriculture and farm activities. The topography of the site is generally flat with a mean elevation of approximately 15 feet. Portions of the site are included within the 100-year floodplain.

Land use impacts associated with plant construction include both impacts to the site and immediate vicinity, including the new reservoir; and impacts to offsite areas such as transmission, cooling water intake pipelines, and transportation rights-of-way (e.g., road and rail). Construction of a new nuclear power plant would include clearing, dredging, grading, excavation, spoil deposition, and dewatering activities. An area of approximately 362 acres for the main power plant site (major structures including switchyard), which would largely be focused in one central location; and approximately 3000 acres (surface area) for a new reservoir and intake structure would be permanently impacted.

Project construction activities at the Glades site would include filling those portions of the site area that are within the 100-year flood zone an additional 15 feet in elevation to bring them to approximately 29 feet MSL. FPL has determined that sufficient fill material would be available onsite, based on the amount of material that would be excavated for the reservoir and storm water retention ponds.

Project construction would have a long-term impact on the current uses which would change to industrial use. Much of the proposed power plant site area has been cleared and is now used for agricultural activities; over 4000 acres of the plant site area are currently in field crops, primarily

sugarcane. Following construction activities, impacted areas without constructed buildings or transportation infrastructure would be reclaimed to the greatest extent feasible.

Construction at the proposed pipeline corridors would have temporary, minor effects on land use during actual construction due to trenching, equipment movement and material laydown. The ability to use current lands for their existing uses (e.g., farmland) along the proposed pipeline corridor would be temporarily lost during construction. Direct and indirect impacts of construction from the proposed transportation infrastructure would be similar to those for the proposed plant.

Development of the conceptual transmission corridor incorporated the most direct route where possible, while considering potential conflicts with natural or man-made areas where important environmental resources were located, and avoiding populated areas and residences to the extent possible. Whenever possible, the new line was routed along existing transmission rights-of-way. The use of lands that are currently used for forests would be altered. Trees would be replaced by low-growth types of ground cover such as grass. The new transmission corridor would not be expected to preclude agricultural activities near the eventual rights-of-way. The land use in the region, including along the conceptual transmission corridor, is generally rural, sparsely populated, and primarily used for agricultural activities. Glades County is not within the Florida Coastal Zone, and the route for the new transmission lines would not pass through any portion of the Florida Coastal Zone.

Table 9.3-7 includes estimates of the potentially affected area(s) of each land cover type (based on GIS FLUCCS Level III data analysis) for the Glades alternative site, including both onsite and offsite components (i.e., access road, rail, pipeline and transmission corridors). It also further breaks out the land cover types along the assumed conceptual transmission corridor only, given the significant acreage this corridor encompasses (63 percent of the total area). As noted previously, regarding the offsite linear features associated with the projects, the estimated acreage requirements assume corridor widths for transmission which may exceed the area that would actually be disturbed during project construction and operation. These estimates are intended to provide the basis for an updated and consistent environmental comparison of alternative sites.

The proposed project would be a change from current land use at the site. Operational impacts to site land use would include a permanent change in land use for approximately 3500 acres of land for the power plant site, reservoir, and rail/highway site access corridors – that would be generally unavailable for other purposes. This area would be excluded from future agricultural and recreational use for the estimated 60-year life of the AP1000 power units (WEC 2007).

Operational impacts to the site and immediate vicinity also would include maintenance operations on project structures that would be small and temporary in nature.

Operational impacts of transmission lines result primarily from line maintenance, and include right-of-way vegetation clearing and control, transmission line maintenance, and other normal access activities. Additional right-of-way acquisition and development would not normally be required as part of plant operational activities. Maintenance activities would be limited to the immediate right-of-way and would be minimal. New transmission corridors would not be expected to preclude agricultural activities near the eventual rights-of-way. Corridor vegetation management and line maintenance procedures would be established by the transmission service provider.

Other offsite land use impacts as a result of plant operational activities would be minimal, temporary, and limited in the area impacted. Such activities could include pipeline, road, and rail maintenance and auxiliary building maintenance. It is likely that most lands above the proposed water intake pipeline and related areas of construction could continue to be used for ranching, farming and any passive uses. The proposed transportation infrastructure could result in the loss of a small amount of ranch land, pasture land and forested land in areas where access road improvements/widening and a rail spur would be needed.

For the purpose of this analysis, land use impacts are considered small if less than 3000 acres are disturbed (including plant footprint, reservoir, rights-of-way, and corridors) and there are no major changes to land use. Impacts are considered moderate if land disturbance is greater than 3000 acres or there are major changes to land use; and large if land disturbance is greater than 6000 acres and there are major changes to land use. Based on a potentially affected area of approximately 9287 acres and the permanent change of land use from agricultural to industrial, land use impacts associated with site preparation, construction, and operation of the proposed nuclear plant at the Glades alternative site and the corresponding conceptual transmission corridor would be LARGE.

9.3.3.1.2 Air Quality

Glades County (the Glades site is within Glades County) is part of the Southwest Florida Intrastate Air Quality Control Region. Glades County, along with the entire state of Florida, is designated as attainment or unclassifiable with respect to the National Ambient Air Quality Standards (NAAQS) (40 CFR 81.310). The nearest non-attainment area is in Georgia, several hundred miles north northwest of the Glades site (40 CFR 81.311).

Criteria pollutant emissions from construction and operation of the proposed nuclear plant at the Glades site would be comparable to the emissions generated at the Turkey Point site, as described in Subsections 4.4.1.2 and 5.8.1.2, respectively. Construction impacts would be temporary and would be similar to any large-scale construction project. Particulate emissions in the form of dust from disturbed land, roads, and construction activities would be generated. Mitigation measures similar to those described in Subsection 4.4.1.2 would be applied as

necessary. Criteria pollutants would also be generated from onsite fossil-fueled construction equipment and construction vehicles, and from commuter and delivery vehicles that travel to and from the site. The quantity of criteria pollutant emissions generated by construction activities would be small compared to total vehicular emissions in the region. It is assumed unlikely that construction-related emissions would cause any violation of the NAAQS.

The project would include standby diesel generators and diesel-driven fire pumps. Annual emissions from these sources are listed in Table 3.6-4. It is expected that standby diesel generators and auxiliary power systems would see limited use and, when used, would operate for a short time interval. The pollutant emissions generated by these systems (nonradiological) would be regulated by the Florida Department of Environmental Protection (FDEP) in accordance with the air rules published under Florida Administrative Code (F.A.C.) Chapter 62. These rules cover general air pollution control provisions, stationary source requirements, preconstruction review, emission standards, air monitoring requirements, and other rules for control of air pollutant emissions. Airborne release of criteria pollutant and hazardous air pollutant emissions would be small and would comply with FDEP rules (FDEP 2008a).

Nonradiological emissions can potentially affect regional visibility, and visibility is an important feature at Federal Class I areas. (The Federal Class I area nearest to the Glades site is the Everglades National Park approximately 63 miles to the south.) Because of the significant distance, and because the anticipated emission levels would be small, pollutant emissions attributable to operation of the new nuclear units would have a negligible impact on visibility at a Federal Class I area. Unfavorable psychometric conditions can result in visible vapor plumes from cooling tower operations. These plumes may be visible for several miles, but would not impact visibility or scenic vistas at any Federal Class I area.

Air quality impacts are considered small if the increase in regional pollutant concentrations attributable to the source (1) would not appreciably alter visibility, (2) would not exceed EPA significant impact levels, and (3) would not cause a violation of the most restrictive ambient air quality standards. Based on this evaluation metric, it is anticipated that the impacts to air quality from construction and operation would be SMALL.

9.3.3.1.3 Hydrology, Water Use, and Water Quality

Florida is divided into five watershed management areas. The Glades site is in the Kissimmee-Everglades watershed and falls under the jurisdiction of the South Florida Water Management District (SFWMD). This watershed region spans over 16 counties and is logically divided into several river basins: Kissimmee River, Upper East Coast, Lower East Coast (which includes the entire southeast coast and the Everglades), and Lower West Coast (which includes the Big Cypress and Caloosahatchee Rivers). This region is the largest watershed region in Florida and is home to 40 percent of Florida's population. The region also contains the Everglades (the

largest subtropical wetland in the United States) and Lake Okeechobee, the second largest freshwater lake in the United States. This lake is of national importance because its water has diverse usage and a large number of people depend on it for agricultural and domestic purposes (University of Florida Jun 2007). Lake Okeechobee is at the center of the south Florida regional water management system. This relatively shallow lake has an average depth of 9 feet and covers approximately 730 square miles. The Lake Okeechobee drainage basin covers more than 4600 square miles (SFWMD 2008).

Water quality and ecological health of Lake Okeechobee are adversely affected by excessive nutrient loading, extreme high and low water levels, and the proliferation of exotic species. To address restoration goals for the lake, the SFWMD, in coordination with the FDEP and the Florida Department of Agricultural and Consumer Services, has developed the Lake Okeechobee Watershed Construction Project Technical Plan. The plan was developed in response to the *Northern Everglades and Estuaries Protection Program* that the Florida Legislature signed into law in 2007. Primary components of the plan include implementing agricultural management practices, constructing treatment wetlands to clean water flows into the lake, and creating 900,000 to 1.3 million acre-feet of water storage north of the lake (SFWMD 2008).

In 2000, the average daily surface freshwater withdrawals in Glades County totaled 53.6 million gallons, which represents 72 percent of the total daily withdrawal rate for the county (USGS Dec 2004). Major surface freshwater sources near the Glades site include Lake Okeechobee (5 miles away) and the C-43 Channel (adjacent to the proposed site reservoir).

The entire state of Florida, and portions of southern Alabama, southeastern Georgia, and southern South Carolina, are atop the Floridan aquifer. This aquifer covers some 100,000 square miles and is one of the most productive aquifers in the world. The Floridan aquifer system provides water for several large cities, such as Savannah and Brunswick in Georgia; and Jacksonville, Tallahassee, Orlando, Tampa Bay, and St. Petersburg in Florida. In addition, the aquifer system provides water for hundreds of thousands of people in smaller communities and rural areas. Locally, the Floridan aquifer is intensively pumped for industrial and irrigation supplies (USGS Jul 1980).

Principal groundwater sources in Glades County include the surficial aquifer and the middle Floridan aquifer. Within Glades County, in year 2000, average daily (fresh) groundwater withdrawals from these aquifers totaled approximately 21 million gallons per day (mgd), and surface freshwater withdrawals totaled approximately 53.6 million gallons per day. Approximately 92 percent of freshwater withdrawals (ground and surface) in Glades County (69 mgd) are used for agriculture. Fresh groundwater was the only source of public water supply in Glades County (USGS Dec 2004).

The depth to the water table near the site is less than 30 feet below ground level. Therefore, it is expected that dewatering may be necessary during the construction phase. This may require construction of temporary retention ponds to allow sediment-laden waters to settle before discharge to surface waters. Dewatering activities would be subject to National Pollutant Discharge Elimination System (NPDES) permit requirements to avoid adverse impacts on surface waters.

Land subsidence related to karst terrain is not anticipated at the site. The site is in karst Area II, where the surface cover is reported to be 30 to 200 feet thick. In such areas, sinkholes are reported to be few, shallow, of small diameter, and develop gradually (Sinclair, et. al, 1985). Furthermore, there were no indications of karst geology, such as voids or loss of circulation, encountered in borings drilled nearby as part of the site investigation for the proposed Glades Power Park, approximately 2 miles away.

Site groundwater wells are expected to be installed in the middle Floridan aquifer. Since the site is inland from the coast, lateral saltwater intrusion is not likely. However, there is a potential for saltwater to migrate vertically into the middle Floridan aquifer from the saline deeper Floridan aquifer. Since the middle Floridan aquifer already produces brackish water, resultant saltwater intrusion could require additional osmosis or dilution with clean water to satisfy potable water quality standards.

As shown in Subsection 4.2.2.1, the peak construction water demand is estimated at 565 gallons per minute (gpm), which is slightly greater than 1 cfs, and the peak estimated potable water demand for operations is 2553 gpm (Table 3.3-1). As described in Section 3.3, an estimated 100 cfs of freshwater would be required to replace consumptive water use associated with operation of the proposed nuclear power units. Lake Okeechobee offers a potential water supply of approximately 360 cfs, and the annual average flow of the Caloosahatchee River/Canal near the site is approximately 592 cfs. The estimated groundwater potential at the Glades site is approximately 155 cfs. These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Glades site. Water use impacts are considered small when water sources are readily available to meet demand. A permittability assessment of the probability of obtaining water permits at the Glades alternative site would be required to develop the documentation necessary to firmly establish conditions under which water from these sources could be made available. Such analysis is beyond the reconnaissance-level evaluations required for alternatives analysis. Instead, these evaluations must be based on statutory and regulatory criteria requiring site-specific analysis of reasonable beneficial use, existing legal users, and public interest factors. Accordingly, because adequate water sources are physically available nearby, the impact on regional water use for both construction and operation would be SMALL.

Water quality impacts are considered small when changes in water quality do not affect or minimally affect aquatic biota and water uses (NUREG-1437). It is assumed that a closed loop, mechanical draft, tower-cooled system would be used for power cycle waste heat rejection, whereby blowdown waters are injected into the Boulder Zone (The Boulder Zone is a deep underground, extremely permeable, cavernous region in southeastern Florida. It is called the Boulder Zone not because it contains boulders, but instead, because efforts to drill into this zone pose difficulties similar to the difficulties posed by subsurface boulders). Plant construction and operation activities at the Glades site would be performed under the authorization of an NPDES permit (construction) Industrial Wastewater (IWW) permit (surface water), or Underground Injection Control (UIC) (groundwater) permit issued by the FDEP (FDEP 2008b). Any releases from the power plant site into Lake Okeechobee, regional streams, or groundwater as result of construction or operation would be regulated by the FDEP through the NPDES, IWW, or UIC permit process to ensure that water quality is protected. To ensure that wetlands and streams are not harmed by petroleum products or other industrial chemicals, FPL would restrict certain activities (e.g., transfer and filling operations) that involve the use of petroleum products and solvents to designated areas such as laydown, fabrication, and shop areas. In addition, construction activities would be guided by a stormwater pollution prevention plan and construction-phase spill prevention, control, and countermeasures plan similar to those proposed for the Turkey Point site as described in Section 4.2. Therefore, any impacts to surface water during plant construction would be SMALL and would not warrant mitigation beyond best management practices required by the permits. The impacts to water quality during operations would also be SMALL because the IWW and UIC permit requirements would ensure that adequate measures are applied to protect water quality.

9.3.3.1.4 Terrestrial Resources and Protected Species

Table 9.3-7 includes estimates of the potentially affected area(s) of each land cover type within the project area for both onsite and offsite components, including any natural vegetation and wetland areas. As can be seen in Table 9.3-7, the Glades site is developed for agricultural and farm use. A topographic survey of the nearby formerly proposed FPL Glades Power Park site was performed. In general, the topographic survey indicates that there is very little natural slope to the ground surface. The average ground surface elevation is approximately 15 feet MSL, and the plant area is surrounded primarily by sugarcane fields. The site has been modified to allow for irrigation using an irrigation/drainage ditch network throughout the site. Water levels in the ditches are controlled manually with pumps to support the irrigation process. Most of the site is an active sugarcane field that is unsuitable habitat for most wildlife species because of the lack of native vegetation and the amount and frequency of human disturbance. The fields are regularly treated with herbicides and pesticides, and the agricultural ditches are routinely maintained. However, wading birds and alligators do use the irrigation canals and opportunistically forage in areas of heavy machinery usage such as ditch maintenance sites and field clearing/preparation

areas for replanting. The wetlands within the surrounding sugarcane fields also provide habitat for avian species and common herpetofauna (FPL Dec 2006).

As shown in Table 9.3-7, there are approximately 306 acres of wetlands within the project area, excluding the conceptual transmission corridor, which could be directly impacted from project construction. Of these, approximately 238 acres are identified as forested wetlands and considered to be high quality. Any wetland functions that are impacted during construction would be replaced or restored. The footprint of the new facilities, excluding the assumed conceptual transmission corridor, would cover approximately 3463 acres.

Non-listed wildlife observed at the nearby formerly proposed FPL Glades Power Park site include a variety of common avian species, such as cattle egret (*Bubulcus ibis*), barn swallow (*Hirundo rustica*), loggerhead shrike (*Lanius ludovicianus*), black vulture (*Coragyps atratus*), turkey vulture (*Cathartes aura*), mourning dove (*Zenaida macroura*), redwinged blackbird (*Agelaius phoeniceus*), ground dove (*Columbina passerina*), swallow-tail kite (*Elanoides forficatus*), cardinal (*Cardinalis cardinalis*), moorhen (*Gallinula chloropus*), green heron (*Butorides virescens*), great egret (*Ardea albus*), glossy ibis (*Plegadis falcinellus*), red-shouldered hawk (*Buteo lineatus*), anhinga (*Anhinga anhinga*), least bittern (*Ixobrychus exilis*), great blue heron (*Ardea herodias*), osprey (*Pandion halieatus*), common nighthawk (*Chordeiles minor*), red-tailed hawk (*Buteo jamaicense*), marsh hawk (*Circus cyaneus*), coot (*Fulica americana*), white-eyed vireo (*Vireo griseus*), black-crowned night heron (*Nycticorax nycticorax*), yellow-crowned night heron (*Nycticorax violaceus*), bobwhite quail (*Colinus virginianus*), purple gallinule (*Porphyrio martinica*), red-bellied woodpecker (*Melanerpes carolinus*), and Eastern meadowlark (*Sturnella magna*) (FPL Dec 2006).

Mammalian species directly observed or identified through tracks or scat include Eastern cottontail (*Sylvilagus floridanus*), feral hog (*Sus scrofa*), raccoon (*Procyon lotor*), armadillo (*Dasypus novemcinctus*), bobcat (*Lynx rufus*), coyote (*Canis latrans*), otter (*Lutra canadensis*), and white-tailed deer (*Odocoileus virginianus*). Herpetofauna observed include Florida cooter (*Pseudemys floridana*), green tree frog (*Hyla cinerea*), soft-shelled turtle (*Trionyx ferox*), pig frog (*Rana grylio*), leopard frog (*Rana pipiens*), and broadhead skink (*Eumeces laticeps*) (FPL Dec 2006).

Threatened, endangered, and/or species of special concern that exist in Glades County are listed in Table 9.3-8. The site has been largely cleared of native vegetation, graded, and planted with sugarcane. The Florida Natural Areas Inventory (FNAI) element occurrence report for the formerly proposed FPL Glades Power Park did not include any documented occurrences of listed plants within that site and vicinity. For fauna, the formerly proposed FPL Glades Power Park site was surveyed in August and December 2006 through pedestrian and vehicular surveys, and observations of protected species were recorded. Three federally listed species – the wood stork, the crested caracara, and the Everglades snail kite – were observed at that site, while seven

species listed by the state were identified. These species include the little blue heron, snowy egret, white ibis, tricolor heron, sandhill cranes and American alligator. No nesting areas were observed, nor do any critical wildlife habitats exist on the site (FPL Dec 2006).

The irrigation ditches within the site provide foraging habitat for a variety of wading birds, which although not classified as threatened or endangered by the U.S. Fish and Wildlife Service (USFWS) or the Florida Fish and Wildlife Conservation Commission (FFWCC), are considered species of special concern by the FFWCC. These include the little blue heron, snowy egret, white ibis, and tricolor heron. A few individual wood storks were also observed associated with irrigation ditches. The wood stork is classified as endangered by both the USFWS and the FFWCC. American alligators also use the irrigation ditches at the site. The alligator is not classified as threatened or endangered, but is listed as a species of special concern by the FFWCC and listed by the USFWS because of its similarity in appearance to the endangered American crocodile (*Crocodylus acutus*) (FPL Dec 2006).

According to the FFWCC Bald Eagle Nest Location Database, no active bald eagle (*Haliaeetus leucocephalus*) nests are at the Glades site. The closest nest is approximately 6 miles from the project area: Nest GL018 is west of the site at 26°47.98′ N 81°16.04′ W (Section 19, Township 42 South, Range 31 East) (FFWCC 2008a).

Further field surveys would be conducted for federally listed and state-protected species as part of the permitting process before any land preparation or construction activities began at the site or along associated transmission or pipeline corridors. Land preparation activities associated with construction of the plant and transmission lines would be conducted in accordance with federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices (e.g., directed drainage ditches, silt fencing) (FPL Dec 2006).

As described in Subsection 9.3.3.1.1, the conceptual transmission corridor connecting the Glades site to the existing FPL transmission system via the Andytown Substation in Broward County, is approximately 121 miles long and varies in width between 200 and 500 feet. The most direct route was generally used between terminations with consideration also given to avoiding possible conflicts with natural areas where important environmental resources are located.

As shown in Table 9.3-7, there are approximately 1567 acres of wetlands found within the conceptual transmission corridor; approximately 411 acres of which are forested wetlands and considered to be high quality. This compares to a 5824-acre area potentially affected by the conceptual transmission corridor, based on the dimensions above. However, the estimated acreage requirements for the conceptual transmission corridor assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation.

These estimates are used to provide the basis for an updated and consistent environmental comparison of alternative sites.

Cooling tower operations can generate vapor plumes that drift downwind. Salt and mineral deposits in the vapor plumes have the potential to adversely impact sensitive plant and animal communities through changes in water and soil chemistry. However, the freshwater sources identified for the Glades site have modest levels of salts and dissolved minerals. Therefore, the impact of salt and mineral deposits from vapor drift would be minimal. The use of drift eliminators, along with proper tower design and operation, would further minimize the potential for impacts.

For the purpose of this analysis, impacts to terrestrial resources are considered small if no sensitive habitats, including wetlands, are disturbed and no important species are affected. Glades County has a low number of sensitive species and there are no known sensitive species onsite. However, the 121-mile conceptual transmission corridor includes a significant area (5824 acres). In addition, up to 1873 acres of wetlands (approximately 650 acres of high quality wetlands) within the entire project area (onsite and offsite features) could potentially be affected by project construction and operation. Construction of the plant and reservoir would result in a loss of primarily agricultural land that may serve as habitat to various common terrestrial species; however, the creation of a new reservoir to support plant operation would provide new habitat for birds and waterfowl that would not be adversely affected by plant operation. FPL concluded that impacts to terrestrial resources, including endangered and threatened species, from construction and operation of the proposed nuclear plant and conceptual transmission corridor at the Glades alternative site would be MODERATE.

9.3.3.1.5 Aquatic Resources and Protected Species

The Glades site is just north of the C-43 Channel and Lake Hicpochee and approximately 5 miles from Lake Okeechobee. Lake Hicpochee sometimes does not resemble a lake and often looks like a sandy desert plain (U.S. Power Squadrons 2008). The lake changes in size as Lake Okeechobee is drained to meet proper levels and acts as a stormwater discharge area. The C-43 Channel connects to Lake Okeechobee just east of the site, and includes similar aquatic resources to those found in Lake Okeechobee.

Lake Okeechobee is at the center of the south Florida regional water management system. The massive lake is a 730-square-mile, relatively shallow lake with an average depth of 9 feet and is the second-largest freshwater lake wholly within the continental United States, second only to Lake Michigan. The Lake Okeechobee drainage basin covers more than 4600 square miles (SFWMD 2008).

Lake Okeechobee supports a nationally recognized sport fishery for largemouth bass (*Micropterus salmoides*) and black crappie (*Pomoxis nigromaculatus*), as well as a commercial

fishery for various catfish and bream (*Lepomis spp.*). These fisheries generate nearly $30 million per year for the local economies, and they have an asset value in excess of $100 million. Another estimate places the value of the recreational fish species at more than $300 million. In addition to the sport and commercial species, Lake Okeechobee supports a diverse community of fish, including (in total) 41 species. These fish are a food resource for wading birds, alligators, and other animals that use the lake (SFWMD 2005a).

For the purpose of this analysis, impacts to aquatic resources are considered small if no sensitive habitats are disturbed and no important species are affected. Water from the C-43 Channel via pipeline is assumed to be the source to cool the new nuclear units constructed at the Glades alternative site. Although recreational sport fish and other aquatic species would be temporarily displaced during construction of a water intake structure, they would be expected to recolonize the area after construction is complete. No listed fish species are known to exist in Glades County (FNAI 2011), that includes the C-43 Channel and the portion of Lake Okeechobee near the Glades site. One state-listed amphibian, the gopher frog (*Rana capito*), has been documented or observed in Glades County. Field surveys would be conducted for federally listed and state-protected aquatic species as part of the permit process before any land preparation or construction activities began at the site or along associated transmission corridors. Because of this, and because land clearing associated with construction of the plant and transmission lines would be conducted in accordance with federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices, impacts to aquatic resources, including endangered and threatened species, from construction of nuclear power facilities at the Glades site would be SMALL.

There would be no direct discharges to the nearby surface waters from plant operation since plant design assumes discharge by underground injection. The most likely aquatic impact from nuclear operations at the Glades site would be entrainment and impingement of aquatic organisms in the C-43 Channel. Because the EPA requires facilities to meet criteria designed to protect organisms from entrainment and impingement, the potential for environmental impacts to aquatic resources, including endangered and threatened species, from nuclear power facility operations at the Glades site would be SMALL.

9.3.3.1.6 Socioeconomics

This subsection evaluates the social and economic impacts to the region from construction and operation of the proposed nuclear plant at the Glades site. Much of the socioeconomic analysis relies on census data gathered by the United States Census Bureau (USCB). The USCB performs an extensive census every 10 years. At the time this evaluation was performed, the most recent decennial U.S. census was conducted in 2000. The USCB assembles the decennial census data into a wide range of reports that can be used to characterize socioeconomic conditions of a region. In addition, the NRC sponsored development of a computer program

called SECPOP2000 that enables an analyst to quickly assemble and quantify customized regional socioeconomic information. However, this program does not produce results for years later than 2000 (U.S. NRC Aug 2003). For years that fall between each decennial census, the USCB issues estimates based on surveys and statistical models. However, the types of data collected and assembled for intermediate years is less extensive than for years when a decennial census is performed; therefore, the decennial census provides the most comprehensive information.

Because the decennial census provides the most comprehensive information, and because the NRC software tool, SECPOP2000, is not available for intermediate years, information from the 2000 census is chosen as a common baseline for socioeconomic comparison for this analysis. Published census data for later years, if available, is presented as supplemental information.

9.3.3.1.6.1 Physical Impacts

Construction activities can cause temporary localized physical impacts such as noise, odor, fugitive dust, vehicle exhaust emissions, ground vibration, and shock from blast activities. The use of public roadways and railways would be necessary to transport construction materials and equipment to the site. Most of the construction activities would occur within the boundaries of the Glades site; however, an access road and a railway connection spur would be constructed on lands adjacent to the site. These new transportation rights-of-way would be routed to avoid residences and populated areas, however, a portion of SR 78 would be widened by two lanes to accommodate anticipated traffic levels attributable to project construction; some residences and commercial services could be temporarily affected during construction. In addition, the conceptual site layout developed for the site includes construction of a 121-mile conceptual transmission corridor that would include off-site impacts. Other offsite areas that would support construction activities (for example, borrow pits, quarries, and disposal sites) are expected to be already permitted and operational. Impacts on those facilities from construction of the new plant would be small incremental impacts from those due to their normal operations.

Potential impacts from power plant operations include noise, odors, exhausts, thermal emissions, and visual intrusions. Operational noise would be generated by pumps, fans, transformers, turbines, generators, onsite traffic, and switchyard equipment. Noise levels attenuate rapidly with distance so that ambient noise levels (attributable to power plant operations) would be minimal at the site boundary. Also, the Glades site is in a rural area surrounded by agricultural land, with few residents in the area. Commuter traffic would be controlled by speed limits. Good road conditions and appropriate speed limits would minimize the dust and noise level generated by the delivery trucks and site workers that travel to and from the site.

The project would have standby diesel generators and auxiliary power systems. Air quality permits would govern operation of this equipment to ensure that air emissions comply with

regulations. In addition, the generators would be operated on a limited, short-term basis. Normal plant operations would not use a quantity of chemicals that could generate odors that exceed odor threshold values.

Physical impacts are considered small when offsite areas are not affected, or only minimally or temporarily affected by noise, odor, dust, emissions, vibration, or shock. In summary, construction activities would be temporary and would occur primarily within the boundaries of the Glades site. Offsite impacts would represent small incremental changes to offsite services that support construction activities. During station operations, ambient noise levels would be minimal at the site boundary. Air quality permits would be required for the diesel generators to ensure emissions comply with regulatory guidelines, and chemical use would be limited, which should limit odors. Therefore, the physical impacts of construction and operation of the new units at the Glades site would be SMALL.

9.3.3.1.6.2 Demography

The population distribution within and around the Glades site is low with typical rural characteristics, and satisfies the 10 CFR Part 100 definition of a low population zone. The nearest population center is Moore Haven, approximately 2 miles east, with a population of 1635 residents. The nearest population center larger than 25,000 residents is Fort Myers, approximately 45 miles west. Conterminous counties include Highlands to the north, Okeechobee to the northeast, Martin to the east, Palm Beach to the southeast, Hendry to the south, Lee to the southwest, Charlotte to the west, and DeSoto to the northwest. Other counties within 50 miles include Hardee to the northwest, St. Lucie to the northeast, Broward to the southeast, and Collier to the south.

To determine which counties best represent the ROI for socioeconomic analysis of the Glades site, counties that fall within 50 miles around the Glades site were initially identified. Several factors were then considered to determine which of these counties would best represent the ROI. These factors, listed below, are evaluated based on historical data from the USCB. Key assumptions of the ROI determination are that (1) workers will seek to live within 50 air miles of the site and within a 60-minute commute time and (2) most workers will seek to live in population centers that generally offer more amenities (stores, medical facilities, schools, churches, a larger selection of houses, etc.) than rural locations.

Factors Considered to Determine Which Counties Would Best Represent the ROI

- County population and population density
- Populations of the largest population centers
- Geographic locations of the population centers in relation to the Glades site

- The land fraction of nearby counties that falls within 50 miles of the site
- Relative distance from nearby counties to the site
- Estimated travel distance and estimated travel time from the population centers to the site
- Mean travel time to work
- County employment
- Worker commuter patterns to and from counties conterminous the site

Based on the results of this evaluation, the counties that best represent the ROI for socioeconomic analysis of the Glades site include Glades, Hendry, Lee, and Okeechobee. Because there is no reliable method to predict the distribution of the workforce among these four counties, the ROI is generally treated as a whole for much of the socioeconomic analysis.

Based on the 2000 census, the total population of the ROI was 523,584, that included 10,576 in Glades County, 36,210 in Hendry County; 440,888 in Lee County, and 35,910 in Okeechobee County (USCB 2000). Census estimates for 2007 showed an ROI population of 681,595, that included 11,109 in Glades County, 39,611 in Hendry County, 590,564 in Lee County, and 40,311 in Okeechobee County (USCB 2009).

NRC guidelines have been established to assess the demographic sparseness and proximity of a proposed site. Sparseness is a combined measure of (1) the population density within 20 miles of the site and (2) the relative population of the nearest metropolitan area within 20 miles of the site. Proximity is a combined measure of (1) the population density within 50 miles of the site and (2) the relative population of the nearest metropolitan area within 50 miles of the site. Based on the sparseness-proximity evaluation, a site is categorized as low, medium, or high (NUREG-1437).

The land area within 20 miles of the Glades site (i.e., excluding water bodies such as Lake Okeechobee) is 979.5 square miles, and based on 2000 census data, the population of this area was 39,196. This yields a population density of 40 people per square mile, based on land area. There are no cities within 20 miles of the Glades site that have a population greater than 25,000. Therefore, the sparseness level is 2 based on a population density of 40 to 60 people per square mile and no community greater than 25,000 people within 20 miles (NUREG-1437).

Similarly, the land area within 50 miles of the Glades site is 6540.3 square miles, and the population of this area was 512,911. This yields a population density of 78.4 people per square mile. There are no cities within 50 miles of the Glades site that have a population greater than 100,000. Therefore, based on NRC guidelines, the proximity level is 2 based on a population

density of 50 to 190 people per square mile and no city greater than 100,000 people within 50 miles. Therefore, the Glades site has a sparseness-proximity measure of 2.2, which is categorized as medium (NUREG-1437).

Based on FPL estimates, the peak construction workforce for the project would be 3548 construction workers. Operations would overlap with peak construction activity for a period of time. Therefore, in addition to the construction workforce, there would be a small number (99) of operations workers on the site during the peak construction period, and some of these workers would also relocate to the area. Because of the location of the Glades site relative to population centers, FPL assumed that 70 percent of the construction workers and 85 percent of the operation workers would relocate from outside the ROI. FPL further assumed that 70 percent of construction workforce and 100 percent of the operation workforce that moved to the area would bring their families. Based on these assumptions, 2484 construction and 84 operation workers would relocate to the area during the project construction phase, and 1823 of these workers would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total increase in population attributable to the peak total workforce at the Glades site would be 6669 people. An influx of 6669 people represents a 1.3 percent increase in the ROI population of 523,584. Impacts are considered small if plant-related population growth is less than 5 percent of the area's total population (NUREG-1437). Therefore, this would pose a SMALL impact on population for the ROI.

FPL estimated the total onsite operations workforce to be 1050 workers, and that 85 percent of these workers (893) would relocate from outside the ROI. For this analysis, FPL assumed that 100 percent of operations workers who relocate will bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total population increase attributable to project operations is 2901 people. This represents a 0.6 percent increase in the four-county ROI population. This would pose a SMALL impact on population for the ROI.

9.3.3.1.6.3 Economy

Based on 2000 census data, Glades County had a civilian labor force of 4034 people and an unemployment rate of 8.8 percent; Hendry County had a civilian labor force of 15,814 people and an unemployment rate of 7.8 percent; Lee County had a civilian labor force of 193,651 people and an unemployment rate of 3.7 percent; and Okeechobee County had a civilian labor force of 14,863 people and an unemployment rate of 4.7 percent. For the entire ROI, 99.9 percent of the labor force was part of the civilian labor force and 0.1 percent was in the armed forces. Of the civilian labor force, 95.8 percent are employed and 4.2 percent are unemployed. The overall unemployment rate for the four-county ROI is slightly lower than that of the state, which is 5.6 percent (USCB 2000).

The economies of the four counties in the ROI are very similar, dominated primarily by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force resides in Lee County (USCB 2000).

Based on the assumptions stated above, the number of workers who relocate from outside the area would include 70 percent of the 3548 peak construction workers and 85 percent of the 99 operations workers for a total of 2568 workers. An influx of 2568 construction and operation workers from outside the region would have positive economic impacts in the four-county region. Based on a multiplier of 1.7604 jobs (direct and indirect) for every construction job and 2.3016 for every operation job (BEA Aug 2009), an influx of 2568 construction and operation workers would create 2006 indirect jobs, for a total of 4574 new jobs in the ROI. This represents a 2 percent increase in the total labor force in the ROI. Economic effects are considered small if peak employment accounts for less than 5 percent of area employment (NUREG-1437). The creation of direct and indirect jobs could potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic impacts attributable to project construction would be beneficial and SMALL within the ROI.

An estimated 1050 workers would be required for the operation of two nuclear power facilities at the Glades site (U.S. DOE May 2004), and FPL assumes that 85 percent of these employees (893) would migrate into the region. Based on a multiplier of 2.3016 jobs (direct and indirect) for every operations job at the new units (BEA Aug 2009), an influx of 893 workers would create 1162 indirect jobs for a total of 2054 new jobs in the region. This represents a 0.9 percent increase in the total labor force in the ROI. The creation of direct and indirect jobs could potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic impacts attributable to project operation would be beneficial and SMALL within the ROI.

9.3.3.1.6.4 Taxes

Taxes collected as a result of construction and operation of the new nuclear units at the Glades site would benefit the state and local tax authorities. FPL would pay property taxes to each taxing authority whose boundaries would contain the plant. Tax payments would be based on the assessed valuation of the plant and local tax rates. If the plant site straddled a jurisdictional boundary, FPL would pay taxes to both entities based on the assessed valuation within each entity.

As described in Subsection 4.4.2.2.2, it is not clear whether FPL corporate income taxes would increase as a result of construction of the new units at the Glades site, because the units would not generate revenues until they became operational. However, once the units were placed in

service, Glades County property taxes would begin and would continue for the 60-year operational life of the facility.

FPL assumed that annual property tax payments at Glades site would be similar to those paid by the nuclear units at Turkey Point plant. In 2007, the annual tax payment for the two units at the Turkey Point nuclear power plant was $6,902,670. For the 2007 fiscal year, Glades County had property tax revenues of $4,735,034 (State of Florida, Mar 2008a).

With respect to the school district, in Florida, local revenue for the school districts is derived almost entirely from property taxes levied by Florida's 67 counties, each of which constitutes a school district (Florida Department of Education 2008). As described in Subsection 2.5.2.3.5, the state of Florida has an established equalized funding program that reallocates tax base funds from counties that have a high economic tax base to counties that have a low economic tax base. The Florida Education Finance Program is the primary mechanism to fund the operational costs of Florida school districts. Funding is based on the number of full-time equivalent students, and considers variations in several factors to determine funding for each district: local property tax bases, education program costs, costs of living, and costs for equivalent educational programs because of the density and distribution of the student population.

It should be noted that school property tax payments would be based on the location of the plant and not necessarily on the district(s) attended by most of the workers' children. Therefore, it is not possible to assess the direct impact of the plant on the school district. In addition, the impact of plant construction and operation on the special tax districts is not assessed here because most of the property tax payment from the plant would go to the county and the school district(s).

The benefits of taxes are considered small when new tax payments by the nuclear plant constitute less than 10 percent of total revenues for local jurisdictions and large when new tax payments represent more than 20 percent of total revenues (NUREG-1437). Therefore, based on the county portion of the FPL property tax payment for the new units, 59 percent of the 2007 property tax revenues for Glades County would be provided by FPL and would constitute a LARGE positive impact.

9.3.3.1.6.5 Transportation

Principal road access to the Glades site would be from U.S. Highway 27/SR 78, both of which run concurrently in an east-west orientation along the northern boundary of the site. This road is a four-lane divided highway. Approximately 2 miles west of the site, U.S. Highway 27/SR 78 diverge, such that U.S. Highway 27 spans northward toward Palmdale and Venus communities, and SR 78 generally spans westward toward La Belle. U.S. Highway 27 and SR 78 also diverge approximately 2 miles east of the site, so that U.S. Highway 27 continues eastward through Moore Haven, and SR 78 continues northward toward Lakeport, Buckhead Ridge, and

Okeechobee. Therefore, commuters from the west (La Belle) would travel eastward along U.S. Highway 27 and SR 78; those from the northwest (Venus, Palmdale) would travel eastward along U.S. Highway 27; those from the northeast (Lakeport, Buckhead Ridge, Okeechobee) would travel south along SR 78; and those from the east and southeast (Moore Haven, Clewiston, Harlem, Lake Harbor, Belle Glade) would travel westward along U.S. Highway 27. Based on the conceptual site layout developed for the Glades site, access to the site is assumed to be provided from SR 78 where it diverges south of U.S. Highway 27 just west of the site. SR 78 is a two-lane undivided rural highway.

The Florida Department of Transportation (FDOT) reports the average annual daily traffic (AADT), the K_{100} demand factor, and direction factors (D-factors) at several points along the travel routes to the site. The product of these parameters yields the directional peak hour volume that is the volume of traffic in the most congested direction for the most congested hour of the day. Monitored locations include U.S. Highway 27 just west of the site at the confluence of U.S. Highway 27 and SR 78, U.S. Highway 27 just east of the site within Moore Haven, and the stretch of SR 78 that spans just north of the site. The AADT count and directional peak hour volume of the western location along U.S. Highway 27 is 7800 vehicles per day and 424 vehicles per hour (FDOT 2008). This directional peak hour volume classifies this western portion of the roadway as a level of service (LOS) of A (FDOT 2007), and the remaining peak hour capacity is 1776 vehicles. In general terms, LOS is an indicator of how effectively the road accommodates the volume of traffic. LOS is represented by one of the letters A through F, A for the freest flow and F for the least free flow. The remaining directional peak hour capacity is the total number of vehicles that can be added to the most congested direction traffic at the peak hour and still remain within the capacity of the road. The directional peak hour volume of the eastern location along U.S. Highway 27 is 10,200 vehicles per day and 554 vehicles per hour (FDOT 2008). This peak hour volume classifies this eastern portion of the roadway as a LOS of A (FDOT 2007), and the remaining directional peak hour capacity is 1676 vehicles. The AADT count and directional peak hour volume of the northern location along SR 78 is 3282 vehicles per day and 173 vehicles per hour (FDOT 2008). This peak hour volume classifies this northern location as a LOS of B, and the remaining directional peak hour capacity is 247 vehicles (FDOT 2007).

Based on the existing population distribution around the site, FPL assumed that most of the workforce would likely travel along the westward portion U.S. Highway 27 and that smaller portions of the workforce would travel along the eastern portion of U.S. Highway 27 and the northern portion of SR 78. Also, the traffic attributable to delivery of construction materials could cause additional congestion on U.S. Highway 27 during certain times of the day. Based on the methodology presented in Subsection 4.4.2.2.4, FPL determined that construction at the Glades site would add 1485 vehicles per day and 488 vehicles during the peak hour to the western and eastern portion of U.S. Highway 27. The additional construction traffic would not cause U.S. Highway 27 to exceed capacity but would drop the roadway to a LOS classification of C in the

western direction, and to a LOS classification of B in the eastern direction. FPL determined that construction at Glades site would add 382 vehicles during the peak hour to the northern portion of SR 78. The additional construction traffic would cause the road to exceed capacity, further add to current traffic congestion, and drop the roadway to a LOS classification of D.

Based on the above analysis, it is likely that the additional traffic would pose delays along U.S. Highway 27 and SR 78. It is anticipated that the drops in LOS classification along U.S. Highway 27 would only pose negligible additional delays or other operational problems. To facilitate the additional traffic, a portion of SR 78 could be widened to a four-lane highway from U.S. 27 to the project site, and acceleration/deceleration lanes could be added to facilitate commuter traffic. The NRC applied significance levels to the LOS classifications that were projected to result from the additional traffic associated with refurbishment activities at nuclear plants (NUREG-1437). FPL considers this approach to be appropriate for construction of a nuclear plant because both plant construction and refurbishment would be large construction projects. The NRC associates small impacts with LOS A and B, moderate impacts with LOS C and D, and large impacts with LOS E and F. Therefore, it is anticipated that the impact of the construction workforce on transportation would be MODERATE and may warrant mitigation.

Operations at the Glades site would add approximately 427 and 140 more vehicles to the western and eastern respective portions of U.S. Highway 27 during the hour of peak traffic. An estimated 110 vehicles would be added the northern portion of SR 78 during the hour of peak traffic as well. The current peak hour capacities of these roadways are sufficient to accommodate the additional traffic expected from operations. Additional traffic as a result of operations would not result in any changes to LOS classifications along U.S. Highway 27, but would drop the LOS classification on SR 78 from B to C. Shift changes could be staggered so that the traffic increase would be less likely to cause congestion. Therefore, it is anticipated that the impact of the operations workforce on transportation would be MODERATE and would not warrant mitigation.

9.3.3.1.6.6 Aesthetics and Recreation

The Glades site is an undeveloped site in an unincorporated area of Glades County, approximately 5 miles southwest of Lake Okeechobee. The site is on flat, swampy land at an approximate elevation of 15 feet above MSL (USGS 1971) and lies within the Everglades physiographic province (USGS 2008).

Because the entire area is relatively flat, the power plant and water intake facilities may be visible from some angles. There would be occasional visible plumes associated with cooling tower operations. Visibility of the plumes would depend on weather conditions and the location of the viewer in the area. Impacts on aesthetic resources are considered to be moderate if there is the potential for diminution in the enjoyment of the physical environment and measurable impacts that do not alter the continued function of socioeconomic institutions and processes. Construction

and operation of an industrial facility on a previously undeveloped site would likely result in some complaints from the affected public with respect to diminution in the enjoyment of the physical environment. Therefore, impacts of construction and operation of the new units on aesthetics would be MODERATE and could warrant mitigation.

The western shoreline of Lake Okeechobee lies within 6 miles of the site, as well as portions of the Lake Okeechobee Scenic Trail and Big Water Heritage Trail, which parallel the shoreline of the lake. Lake Hicpochee is approximately 2 miles southeast of the site. There are no state parks or federal parks within 6 miles of the Glades site.

Lake Okeechobee occupies 730 square miles and is the second largest freshwater lake wholly within the United States. The lake is the epicenter of Florida and is renowned for its unique natural habitat, rich heritage, recreational fishing, and birding (SFRPC 2008).

The Lake Okeechobee Scenic Trail spans 110 miles along the perimeter of Lake Okeechobee. The trail is designated as a segment of the Florida National Scenic Trail. The trail is atop the Herbert Hoover Dike, which surrounds the lake for flood protection, and provides views ranging from scenic lakeside to working agricultural landscapes. The trail affords opportunities to view wildlife and to fish, bike, and hike. The nearest access point to the trail from the Glades site is the Moore Haven Recreation Area, which is east of the site at the confluence of Lake Okeechobee and the Caloosahatchee River (USACE 2008a).

The Big Water Heritage Trail is a designated vehicle roadway that provides vehicular access to the landscapes created by south central Florida's watersheds. The trail begins at the Kissimmee River and continues through the communities around Lake Okeechobee and south through the Everglades. It includes portions of SR 78, U.S. Highway 27, SR 76, U.S. Highway 98, and U.S. Highway 441, and spans within a few miles of the Glades site. The Big Water Heritage Trail is a partnership project that promotes public awareness of natural and cultural features (SFRPC 2008).

Within 50 miles of the Glades site there are several lakes, rivers, swamps, wetlands, and other areas of interest. The Nicodemus Slough is approximately 5.8 miles northeast of the Glades site. The slough contains wet prairies, freshwater marsh wetlands, and pasturelands bordered on the north by a portion of the Herbert Hoover Dike. The property was historically used to graze cattle. In the 1990s, the SFWMD purchased 2219 acres of Nicodemus Slough for hydrologic restoration and public recreational use and designated the area as the Nicodemus Slough Management Area. The area was sparsely used by recreational enthusiasts; therefore, as part of a large land acquisition, the land, encumbered with the continued right to flow water over it, reverted to private ownership in the summer of 2006 and public access was closed (FPL Dec 2006).

Fisheating Creek Wildlife Management Area (FECWMA) is approximately 9.7 miles north-northeast of the Glades site. The FECWMA is bounded on the north and south by the Herbert Hoover Dike, and north and west of the Nicodemus Slough. Fisheating Creek travels approximately 50 miles from its origin in Highlands County through Glades County into Lake Okeechobee. The FECWMA spans 40 miles along this course and includes cypress swamps, hardwood hammocks, freshwater marsh, and mesic hammock habitats. Fisheating Creek has become incorporated into the Fisheating Creek ecosystem project in Glades and Highlands Counties, which is a part of the Florida Forever land acquisition and restoration program. The ecosystem project entails purchase of lands for conservation along the shores of Fisheating Creek for hikers, hunters, and wildlife observers, and to help maintain populations of rare plant and animal communities. The Fisheating Creek ecosystem project is designed to conserve lands that link Fisheating Creek to the Okaloacoochee Slough, Big Cypress swamp, and Babcock-Webb Wildlife Management Area, and Lake Okeechobee. The Fisheating Creek ecosystem project plans include 176,876 acres, 59,910 of which have been acquired by the state of Florida (FPL Dec 2006).

The Lake Wales Ridge National Wildlife Refuge is approximately 23 miles northwest of the site. The refuge occupies approximately 1858 acres and was established in 1993 as the first refuge designated for the recovery of endangered and threatened plants (USFWS 2008a). The northern portion of the Big Cypress National Preserve is approximately 39 miles south of the Glades site, and the Florida Panther National Wildlife Refuge is due west and adjacent to the Big Cypress National Preserve. The Big Cypress Preserve protects more than 720,000 acres of vast swamp containing a dynamic mixture of tropical and temperate plant communities that are home to diverse wildlife. The preserve provides a variety of recreational opportunities including hiking, backpacking, paddling, biking, camping, fishing, hunting, and off-road vehicle access (NPS 2008a). The Florida Panther National Wildlife Refuge consists of 26,400 acres and was established in 1989 under the authority of the Endangered Species Act to protect the Florida panther and its habitat (USFWS 2008b).

Two of the 154 state parks in Florida are within 50 miles of the Glades site and include the Highlands Hammock State Park and the Lake June in Winter Scrub State Park, both of which are more than 35 miles northwest of the Glades site.

Construction activities at the Glades site would pose temporary aesthetic impacts in the region. Construction activities would generate noise and fugitive dust, and the use of cranes (which could exceed 400 feet in height) would alter a portion of the regional viewscape. Construction of the transmission lines would pose similar impacts. Because the parks, trails, and other scenic areas in the region are several miles away, the aesthetic impacts from construction would be SMALL.

When completed, the presence of the power plant and transmission lines would pose a visual disturbance in the viewscape for the life of the structures. Vapor plumes generated by operations could also be visible. Plume visibility would depend on weather conditions and the location of the viewer; however, the visible portion of a vapor plume generally dissipates within 200 meters of the source. Because the region is sparsely populated and is used mainly as farmland, and because the parks, trails, and other scenic areas in the region are several miles away, the aesthetic impacts from operations would be SMALL.

Construction and operation of the new units at the Glades site could impact the attractiveness of recreational areas in the region. Recreational facilities could also be affected by increased traffic on area roads at peak travel periods; however, impacts would be minimal. During plant operations, some employees and their families would use the regional recreational facilities. However, the increase attributable to plant operations would be small compared to overall use of these facilities. Impacts on tourism and recreation are considered small if current facilities are adequate to handle local levels of demand. Therefore, impacts of facility construction and operation on tourism and recreation would be SMALL.

9.3.3.1.6.7 Housing

FPL estimates that 2568 construction and operation workers would move from outside the 50-mile radius of the Glades site to one of the counties within 50 miles, and each of these workers would need a place to live. Some of the workers would seek permanent residence, generally owner-occupied; some would choose to rent; and others would choose a transitional residence such as a hotel, a room in a private home, or a camper or mobile home.

Based on 2000 census data, within the four-county ROI, there are 278,993 housing units of which 63,099 are vacant (22.6 percent). The number of vacant housing units within each of these counties was 1938 (33.5 percent) in Glades County, 1444 (11.7 percent) in Hendry County, 56,806 (23.1 percent) in Lee County, and 2911 (18.8 percent) in Okeechobee County. This includes housing that is designated as seasonal, recreational, or occasional use (USCB 2000).

FPL estimates that, in absolute numbers, the available housing would be sufficient to house the construction workforce. Workers who relocate could secure housing from the existing stock in any of the four counties within the region, have new homes constructed, or bring their own residence (mobile home or trailer) to the region.

Because Glades, Hendry, and Okeechobee Counties have relatively small populations, their housing markets would likely be the most impacted. Impacts on housing are considered to be small when a small and not easily discernable change in housing availability occurs (NUREG-1437). The entire construction and operation workforce would occupy no more than 4.1

percent of vacant housing units in the ROI. Therefore, the impacts during plant construction would be SMALL, and mitigation would not be warranted.

FPL estimated that approximately 1050 workers would be needed for operation of two nuclear power facilities at the Glades site (U.S. DOE May 2004). FPL assumed that 85 percent of these workers (893) would relocate from outside the region and would settle in the four-county ROI. Based on these assumptions, the entire operations workforce would occupy no more than 1.4 percent of vacant housing units in the ROI. Therefore, the impacts from plant operations would be SMALL, and mitigation would not be warranted.

9.3.3.1.6.8 Public Services

Public services in the ROI include water supply and wastewater treatment facilities; law enforcement, fire, and medical facilities; libraries, parks and recreation, roadway maintenance, and other social services. Construction or operations employees who relocate from outside the region would most likely live in residentially developed areas where adequate water supply and wastewater treatment facilities already exist. The medical facilities in the four-county ROI provide medical care to much of the population within the 50-mile region, and, therefore, the small increases in the regional population would not materially impact the availability of medical services. Although the workers and their families would pose an additional overall demand on other public services, it is anticipated that the current capacity of the public services within the four-county ROI would be adequate to accommodate the increased demand. Therefore, the impact would be SMALL.

The new nuclear plant and the associated population influx would likely economically benefit the disadvantaged population served by the Florida Department of Children and Families. Direct jobs created by the project would bring indirect jobs that could be filled by currently unemployed workers and, therefore, remove them from the care of social services.

The ratio of residents to law enforcement officers in Glades, Hendry, Lee, and Okeechobee Counties was 353:1, 624:1, 796:1, and 399:1, respectively (FBI 2008). Within the ROI, the resident-to-law-enforcement-officer ratio was 715:1, and for the state of Florida, the resident-to-law-enforcement-officer ratio was 851:1. Ratios partly depend on population density. In general, fewer law enforcement safety officers are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional law enforcement officers were hired, the population increase attributable to project construction at the Glades site would increase the resident-to-law-enforcement-officer ratio by 1.3 percent to 724:1. This is a small increase and would still yield a lower resident-to-law-enforcement-officer ratio than the average for the state of Florida. Similarly, the increase in the resident-to-law-enforcement-officer ratio attributable to operations would yield less than a 0.6 percent increase.

The ratio of residents to firefighters in Glades, Hendry, Lee, and Okeechobee Counties was 82:1, 394:1, 431:1 and 492:1, respectively. Within the ROI, the resident-to-firefighter ratio was 397:1, and for the state of Florida, the resident-to-firefighter ratio was 1230:1 (USFA 2009). As described above concerning law enforcement officers, ratios partly depend on population density. In general, fewer firefighters are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional firefighters were hired, the population increase attributable to project construction at the Glades site would increase the resident-to-firefighter ratio by 1.3 percent to 402:1. This is a small increase and would still yield a lower resident-to-firefighter ratio than the average for the state of Florida. Similarly, the increase in the resident-to-firefighter ratio attributable to operations would yield less than a 0.6 percent increase.

Impacts on public services are considered small if there is little or no need for additional personnel. Impacts are considered moderate if some permanent additions or some new capital equipment purchases are needed (NUREG-1437). The population increase in the four-county region attributable to construction or operation of the new power units could pose a need to hire additional emergency personnel. However, any additional need would be small, and increased tax revenues generated by the project would be adequate to pay the salaries of any additional emergency personnel hired. Therefore, it is not expected that public services would be materially impacted by new construction or operations employees that relocate from outside the region. Therefore, impacts are considered SMALL, and mitigation would not be warranted.

9.3.3.1.6.9 Education

Based on data for the 2006–2007 school year, Glades County had 8 schools that covered prekindergarten through 12th grade (PK-12) schools with a total enrollment of 1256 students; Hendry County had 17 PK-12 schools with a total enrollment of 7463 students; Lee County has 112 PK-12 schools with a total enrollment of 78,981 students; and Okeechobee County had 17 PK-12 schools with a total enrollment of 7289 students (NCES 2009). In the four-county ROI, there are 154 schools with a total enrollment of 94,989 students.

FPL estimated that 2568 construction and operation workers would migrate to the area, and that 1823 workers would bring a family. This would yield a total population increase of 6669 people. Based on an estimate of 0.8 school-aged children per family (BMI Apr 1981), an estimated 1458 of the 6669 people who relocate to the four-county area would be school-aged children. This would yield a 1.5 percent increase in the student population within the four-county ROI. Small impacts are generally associated with project-related enrollment increases of up to 3 percent, and moderate impacts on local school systems are generally associated with project-related enrollment increases of 3 to 8 percent (NUREG-1437). Therefore, this would pose a SMALL impact on the ROI, and mitigation would not be warranted.

FPL assumed that 893 operations workers and their families would relocate from outside the region and that the total population increase attributable to operations would be 2901 people. This would include an estimated 714 children in the PK-12 school range. This influx of students would increase the student population in the ROI by 0.8 percent within the four-county ROI. The impacts on public education are considered SMALL, and mitigation would not be warranted.

9.3.3.1.7 Historic and Cultural Resources

FPL conducted historical and archaeological records searches on the National Park Service National Register Information System (NRIS) and reviewed information on historic and archeological sites provided in documents associated with the formerly proposed FPL Glades Power Park project, which was located near the Glades site. Where applicable, historic and archeological sites are identified by their historic site structure identifier.

In 2006, FPL conducted an archeological reconnaissance survey for a 4900-acre undeveloped area for the formerly-proposed FPL Glades Power Park project (FPL Dec 2006). The FPL Glades Power Park site is approximately 3 miles north of the Glades site.

No archaeological sites were identified during the FPL archeological reconnaissance survey. Background research conducted as part of the 2006 FPL Glades Power Park archeological survey indicates that one archaeological site (8GL60) is within the FPL Glades Power Park project boundary. The site was recorded as a Belle Glade mound based on its designation as an “Indian Mound” on a topographic map. Because of lack of previous field investigation of the site, it has not been evaluated for its National Register of Historic Places (NRHP) eligibility. Other notable archaeological sites in the vicinity of the Glades site are described below.

Gator Mound (8GL53) is just outside the northeastern corner of FPL Glades Power Park project boundary and just south of the Nicodemus Slough. This site is recorded as a prehistoric mound and earthworks of unknown cultural affiliation, and has not been evaluated for NRHP eligibility.

The Nicodemus Earthworks site (8GL9) is approximately 2500 feet north of the FPL Glades Power Park site and Nicodemus Slough. It is recorded as a destroyed white sand burial mound and linear crescent earthworks with linear ridge and mound components that are associated with the Belle Glade culture. The burial mound has been recorded as containing human remains. This site has not been evaluated for its NRHP eligibility.

An unnamed site (8GL61) is approximately 6500 feet north of the FPL Glades Power Park site. It is recorded as a prehistoric mound associated with Belle Glade culture. This site has not been evaluated for its NRHP eligibility.

The Glades Circle Ditch (8GL38) is 7000 feet north of the FPL Glades Power Park site and Nicodemus Slough. The site is recorded as a prehistoric earthwork associated with the Glades culture. It has not been evaluated for its NRHP eligibility.

The Fort Center Archeological District (8GL13) is composed of numerous middens and earthworks associated with the Belle Glade I and II culture. The earthworks include mounds, linear embankments, a burial mound, borrow areas, and circular ditches. This complex includes archeological sites 8GL11–8GL13, 8GL15–8GL25, 8GL375 and 8GL376. The site is named for a 19th century Seminole war fort (8GL23) built on the site. The complex is situated in both hammock and savannah adjacent to the south bank of Fisheating Creek. The Fort Center Archaeological District is an important prehistoric site group with the potential to be a state park, but it has not been evaluated for NRHP eligibility.

The Herbert Hoover Dike (8GL421) that surrounds Lake Okeechobee is listed in the Florida Master Site File as a district or resource group. The site consists of five historic structures in five different counties; 8GL421A is the historic site structure number for the segment in Glades County. Construction of the dike began in the early 1930s by the U.S. Army Corps of Engineers (USACE) and was completed in 1938. The 34-foot high dike is composed of shell, rock, and gravel covered with grass, trees, and a service drive on top of the levee. It is considered to be the largest civil engineering work in south Florida and continues to control the waters around Lake Okeechobee. This historic resource has been previously determined by the State Historic Preservation Officer (SHPO) to be NRHP-eligible.

The archeological background research did not reveal any military forts, encampments or roads, battle sites, homesteads, farmsteads, trails, or Native American villages within 3 miles of the FPL Glades Power Park site.

There are two Seminole Indian Reservations within the four-county ROI (Seminole Tribe of Florida 2008). The Brighton Seminole Reservation is in Glades County approximately 12 miles northeast of the Glades site. The northern portion of the Big Cypress Seminole Reservation is in the southwest corner of Hendry County approximately 33 miles southeast of the Glades site.

The NRHP identifies 61 properties in the four-county ROI, including two properties in Glades County, 46 properties in Lee County, two properties in Okeechobee County, and 11 properties in Hendry County. Two of these properties, the Glades Moore Haven Downtown Historic District and the Glades Moore Haven Residential Historic District, are within 10 miles of the Glades site (NPS 2008b).

Siting the proposed nuclear plant at the Glades site would require a formal cultural resources survey, and consultation with the SHPO would be conducted so that any adverse effects to onsite archeological or historic resources would be avoided, minimized, or mitigated. Sites are

considered to have small impacts to historic and cultural resources if the SHPO identifies no significant resources on or near the site or determines they would not be affected by plant construction or operation. Mitigation measures would be applied to resolve any adverse effects and reduce impacts to onsite cultural resources from construction or operation of the new units at the Glades site to SMALL.

Sites are considered to have large impacts to historic resources if they would be disturbed or otherwise have their historic character altered by construction. Two historic properties and several archeological areas were identified within 10 miles of the Glades site. Construction of the new units at the Glades site would result in adverse effects to the historic and cultural landscape through introduction of visual elements that would be out of character with the property and its setting. The visual impacts would be LARGE and would warrant mitigation.

Siting the proposed nuclear plant at the Glades site would require a formal determination of areas of potential effect from physical disturbance or visual impacts, identification of historic properties within the areas of potential effect, and a determination of adverse effects. FPL would consult with the SHPO to identify measures for avoidance, minimization, or mitigation of any adverse effects.

9.3.3.1.8 Environmental Justice

Environmental justice refers to a federal policy under which each federal agency identifies and addresses, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority or low-income populations. The NRC has a policy on the treatment of environmental justice matters in licensing actions (69 FR 52040) and guidance (U.S. NRC May 2004). Subsection 2.5.4.1 describes the methodology FPL used to establish locations of minority and low-income populations.

The 2000 census block groups were used to ascertain minority and low-income population distributions in the area. There are 499 block groups within 50 miles of the Glades site. The census data for Florida characterizes 14.6 percent of the population as black; 0.3 percent American Indian or Alaskan Native; 1.7 percent Asian; 0.1 percent Native Hawaiian or other Pacific Islander; 3.0 percent as other single minorities; 2.4 percent multiracial; 22.0 percent aggregate of minority races; and 16.8 percent Hispanic ethnicity. If any block group percentage exceeded the state percentage by more than 20 percent or was greater than 50 percent, then the block group was considered to have a significant minority population.

Significant black minority populations exist in 54 block groups; significant American Indian or Alaskan Native populations exist in 3 block groups; significant other minority populations exist in 21 block groups; significant multiracial minority populations exist in 3 block groups; significant “aggregate of minority races” populations exist in 80 block groups; and significant Hispanic

ethnicity populations exist in 53 block groups. There are no block groups containing significant Asian or Native Hawaiian or other Pacific Islander minority populations within 50 miles of the Glades site.

Three Indian Reservations lie within 50 miles of the Glades site: the Brighton Indian Reservation, the Big Cypress Indian Reservation, and a portion of the Miccosukee Indian Reservation. The Brighton and Big Cypress Indian Reservations are both part of the Seminole Tribe of Florida. The Brighton Indian Reservation, 10 miles north of the Glades site, offers several tourist attractions including Indian arts and crafts shops, the Seminole Casino Brighton, a rodeo arena, the Brighton Citrus Grove, and the Brighton Seminole Campground. The Big Cypress Reservation, an 85-acre complex 40 miles south of the Glades site, offers the Ah-Tah-Thi-Ki Museum, the Billie Swamp Safari, the Big Cypress RV Resort, the Big Cypress Citrus Grove, the Swamp Water Café, and Big Cypress Hunting Adventures. Today, most Seminole Tribal members are afforded modern housing and health care. In fact, today the Seminole Indians live much the same way as those who live outside Seminole County (Seminole Tribe of Florida 2008).

A portion of the Alligator Alley Miccosukee Indian Reservation also lies within the 50-mile radius. The Miccosukee Tribe of Indians was originally part of the Creek Nation, an association of clan villages that inhabited the areas now known as Alabama and Georgia. There are approximately 650 people enrolled in the Miccosukee Tribe. However, The Tamiami Trail Reservation, 40 miles west of Miami in Miami-Dade County, is the site of most Tribal operations and the center of the Miccosukee Indian population. Alligator Alley is the largest of the Miccosukee Tribe reservations and covers approximately 75,000 acres. This land consists of 20,000 acres with potential for development and 55,000 acres of wetlands. The reservation contains a modern service station plaza, a police substation, and 13,000 acres of land that is leased for cattle grazing. Plans are currently underway for additional commercial and agricultural development as well as community facilities and homes sites (Miccosukee Resort and Gaming 2007).

The locations of the minority populations and Indian Reservations within 50 miles of the Glades site are shown in Figure 9.3-9.

The census data characterizes 11.7 percent of Florida households as low income. Based on the “more than 20 percent” criterion, 45 block groups out of a possible 499 contain a significant number of low-income households. The locations of the low-income populations within 50 miles of the Glades site are shown in Figure 9.3-10.

Although the Glades site is within a minority block group, construction activities (noise, fugitive dust, and air emissions) would be contained with site boundaries and would not disproportionately impact minority populations. In fact, minority and low-income populations would most likely benefit from construction activities through an increase in construction-related

jobs. Operating the new units at the Glades site is also unlikely to have disproportionate impacts on minority or low-income populations.

FPL concludes that construction and operation of the proposed nuclear plant at the Glades site would not disproportionately impact minority or low-income populations and that mitigation would not be warranted, and the impacts to these populations would be SMALL.

9.3.3.1.9 Other Projects in the Vicinity of the Glades Site

The cumulative impacts of past, present, and reasonably foreseeable federal (e.g. USCOE, USGS), non-federal (e.g., FDEP, FDOT, county), and private projects within a 50-mile radius of the Glades site, excluding Brownfield and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites, that could have cumulative impacts with the proposed action are described in Table 9.3-9. These projects have either requested an air or water permit/license or had an environmental impact statement complete. Projects included in the Table 9.3-9 are within the 50-mile radius of the Glades site and the appropriate timeframe for construction and operation of the new units (Figure 9.3-8) from 2013 to 2063 (based on a construction start date of 2013, a Unit 7 in-service date of 2023, and a 40-year operating license). Nuclear power projects within 100 miles of the Glades site (i.e., St. Lucie) are also described in Table 9.3-9. The Turkey Point site is more than 100 miles from the Glades site and is therefore not included in the table. The only other nuclear power plant currently operating in Florida, Crystal River, is more than 170 miles from the Glades site and therefore is also not included in the table. The proposed nuclear power plant in Levy County is approximately the same distance as the Crystal River site and is not in the table. It should be noted that this list is not intended to be exhaustive and should not be used to imply that no other past, present, or reasonably foreseeable projects exist that could contribute to cumulative impacts within each alternative site project area.

The impacts to land use that would have a cumulative impact on alternative sites would generally be characterized as a change to the land use designation from “agriculture” to “industrial.” A positive land-use impact, for example, would be the Comprehensive Everglades Restoration Plan (CERP) projects. These projects within the 50-mile radius would redevelop, reuse, or develop additional land for conservation. The cumulative impacts to hydrology and water use would be minimally negative due to the restrictions placed on all surface water and groundwater use. There also would be beneficial impacts due to the large scale CERP projects for reservoir and storage areas which would provide additional water to the southern Everglades Agricultural Area and reestablish wetland hydropatterns. The cumulative impacts for terrestrial/aquatic resources would be associated with the minimal loss of wetlands, which is offset by the restoration of developed lands for conservation and restoration of native species through CERP projects. The cumulative impacts for socioeconomics for the Glades Site would appear as beneficial impacts to

taxes and adverse impacts on transportation. Also, because there would not be any disproportionate impact to low-income or minority populations by the activities at the Glades site.

9.3.3.2 Evaluation of the Martin Site

The Martin site is an 11,300-acre area that includes five fossil-fired power units and a solar unit. The site is owned by FPL (FPL Apr 2009) although additional land would need to be acquired to the south of the site to develop it for two new nuclear power plant units given that a new 3000-acre cooling water storage reservoir would be required and the amount of FPL-owned land currently available for development is less than 600 acres. The site is located in western Martin County, approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown. The Miami load center is approximately 65 miles south southeast. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent SFWMD L-65 Canal; on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway); and on the northeast by State Route 710 and the adjacent CSX Railroad (FPL Apr 2009). Site elevation is 28 feet above sea level and outside the 100-year floodplain. The location of the Martin site is shown in Figure 9.3-11.

9.3.3.2.1 Land Use Including Site and Transmission Line Rights-of-Way

Power plant units and related facilities occupy approximately 300 acres of the Martin site. The site also includes a 6800-acre water reservoir (6500 acres of water surface and 300 acres of dike area) used to cool the existing fossil-fired power units. To the east of the power plant there is an area of mixed pine flat wood and scattered small wetlands. To the north of the onsite water reservoir is a 1200-acre area that has been set aside as a mitigation area. There is a peninsula of wetland forest on the west side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swamp encompasses 400 acres and is preserved as a natural area (FPL Apr 2009). These on-site protected areas would be avoided in development of the site for two nuclear units.

Based on the conceptual site layout developed for the Martin site, the following land requirement assumptions were made which form the basis of the environmental comparison of alternative sites:

- The assumed facility footprint would require approximately 362 acres and the assumed cooling water storage reservoir would require approximately 3000 acres for an on-site cooling water makeup reservoir (including intake structure); the existing 6500 acre on-site reservoir at Martin would not be available to the new nuclear units. New facilities at the plant site would include the nuclear power units, support buildings, a switchyard, storage areas, storm water retention ponds, and deep injection wells for subsurface water disposal.

- The assumed extent of non-transmission linear features, including access road corridors, pipeline corridors and rail access, is as follows:

    — Access road: 473.3 acres – assuming a corridor length of approximately 39.3 miles and a corridor width of 100 feet. Based on conceptual site layouts developed for the Martin site, site access would be from SR 710, and a significant span of SR 710 would need to be widened to accommodate anticipated traffic levels attributable to construction.

    — Rail: 51.5 acres – based on an assumed length of 4.3 miles and a corridor width of 100 feet, to provide access to the nearest railway northeast of the site.

    — Intake/makeup pipeline corridors: 21.7 acres, including pipeline connecting the reservoir to the C-44 Canal/St. Lucie canal (assumed cooling water source) directly to the south of the site. The Channel/canal connects Lake Okeechobee to the South Fork of the St. Lucie River and the Atlantic Coast.

- The assumed extent of conceptual transmission corridor routing is 763.6 acres based on an assumed length of 31 miles and a corridor width that varies between 200 and 300 feet. The corridor would connect the new nuclear units to the existing FPL transmission system at the Corbett substation inside Palm Beach County.

- Based on subtotals above for both onsite and offsite plant components, the total area potentially affected at the Martin site is estimated at approximately 4672 acres. With respect to the transmission line corridor included within this total, the estimated acreage requirements assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. However, these estimates provide the basis for an updated and consistent environmental comparison of alternative sites.

- Additional acreage (up to several hundred acres) may be required to support construction activities (e.g., additional laydown areas, batch plant, fill/spoil areas, especially from reservoir excavation until fill material can be transported offsite). However, cleared land would be used to the greatest extent possible. The impact on this acreage would be temporary, and it would also be reclaimed to the extent possible following construction.

Agricultural uses such as croplands, pastures, and groves account for much of the land use and cover within 5 miles of the Martin site. Three types of wetlands (forested freshwater, non-forested freshwater, and mixed forested and forested freshwater) also account for a large portion of nearby land use. Forested cover found nearby includes coniferous and other mixed species (FPL May 2008).

Land use impacts associated with plant construction include both impacts to the site and immediate vicinity, including the new reservoir; and impacts to offsite areas such as transmission, cooling water intake pipelines, and transportation rights-of-way (e.g., road and rail). Construction of a new nuclear power plant would include clearing, dredging, grading, excavation, spoil deposition, and dewatering activities. An area of approximately 362 acres for the main power plant site (major structures including switchyard), which would largely be focused in one central location; and approximately 3000 acres (surface area) for a new reservoir and intake structure would be permanently impacted.

While the site already hosts multiple power generation units, construction of additional power units at the site would be located in an area, based on conceptual site layouts, that includes primarily pine flatwoods, palmetto prairies and pastureland, along with several acres of freshwater marshes and hardwood-coniferous mixed forest. This land would be altered, as would existing agricultural lands to the south of the FPL-owned site, from construction of the new reservoir.

Project construction would have a long-term impact on the current uses which would change to industrial use. Much of the proposed power plant site area within existing FPL-owned land has already been cleared and is in an industrial area, but the agricultural area to be acquired for reservoir construction, consisting primarily of citrus groves, would be permanently altered. Following construction activities, impacted areas without constructed buildings or transportation infrastructure would be reclaimed to the greatest extent feasible.

Construction at the proposed pipeline corridors would have temporary, minor effects on land use during actual construction due to trenching, equipment movement and material laydown. The ability to use current lands for their existing uses (e.g., farmland) along the proposed pipeline corridor would be temporarily lost during construction. Direct and indirect impacts of construction from the proposed transportation infrastructure would be similar to those for the proposed plant. The widening of State Route 710 would affect pasture land, citrus groves, wetland areas, as well as residential, commercial and other light industrial areas.

Development of the conceptual transmission corridor incorporated the most direct route where possible, while considering potential conflicts with natural or man-made areas where important environmental resources were located, and avoiding populated areas and residences to the extent possible. Whenever possible, the new line was routed along existing transmission rights-of-way. The use of lands that are currently used for forests would be altered. Trees would be replaced by low-growth types of ground cover such as grass. The new transmission corridor would not be expected to preclude agricultural activities near the eventual rights-of-way. The land use in the region along the new transmission corridors is generally rural, sparsely populated, and primarily used for agricultural activities. Because Martin County is within the Florida Coastal

Zone, the route for the new transmission lines may be subject to Florida Coastal Zone Management requirements.

Table 9.3-10 includes estimates of the potentially affected area(s) of each land cover type (based on GIS FLUCCS Level III data analysis) for the Martin site, including both onsite and offsite components (i.e., access road, rail, pipeline and transmission corridors). It also further breaks out the land cover types along the assumed conceptual transmission corridor only, as a basis for comparison of land use impacts from the conceptual transmission corridor versus other project components. Note that assumed conceptual transmission corridors account for 16% of the total potentially affected area listed for the Martin site.

As noted previously, regarding the offsite linear features associated with the projects, the estimated acreage requirements assume corridor widths for transmission which may exceed the area that would actually be disturbed during project construction and operation. These estimates are intended to provide the basis for an updated and consistent environmental comparison of alternative sites.

Operational impacts to site land use would include a permanent change in land use for approximately 3908 acres of land for the power plant site, reservoir and rail/highway access corridors that extend outside the existing Martin plant boundaries and would be generally unavailable for other purposes. This area would be excluded from future agricultural and recreational use for the estimated 60-year life of the AP1000 power units (WEC 2007). While the proposed changes occurring outside the existing plant boundaries would be a change from current land use in the area, they would be somewhat compatible given their occurrence immediately adjacent to the Martin power plant industrial area.

Operational impacts to the site and immediate vicinity also would include maintenance operations on project structures that would be small and temporary in nature.

Operational impacts of transmission lines result primarily from line maintenance, and include right-of-way vegetation clearing and control, transmission line maintenance, and other normal access activities. Additional right-of-way acquisition and development would not normally be required as part of plant operational activities. Maintenance activities would be limited to the immediate right-of-way and would be minimal. New transmission corridors would not be expected to preclude agricultural activities near the eventual rights-of-way. Corridor vegetation management and line maintenance procedures would be established by the transmission service provider.

Other offsite land use impacts as a result of plant operational activities would be minimal, temporary, and limited in the area impacted. Such activities could include pipeline, road, and rail maintenance and auxiliary building maintenance. It is likely that most lands above the proposed

water intake pipeline and related areas of construction could continue to be used for ranching, farming and any passive uses. The proposed transportation infrastructure could result in the loss of a small amount of ranch land, pasture land and forested land in areas where access road improvements/widening and a rail spur would be needed.

For the purpose of this analysis, land use impacts are considered small if less than 3000 acres are disturbed (including plant footprint, rights-of-way, and corridors) and there are no major changes to land use. Impacts are considered moderate if land disturbance is greater than 3000 acres or there are major changes to land use; and large if land disturbance is greater than 6000 acres and there are major changes to land use. Based on a potentially affected area of approximately 4674 acres, including over 4000 acres that would occur outside the existing Martin plant boundaries, and the existing industrial use, land use impacts associated with site preparation, construction, and operation of the proposed nuclear plant at the Martin site and the conceptual transmission corridor would be MODERATE.

9.3.3.2.2 Air Quality

Martin County (the Martin site is within Martin County) is part of the Southeast Florida Intrastate Air Quality Control Region. Martin County, along with the entire State of Florida, is designated as attainment or unclassifiable with respect to the NAAQS (40 CFR 81.310). The nearest non-attainment area is in Georgia, several hundred miles north northwest of the Martin site (40 CFR 81.311).

Criteria pollutant emissions from construction and operation of the proposed nuclear plant at the Martin site would be comparable to the emissions generated at the Turkey Point site, as described in Subsections 4.4.1.2 and 5.8.1.2, respectively. Construction impacts would be temporary and would be similar to those from large-scale construction projects. Particulate emissions in the form of dust from disturbed land, roads, and construction activities would be generated. Mitigation measures similar to those described in Subsection 4.4.1.2 would be applied as necessary. Criteria pollutants would also be generated from onsite fossil-fueled construction equipment and construction vehicles, and from commuter and delivery vehicles that travel to and from the site. The quantity of criteria pollutant emissions generated by construction activities would be small compared to total emissions from the fossil units at the Martin plant and other emission sources in the region; therefore, it is assumed unlikely that construction-related emissions would cause any violation of the NAAQS.

The project would include standby diesel generators and diesel-driven fire pumps. Annual emissions from these sources are listed in Table 3.6-4. It is expected that standby diesel generators and auxiliary power systems would see limited use and, when used, would operate for a short time interval. The pollutant emissions generated by these systems (nonradiological) would be regulated by the FDEP in accordance with the air rules published under FAC Chapter

62. These rules cover general air pollution control provisions, stationary source requirements, preconstruction review, emission standards, air monitoring requirements, and other rules for control of air pollutant emissions. Airborne release of criteria pollutant and hazardous air pollutant emissions would be small and would comply with FDEP rules (FDEP 2008a).

Nonradiological emissions can potentially affect regional visibility, and visibility is an important feature at Federal Class I Areas. The Federal Class I Area nearest to the Martin site is the Everglades National Park more than 100 miles to the south. Because the distance is large, and because the anticipated emission levels would be small, pollutant emissions attributable to operation of the new nuclear units would have a negligible impact on visibility at a Federal Class I Area. Unfavorable psychometric conditions can result in visible vapor plumes from the cooling tower operations. These plumes may be visible for several miles, but would not impact visibility or scenic vistas at any Federal Class I Area.

Air quality impacts are considered small if the increase in regional pollutant concentrations attributable to the source (1) would not appreciably alter visibility, (2) would not exceed EPA significant impact levels, and (3) would not cause a violation of the most restrictive ambient air quality standards. Based on this evaluation metric, it is anticipated that the impacts to air quality from construction and operation would be SMALL.

9.3.3.2.3 Hydrology, Water Use, and Water Quality

The state of Florida is divided into five watershed management areas. The Martin site is in the Kissimmee-Everglades watershed and falls under the jurisdiction of the SFWMD. This watershed region spans more than 16 counties and is logically divided into several river basins: Kissimmee River, Upper East Coast, Lower East Coast (which includes the entire southeast coast and the Everglades), and Lower West Coast (which includes the Big Cypress and Caloosahatchee Rivers). This region is the largest watershed region in the state of Florida and is home to 40 percent of Florida's population. The region also contains the Everglades (the largest subtropical wetland in the United States) and Lake Okeechobee, the second largest freshwater lake in the United States. This lake is of national importance, because its water has diverse usage and a large number of people depend on it for agricultural and domestic purposes (University of Florida Jun 2007).

Currently, Lake Okeechobee’s water quality and ecological health are adversely affected by excessive nutrient loading, extreme high and low water levels, and the proliferation of exotic species. To address restoration goals for the lake, the SFWMD in coordination with the FDEP and the Florida Department of Agricultural and Consumer Services has developed the Lake Okeechobee Watershed Construction Project Technical Plan. The plan was developed in response to the Northern Everglades and Estuaries Protection Program that the Florida Legislature signed into law in 2007. Primary components of the plan include implementing

agricultural management practices, building treatment wetlands to clean water flowing into the lake, and creating between 900,000 and 1.3 million acre-feet of water storage north of the lake (SFWMD 2008).

The entire state of Florida, and portions of southern Alabama, southeastern Georgia, and southern South Carolina, are atop the Floridan aquifer. This aquifer covers some 100,000 square miles and is one of the most productive aquifers in the world. The Floridan aquifer system provides water for several large cities, such as Savannah and Brunswick in Georgia; and Jacksonville, Tallahassee, Orlando, Tampa Bay, and St. Petersburg in Florida. In addition, the aquifer system provides water for hundreds of thousands of people in smaller communities and rural areas. The Floridan aquifer is intensively pumped for industrial and irrigation supplies (USGS Jul 1980). For the year 2000, the average groundwater withdrawals in Martin County were 43.6 million gallons per day – approximately 87 percent of this was from surficial aquifers (37.8 million gallons per day) and the other 13 percent (5.8 million gallons per day) was from the Floridan aquifer (USGS Dec 2004).

The average daily water withdrawal rate in Martin County (from both groundwater and surface water sources) in year 2000 was 198.87 million gallons. Approximately 78.1 percent (155.3 million gallons) was from fresh surface water, and 21.9 percent (43.6 million gallons) was from fresh groundwater. No saline water withdrawals were reported (USGS Dec 2004). Average withdrawal for agricultural use in the year 2000 was 140 million gallons per day that represented 70 percent of daily withdrawals from available sources. The second largest user was the power generation industry with an average withdrawal rate of 24.63 million gallons per day (12.4 percent) (USGS Dec 2004). Major surface freshwater sources near the Martin site include Lake Okeechobee (5 miles away), the C-44 Channel (adjacent to the proposed cooling water storage reservoir), and the SFWMD L-65 Canal (5.8 miles away) (FPL Apr 2009).

The depth to the water table near the site is less than 30 feet below ground level (USGS 2008). Therefore, it is expected that dewatering may be necessary during the construction phase. This may require construction of temporary retention ponds to allow sediment-laden waters to settle before discharge to surface waters. Dewatering activities would be subject to NPDES permit requirements to avoid adverse impacts on surface waters.

Land subsidence related to karst terrain is not anticipated at the site. The site is in karst Area II where the surface cover is reported to be 30 to 200 feet thick. In such areas, sinkholes are reported to be few, shallow, of small diameter, and develop gradually (Sinclair, et al.,1985).

As shown in Subsection 4.2.2.1, the peak construction water demand is estimated at 565 gpm which is slightly greater than 1 cubic foot per second, and the peak estimated potable water demand for operations is 2553 gpm (Table 3.3-1). As described in Section 3.3, an estimated 100 cfs of freshwater would be required to replace consumptive water use associated with operation

of the proposed nuclear power units. Lake Okeechobee offers a potential water supply of more than 360 cfs, and the annual average flow of the St. Lucie Canal near the site is approximately 842 cfs. The estimated groundwater potential at the Martin site is approximately 155 cfs. These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Martin site. Water use impacts are considered small when water sources are readily available to meet demand. A permittability assessment of the probability of obtaining water permits at the Martin alternative site would be required to develop the documentation necessary to firmly establish conditions under which water from these sources could be made available. Such analysis is beyond the reconnaissance-level evaluations required for alternatives analysis. Instead, these evaluations must be based on statutory and regulatory criteria requiring site-specific analysis of reasonable beneficial use, existing legal users, and public interest factors. Accordingly, because adequate water sources are physically available nearby, the impact on regional water use for both construction and operation would be SMALL.

Water quality impacts are considered small when changes in water quality do not affect or minimally affect aquatic biota and water uses (NUREG-1437). For the Martin site, FPL assumed that a closed loop, mechanical draft, tower-cooled system would be used for power cycle waste heat rejection, whereby blowdown water is injected into the Boulder Zone. The Boulder Zone is a deep underground, extremely permeable, cavernous region in southeastern Florida. It is called the Boulder Zone not because it contains boulders, but instead, because efforts to drill into this zone pose difficulties similar to the difficulties posed by subsurface boulders. Construction and operation activities at the Martin site would be performed under the authorization of an NPDES permit (construction), IWW permit (surface water), or UIC permit (groundwater) issued by the FDEP (FDEP 2008b). Any releases from the power plant site into Lake Okeechobee or regional streams as result of construction or operation would be regulated by the FDEP through the NPDES, IWW, or UIC permit process to ensure that water quality is protected. To ensure that wetlands and streams are not harmed by petroleum products or other industrial chemicals, FPL would restrict certain activities (e.g., transfer and filling operations) that involve the use of petroleum products and solvents to designated areas, such as laydown, fabrication, and shop areas. In addition, construction activities would be guided by a stormwater pollution prevention plan and a construction-phase spill prevention, control, and countermeasures plan similar to those proposed for the Turkey Point site as described in Section 4.2. Therefore, any impacts to surface water during plant construction would be SMALL and would not warrant mitigation beyond best management practices required by the permits. The impacts to water quality during operations would also be SMALL because the IWW and UIC permit requirements would ensure that adequate measures are applied to protect water quality.

9.3.3.2.4 Terrestrial Resources and Protected Species

The terrestrial systems within the Martin site area include palmetto prairie and pine flatwoods. Surrounding areas also include unimproved pasture, herbaceous rangeland, mixed hardwood/

conifer forest, mixed wetland hardwoods, cypress, mixed wetland forest, freshwater marsh, and wet prairie (FPL May 2008). Table 9.3-10 includes estimates of the potentially affected area(s) of each land cover type within the project area for both onsite and offsite components, including natural vegetation and wetland areas.

Although the palmetto prairie and pine flatwoods areas at the site provide habitat for common wildlife species such as feral pig, turkey, armadillo, and white-tailed deer, no unique wildlife species or critical habitat for listed species would be impacted. These habitats are also common in the surrounding area (FPL May 2008). A portion of the site has been severely altered by the past construction of the existing Martin plant and provides poor wildlife habitat. The ditches and stormwater basin provide foraging opportunities for wading birds. Habitat for fish and wildlife is provided by the makeup water reservoir (FPL May 2008).

As shown in Table 9.3-10, there are approximately 163 acres of wetlands within the project area, excluding the conceptual transmission corridor, which could be directly impacted from project construction. Of these, approximately 82 acres are identified as forested wetlands and considered to be high quality. Any wetland functions that are impacted during construction would be replaced or restored. The footprint of the new facilities, excluding the assumed conceptual transmission corridor, would cover approximately 3910 acres.

A vegetation/land use survey of the project area and surrounding areas was conducted in March 2008 as part of the Site Certification Modification for the Martin Solar Energy Center. Before the 2008 field surveys, literature reviews were undertaken to determine the species that could potentially be present in the habitats found on the project area (FPL May 2008). Threatened, endangered, and/or species of special concern that occur within Martin County are listed in Table 9.3-11. The field surveys and FNAI database review did not result in any occurrences of listed plant species in the vicinity of the project area. Listed fauna species observed or likely to occur within the project area include the American alligator as well as several species of wading birds: white ibis, little blue heron, tricolored heron, snowy egret, wood stork, and sandhill crane. According to the FFWCC Bald Eagle Nest Location Database, two active bald eagle (*Haliaeetus leucocephalus*) nests are within approximately 2 miles of the project area. Nest MT012 is within the Northwest Mitigation Area just north of the cooling pond at 27°04.64′ N 80°36.42′ W (Section 14, Township 39 South, Range 37 East). Nest MT002 is in the Barley Barber Swamp at 27°02.77′ N 80°35.66′ W (Section 25, Township 39 South, Range 37 East). The FNAI database review found one occurrence of an active bald eagle nest in the Barley Barber Swamp (Nest MT002) and another nest approximately 0.25 miles west of the Northwest Mitigation Area. In addition, the Florida Game and Freshwater Fish Breeding Bird Atlas Project identified both the bald eagle and the Florida sandhill crane (*Grus canadensis pratensis*) as breeding in the cooling pond to the west of the project area. A bald eagle was observed between the cooling pond and the Northwest Mitigation Area during field reconnaissance conducted in March 2008 (FPL May 2008).

Further field surveys would be conducted for federally listed and state protected species as part of the permitting process before any clearing or construction activities at the site or along associated transmission or pipeline corridors. Land preparation activities associated with construction of the plant and transmission lines would be conducted in accordance with federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices (e.g., directed drainage ditches, silt fencing) (FPL Dec 2006).

FPL assumed that a new transmission corridor would be routed to the existing FPL transmission system via the Corbett Substation in northern Palm Beach County. Based on the conceptual site layout, the conceptual transmission corridor is approximately 31 miles long and varies in width between 200 and 300 feet. Although the most direct route was generally used between terminations, consideration was also given to avoiding possible conflicts with natural areas where important environmental resources are, such as the bald eagle and the Florida sandhill crane.

As shown in Table 9.3-10, there are approximately 315 acres of wetlands found within the conceptual transmission corridor; approximately 63 acres are forested wetlands and considered to be high quality. This compares to a 764-acre area potentially affected by the conceptual transmission corridor, based on the dimensions above. Any wetland functions that are impacted during construction would be replaced or restored. The estimated acreage requirements for the conceptual transmission corridor assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. These estimates are used to provide the basis for an updated and consistent environmental comparison of alternative sites.

Cooling tower operations can generate vapor plumes that drift downwind. Salt and mineral deposits in the vapor plume have the potential to adversely impact sensitive plant and animal communities through changes in water and soil chemistry; however, the freshwater sources identified for the Martin site have modest levels of salts and dissolved minerals; therefore, the impact of salt and mineral deposits from vapor drift would be minimal. The use of drift eliminators, along with proper tower design and operation, would further minimize the potential for impacts.

For the purpose of this analysis, impacts to terrestrial resources are considered small if no sensitive habitats, including wetlands, are disturbed and no important species are affected. There are no known sensitive species onsite, and the transmission corridors would be relatively short. Portions of the proposed site area would be located within the existing Martin plant boundary, and the new reservoir would be constructed in an area planted in crop (primarily citrus groves). Much of the proposed project area located within the existing Martin plant boundary (approximately 360 acres), would include wood palmetto prairies, pine flatwoods, unimproved pasture and some freshwater marshes. Construction of the plant and reservoir would result in a loss of primarily pasture land and wet prairies that may serve as habitat to numerous common terrestrial species;

however, the creation of a new reservoir to support plant operation would provide new habitat for birds and waterfowl that would not be adversely affected by plant operation. FPL concluded that impacts to terrestrial resources, including endangered and threatened species, from construction and operation of the proposed nuclear plant and conceptual transmission corridor at the Martin site would be SMALL.

9.3.3.2.5 Aquatic Resources and Protected Species

The Martin site is on the St. Lucie Canal approximately 5 miles from Lake Okeechobee. The surface waters near the project area, which potentially could be affected by site preparation and construction activities, include the L-65 Canal and the St. Lucie Canal. The St. Lucie Canal connects to Lake Okeechobee just west of the site and includes similar aquatic resources to those found in Lake Okeechobee. There are also four onsite surface water bodies on the Martin plant site: the cooling pond, the Barley Barber Swamp, the Northwest Parcel wetland mitigation area, and the make-up (intake/discharge) canal (FPL May 2008).

Lake Okeechobee is at the center of south Florida's regional water management system, and is in south-central Florida. The massive lake is a 730 square mile, relatively shallow lake with an average depth of 9 feet and is the second-largest freshwater lake wholly within the continental United States, second only to Lake Michigan. Lake Okeechobee's drainage basin covers more than 4600 square miles (SFWMD 2008).

Lake Okeechobee supports a nationally recognized sport fishery for largemouth bass (*Micropterus salmoides*) and black crappie (*Pomoxis nigromaculatus*), as well as a commercial fishery for various catfish and bream (*Lepomis spp.*). These fisheries generate nearly $30 million per year for the local economies, and they have an asset value that is in excess of $100 million. Another estimate places the value of the recreational fish species at more than $300 million. In addition to the sport and commercial species, Lake Okeechobee supports a diverse community of fish, including (in total) 41 species. These fish are a food resource for wading birds, alligators, and other animals that use the lake (SFWMD 2005a).

For the purpose of this analysis, impacts to aquatic resources are considered small if no sensitive habitats are disturbed and no important species are affected. Water from the St. Lucie Canal (the C-44 Canal) via pipeline is assumed to be the source to cool the new nuclear units constructed at the Martin site. Although recreational sport fish and other aquatic species would be temporarily displaced during construction of a water intake structure, they would be expected to recolonize the area after construction is complete. No federally or state-listed aquatic species are known to exist in the St. Lucie Canal in the vicinity of the Martin site (FNAI 2008b). Field surveys would be conducted for federally listed and state-protected aquatic species as part of the permitting process before any clearing or construction activities at the site or along associated transmission corridors. Because of this, and because land clearing associated with construction of the plant

and transmission lines would be conducted according to federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices, impacts to aquatic resources, including endangered and threatened species, from construction of nuclear power facilities at the Martin site would be SMALL.

There would be no direct discharges to the nearby surface waters from plant operation since plant design assumes discharge by underground injection. The most likely aquatic impact from nuclear operations at the Martin site would be entrainment and impingement of aquatic organisms in the St. Lucie Canal. Because the EPA requires facilities to meet criteria designed to protect organisms from entrainment and impingement, the potential for environmental impacts to aquatic resources, including endangered and threatened species, from nuclear power facility operations at the Martin site would be SMALL.

9.3.3.2.6 Socioeconomics

This subsection evaluates the social and economic impacts to the region from construction and operation of the proposed nuclear plant at the Martin site. Much of the socioeconomic analysis relies on census data gathered by the USCB. The USCB performs an extensive census every ten years. At the time this evaluation was performed, the most recent decennial census was conducted in 2000. The USCB assembles the decennial census data into a wide range of reports that can be used to characterize socioeconomic conditions of a region. In addition, the NRC sponsored the development of a computer program called SECPOP2000 that enables an analyst to quickly assemble and quantify customized regional socioeconomic information; however, this program does not produce results for years later than 2000 (U.S. NRC Aug 2003). For years that fall between each decennial census, the USCB issues estimates based on surveys and statistical models; however, the types of data collected and assembled for intermediate years is less extensive than for years when a decennial census is performed; therefore, the decennial census provides the most comprehensive information.

Because the decennial census provides the most comprehensive information, and because the NRC software tool, SECPOP2000, is not available for intermediate years, information from the 2000 census was chosen as a common baseline for socioeconomic comparison for this analysis. Published census data for later years, if available, is presented as supplemental information.

9.3.3.2.6.1 Physical Impacts

Construction activities can cause temporary localized physical impacts such as noise, odor, fugitive dust, vehicle exhaust emissions, ground vibration, and shock from blast activities. The use of public roadways and railways would be necessary to transport construction materials and equipment to the site. Most construction activities would occur within the boundaries of the Martin site. However, an access road and a railway connection spur would be constructed on lands

adjacent to the site. These new transportation rights-of-way would be routed to avoid residences and populated areas where possible, however, a significant portion of State Route 710 would be widened to four lanes to accommodate anticipated traffic levels attributable to project construction, including workforce commuters, truck deliveries and the transfer of fill (primarily from reservoir construction) to an offsite location. Some residences and commercial services could be temporarily affected during construction. In addition, the conceptual site layout developed for the site also includes construction of a 31-mile conceptual transmission corridor that would include off-site impacts. Other offsite areas that would support construction activities (for example, borrow pits, quarries, and disposal sites) are expected to be already permitted and operational. Impacts on those facilities from construction of the new plant would be small incremental impacts associated with their normal operations.

Potential impacts from power plant operations include noise, odors, exhausts, thermal emissions, and visual intrusions. Operational noise would be generated by pumps, fans, transformers, turbines, generators, onsite traffic, and switchyard equipment. Noise levels attenuate rapidly with distance so that ambient noise levels (attributable to power plant operations) would be minimal at the site boundary. Also, the Martin site is in a rural area generally surrounded by agricultural land and with few residents in the area. Commuter traffic would be controlled by speed limits. Good road conditions and appropriate speed limits would minimize the dust and noise level generated by the delivery trucks and site workers that travel to and from the site.

The project would have standby diesel generators and auxiliary power systems. Air quality permits would govern operation of this equipment to ensure that air emissions comply with regulations. In addition, the generators would be operated on a limited, short-term basis. Normal plant operations would not use a quantity of chemicals that could generate odors that exceed odor threshold values.

Physical impacts are considered small when offsite areas are not affected or only minimally or temporarily affected by noise, odor, dust, emissions, vibration, or shock. In summary, construction activities would be temporary and would occur mainly within the boundaries of the Martin site. Offsite impacts would represent small incremental changes to offsite services that support construction activities. During station operations, ambient noise levels would be minimal at the site boundary. Air quality permits would be required for the diesel generators to ensure emissions comply with regulatory guidelines, and chemical use would be limited, which should limit odors. Therefore, the physical impacts of construction and operation of the new units at the Martin site would be SMALL.

9.3.3.2.6.2 Demography

The population distribution near the Martin site is low with typical rural characteristics and satisfies the 10 CFR Part 100 definition of a low population zone. The nearest population center

larger than 25,000 residents is Port St. Lucie 20 miles east. Coterminous counties include St. Lucie to the north, Okeechobee to the northeast, and Palm Beach to the south.

The entire Martin plant workforce lives in a four-county region that includes Martin County (32.7 percent), Okeechobee County (24.0 percent), St. Lucie County (23.1 percent), and Palm Beach County (20.2 percent) (FPL Dec 1989). Based on this workforce demographic, these same counties are selected to represent the ROI for socioeconomic analysis of the Martin site.

Based on the 2000 census, the total population within the ROI was 1,486,520 which included 126,731 in Martin County; 35,910 in Okeechobee County; 1,131,184 in Palm Beach County; and 192,695 in St. Lucie County (USCB 2000). Census estimates for year 2007 show an ROI population of 1,706,883 people, which included 139,182 in Martin County; 40,311 in Okeechobee County; 1,266,451 in Palm Beach County; and 260,939 in St. Lucie County (USCB 2009).

NRC guidelines have been established to assess the demographic sparseness and proximity of a proposed site. Sparseness is a combined measure of (1) the population density within 20 miles of the site, and (2) the relative population of the nearest metropolitan area within 20 miles of the site. Proximity is a combined measure of (1) the population density within 50 miles of the site, and (2) the relative population of the nearest metropolitan area within 50 miles of the site. Based on the sparseness-proximity evaluation, a site is categorized as low, medium, or high (NUREG-1437).

The land area within 20 miles of the Martin site (i.e., excluding water bodies such as Lake Okeechobee) is 870.0 square miles, and based on 2000 census data, the population of this area was 95,093 (U.S. NRC Aug 2003). This yields a population density of 109.3 people per square mile, based on land area. There is at least one city within 20 miles of the Martin site that has a population greater than 25,000. Therefore, the sparseness level is 3 (population density of 60 to 120 people per square mile and at least one community greater than 25,000 people within 20 miles) (NUREG-1437).

Similarly, the land area within 50 miles of the Martin site is 5486.6 square miles, and the population of this area was 1,380,905 (U.S. NRC Aug 2003). This yields a population density of 251.7 people per square mile. Therefore, based on NRC guidelines, the proximity level is 4 (population density greater than or equal to 190 people per square mile within 50 miles). Therefore, the Martin site has a sparseness-proximity measure of 3.4, which is categorized as high (NUREG-1437).

Based on FPL estimates, the peak construction workforce for the project would be 3548 construction workers. Operations would overlap with peak construction activity for a period of time; therefore, in addition to the construction workforce, there would be a small number (99) of operations workers on the site during the peak construction period, and these workers would also

relocate to the area. Because of the location of the Martin site relative to population centers, FPL assumed that 50 percent of the construction and operation workers would relocate from outside the ROI. FPL further assumed that 70 percent of construction and 100 percent of operation workforce that moved to the area would bring their families. Based on these assumptions, a total of 1824 construction and operation workers would relocate to the area in the project construction phase, and 1291 would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total increase in population attributable to construction at the Martin site would be 4729 people. An influx of 4729 people represents a 0.3 percent increase in the ROI population of 1,486,520 people. Impacts are considered small if plant-related population growth is less than 5 percent of the area's total population (NUREG-1437). Therefore, construction worker influx would pose a SMALL impact on population for the ROI.

At the county level, if the demographic distribution of the construction workforce follows that of the Martin plant workforce, the addition of the construction and operation workforce employees and their families would increase the population in Martin, Okeechobee, Palm Beach, and St. Lucie Counties by 1.2 percent, 3.2 percent, 0.1 percent, and 0.6 percent, respectively. These represent SMALL increases in the county population levels.

FPL estimated the total onsite operations workforce to be 1050 workers and assumed that 50 percent of these workers (525) would relocate from outside the ROI. For this analysis, FPL assumed that 100 percent of operations workers who relocated would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total population increase attributable to project would be 1706 people. This represents a 0.1 percent increase in the ROI population. At the county level, if the demographic distribution of the operations workforce follows that of the Martin plant workforce, the addition of the operations workforce employees and their families would increase the population in Martin, Okeechobee, Palm Beach, and St. Lucie Counties by 0.4 percent, 1.1 percent, 0.03 percent, and 0.2 percent, respectively. These represent SMALL increases in the county population levels.

In summary, the population increase in the ROI would pose a SMALL demographic impact. Likewise, it is anticipated that the population increase in each of the four counties would pose a SMALL impact during operations.

9.3.3.2.6.3 Economy

Based on 2000 census data, Martin County had a civilian labor force of 53,301 people and an unemployment rate of 4.2 percent; Okeechobee County had a civilian labor force of 14,863 people and an unemployment rate of 4.7 percent; Palm Beach County had a civilian labor force of 510,046 people and an unemployment rate of 5.0 percent; and St. Lucie County had a civilian labor force of 82,070 people and an unemployment rate of 5.2 percent. For the entire ROI, 99.92 percent of the labor force was part of the civilian labor force and 0.08 percent was in the armed

forces. Of the civilian labor force, 95.1 percent were employed and 4.9 percent were unemployed. The overall unemployment rate for the four-county ROI is slightly lower than that of the State, which is 5.6 percent (USCB 2000).

The principal economies of the counties in the ROI are the same, dominated mainly by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force within the four-county ROI resides in Palm Beach County (USCB 2000).

As described above, the peak number of workers at the Martin site would include 3548 construction workers and 99 operations workers, and half of these workers (1824) are assumed to relocate from outside the area. An influx of 1824 construction and operation workers from outside the region would have positive economic impacts in the four-county region. Based on a multiplier of 1.7289 jobs (direct and indirect) for every construction job and 2.2799 for every operation job (BEA Aug 2009), an influx of 1824 construction and operation workers would create 1384 indirect jobs, for a total of 3207 new jobs in the ROI. The creation of such a large number of direct and indirect jobs could reduce unemployment and would create business opportunities for goods and service-related industries and the housing industry. Based on the workforce demographics of the Martin plant, the additional jobs created would represent 2 percent, 5.2 percent, 0.1 percent, and 0.9 percent of the workforce in Martin, Okeechobee, Palm Beach, and St. Lucie Counties, respectively. Economic effects are considered small if peak employment accounts for less than 5 percent of area employment (NUREG-1437). Economic impacts attributable to project construction are considered beneficial and therefore require no mitigation. The number of new jobs created would represent only a 0.5 percent increase in jobs within the ROI, therefore, the economic impacts for the ROI would be SMALL. The projected increase in Okeechobee County would be MODERATE, and the projected increases in the other counties would be SMALL.

An estimated 1050 workers would be required for the operation of two nuclear power facilities at the Martin site (U.S. DOE May 2004), and FPL assumed that 50 percent of these employees would migrate into the region. Based on a multiplier of 2.2799 jobs (direct and indirect) for every operations job at the new units (BEA Aug 2009), an influx of 525 operations workers would create 672 indirect jobs for a total of approximately 1197 new jobs in the region. Based on the workforce demographics of the Martin plant, the additional jobs created would represent 0.7 percent, 1.9 percent, 0.05 percent, and 0.3 percent of the workforce in Martin, Okeechobee, Palm Beach, and St. Lucie Counties, respectively. FPL concluded that the impacts of operation of two nuclear power facilities on the economy would be beneficial and SMALL in the ROI and mitigation would not be warranted.

9.3.3.2.6.4 Taxes

Taxes collected as a result of construction and operation of the new nuclear units at the Martin site would benefit the state and local tax authorities. FPL would pay property taxes to each of the taxing authorities whose boundaries would contain the plant. Tax payments would be based on the assessed valuation of the plant and local tax rates. If the plant site straddled a jurisdictional boundary, FPL would pay taxes to both entities based on the assessed valuation within each entity.

As described in Subsection 4.4.2.2.2, it is not clear whether FPL corporate income taxes would increase as a result of construction of the new units at the Martin site, because the units would not generate revenues until they become operational. However, once the units were placed in service, Martin County property taxes would begin and would continue for the 60-year operational life of the facility.

FPL assumed that annual property tax payments at Martin site would be similar those paid by the nuclear units at Turkey Point plant. In 2007, the annual tax payment for the two units at the Turkey Point nuclear power plant was $6,902,670. For the 2006 fiscal year, Martin County had property tax revenues of $139,155,807 (State of Florida Dec 2007).

With respect to the school districts in Florida, local revenue for the school districts is derived almost entirely from property taxes levied by Florida's 67 counties, each of which constitutes a school district (Florida Department of Education 2008). As described in Subsection 2.5.2.3.5, the state of Florida has an established equalized funding program that re-allocates tax base funds from counties that have a high economic tax base to counties that have a low economic tax base. The Florida Education Finance Program is the primary mechanism to fund the operational costs of Florida school districts. Funding is based on the number of full-time equivalent students, and considers variations in several factors to determine funding for each district: local property tax bases, education program costs, costs of living, and costs for equivalent educational programs because of the density and distribution of the student population.

It should be noted that school property tax payments would be based on the location of the plant and not necessarily on the district(s) attended by the workers' children. Therefore, it is not possible to assess the direct impact of the plant on the school districts. In addition, the impact of plant construction and operation on the special tax districts is not assessed here because most of the property tax payment from the plant would go to the county and the school district(s).

The benefits of taxes are considered small when new tax payments by the nuclear plant constitute less than 10 percent of total revenues for local jurisdictions and large when new tax payments represent more than 20 percent of total revenues (NUREG-1437). Therefore, based on the county portion of the FPL property tax payment for the new units, 4.7 percent of 2007

property tax payments for Martin County would be provided by FPL and would constitute a SMALL positive impact.

9.3.3.2.6.5 Transportation

Roadways close to the proposed site include U.S. Highway 98 (a two-lane highway) that spans north-south between the Martin site and Lake Okeechobee, State Route 76 (a two-lane highway) that spans generally east-west near the southern boundary of the site, and SR 710 (a two-lane highway) that spans in a northwesterly direction from Indiantown. Based on the conceptual site layout for the Martin site, principal road access to the Martin site would be from SR 710 that spans in northwest-southeast orientation along the northeast site boundary. SR 710 intersects with SR 70 near Okeechobee approximately 20 miles northwest, and intersects with SR 76 approximately 7 miles southeast at Indiantown. The region east and northeast of SR 710 is rural and sparsely populated with few roads; therefore, most workforce commuters access SR 710 from SR 76 or SR 70.

FDOT reports the AADT count at two locations along SR 710, one in Okeechobee County approximately 18 miles northwest of the site, and one in Martin County approximately 4 miles southeast of the site. The AADT count and directional peak hour volume of the northwestern location is 8300 vehicles per day and 482 vehicles per hour (FDOT 2008). This peak hour volume classifies this location as a LOS of D (FDOT 2007) and already exceeds the Martin County peak hour capacity by 62 vehicles. The AADT count and directional peak hour volume of the southeastern location is 9600 vehicles per day and 543 vehicles per hour (FDOT 2008). This directional peak hour volume also classifies this location as a LOS of D (FDOT 2007) and already exceeds the Martin County peak hour capacity by 12 vehicles.

Based on the existing workforce at the Martin site, nearly equal amounts of the construction workforce would use the northwestern and southeastern portions of SR 710. Also, the traffic attributable to construction material deliveries could cause additional congestion on SR 710 during certain times of the day. Based on the methodology presented in Subsection 4.4.2.2.4, FPL determined that construction at the Martin site would add 1125 and 944 vehicles during the peak hour to the respective northwestern and southeastern portions of SR 710. This would cause the road to further exceed capacity, add to existing traffic congestion, and drop both roadway locations to a LOS classification of F.

Based on the above analysis, it is likely that the additional traffic would pose delays along SR 710. To facilitate the additional traffic, a large span (almost 40 miles) of SR 710 could be widened to a four-lane highway, and acceleration/deceleration lanes could be added to facilitate commuter traffic. These roadway modifications would be needed along SR 710 between Okeechobee and Indiantown in the vicinity of the Martin site. The NRC applied significance levels to the LOS classifications that were projected to result from the additional traffic associated with

refurbishment activities at nuclear plants (NUREG-1437). FPL considers this approach to be appropriate for construction of a nuclear plant since both refurbishment and new plant construction would be large construction projects. The NRC associates small impacts with LOS A and B, moderate impacts with LOS C and D, and large impacts with LOS E and F. It is therefore anticipated that the impact of the construction workforce on transportation would be LARGE.

Operations at the Martin site would add approximately 323 and 271 more vehicles to the northwestern and southeastern portions of SR 710 during the hour of peak traffic, respectively. If the roadway modifications to SR 710 (mentioned above) were undertaken, the directional peak hour capacity of this roadway would accommodate the additional traffic from operations. Without these modifications, shift changes could also be staggered so that the traffic increase would be less likely to cause congestion. However, based on the NRC LOS significance levels, in the absence of road modifications that increase road capacity, the impact of the operations workforce on transportation would be LARGE.

9.3.3.2.6.6 Aesthetics and Recreation

The Martin site is an 11,300-acre area that includes five fossil-fired power units and a solar unit. The site is owned by FPL and is in western Martin County approximately 5 miles east of Lake Okeechobee. The site is on flat land with minor relief at an approximate elevation of 28 feet above MSL (USGS 1953) and lies within the Everglades physiographic province (USGS 2008).

The construction of the new units at the Martin site could be viewed from offsite at certain locations, but the addition of two nuclear facilities would not substantially change the viewscape that results from the current fossil-fired units. There would be a need to construct cooling water intake structures at the C-44 Canal. Additional cooling towers would be required. Operation of the new nuclear units probably would have visual impacts similar to those of the fossil-fired units at the Martin plant, but with occasional visible vapor plumes associated with cooling tower operations. Visibility of the plumes would depend on weather conditions and the location of the viewer in the area. Impacts on aesthetic resources are considered small if there is no potential for diminution in the enjoyment of the physical environment and no measurable impact on socioeconomic institutions and processes. Therefore, impacts of construction and operation of the new units on aesthetics would be SMALL and would not warrant mitigation.

The western shoreline of Lake Okeechobee lies within 5 miles of the Martin site, as well as portions of the Lake Okeechobee Scenic Trail and Big Water Heritage Trail, which parallel the Lake Okeechobee shoreline. Lake Okeechobee occupies 730 square miles and is the second largest freshwater lake wholly within the United States. The lake is the epicenter of Florida and is renowned for its unique natural habitat, rich heritage, and recreational opportunities to fish and view birds (SFRPC 2008).

The Lake Okeechobee Scenic Trail spans 110 miles along the perimeter of Lake Okeechobee. The Trail is designated as a segment of the Florida National Scenic Trail. The trail is atop the Herbert Hoover Dike, which surrounds the lake for flood protection, and provides views ranging from scenic lakeside to working agricultural landscapes. The trail affords opportunities to view wildlife, fish, bike, and hike. The nearest access point to the trail from the Martin site is the Port Mayaca Recreation Area, which is west of the site (USACE 2008a).

The Big Water Heritage Trail is a designated vehicle roadway that provides vehicular access to the landscapes created by south central Florida's watersheds. The trail begins at the Kissimmee River and continues through the communities around Lake Okeechobee and south through the Everglades. It includes portions of SR 78, U.S. Highway 27, SR 76, U.S. Highway 98, U.S. Highway 441, and spans within a few miles of the Martin site. The Big Water Heritage Trail is a partnership project that promotes public awareness of natural and cultural features (SFRPC 2008).

The Barley Barber Swamp is approximately 2 miles west of the Martin site and comprises a 400-acre freshwater cypress swamp preserve. The swamp is managed by FPL as a nature preserve that provides visitors with an example of how Florida may have appeared more than 100 years ago. The swamp is open to the public by appointment only (FPL Dec 1989).

The DuPuis Wildlife and Environmental Area and J. W. Corbett Wildlife Management Area are less than 5 miles south of the Martin site (SFWMD 2005b). The Dupuis Management Area consists of nearly 22,000 acres that were part of the Everglades ecosystem before conversion to a ranch, which altered the hydrology of the area. The South Florida Water Management District is currently restoring portions of the land by rehydrating interior wetlands. The DuPuis Wildlife and Environmental Area offers hunting, hiking, camping, horseback riding, and scenic driving (FFWCC 2008b). The J.W. Corbett Wildlife Management Area consists of approximately 60,230 acres and also offers hunting, hiking, camping, horseback riding, and scenic driving (FFWCC 2008c).

Within 50 miles of the Martin site there are a number of lakes, rivers, swamps, wetlands, and other areas of interest that include three National Wildlife Refuges: Arthur R. Marshall Loxahatchee, Hobe Sound, and Pelican Island National Wildlife Refuges.

Of the 154 state parks in Florida, 10 are within 50 miles of the Martin site. The closest state park to the site is the Atlantic Ridge State Preserve, approximately 19 miles east of the site (SFWMD 2005b).

Because the Martin site already hosts a power plant with tall structures and transmission towers, the construction and operation of the two new nuclear power units and associated transmission

lines would not pose an appreciable change in viewscape. Therefore, visual impacts on the region would be SMALL.

The attractiveness of the Okeechobee Lake for fishing and other recreational uses could be impacted during construction of intake and discharge structures. During operation, some employees and their families would use the regional recreational facilities; however, the increase attributable to plant operation would be small compared to overall use of these facilities. Impacts on tourism and recreation are considered small if current facilities are adequate to handle local levels of demand. Therefore, impacts of facility construction and operation on tourism and recreation would be SMALL.

9.3.3.2.6.7 Housing

FPL estimated that 1824 construction and operation workers would move from outside the ROI to the counties within the ROI. These 1824 workers would need housing. Some of the workers would seek permanent residence, generally owner-occupied; some would choose to rent; and others would choose a transitional residence such as a hotel, a room in a private home, or a camper or mobile home.

Based on 2000 census data, within the four-county ROI, there were 728,665 housing units of which 109,676 were vacant (15.1 percent). At the county level, the number of vacant housing units was 10,183 (15.6 percent) in Martin County; 2911 (18.8 percent) in Okeechobee County; 82,253 (14.8 percent) in Palm Beach County; and 14,329 (15.7 percent) in St. Lucie County. This includes housing that is designated as seasonal, recreational, or occasional use (USCB 2000).

Based on absolute numbers, FPL estimated that the available housing would be sufficient to house the construction workforce. Workers who relocated could secure housing from the existing stock in any of the four counties within the region, have new homes constructed, or bring their own residence (mobile home or trailer) to the region. At the county level, if the construction workforce that moved to the ROI followed that of the workforce at the Martin plant, the percentage of vacant housing required in each county would be 5.9 percent, 15 percent, 0.4 percent, and 2.9 percent for Martin, Okeechobee, Palm Beach, and St. Lucie Counties, respectively. Impacts on housing are considered to be small when a small and not easily discernable change in housing availability occurs (NUREG-1437). In summary, FPL concluded that the impacts on housing could be Moderate in Okeechobee County but would be SMALL in the other individual counties of the ROI. For the ROI, the impacts on housing during plant construction would be SMALL and mitigation would not be warranted.

FPL estimated that 1050 workers would be needed for operation of two nuclear power facilities at the Martin site (U.S. DOE May 2004). An estimated 50 percent of these workers (525) would come from within the ROI, and 50 percent (525) would relocate to the area. This would represent

less than 1 percent of the vacant housing in the ROI. At the county level, if the construction workforce that moved to the ROI followed that of the workforce at the Martin plant, the percentage of vacant housing required in each county during plant operations would be 1.7 percent, 4.3 percent, 0.1 percent, and 0.8 percent for Martin, Okeechobee, Palm Beach, and St. Lucie Counties, respectively. In summary, FPL concluded that the impacts on housing in the ROI and for any individual county would be SMALL and mitigation would not be warranted.

9.3.3.2.6.8 Public Services

Public services in the ROI include water supply and wastewater treatment facilities, law enforcement, fire and medical facilities, libraries, parks and recreation, roadway maintenance, and other social services. Construction or operations employees who relocate from outside the region would most likely live in residentially developed areas where adequate water supply and wastewater treatment facilities already exist. The medical facilities in the four-county ROI provide medical care to much of the population within the 50-mile region, and therefore the small increases in the regional population would not materially impact the availability of medical services. Although the workers and their families would pose an additional overall demand on other public services, it is anticipated that the current capacity of public services within the four-county ROI would be adequate to accommodate the increased demand. Therefore, the impact would be SMALL.

The new nuclear plant and the associated population influx would likely pose an economic benefit for the disadvantaged population served by the Florida Department of Children and Families. Direct jobs created by the project would bring indirect jobs that could be filled by currently unemployed workers and therefore remove them from the care of social services.

The ratio of residents-to-law enforcement officers in Martin, Okeechobee, Palm Beach, and St. Lucie Counties was 466:1, 399:1, 928:1, and 722:1, respectively (FBI 2008). Within the ROI, the resident-to-law enforcement officer ratio was 804:1, and for the state of Florida, the resident-to-law enforcement officer ratio was 851:1. Ratios are partly dependent on population density. In general, fewer law enforcement safety officers are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional law enforcement officers were hired, the population increase attributable to project construction at the Martin site would increase the resident to law enforcement officer ratio by 0.32 percent to 807:1. This is a small increase and would still yield a lower resident-to-law enforcement officer ratio than the average for the state of Florida. Similarly, the increase in the resident-to-law enforcement officer ratio attributable to operations would yield only a 0.11 percent increase.

The ratio of residents to firefighters in Martin, Okeechobee, Palm Beach, and St. Lucie Counties was 363:1, 492:1, 519:1 and 563:1, respectively. Within the ROI, the resident-to-firefighter ratio was 505:1, and for the state of Florida, the resident-to-firefighter ratio was 1230:1 (USFA 2009).

As was described above in the description of law enforcement officers, ratios are partly dependent on population density. In general, fewer firefighters are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional firefighters were hired, the population increase attributable to project construction at the Martin site would increase the resident-to-firefighter ratio by 0.32 percent to 506:1. This is a small increase and would still yield a lower resident-to-firefighter ratio than the average for the state of Florida. Similarly, the increase in the resident-to-firefighter ratio attributable to operations would yield less than a 0.12 percent increase.

Impacts on public services are considered small if there is little or no need for additional personnel. Impacts are considered moderate if some permanent additions or some new capital equipment purchases are needed (NUREG-1437). The population increase in the four-county region attributable to construction or operation of the new power units could pose a need to hire additional emergency personnel; however, any additional need would be small, and increased tax revenues generated by the project would be adequate to pay the salaries of any additional emergency personnel hired. Therefore, it is not expected that public services would be materially impacted by new construction or operations employees that relocate from outside the region. Impacts are therefore considered SMALL, and mitigation would not be warranted.

9.3.3.2.6.9 Education

Based on data for the 2006–2007 school year, Martin County had 36 prekindergarten through 12 (PK-12) schools with a total enrollment of 18,239 students; Okeechobee County had 17 PK-12 schools with a total enrollment of 7289 students; Palm Beach County had 264 PK-12 schools with a total enrollment of 171,431 students; and St. Lucie County had 46 PK-12 schools with a total enrollment of 38,793 students (NCES 2009). In the four-county ROI, there were 363 PK-12 schools with a total enrollment of 235,752 students (NCES 2009).

FPL estimated that 1824 construction and operation workers would migrate to the area, and that 1291 of these workers would bring a family. This would yield a total population increase of 4729 people. Based on an estimate of 0.8 school-aged children per family, 1033 of the 4740 people who relocated to the four-county area would be school-aged children. This would yield a 0.4 percent increase in the student population within the ROI.

Based on the demographic distribution of the Martin plant workforce, an increase of 1033 students would increase the student populations in Martin, Okeechobee, Palm Beach, and St. Lucie Counties by 1.9 percent, 3.4 percent, 0.1 percent, and 0.6 percent, respectively. Small impacts are generally associated with project-related enrollment increases less than 3 percent and moderate impacts on local school systems are generally associated with project-related enrollment increases of 3 to 8 percent (NUREG-1437). Therefore, projected increases in the student populations for the ROI would be SMALL. The projected increase in Okeechobee County

would be MODERATE, and the projected increases in the other counties would be SMALL. The quickest mitigation would be to hire additional teachers and move modular classrooms to existing schools. Increased property and special option sales tax revenues as a result of the increased population would fund additional teachers and facilities. No additional mitigation would be warranted.

FPL assumed that 525 operations workers and their families would relocate from outside the region, and that the total population increase would be 1706 people. This would include an estimated 420 children in the PK-12 school range. This influx of students would increase the student population in the ROI by 0.2 percent. Based on the demographic distribution of the Martin plant workforce, an increase of 420 students would increase the student populations in Martin, Okeechobee, Palm Beach, and St. Lucie Counties by 0.8 percent, 1.4 percent, 0.05 percent, and 0.25 percent, respectively. Therefore, projected increases in the student populations for the ROI and for each individual county are expected to be SMALL and mitigation would not be warranted.

9.3.3.2.7 Historic and Cultural Resources

FPL conducted historical and archaeological records searches on the National Park Service National Register Information System, and reviewed information on historic and archeological sites provided in documents associated with the FPL Martin Expansion project. Where applicable, historic and archeological sites are identified by their historic site structure identifier.

A detailed cultural resource assessment was conducted at the Martin site in 1989 in support of the Martin Coal Gasification/Combined Cycle (CG/CC) project (FPL May 2008). Approximately 3300 acres of the Martin Power plant site were proposed for use for that project that encompassed the area for the proposed nuclear plant at the Martin site. As a result, an evaluation of sites with archaeological or historical importance was performed for the Martin site.

The evaluation consisted of a review of the Florida Master site File and the examination of the historical and archeological literature and historic records. The search revealed that no archeological sites have been recorded on the FPL Martin plant site.

Areas of potential high archaeological importance were identified based on U.S. Geological Survey (USGS) Quadrangle Maps and aerial photographs before the 1989 field survey. The archeological field survey included each of these areas plus other areas identified in the field with potential significance. The survey strategy required an intensive, systematic, cultural resource survey of these areas and limited systematic and judgmental survey of the remaining areas. The surveys found no archaeological sites within those areas currently designated for the Martin site (FPL May 2008).

The NRHP identifies 100 sites in the four-county ROI; including 70 sites in Palm Beach County, 12 sites in Martin County, 16 sites in St. Lucie County, and two sites in Okeechobee County. One

of these properties, the Seminole Inn, is within 10 miles of the Martin site (NPS 2008c). The Seminole Inn is an historic hotel in Indiantown, Florida (Martin County). It was built by S. Davies Warfield, who was president of the Seaboard Air Line Railroad, which developed Indiantown.

Sites are considered to have small impacts to historic and cultural resources if the SHPO identifies no significant resources on or near the site or determines they would not be affected by plant construction or operation. A detailed cultural resource assessment conducted at the Martin site in 1989 found no archaeological sites within those areas currently designated for the Martin site; therefore, FPL concludes that impacts to cultural sites during construction or operation of the proposed nuclear plant at the Martin site would be SMALL.

Construction of the new units at the Martin site could be viewed from the historic and cultural sites within 10 miles of the site, but the addition of two nuclear power facilities would not substantially change the view. The operation of the new units probably would have visual impacts similar to those of the existing FPL Martin power plant, with the addition of cooling tower plumes. Therefore, visual impacts of construction and operation of the Martin site relative to historic and culture sites would be SMALL and would not warrant mitigation.

9.3.3.2.8 Environmental Justice

Environmental justice refers to a federal policy under which each federal agency identifies and addresses, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority or low-income populations. The NRC has a policy on the treatment of environmental justice matters in licensing actions (69 FR 52040) and guidance (U.S. NRC May 2004). Subsection 2.5.4.1 describes the methodology FPL used to establish locations of minority and low-income populations.

The 2000 census block groups were used to ascertain minority and low-income population distributions in the area. There are 794 block groups within 50 miles of the Martin site. The census data for Florida characterizes 14.6 percent of the population as black; 0.3 percent American Indian or Alaskan Native; 1.7 percent Asian; 0.1 percent Native Hawaiian or other Pacific Islander; 3.0 percent as other single minorities; 2.4 percent multiracial; 22.0 percent aggregate of minority races; and 16.8 percent Hispanic ethnicity. If any block group percentage exceeded the state percentage by more than 20 percent or was greater than 50 percent, then the block group was considered to have a significant minority population. Significant black minority populations exist in 118 block groups; significant American Indian or Alaskan Native populations exist in 1 block group; significant other race minority populations exist in 7 block groups; significant multiracial minority populations exist in 3 block groups; significant aggregate of minority races populations exist in 139 block groups; and significant Hispanic ethnicity populations exist in 55 block groups. There are no block groups containing significant Asian or Native Hawaiian or other Pacific Islander minority populations within 50 miles of the Martin site.

The Brighton Seminole Indian Reservation is 30 miles west of the Martin site. As described in Subsection 9.3.3.1.7, the reservation offers several tourist attractions including Indian arts and crafts shops, the Seminole Casino Brighton, a rodeo arena, the Brighton Citrus Grove, and the Brighton Seminole Campground. Today, most Seminole Tribal members are afforded modern housing and health care. In fact, today the Seminole Indians live much the same way as those who live outside Seminole County (Seminole Tribe of Florida 2008).

The locations of the minority populations within 50 miles of the Martin site and the Brighton Indian Reservation are shown in Figure 9.3-12.

The USCB data characterizes 11.7 percent of Florida households as low income. Based on the more than 20 percent criterion, 53 block groups out of a possible 794 contain a significant number of low-income households. The locations of the low-income populations within 50 miles of the Martin site are shown in Figure 9.3-13.

Although the Martin site is within a minority block group, construction activities (noise, fugitive dust, and air emissions) would be contained with site boundaries and would not disproportionately impact minority populations. In fact, minority and low-income populations would most likely benefit from construction activities through an increase in construction-related jobs. Operation of the new units at the Martin site is also unlikely to have disproportionate impacts on minority or low-income populations.

FPL concluded that construction and operation of the proposed nuclear plant at the Martin site would not disproportionately impact minority or low-income populations and that mitigation would not be warranted, and the impacts to these populations would be SMALL.

9.3.3.2.9 Other Projects in the Vicinity of the Martin Site

The cumulative impacts of past, present, and reasonably foreseeable federal (e.g. USCOE, USGS), non-federal (e.g. FDEP, FDOT, county), and private projects within a 50-mile radius of the Martin site, excluding Brownfield and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites, that could have cumulative impacts with the proposed action are described in Table 9.3-12. These projects have either requested an air or water permit/license or had an environmental impact statement complete. Projects included in Table 9.3-12 are within the 50-mile radius of the Martin site and the appropriate timeframe for construction and operation of the new units (Figure 9.3-11) from 2013 to 2063 (based on a construction start date of 2013, a Unit 7 in-service date of 2023, and a 40-year operating license). Nuclear power projects within 100 miles of the Martin site (i.e., St. Lucie) are also described in Table 9.3-12. The Turkey Point site is more than 110 miles from the Martin site and is therefore not included in the table. The only other nuclear power plant currently operating in Florida, Crystal River, is more than 180 miles from the Martin site and therefore is also not included in the

table. The proposed nuclear power plant in Levy County is approximately the same distance as the Crystal River site and is not included in the table. It should be noted that this list is not intended to be exhaustive and should not be used to imply that no other past, present, or reasonably foreseeable projects exist that could contribute to cumulative impacts within each alternative site project ares.

The impacts to land use that would have a cumulative impact on alternative sites would generally be characterized as a change to the land use designation from “agriculture” to “industrial.” A positive land-use impact, for example, would be the CERP projects. These projects within the 50-mile radius would redevelop, reuse, or develop additional land for conservation. The cumulative impacts to hydrology and water use would be minimally negative due to the restrictions placed on all surface water and groundwater use, also beneficial impact due to the large scale CERP projects for reservoir and storage areas which would provide additional water to the southern Everglades Agricultural Area, reestablish wetland hydropatterns and improve Everglades water quality by treating urban stormwater runoff. The cumulative impacts for terrestrial/aquatic resources would be associated with the minimal loss of wetlands, which is offset by the restoration of developed lands for conservation and restoration of native species through CERP projects. The cumulative impacts for socioeconomics for the Martin site would appear as beneficial impacts to taxes and adverse impacts on transportation. Also, there would not be any disproportionate impact to low-income or minority populations by the activities at the Martin site.

9.3.3.3 Evaluation of the Okeechobee 2 Site

During the site selection process, the Okeechobee 2 site was identified as a 3000-acre undeveloped site in Okeechobee County located approximately 8 miles west of the town of Okeechobee, just north of SR 70 along County Road 128th Avenue Northwest. The site is not owned by FPL but is considered potentially available and feasible for a power generation project. Nearby towns include Okeechobee (8 miles east), Buckhead Ridge (10 miles south), Lakeport (22 miles southwest), Cypress Quarters (10 miles east southeast), Taylor Creek (11 miles east southeast), Indiantown (34 miles southeast), Fort Pierce (40 miles northeast), Lorida (14 miles northwest), Lake Placid (19 miles west), Moore Haven (29 miles south), and Port St. Lucie (30 miles east). (Rand McNally 1999) The Miami Load Center is approximately 90 miles to the south. Nearby water bodies include the Kissimmee River (2 miles west) and Lake Okeechobee (7.6 miles southeast). Portions of the site are located within the 100-year floodplain. The location of the Okeechobee 2 site is shown in Figure 9.3-14.

9.3.3.3.1 Land Use Including Site and Transmission Line Rights-of-Way

Based on the conceptual site layout developed for the Okeechobee 2 greenfield site, the following land requirement assumptions were made which form the basis of the environmental comparison of alternative sites:

- The assumed facility footprint would require approximately 362 acres and the assumed cooling water storage reservoir would require approximately 3002 acres. New facilities at the plant site would include the nuclear power units, support buildings, a switchyard, storage areas, stormwater retention ponds, and deep injection wells for subsurface water disposal.

- The assumed extent of non-transmission linear features, including access road corridors, pipeline corridors and rail access, is as follows:

    — Access road: 112.3 acres – assuming a corridor length of approximately 9.3 miles and corridor width of 100 feet. Based on conceptual site layouts developed for the Okeechobee 2 site, site access would be from SR 70. Improvements to SR 70 would include widening a portion of SR 70 from two lanes to four lanes to accommodate anticipated traffic levels attributable to construction.

    — Rail: 46.6 acres – based on assumed length of approximately 3.9 miles and corridor width of 100 feet, to provide access to the nearest railway northeast of the site.

    — Intake/makeup pipeline corridors: 22.5 acres, including pipeline connecting the reservoir to the Kissimmee River (assumed cooling water source) to the south.

- The assumed extent of conceptual transmission corridor routing is 3022 acres based on an assumed length of approximately 38 miles and a corridor width of 660 feet, to connect to the existing FPL transmission system at the Corbett substation inside Palm Beach County.

- Based on sub-totals above for both onsite and offsite plant components, the total area potentially affected at the Okeechobee 2 site is estimated at approximately 6567 acres. With respect to the transmission line corridor included within this total, the estimated acreage requirements assume a corridor width which may exceed the area that would actually be disturbed during project construction and operation. However, these estimates provide the basis for an updated and consistent environmental comparison of alternative sites.

- Additional acreage (up to several hundred acres) may be required to support construction activities (e.g., additional laydown areas, batch plant, fill/spoil areas). However, cleared land would be used to the greatest extent possible. The impact on this acreage would be temporary, and it would also be reclaimed to the extent possible following construction.

The Okeechobee 2 site is used mainly for farmland and agriculture. The county has substantial cattle, dairy, and citrus operations. The site is generally flat with a mean elevation of 28 feet. Portions of the site are located within the 100-year floodplain and may require filling to increase the elevation. Should FPL determine that some areas would require filling, sufficient quantities of fill material would be available from excavation of the reservoir and/or storm water retention

ponds. An area of approximately 362 acres for the main power plant site (major structures including switchyard), which would largely be focused in one central location; and approximately 3000 acres (surface area) for a new reservoir and intake structure would be permanently impacted.

Land use impacts associated with plant construction include both impacts to the site and immediate vicinity, including the new reservoir; and impacts to offsite areas such as transmission, cooling water intake pipelines, and transportation rights-of-way (e.g., road and rail).

Project construction activities at the Okeechobee 2 site may require filling those portions of the site area that are within the 100-year flood zone. FPL has determined that sufficient fill material could be available onsite, based on the amount of material that would be excavated for the reservoir and storm water retention ponds.

Construction of the power plant and transmission lines would alter land use at the site from agricultural to industrial. Much of the proposed power plant site area has already been cleared and is now used for agricultural activities; nearly 2000 acres of the plant site area are currently in pasture; another 1200 acres consist of wet prairies. Following construction activities, impacted areas without constructed buildings or transportation infrastructure would be reclaimed to the greatest extent feasible.

Construction at the proposed pipeline corridors would have temporary, minor effects on land use during actual construction due to trenching, equipment movement and material laydown. The ability to use current lands for their existing uses (e.g., farmland) along the proposed pipeline corridor would be temporarily lost during construction. Direct and indirect impacts of construction from the proposed transportation infrastructure would be similar to those for the proposed plant.

Development of the conceptual transmission corridor incorporated the most direct route where possible, while considering potential conflicts with natural or man-made areas where important environmental resources were located, and avoiding populated areas and residences to the extent possible. Whenever possible, the new line was routed along existing transmission rights-of-way. The use of lands that are currently forested would be altered. Trees would be replaced by low-growth types of ground cover such as grass. The new transmission corridor would not be expected to preclude agricultural activities near the eventual rights-of-way. The land use in the region (along the new transmission corridors) is generally rural, sparsely populated, and primarily used for agricultural activities. The Okeechobee 2 site is 45 miles inland from the Atlantic Ocean and is therefore not part of the Florida Coastal Zone. The route for the new transmission line includes 38 inland miles and would not pass through any portion of the Florida Coastal Zone.

Table 9.3-13 includes estimates of the potentially affected area(s) of each land cover type (based on GIS FLUCCS Level III data analysis) for the Okeechobee 2 site, including both onsite

and offsite components (i.e., access road, rail, pipeline and transmission corridors). It also further breaks out the land cover types along the assumed conceptual transmission corridor only, given the significant acreage this corridor encompasses (46 percent of the total area). As noted previously, regarding the offsite linear features associated with the projects, the estimated acreage requirements assume corridor widths for transmission which may exceed the area that would actually be disturbed during project construction and operation. These estimates are intended to provide the basis for an updated and consistent environmental comparison of alternative sites.

The proposed project would be a change from current land use at the site. Operational impacts to site land use would include a permanent change in land use approximately 3500 acres of land for the power plant site, reservoir, and rail/highway site access corridors – that would be generally unavailable for other purposes. The entire plant footprint, reservoir and offsite access road and rail spur would be excluded from future agricultural and recreational use for the estimated 60-year life of the AP1000 power units (WEC 2007).

Operational impacts to the site and immediate vicinity also would include maintenance operations on project structures that would be small and temporary in nature.

Operational impacts of transmission lines result primarily from line maintenance, and include right-of-way vegetation clearing and control, transmission line maintenance, and other normal access activities. Additional right-of-way acquisition and development would not normally be required as part of plant operational activities. Maintenance activities would be limited to the immediate right-of-way and would be minimal. New transmission corridor would not be expected to preclude agricultural activities near the eventual rights-of-way. Corridor vegetation management and line maintenance procedures would be established by the transmission service provider.

Other offsite land use impacts as a result of plant operational activities would be minimal, temporary, and limited in the area impacted. Such activities could include pipeline, road, and rail maintenance and auxiliary building maintenance. It is likely that most lands above the proposed water intake pipeline and related areas of construction could continue to be used for ranching, farming and any passive uses. The proposed transportation infrastructure could result in the loss of a small amount of ranch land, pasture land and forested land in areas where access road improvements/widening and a rail spur would be needed.

For the purpose of this analysis, land use impacts are considered small if less than 3000 acres are disturbed (including plant footprint, reservoir, rights-of-way, and corridors) and there are no major changes to land use. Impacts are considered moderate if land disturbance is greater than 3000 acres or there are major changes to land use; and large if land disturbance is greater than 6000 acres and there are major changes to land use. Based on a potentially affected area of

approximately 6568 acres, and the permanent change of land use from agricultural to industrial, land use impacts associated with site preparation, construction, and operation of the proposed nuclear plant at the Okeechobee 2 site and the conceptual transmission corridor would be LARGE.

9.3.3.3.2 Air Quality

Okeechobee County (which includes the Okeechobee 2 site) is part of the Southeast Florida Intrastate Air Quality Control Region. Okeechobee County, along with the entire state of Florida, is designated as attainment or unclassifiable with respect to the NAAQS (40 CFR 81.310). The nearest non-attainment area is in Georgia, several hundred miles north northwest of the Okeechobee 2 site (40 CFR 81.311).

Criteria pollutant emissions from construction and operation of the proposed nuclear plant at the Okeechobee 2 site would be comparable to the emissions generated at the Turkey Point site as described in Subsections 4.4.1.2 and 5.8.1.2, respectively. Construction impacts would be temporary and would be similar to those associated with any large-scale construction project. Particulate emissions in the form of dust from disturbed land, roads, and construction activities would be generated. Mitigation measures similar to those described in Subsection 4.4.1.2 would be applied as necessary. Criteria pollutants would also be generated from onsite fossil-fueled construction equipment and construction vehicles, and from commuter and delivery vehicles that travel to and from the site. The quantity of criteria pollutant emissions generated by construction activities would be small compared to total vehicular emissions in the region. It is assumed unlikely that construction-related emissions would cause any violation of the NAAQS.

The project would include standby diesel generators and diesel-driven fire pumps. Annual emissions from these sources are listed in Table 3.6-4. It is expected that standby diesel generators and auxiliary power systems would see limited use and, when used, would operate for a short time interval. The pollutant emissions generated by these systems (nonradiological) would be regulated by the FDEP in accordance with the air rules published under FAC Chapter 62. These rules cover general air pollution control provisions, stationary source requirements, preconstruction review, emission standards, air monitoring requirements, and other rules for control of air pollutant emissions. Airborne release of criteria pollutant and hazardous air pollutant emissions would be small and would comply with FDEP rules (FDEP 2008a).

Nonradiological emissions can potentially affect regional visibility, and visibility is an important feature at Federal Class I areas. The Federal Class I area nearest to the Okeechobee 2 site is the Everglades National Park nearly 100 miles to the south. Because the distance is large, and because the anticipated emission levels would be small, pollutant emissions attributable to operation of the new nuclear units would have a negligible impact on visibility at a Federal Class I area. Unfavorable psychometric conditions can result in visible vapor plumes from the cooling

tower operations. These plumes may be visible for several miles, but would not impact visibility or scenic vistas at any Federal Class I area.

Air quality impacts are considered small if the increase in regional pollutant concentrations attributable to the source (1) would not appreciably alter visibility, (2) would not exceed EPA significant impact levels, and (3) would not cause a violation of the most restrictive ambient air quality standards. Based on this evaluation metric, it is anticipated that the impacts to air quality from construction and operation would be SMALL.

9.3.3.3.3 Hydrology, Water Use, and Water Quality

The state of Florida is divided into five watershed management areas. The Okeechobee 2 site is in the Kissimmee-Everglades watershed and falls under the jurisdiction of the SFWMD. This watershed region spans over 16 counties and is logically divided into several river basins: Kissimmee River, Upper East Coast, Lower East Coast (which includes the entire southeast coast and the Everglades), and Lower West Coast (which includes the Big Cypress and Caloosahatchee Rivers). This region is the largest watershed region in the state of Florida and is home to 40 percent of Florida's population. The region also contains the Everglades (the largest subtropical wetland in the United States) and Lake Okeechobee, the second largest freshwater lake in the United States. This lake is of national importance because its water has diverse usage and a large number of people depend on it for agricultural and domestic purposes (University of Florida Jun 2007).

Currently, Lake Okeechobee's water quality and ecological health are adversely affected by excessive nutrient loading, extreme high and low water levels, and the proliferation of exotic species. To address restoration goals for the lake, the SFWMD in coordination with the FDEP and the Florida Department of Agricultural and Consumer Services has developed the Lake Okeechobee Watershed Construction Project Technical Plan. The plan was developed in response to the Northern Everglades and Estuaries Protection Program that the Florida Legislature signed into law in 2007. Primary components of the plan include implementing agricultural management practices, building treatment wetlands to clean water flowing into the lake, and creating between 900,000 and 1.3 million acre-feet of water storage north of the lake (SFWMD 2008).

In the year 2000, the average daily surface freshwater withdrawals in Okeechobee County totaled 12.0 million gallons, which represents 16.7 percent of the total daily withdrawal rate for the county (71.83 million gallons) (USGS Dec 2004). Major surface freshwater sources near the Okeechobee 2 site include Lake Okeechobee (7.6 miles away) and the Kissimmee River (2 miles away).

The entire state of Florida, and portions of southern Alabama, southeastern Georgia, and southern South Carolina, are atop the Floridan aquifer. This aquifer covers some 100,000 square miles and is one of the most productive aquifers in the world. The Floridan aquifer system provides water for several large cities, such as Savannah and Brunswick in Georgia; and Jacksonville, Tallahassee, Orlando, Tampa Bay, and St. Petersburg in Florida. In addition, the aquifer system provides water for hundreds of thousands of people in smaller communities and rural areas. The Floridan aquifer is intensively pumped for industrial and irrigation supplies (USGS July 1980).

In the year 2000, average daily water withdrawals in Okeechobee County included groundwater (59.8 million gallons) and surface water (12 million gallons) for a total of 71.8 million gallons. Principal groundwater sources in the county included the Floridan and surficial aquifers. Nearly 96 percent of groundwater withdrawals (57.29 million gallons per day) and 93 percent of surface water withdrawals (9.75 million gallons per day) were used for agriculture. Average daily public water supply in Okeechobee County for the year 2000 was 2.23 million gallons per day, which included 24 percent fresh groundwater and 76 percent fresh surface water (USGS Dec 2004).

The depth to the water table near the site is less than 20 feet below ground level. Therefore, it is expected that dewatering may be necessary during the construction phase. This may require construction of temporary retention ponds to allow sediment-laden waters to settle before discharge to surface waters. Dewatering activities would be subject to NPDES permit requirements to avoid adverse impacts on surface waters.

Land subsidence related to karst terrain is not anticipated at the site. The site is in karst Area II where the surface cover is reported to be 30 to 200 feet thick. In such areas, sinkholes are reported to be few, shallow, of small diameter, and develop gradually (Sinclair, et al.,1985).

Site groundwater wells are expected to be installed in the middle Floridan aquifer. Since the site is inland from the coast, lateral saltwater intrusion is not likely. However, there is a potential for saltwater to migrate vertically into the middle Floridan aquifer from the saline deeper Floridan aquifer. Since the middle Floridan aquifer already produces brackish water, resultant saltwater intrusion could require additional osmosis or freshwater mixing to satisfy potable water quality standards.

As shown in Subsection 4.2.2.1, the peak construction water demand is estimated at 565 gpm which is slightly greater than one cubic foot per second, and the peak estimated potable water demand for operations is 2553 gpm (Table 3.3-1). As described in Section 3.3, an estimated 100 cfs of freshwater would be required to replace consumptive water use associated with operation of the proposed nuclear power units. Lake Okeechobee offers a potential water supply of more than 360 cfs, and the annual average flow of the Kissimmee River near the site is approximately 919 cfs. The estimated groundwater potential at the Okeechobee 2 site is approximately 155 cfs.

These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Okeechobee 2 site. Water use impacts are considered small when water sources are readily available to meet demand. A permittability assessment of the probability of obtaining water permits at the Okeechobee 2 alternative site would be required to develop the documentation necessary to firmly establish conditions under which water from these sources could be made available. Such analysis is beyond the reconnaissance-level evaluations required for alternatives analysis. Instead, these evaluations must be based on statutory and regulatory criteria requiring site-specific analysis of reasonable beneficial use, existing legal users, and public interest factors. Accordingly, because adequate water sources are physically available nearby, the impact on regional water use for both construction and operation would be SMALL.

Water quality impacts are considered small when changes in water quality do not affect or minimally affect aquatic biota and water uses (NUREG-1437). For the Okeechobee 2 site, FPL assumed that a closed-loop, mechanical draft, tower-cooled system would be used for power cycle waste heat rejection, whereby blowdown water is injected into the Boulder Zone. The Boulder Zone is a deep underground, extremely permeable, cavernous region in southeastern Florida. It is called the Boulder Zone not because it contains boulders, but instead, because efforts to drill into this zone pose difficulties similar to the difficulties posed by subsurface boulders. Construction and operation activities at the Okeechobee 2 site would be performed under the authorization of an NPDES permit (construction), IWW permit (surface water), or UIC permit (groundwater) issued by the FDEP (FDEP 2008b). Any releases from the water storage reservoir into Lake Okeechobee or regional streams as result of construction or operation would be regulated by the FDEP through the NPDES, IWW, or UIC permit process to ensure that water quality was protected. To ensure that wetlands and streams are not harmed by petroleum products or other industrial chemicals, FPL would restrict certain activities (e.g., transfer and filling operations) that involve the use of petroleum products and solvents to designated areas, such as laydown, fabrication, and shop areas. In addition, construction activities would be guided by a stormwater pollution prevention plan and a construction-phase spill prevention, control, and countermeasures plan similar to those proposed for the Turkey Point site as described in Section 4.2. Therefore, any impacts to surface water during plant construction would be SMALL and would not warrant mitigation beyond best management practices required by the permits. The impacts to water quality during operations would also be SMALL because the IWW and UIC permit requirements would ensure that adequate measures are applied to protect water quality.

9.3.3.3.4 Terrestrial Resources and Protected Species

Table 9.3-13 includes estimates of the potentially affected area(s) of each land cover type within the project area for both onsite and offsite components, including natural vegetation and wetland areas. As can be seen in Table 9.3-13, the Okeechobee 2 site consists mainly of improved pasture and wet prairies. The site is generally flat with a mean elevation of 28 feet.

As shown in Table 9.3-13, there are approximately 1500 acres of wetlands within the project area, excluding the conceptual transmission corridor, which could be directly impacted from project construction. Of these, approximately 89 acres are identified as forested wetlands and considered to be high quality. Any wetland functions that are impacted during construction would be replaced or restored. The footprint of the new facilities, excluding the assumed conceptual transmission corridor, would cover approximately 3545 acres.

Wildlife viewing along the nearby Lake Okeechobee Scenic Trail, which encircles Lake Okeechobee, includes herons, egrets, and wintering waterfowl, which are prevalent along the rim of the lake and in open water. Dry prairies interspersed with oak and cabbage palm hammocks provide habitat for crested caracaras (*Caracara cheriway*), burrowing owls (*Athene cunicularia floridana*), and sandhill cranes (*Grus canadensis pratensis*). Alligators, snakes, and turtles are common in the marshes (FFWCC 2008d). In neighboring Highlands County, the Lake Wales Ridge Wildlife and Environmental Area, which contains habitat similar to the Okeechobee 2 site, has a number of species present: amphibians and reptiles include the American alligator (*Alligator mississippiensis*), dusky pygmy rattlesnake (*Sistrurus miliarius barbouri*), eastern indigo snake (*Drymarchon corais couperi*), gopher frog (*Rana capito*), gopher tortoise (*Gopherus polyphemus*), green anole (*Anolis carolinensis*), short-tailed snake (*Stilosoma extenuatum*), and southern black racer (*Coluber constrictor priapus*). Birds include the bald eagle (*Haliaeetus leucocephalus*), common loon (*Gavia immer*), Florida scrub-jay (*Aphelocoma coerulescens*), great egret (*Ardea alba*), little blue heron (*Egretta caerulea*), osprey (*Pandion haliaetus*), roseate spoonbill (*Platalea ajaja*), sandhill crane (*Grus canadensis pratensis*), snowy egret (*Egretta thula*), and swallow-tailed kite (*Elanoides forficatus*). Mammals include the bobcat (*Lynx rufus*), coyote (*Canis latrans*), Florida black bear (*Ursus americanus floridanus*), Florida mouse (*Podomys floridanus*), Florida weasel (*Mustela frenata peninsulae*), gray fox (*Urocyon cinereoargenteus*), and river otter (*Lutra canadensis*) (FFWCC 2008e).

Threatened, endangered, and/or species of special concern that exist in Okeechobee County are listed in Table 9.3-14. The FNAI biodiversity matrix query results for the matrix units encompassing the Okeechobee 2 site did not include any documented occurrences of rare species tracked by FNAI (FNAI 2011).

According to the FFWCC Bald Eagle Nest Location Database, no active bald eagle (*Haliaeetus leucocephalus*) nests are at the Okeechobee 2 site. The closest nest is approximately 1.4 miles from the project area, and there are five nests within 2 miles: Nests OK005, OK006, OK017, OK026, and OK027 (FFWCC 2008a).

Further field surveys would be conducted for federally listed and state-protected species as part of the permitting process before any clearing or construction activities were conducted at the site or along associated transmission or pipeline corridors. Land preparation associated with construction of the plant and transmission lines would be conducted in accordance with federal

and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices (e.g., directed drainage ditches, silt fencing) (FPL Dec 2006).

As described in Subsection 9.3.3.3.1, FPL assumed that two 230 kV transmission lines and two 500 kV transmission lines would be required to connect the new nuclear units to the existing FPL transmission system via the Corbett Substation in northern Palm Beach County. The transmission lines would be routed in two parallel corridors. Based on the site layout for Okeechobee 2, the conceptual corridor encompassing the four lines would be approximately 38 miles long and nominally 660 feet wide. The conceptual transmission corridor generally follows the most direct route between terminations while consideration was also given to avoiding possible conflicts with natural areas where important environmental resources are located.

As shown in Table 9.3-13, there are approximately 542 acres of wetlands found within the conceptual transmission corridor; approximately 211 acres are forested wetlands and considered to be high quality. This compares to a 3022-acre area potentially affected by the conceptual transmission corridor, based on the dimensions above. Any wetland functions that are impacted during construction would be replaced or restored. Construction of the new transmission lines would potentially impact approximately 3022 acres within the conceptual transmission corridor. However, the estimated acreage requirements for the transmission corridor assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. These estimates are used to provide the basis for an updated and consistent environmental comparison of alternative sites.

Cooling tower operations can generate vapor plumes that drift downwind. Salt and mineral deposits in the vapor plume have the potential to adversely impact sensitive plant and animal communities through changes in water and soil chemistry; however, the freshwater sources identified for the Okeechobee 2 site have modest levels of salts and dissolved minerals; therefore, the impact of salt and mineral deposits from vapor drift would be minimal. The use of drift eliminators, along with proper tower design and operation, would further minimize the potential for impacts.

For the purpose of this analysis, impacts to terrestrial resources are considered small if no sensitive habitats, including wetlands, are disturbed and no important species are affected. Okeechobee County has a low number of sensitive species, and there are no known sensitive species onsite. The site area includes a relatively small area of undisturbed woodlands that could be potentially affected by project construction and operation. However, it also includes over 2000 acres of wetlands, including approximately 1300 acres of wet prairies and 300 acres of high quality wetlands that could be potentially affected. Construction of the plant and reservoir would result in a loss of primarily pasture land and wet prairies that may serve as habitat to various common terrestrial species; however, the creation of a new reservoir to support plant operation

would provide new habitat for birds and waterfowl that would not be adversely affected by plant operation. FPL concluded that impacts to terrestrial resources, including endangered and threatened species, from construction and operation of the proposed nuclear plant and conceptual transmission corridor at the Okeechobee 2 site would be MODERATE.

9.3.3.3.5 Aquatic Resources and Protected Species

The Okeechobee 2 site is approximately 2 miles from the Kissimmee River and 7.6 miles from Lake Okeechobee. Historically the Kissimmee River meandered approximately 103 miles from Lake Kissimmee to Lake Okeechobee through a one to 2-mile wide floodplain. The river and its flanking floodplain consisted of a mosaic of wetland plant communities and supported a diverse group of waterfowl, wading birds, fish, and other wildlife. The historic Kissimmee River was hydrologically unique among North American river systems in that it had prolonged periods of extended floodplain inundation. Between 1962 and 1971, the river was channelized and two-thirds of the historical floodplain was drained. Excavation of the canal and placement of the spoil material destroyed one-third of the river channel. Implementation of the Kissimmee Flood Control project led to drastic declines in wintering waterfowl, wading bird and game fish populations, and the loss of ecosystem functions. A restoration project, to be undertaken by the U.S. Army Corps of Engineers, is expected to include filling 22 miles of the C-38 Canal, excavation of nearly 9 miles of river channel in the river's lower basin, and the removal of the S-65B and S-65C water control structures. These actions will provide a more natural fluctuation of water levels in both the upper and lower basins that will enhance marshes around the lakes and reestablish the river's hydrology. Fish and wildlife habitat in the river's one to 2-mile-wide floodplain would benefit substantially from this restoration project (USACE 2008b).

Lake Okeechobee is at the center of south Florida's regional water management system, and is in south-central Florida. The massive lake is a 730 square mile, relatively shallow lake with an average depth of 9 feet and is the second-largest freshwater lake wholly within the continental United States, second only to Lake Michigan. Lake Okeechobee's drainage basin covers more than 4600 square miles (SFWMD 2008).

Lake Okeechobee supports a nationally recognized sport fishery for largemouth bass (*Micropterus salmoides*) and black crappie (*Pomoxis nigromaculatus*), as well as a commercial fishery for various catfish and bream (*Lepomis spp.*). These fisheries generate nearly $30 million per year for the local economies, and they have an asset value that is in excess of $100 million. Another estimate places the value of the recreational fish species at more than $300 million. In addition to the sport and commercial species, Lake Okeechobee supports a diverse community of fish, including (in total) 41 species. These fish are a food resource for wading birds, alligators, and other animals that use the lake (SFWMD 2005a).

For the purpose of this analysis, impacts to aquatic resources are considered small if no sensitive habitats are disturbed and no important species are affected. Water from the Kissimmee River via pipeline would be the source to cool the new nuclear units constructed at the Okeechobee 2 site. Although recreational sport fish and other aquatic species would be temporarily displaced during construction of a water intake structure, they would be expected to recolonize the area after construction is complete. No listed fish species are known to exist in Okeechobee County (FNAI 2011), which includes the Kissimmee River and portion of Lake Okeechobee near the Okeechobee 2 site. One state-listed amphibian, the gopher frog (*Rana capito*), has been documented or observed in Okeechobee County. Field surveys would be conducted for federally listed and state protected aquatic species as part of the permitting process before any clearing or construction activities at the site or along associated transmission corridors. Because of this, and because land clearing associated with construction of the plant and transmission lines would be conducted according to federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established Best Management Practices, impacts to aquatic resources, including endangered and threatened species, from construction of nuclear power facilities at the Okeechobee 2 site would be SMALL.

There would be no direct discharges to the nearby surface waters from plant operation since plant design assumes discharge by underground injection. The most likely aquatic impact from nuclear operations at the Okeechobee 2 site would be entrainment and impingement of aquatic organisms in the Kissimmee River. Because the EPA requires facilities to meet criteria designed to protect organisms from entrainment and impingement, the potential for environmental impacts to aquatic resources, including endangered and threatened species, from nuclear power facility operations at the Okeechobee 2 site would be SMALL.

9.3.3.3.6 Socioeconomics

This subsection evaluates the social and economic impacts to the region from construction and operation of the proposed nuclear plant at the Okeechobee 2 site. Much of the socioeconomic analysis relies on census data gathered by the USCB. The USCB performs an extensive census every 10 years. The most recent decennial U.S. census was performed in year 2000. The USCB assembles the decennial census data into a wide range of reports that can be used to characterize socioeconomic conditions of a region. In addition, the NRC sponsored development of a computer program called SECPOP2000 that enables an analyst to quickly assemble and quantify customized regional socioeconomic information; however, this program does not produce results for years later than 2000 (U.S. NRC Aug 2003). For years that fall between each decennial census, the USCB issues estimates based on surveys and statistical models; however, the types of data collected and assembled for intermediate years is less extensive than for years when a decennial census is performed; therefore, the decennial census provides the most comprehensive information.

Because the decennial census provides the most comprehensive information, and because the NRC software tool, SECPOP2000, is not available for intermediate years, information from the 2000 census is chosen as a common baseline for socioeconomic comparison for this analysis. Published census data for later years, if available, is presented as supplemental information.

9.3.3.3.6.1 Physical Impacts

Construction activities can cause temporary localized physical impacts such as noise, odor, fugitive dust, vehicle exhaust emissions, ground vibration, and shock from blast activities. The use of public roadways and railways would be necessary to transport construction materials and equipment to the site. Most activities would occur within the boundaries of the Okeechobee 2 site; however, an access road and a railway connection spur would be constructed on lands adjacent to the site. These new transportation rights-of-way would be routed to avoid residences and populated areas, although a portion of SR 70 would be widened by two lanes to accommodate anticipated traffic levels attributable to project construction; some residences and commercial services could be temporarily affected during construction. In addition, the conceptual site layout developed for the site also includes construction of a 38-mile conceptual transmission corridor that would include off-site impacts. Other offsite areas that would support construction activities (for example, borrow pits, quarries, and disposal sites) would be expected to be already permitted and operational. Impacts on those facilities from construction of the new plant would be small incremental impacts from those associated with their normal operations.

Potential impacts from power plant operations include noise, odors, exhausts, thermal emissions, and visual intrusions. Operational noise would be generated by pumps, fans, transformers, turbines, generators, onsite traffic, and switchyard equipment. Noise levels attenuate rapidly with distance so that ambient noise levels (attributable to power plant operations) would be minimal at the site boundary. Also, the Okeechobee 2 site is in a rural area surrounded by agricultural land, with few residents in the area. Commuter traffic would be controlled by speed limits. Good road conditions and appropriate speed limits would minimize the dust and noise level generated by the delivery trucks and site workers that travel to and from the site.

The project would have standby diesel generators and auxiliary power systems. Air quality permits obtained for this equipment would ensure that air emissions comply with regulations. In addition, the generators would be operated on a limited, short-term basis. Normal plant operations would not use a quantity of chemicals that could generate odors that exceed odor threshold values.

Physical impacts are considered small when offsite areas are not affected or only minimally or temporarily affected by noise, odor, dust, emissions, vibration, or shock. In summary, construction activities would be temporary and would occur mainly within the boundaries of the Okeechobee 2 site. Offsite impacts would represent small incremental changes to offsite services

that support construction activities. During station operations, ambient noise levels would be minimal at the site boundary. Air quality permits would be required for the diesel generators to ensure emissions comply with regulatory guidelines, and chemical use would be limited, which should limit odors. Therefore, the physical impacts of construction and operation of the new units at the Okeechobee 2 site would be SMALL.

9.3.3.3.6.2 Demography

The population distribution at and around the Okeechobee 2 site is low with typical rural characteristics. The nearest population center larger than 25,000 residents is Port St. Lucie approximately 30 miles east. The site satisfies the 10 CFR Part 100 definition of a low population zone. Coterminous counties include Osceola to the north, Indian River to the northeast, St. Lucie to the east, Martin to the southeast, Glades to the southwest, Polk to the northwest, and Highlands to the west.

To determine which counties best represent the ROI for socioeconomic analysis of the Okeechobee 2 site, each county that falls within 50 miles of the site were initially identified. Several factors were then considered to determine which of these counties would best represent the ROI. These factors, listed below, are evaluated based on historical data from the U.S. census. Key assumptions of the ROI determination are that (1) workers will seek to live within 50 air miles of the site and within a 60-minute commute time and (2) most workers will seek to live in population centers that generally offer more amenities (stores, medical facilities, schools, churches, a larger selection of houses, etc.) than rural locations.

Factors Considered to Determine Which Counties Would Best Represent the ROI

- County population and population density
- Populations of the largest population centers
- Geographic locations of the population centers in relation to the Glades site
- The land fraction of nearby counties that falls within 50 miles of the site
- Relative distance from nearby counties to the site
- Estimated travel distance and estimated travel time from the population centers to the site
- Mean travel time to work
- County employment
- Worker commuter patterns to and from counties conterminous the site

Based on the results of this evaluation, the counties that best represented the ROI for socioeconomic analysis of the Okeechobee 2 site include Glades, Highlands, Okeechobee, and St. Lucie. Because there is no reliable method to predict the distribution of the workforce among these four counties, the ROI is generally treated as a whole for much of the socioeconomic analysis.

Based on the 2000 census, the total population of the ROI was 326,547 people, which included 10,576 in Glades County; 87,366 in Highlands County; 35,910 in Okeechobee County; and 192,695 in St. Lucie County (USCB 2000). Census estimates for year 2007 show an ROI population of 411,708 people, which included 11,109 in Glades County; 99,349 in Highlands County; 40,311 in Okeechobee County; and 260,939 in St. Lucie County (USCB 2009).

NRC guidelines have been established to assess the demographic sparseness and proximity of a proposed site. Sparseness is a combined measure of (1) the population density within 20 miles of the site and (2) the relative population of the nearest metropolitan area within 20 miles of the site. Proximity is a combined measure of (1) the population density within 50 miles of the site and (2) the relative population of the nearest metropolitan area within 50 miles of the site. Based on the sparseness-proximity evaluation, a site is categorized as low, medium, or high (NUREG-1437).

The land area within 20 miles of the Okeechobee 2 site (i.e., excluding water bodies such as Lake Okeechobee) is 967.59 square miles, and based on 2000 census data, the population of this area was 38,539. This yields a population density of 39.8 people per square mile, based on land area. There are no cities within 20 miles of the Okeechobee 2 site that have a population greater than 25,000. Therefore, the sparseness level is 1 based on a population density of less than 40 people per square mile and no community greater than 25,000 people within 20 miles (NUREG-1437).

Similarly, the land area within 50 miles of the Okeechobee 2 site is 6513.3 square miles, and the population of this area was 647,980. This yields a population density of 99.5 people per square mile. Based on the 2000 census, there were no cities within 50 miles of the Okeechobee 2 site that have a population greater than 100,000 (USCB 2000). Therefore, based on NRC guidelines, the proximity level is 2 based on a population density of 50 to 190 people per square mile and no city greater than 100,000 people within 50 miles. Therefore, the Okeechobee 2 site has a sparseness-proximity measure of 1.2, which is categorized as “low” (NUREG-1437).

Based on FPL estimates, the peak construction workforce for the project would be 3548 construction workers. Operations would overlap with peak construction activity for a period of time; therefore, in addition to the construction workforce, there would be a small number (99) of operations workers on the site during the peak construction period, and these workers would also relocate to the area. Because of the location of the Okeechobee 2 site relative to population

centers, FPL assumed that 70 percent of the construction and 85 percent of the operation workers would relocate from outside the ROI. FPL further assumed that 70 percent of the construction and 100 percent of the operation workforce that moved to the area would bring their families. Based on these assumptions, a total of 2568 construction and operation workers would relocate to the area in the project construction phase, and 1823 would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total increase in population attributable to construction at the Okeechobee 2 site would be 6669 people. An influx of 6669 people represents a 2.0 percent increase in the ROI population of 326,547 people. Impacts are considered small if plant-related population growth is less than 5 percent of the area's total population (NUREG-1437). Therefore, this would pose a SMALL impact on population for the ROI.

FPL estimated the total onsite operations workforce to be 1050 workers, and that 85 percent of these workers (893) would relocate from outside the ROI. For the purpose of this analysis, FPL assumed that 100 percent of operations workers who relocated would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total population increase attributable to project operations is 2901 people. This represents a 0.9 percent increase in the four-county ROI population. This would pose a SMALL impact on population for the ROI.

9.3.3.3.6.3 Economy

Based on 2000 census data, Glades County had a civilian labor force of 4034 people and an unemployment rate of 8.8 percent; Highlands County had a civilian labor force of 31,437 people and an unemployment rate of 4.4 percent; Okeechobee County had a civilian labor force of 14,863 people and an unemployment rate of 4.7 percent; and St. Lucie County had a civilian labor force of 82,070 people and an unemployment rate of 5.2 percent. For the entire ROI, 99.9 percent of the labor force was part of the civilian labor force and 0.1 percent was in the armed forces. Of the civilian labor force, 95.0 percent are employed and 5.0 percent are unemployed. The overall unemployment rate for the four-county ROI is slightly lower than that of the State, which is 5.6 percent (USCB 2000).

The economies of the four-county ROI are very similar, dominated mainly by educational, health, and social services; retail trade; and agriculture, forestry, fishing and hunting, and mining. Most of the labor force resides in St. Lucie County (USCB 2000).

Based on the assumptions stated above, the number of workers who relocated from outside the area would include 70 percent of the 3548 peak construction workers and 85 percent of the 99 operations workers for a total of 2568 workers. An influx of 2568 construction and operation workers from outside the region would have positive economic impacts in the four-county region. Based on a multiplier of 1.6260 jobs (direct and indirect) for every construction job and 2.4679 for every operation job (BEA Aug 2009), an influx of 2568 construction and operation workers would

create 1691 indirect jobs, for a total of 4259 new jobs in the ROI. This represents a 3.2 percent increase in the total labor force in the ROI. Economic effects are considered small if peak employment accounts for less than 5 percent of area employment (NUREG-1437). The creation of direct and indirect jobs could potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic impacts attributable to project construction would be beneficial and SMALL within the ROI.

An estimated 1050 workers would be required for the operation of two nuclear power facilities at the Okeechobee 2 site (U.S. DOE May 2004), and FPL assumed that 85 percent of these employees would migrate into the region. Based on a multiplier of 2.4679 jobs (direct and indirect) for every operations job at the new units (BEA Aug 2009), an influx of 893 workers would create 1310 indirect jobs for a total of 2203 new jobs in the region. This represents a 1.7 percent increase in the total labor force in the ROI. The creation of direct and indirect jobs could potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic impacts attributable to project operation would be beneficial and SMALL within the ROI.

9.3.3.3.6.4 Taxes

Taxes collected as a result of construction and operation of the new nuclear units at the Okeechobee 2 site would benefit the State and local tax authorities. FPL would pay property taxes to each taxing authorities whose boundaries contained the plant. Tax payments would be based on the assessed valuation of the plant and local tax rates. If the plant site straddled a jurisdictional boundary, FPL would pay taxes to both entities based on the assessed valuation within each entity.

As described in Subsection 4.4.2.2.2, it is not clear whether FPL corporate income taxes would increase because of construction of the new units at the Okeechobee 2 site, because the units would not generate revenues until they became operational. However, once the units were placed in service, Okeechobee County property taxes would begin and would continue for the 60-year operational life of the facility.

FPL assumed that annual property tax payments at Okeechobee 2 site would be similar those paid by the nuclear units at Turkey Point plant. In 2007, the annual tax payment for the two units at the Turkey Point nuclear power plant was $6,902,670. For the 2007 fiscal year, Okeechobee County had property tax revenues of approximately $17,558,005 (State of Florida Mar 2008b).

With respect to the school districts, in Florida, local revenue for the school districts is derived almost entirely from property taxes levied by Florida's 67 counties, each of which constitutes a school district (Florida Department of Education 2008). As described in Subsection 2.5.2.3.5, the

state of Florida has an established equalized funding program that re-allocates tax base funds from counties that have a high economic tax base to counties that have a low economic tax base. The Florida Education Finance Program is the primary mechanism to fund the operational costs of Florida school districts. Funding is based on the number of full-time equivalent students, and considers variations in several factors to determine funding for each district: local property tax bases, education program costs, costs of living, and costs for equivalent educational programs because of the density and distribution of the student population.

It should be noted that school property tax payments would be based on the location of the plant and not necessarily on the district(s) attended by the workers' children. Therefore, it is not possible to assess the direct impact of the plant on the school districts. In addition, the impact of plant construction and operation on the special tax districts is not assessed here because most of the property tax payment from the plant would go to the county and the school district(s).

The benefits of taxes are considered small when new tax payments by the nuclear plant constitute less than 10 percent of total revenues for local jurisdictions and large when new tax payments represent more than 20 percent of total revenues (NUREG-1437). Therefore, based on the county portion of the FPL property tax payment for the new units, 28 percent of the 2007 property tax revenues for Okeechobee County would be provided by FPL and would constitute a LARGE positive impact.

9.3.3.3.6.5 Transportation

Principal roadways close to the Okeechobee 2 site include SR 70 (a two-lane highway) which spans westward from the town of Okeechobee approximately 1 mile south of the site, and U.S. Highway 98 (a two-lane highway) that spans in a northwest direction approximately 2 miles from the site. Directly east of the site is a county road (128th Avenue Northwest) which spans northward between SR 70 and Highway 98.

Principal road access to the Okeechobee 2 site would be SR 70. Commuters from most cities in the region (Buckhead Ridge, Cypress Quarters, Fort Pierce, Indiantown, Lakeport, Okeechobee, Port St Lucie, Taylor Creek) would travel westbound on SR 70 to reach the site. Commuters from Lake Placid and Lorida would travel eastbound along SR 70 to reach the site.

FDOT reports the AADT count at two locations along SR 70, one at 3.7 miles east of the site, and one at 2.0 miles west of the site. The AADT count and directional peak hour volume of the eastern location is 7700 vehicles per day and 447 vehicles per hour (FDOT 2008). This peak hour volume classifies this portion of the roadway as a LOS of D and already exceeds the Okeechobee County directional peak hour capacity by 27 vehicles (FDOT 2007). The western location has an AADT count and directional peak hour volume of 4800 vehicles per day and 279 vehicles per hour (FDOT 2008). This directional peak hour volume classifies this western portion

of the roadway as a LOS of C (FDOT 2007), and the remaining peak hour capacity is 140 vehicles.

Based on the existing population distribution around the site, FPL assumed that most of the workforce would likely travel along the eastward portion SR 70 and that a smaller amount of the workforce would travel along the western portion. Also, the traffic attributable to construction material deliveries could cause additional congestion on SR 70 during certain times of the day. Based on the methodology presented in Subsection 4.4.2.2.4, FPL determined that construction at the Okeechobee 2 site would add approximately 1611 vehicles during the peak hour to the eastern portion of SR 70. This would cause the road to further exceed capacity, add to existing traffic congestion, and drop the roadway in the eastern direction to a LOS classification of F. As described above, SR 70 west of the site currently operates very close to capacity. The additional construction traffic would cause the road to exceed capacity, further add to current traffic congestion, and drop the roadway to a LOS classification of E. Construction would also add approximately 448 vehicles to the western portion of SR 70 during the hour of peak traffic. Based on this analysis, it is likely that the additional traffic would pose delays along SR70. To facilitate the additional traffic, a portion of SR 70 could be widened to a four-lane highway, and acceleration/deceleration lanes could be added to facilitate commuter traffic. These roadway modifications would likely be needed between Highway 98 east of the site to the Kissimmee River west of the site. NRC applied significance levels to the LOS classifications that were projected to result from the additional traffic associated with refurbishment activities at nuclear plants (NUREG-1437). FPL considers this approach to be appropriate for construction of a nuclear plant since both would be large construction projects. The NRC associates small impacts with LOS A and B, moderate impacts with LOS C and D, and large impacts with LOS E and F. It is therefore anticipated that the impact of the construction workforce on transportation would be LARGE.

Operations at Okeechobee 2 site would add approximately 463 and 129 more vehicles to the eastern and western portions of SR 70 during the hour of peak traffic, respectively. The roadway modifications (mentioned above) to the eastern part of SR 70 would raise the peak hour capacity of this roadway sufficiently to accommodate the additional traffic from operations. Shift changes could be also be staggered so that the traffic increase would be less likely to cause congestion. However, based on the NRC LOS significance levels, in the absence of road modifications that increase road capacity, the impact of the operations workforce on transportation would be LARGE.

9.3.3.3.6.6 Aesthetics and Recreation

The Okeechobee 2 site is an undeveloped site in Okeechobee County approximately 8 miles west of Lake Okeechobee. The site is on flat, swampy land at an approximate elevation of 28 feet MSL and lies within the Flatwoods physiographic province (USGS 2008).

Because the entire area is relatively flat, the power plant and water intake facilities may be visible from some angles. There would be occasional visible plumes associated with the cooling towers. Visibility of the plumes would depend on weather conditions and the location of the viewer in the area. Impacts on aesthetic resources are considered to be moderate if there is the potential for diminution in the enjoyment of the physical environment and measurable impacts that do not alter the continued function of socioeconomic institutions and processes. Construction and operation of an industrial facility on a previously undeveloped site would likely result in some complaints from the affected public with respect to diminution in the enjoyment of the physical environment. Therefore, impacts of construction and operation of the new units on aesthetics would be MODERATE and could warrant mitigation.

The Kissimmee River is approximately 2 miles west of the Okeechobee 2 site. Two SFWMD recreational areas, both remnants of the old Kissimmee River, are within 6 miles of the site. Yates Marsh is a few miles north of the site and offers paddling, camping, wildlife viewing, and hiking along a section of the Florida National Scenic Trail (SFWMD 2008). Several miles southeast of the Okeechobee 2 site is a section of the Kissimmee River that has been designed as the S-65E Impoundment and Paradise Run Management Units. These units are remnants of the end of the old Kissimmee River and consist of thick marshes that are virtually inaccessible; therefore, the area is not heavily visited. The units also offer paddling, hunting, and bird watching (SFWMD 2008).

The northern shoreline of Lake Okeechobee lies within 8 miles of the site. As described in Subsection 9.3.3.1.6.6, both the Lake Okeechobee Scenic Trail and the Big Water Heritage Trail parallel the shoreline of the lake.

The Lake Wales National Wildlife Refuge, the Hobe Sound National Wildlife Refuge, and the Pelican Island National Wildlife Refuge are within 50 miles of the Okeechobee 2 site, none of which are within 6 miles of the site.

Of the 154 state parks in Florida, 12 are within 50 miles of the Okeechobee 2 site and include the Highlands Hammock State Park and Lake June in Winter Scrub State Park, both of which are more than 29 miles northwest and north, respectively, of the Okeechobee 2 site.

Construction and operation of the new units at the Okeechobee 2 site could impact the attractiveness of recreational areas within the region. Construction of new transmission lines in the region would also alter the viewscape. However, the route for the new transmission lines would be selected to minimize these impacts, and the overall aesthetic impacts to the region would be SMALL. Recreational facilities could also be affected by increased traffic on area roads at peak travel periods; however, impacts would be minimal. During plant operations, some employees and their families would use the regional recreational facilities; however, the increase attributable to plant operations would be small compared to overall use of these facilities.

Impacts on tourism and recreation are considered small if current facilities are adequate to handle local levels of demand. Therefore, impacts of facility construction and operation on tourism and recreation would be SMALL.

9.3.3.3.6.7 Housing

FPL estimated that 2568 construction and operation workers would move from outside the 50-mile radius of the Okeechobee 2 site to one of the counties within the 50-mile radius, and each of these workers would need a place to live. Some of the workers would seek permanent residence, generally owner-occupied; some would choose to rent; and others would choose a transitional residence such as a hotel, a room in private home, or a camper or mobile home.

Based on 2000 census data, within the four-county ROI, there are 161,402 housing units of which 30,553 are vacant (18.9 percent). The number of vacant housing units within each of these counties was 1938 (33.5 percent) in Glades County; 11,375 (23.3 percent) in Highlands County; 2911 (18.8 percent) in Okeechobee County; and 14,329 (15.7 percent) in St. Lucie County. This includes housing that is designated as seasonal, recreational, or occasional use (USCB 2000).

FPL estimated that, in absolute numbers, the available housing would be sufficient to house the construction workforce. Workers who relocated could secure housing from the existing stock in any of the four counties within the region, have new homes constructed, or bring their own residence (mobile home or trailer) to the region.

Because Glades, Highlands, and Okeechobee Counties have relatively small populations, their housing markets would likely be the most impacted. Impacts on housing are considered to be small when a small and not easily discernable change in housing availability occurs (NUREG-1437). The entire construction and operation workforce would occupy no more than 8.4 percent of vacant housing units in the ROI; therefore, the impacts during plant construction would be SMALL TO MODERATE, and mitigation would not be warranted.

FPL estimated that approximately 1050 workers would be needed for operation of two nuclear power facilities at the Okeechobee 2 site (U.S. DOE May 2004). FPL assumed that 85 percent of these workers (893) would relocate from outside the region and would settle in the four-county ROI. Based on these assumptions, the entire operations workforce would occupy no more than 2.9 percent of vacant housing units in the ROI; therefore, the impacts during plant operations would be SMALL, and mitigation would not be warranted.

9.3.3.3.6.8 Public Services

Public services in the ROI include water supply and wastewater treatment facilities; law enforcement, fire, and medical facilities; libraries, parks and recreation, roadway maintenance; and other social services. Construction or operations employees who relocated from outside the

region would most likely live in residentially developed areas where adequate water supply and wastewater treatment facilities already exist. The medical facilities in the four-county ROI provide medical care to much of the population within the 50-mile region, and therefore the small increases in the regional population would not materially impact the availability of medical services.

Although the workers and their families would pose an additional overall demand on other public services, it is anticipated that the current capacity of public services within the four-county ROI would be adequate to accommodate the increased demand. Therefore, the impact would be SMALL.

The new nuclear plant and the associated population influx would likely economically benefit the disadvantaged population served by the Florida Department of Children and Families. Direct jobs created by the project would bring indirect jobs that could be filled by currently unemployed workers and therefore remove them from the care of social services.

The ratio of residents-to-law enforcement officers in Glades, Highlands, Okeechobee, and St. Lucie Counties was 353:1, 722:1, 399:1, and 722:1, respectively (FBI 2008). Within the ROI, the resident-to-law enforcement officer ratio was 643:1, and for the state of Florida, the resident-to-law enforcement officer ratio was 851:1. Ratios are partly dependent on population density. In general, fewer law enforcement safety officers are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional law enforcement officers were hired, the population increase attributable to project construction at the Okeechobee 2 site would increase the resident-to-law enforcement officer ratio by 2 percent to 656:1. This is a small increase and would still yield a lower resident-to-law enforcement officer ratio than the average for the state of Florida. Similarly, the increase in the resident-to-law enforcement officer ratio attributable to operations would yield less than a 0.9 percent increase.

The ratio of residents to firefighters in Glades, Highlands, Okeechobee, and St. Lucie Counties was 82:1, 491:1, 492:1 and 563:1, respectively. Within the ROI, the resident-to-firefighter ratio was 452:1, and for the state of Florida, the resident-to-firefighter ratio was 1,230:1 (USFA 2009). As was described above in the description of law enforcement officers, ratios are partly dependent on population density. In general, fewer firefighters are necessary for the same population if the population resides in a smaller area. Within the ROI, if no additional firefighters were hired, the population increase attributable to project construction at the Okeechobee 2 site would increase the resident-to-firefighter ratio by 2 percent to 462:1. This is a small increase and would still yield a lower resident-to-firefighter ratio than the average for the state of Florida. Similarly, the increase in the resident-to-firefighter ratio attributable to operations would yield less than a 0.9 percent increase.

Impacts on public services are considered small if there is little or no need for additional personnel. Impacts are considered moderate if some permanent additions or some new capital equipment purchases are needed (NUREG-1437). The population increase in the four-county region attributable to construction or operation of the new power units could pose a need to hire additional emergency personnel; however, any additional need would be small, and increased tax revenues generated by the project would be adequate to pay the salaries of any additional emergency personnel hired. Therefore, it is not expected that public services would be materially impacted by new construction or operations employees that relocate from outside the region. Impacts are therefore considered SMALL, and mitigation would not be warranted.

9.3.3.3.6.9 Education

Based on data for the 2006–2007 school year, Glades County had 8 schools that covered prekindergarten through 12 (PK-12) schools with a total enrollment of 1256 students; Highlands County had 18 PK-12 schools with a total enrollment of 12,456 students; Okeechobee County has 17 PK-12 schools with a total enrollment of 7289 students; and St. Lucie County has 46 PK-12 schools with a total enrollment of 38,793 students (NCES 2009). In the four-county ROI, there are 89 schools with a total enrollment of 59,794 students.

FPL estimated that 2568 construction and operation workers would migrate to the area, and that 1823 of these would bring a family. This would yield a total population increase of 6669 people. Based on an estimate of 0.8 school-aged children per family (BMI Apr 1981), an estimated 1458 of the 6669 people who relocated to the four-county area would be school-aged children. This would yield a 2.4 percent increase in the student population within the four-county ROI. Small impacts are generally associated with project-related enrollment increases of up to 3 percent, and moderate impacts on local school systems are generally associated with project-related enrollment increases of 3 to 8 percent (NUREG-1437). Therefore, this would pose a SMALL impact on the ROI, and mitigation would not be warranted.

FPL has assumed that 893 operations workers and their families would relocate from outside the region, and that the total population increase attributable to operations would be 2901 people. This would include an estimated 714 children in the PK-12 school range. This influx of students would increase the student population in the ROI by 1.2 percent within the four-county ROI. The impacts on public education are considered SMALL, and mitigation would not be warranted.

9.3.3.3.7 Historic and Cultural Resources

FPL conducted historical and archaeological records searches on the National Park Service NRIS. The NRHP identifies 34 sites in the four-county ROI, including two sites in Glades County, 14 sites in Highlands County, 16 sites in St. Lucie County, and two sites in Okeechobee County.

Two of these properties, the Freedman-Raulerson House and Okeechobee Battlefield, are within 10 miles of the Okeechobee 2 site (NPS 2008d).

Siting the proposed nuclear plant at the Okeechobee 2 site would require a formal cultural resources survey be conducted so that no archeological or historic resources would be damaged during construction. Sites are considered to have small impacts to historic and cultural resources if the SHPO identifies no significant resources on or near the site or determines they would not be affected by plant construction or operation. Mitigation measures would be applied to prevent permanent damage and ensure that any impacts to cultural resources from construction or operation of the new units at the Okeechobee 2 site would be SMALL.

Sites are considered to have large impacts to historic resources if they would be disturbed or otherwise have their historic character altered by construction. Two historic properties and several archeological areas were identified within 10 miles of the Okeechobee site. Construction of the new units at the Okeechobee 2 site would result in adverse effects to the historic and cultural landscape through physical disturbance to these elements and through introduction of visual elements that would be out of character with the property and its setting. The visual impacts would be LARGE and would warrant mitigation.

Siting the proposed nuclear plant at the Okeechobee site would require a formal determination of areas of potential effect from physical disturbance or visual impacts from the site. FPL would consult with the SHPO to identify measures for avoidance, minimization, or mitigation of any adverse effects.

9.3.3.3.8 Environmental Justice

Environmental justice refers to a federal policy under which each federal agency identifies and addresses, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority or low-income populations. The NRC has a policy on the treatment of environmental justice matters in licensing actions (69 FR 52040) and guidance (U.S. NRC May 2004). Subsection 2.5.4.1 describes the methodology FPL used to establish locations of minority and low-income populations.

The 2000 census block groups were used to ascertain minority and low-income population distributions in the area. There are 452 block groups within 50 miles of the Okeechobee 2 site. The census data for Florida characterizes 14.6 percent of the population as black; 0.3 percent American Indian or Alaskan Native; 1.7 percent Asian; 0.1 percent Native Hawaiian or other Pacific Islander; 3.0 percent as other single minorities; 2.4 percent multiracial; 22.0 percent aggregate of minority races; and 16.8 percent Hispanic ethnicity. If any block group percentage exceeded the state percentage by more than 20 percent or was greater than 50 percent, then the block group was considered to have a significant minority population. Significant black minority

populations exist in 62 block groups; significant American Indian or Alaskan Native populations exist in 1 block group; significant other race minority populations exist in 10 block groups; significant multiracial minority populations exist in 3 block groups; significant aggregate of minority races populations exist in 74 block groups; and significant Hispanic ethnicity populations exist in 26 block groups. There are no block groups containing significant Asian, Native Hawaiian, or other Pacific Islander minority populations within 50 miles of the Okeechobee 2 site.

The Brighton Seminole Indian Reservation is approximately 10 miles southwest of the Okeechobee 2 site. As described in Subsection 9.3.3.1.8, the reservation offers several tourist attractions including Indian arts and crafts shops, the Seminole Casino Brighton, a rodeo arena, the Brighton Citrus Grove, and the Brighton Seminole Campground. Today, most Seminole Tribal members are afforded modern housing and health care. In fact, today the Seminole Indians live much the same way as those who live outside Seminole County (Seminole Tribe of Florida 2008).

The locations of the minority populations within 50 miles of the Okeechobee 2 site and the Brighton Indian Reservation are shown in Figure 9.3-15.

The census data characterizes 11.7 percent of Florida households as low income. Based on the more than 20 percent criterion, 49 block groups out of a possible 452 contain a significant number of low-income households. The locations of the low-income populations within 50 miles of the Okeechobee 2 site are shown in Figure 9.3-16.

The Okeechobee 2 site is approximately 1 mile from a minority and low-income block group. However, construction activities (noise, fugitive dust, and air emissions) would be contained with site boundaries and would not impact minority populations. In fact, minority and low-income populations would most likely benefit from construction activities through an increase in construction-related jobs. Operation of the new units at the Okeechobee 2 site is also unlikely to have disproportionate impacts on minority or low-income populations.

FPL concludes that construction and operation of the proposed nuclear plant at the Okeechobee 2 site would not disproportionately impact minority or low-income populations and that mitigation would not be warranted, and the impacts to these populations would be SMALL.

9.3.3.3.9 Other Projects in the Vicinity of the Okeechobee 2 Site

The cumulative impacts of past, present, and reasonably foreseeable federal (e.g. USCOE, USGS), non-federal (e.g. FDEP, FDOT, county), and private projects within a 50-mile radius of the Okeechobee 2 site, excluding Brownfield and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites, that could have cumulative impacts with the proposed action are described in Table 9.3-15. These projects have either requested an air or water permit/license or had an environmental impact statement complete. Projects included in Table 9.3-15 are within the 50-mile radius of the Okeechobee 2 site and the appropriate

timeframe for construction and operation of the new units (Figure 9.3-14) from 2013 to 2063 (based on a construction start date of 2013, a Unit 7 in-service date of 2023, and a 40-year operating license). Nuclear power projects within 100 miles of the Okeechobee 2 site (i.e., St. Lucie) are also described in Table 9.3-15. The Turkey Point site is more than 110 miles from the Okeechobee 2 site and is therefore not included in the table. The only other nuclear power plant currently operating in Florida, Crystal River, is more than 180 miles from the Okeechobee 2 site and therefore is also not included in the table. The proposed nuclear power plant in Levy County is approximately the same distance as the Crystal River site and is not included in the table. It should be noted that this list is not intended to be exhaustive and should not be used to imply that no other past, present or reasonably foreseeable projects exist that could contribute to cumulative impacts within each alternative site project area.

The impacts to land use that would have a cumulative impact on alternative sites would generally be characterized as a change to the land use designation from “agriculture” to “industrial.” A positive land-use impact, for example, would be the CERP projects. These projects are within the 50-mile radius would redevelop, reuse, or develop additional land for conservation. The cumulative impacts to hydrology and water use would be minimally negative due to the restrictions placed on all surface water and groundwater use, also beneficial impact due to the large scale CERP projects for reservoir and storage areas which would provide additional water to the southern Everglades Agricultural Area, reestablish wetland hydropatterns and improve water quality in several different watersheds by treating excessive discharge. The cumulative impacts for terrestrial/aquatic resources would be associated with the minimal loss of wetlands, which is offset by the restoration of developed lands for conservation and restoration of native species through CERP projects. The cumulative impacts for socioeconomics for the Okeechobee 2 site would appear as beneficial impacts to taxes and adverse impacts on transportation. Also, there would not be any disproportionate impact to low-income or minority populations by the activities at the Okeechobee site.

9.3.3.4 Evaluation of the St. Lucie Site

The 1130-acre St. Lucie site is an FPL-owned nuclear power generation station on Hutchinson Island in St. Lucie County. St. Lucie Units 1 & 2 and associated support facilities occupy less than half of the 1130-acre site. The St. Lucie nuclear units (Units 1 & 2) provide 1553 MW of summer capacity to the regional power grid. The site is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west (FPL Apr 2009). The nearest municipalities are Fort Pierce, approximately 7 miles northwest; Port St. Lucie, approximately 4.5 miles to the west; and Stuart, approximately 8 miles to the south. The nominal site elevation is 0 to 5 feet above sea level which falls within the 100-year floodplain. The location of the St. Lucie site is shown in Figure 9.3-17.

9.3.3.4.1 Land Use Including Site and Transmission Line Rights-of-Way

St. Lucie Units 1 & 2 are on the west side of SR A1A in a relatively flat, sheltered area of Hutchinson Island. The site lies within the 100-year floodplain. West of the facility, the land gradually slopes downward to a mangrove fringe that borders the intertidal shoreline of the Indian River Lagoon. East of the facility, land rises from the ocean shore to form dunes and ridges approximately 15 feet above mean low water. Two county parks with beach access, Blind Creek Pass Park and Walton Rocks Park, lie within the St. Lucie Units 1 & 2 property boundary. Recreational facilities for FPL employees and their families are also available within the site property boundary.

The Indian River Lagoon is a long, shallow, tidally-influenced estuary that stretches along the central east coast of Florida between the mainland and a series of offshore islands. At St. Lucie Units 1 & 2, the Indian River Lagoon is approximately 7200 feet wide. Blind Creek and Big Mud Creek, inlets off the Indian River Lagoon, are adjacent to the site. The stretch of lagoon adjacent to the site is designated as the Jensen Beach to Jupiter Inlet Aquatic Preserve. The North Fork St. Lucie River Aquatic Preserve is located on the north fork of the St. Lucie River at Port St. Lucie. The St. Lucie Canal connects the St. Lucie River with Lake Okeechobee and parallels SR 76, south of the town of Stuart (NUREG-1437, Supplement 11).

Based on the conceptual site layout developed for the St. Lucie site, the following land requirement assumptions were made which form the basis of the environmental comparison of alternative sites:

- The assumed facility footprint would require approximately 357 acres, split between 320.5 acres on the west side of Ocean Drive (SR A1A), and 37 acres for nuclear administration/ parking on the east side of Ocean Drive. New facilities at the plant site would include the nuclear power units, support buildings, a switchyard, storage areas and the water intake and discharge canals.

- The assumed extent of non-transmission linear features, including access road corridors, pipeline corridors and rail access, is as follows:

    — Access road: 266.8 acres – assuming a corridor length of approximately 22 miles and a corridor width of 100 feet to include widening of SR A1A which spans north-south along Hutchinson Island. Because the access road (A1A) extends through the site, there would be no need to develop road access directly to the site. However, FPL has determined that there would be a need widen A1A from two lanes to four lanes to accommodate anticipated traffic levels attributable to construction (including truck transfer of significant quantities of fill material to the site) and to mitigate traffic delays for island residents and delivery trucks.

— Rail: Rail access does not extend to the St. Lucie site and is not necessary to support operation of Units 1 & 2 as barge access is available at the site (NUREG-1437, Supplement 11); therefore, rail access would not be needed to support operation of the proposed new units.

— Heavy Haul: 6.3 acres – the conceptual site layout developed for the St. Lucie site has identified the need for a heavy haul road, connecting the barge access location and the project site, to include a two-lane, approximately 0.5-mile road with a corridor width of 100 feet.

— Intake/blowdown pipeline corridors: 10.5 acres – Units 1 & 2 are cooled by a once-through system that withdraws water from the Atlantic Ocean and then discharges the heated water back into the Atlantic Ocean. Water canals channel the intake water to the west side of the plant. The intake canal spans approximately 4920 feet and has a trapezoidal cross section that is 180 feet wide and 30 feet deep. The discharge canal is approximately 2200 feet long with cross-sectional dimensions similar to those of the intake canal (NUREG-1437, Supplement 11).

  FPL assumed that the proposed new units at the St. Lucie site would use a closed loop, tower-cooled system for power cycle waste heat rejection, whereby consumptive losses are replaced from the Atlantic Ocean and blowdown water is routed to the Atlantic Ocean. This system would require little land use because the water source, the Atlantic Ocean, borders the St. Lucie site (i.e., it would only be necessary to construct a pipeline to transfer the water). Based on the conceptual site layout developed for the site, FPL has determined that approximately 10.5 acres would be affected by construction.

- The assumed extent of conceptual transmission corridor routing is 2187 acres based on an assumed length of 63 miles, to connect to the existing FPL transmission system at the Corbett substation inside Palm Beach County, and a corridor width that varies from approximately 200 to 660 feet.

- Based on subtotals above for both onsite and offsite plant components, the total area potentially affected at the St. Lucie site is estimated at approximately 2828 acres. With respect to the transmission line corridor included within this total, the estimated acreage requirements assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. However, these estimates provide the basis for an updated and consistent environmental comparison of alternative sites.

- Additional acreage may be required to support construction activities (e.g., additional laydown areas, batch plant, fill/spoil areas). Although the undeveloped acreage of St. Lucie

site is adequate to support construction of the new units, the physical layout of the site and the proximity of the site (midspan along a long island) would likely pose special logistical challenges for construction that would not be incurred on non-island sites.

Land use impacts associated with plant construction include both impacts to the site and immediate vicinity, and impacts to offsite areas such as transmission, and transportation rights-of-way (e.g., access road). As mentioned previously, the physical layout of the site and the proximity of the site (midspan along a long island) would likely pose special logistical challenges for construction that would not be incurred on non-island sites.

Construction of a new nuclear power plant would include clearing, dredging, grading, excavation, spoil deposition, and dewatering activities. An area of approximately 357 acres would be required for the main power plant site (major structures including switchyard), which would largely be focused essentially in one central location and would be permanently impacted.

While the site location is owned by FPL and adjacent to the existing St. Lucie Nuclear Power Plant, the proposed facility footprint area would be located primarily in an area of mangrove swamps, based on the conceptual site layout.

The nominal site elevation of the St. Lucie site is 0 to 5 feet above sea level, which falls within the 100-year floodplain. Because the St. Lucie site is within the 100-year floodplain, FPL assumed that site development would require filling to bring the elevation to approximately 20 feet MSL. It is assumed that currently operating public sources of fill material (sources already permitted and land types already potentially disturbed) would be utilized, as well as fill from construction of the onsite storm water retention ponds.

Following construction activities, impacted areas without constructed buildings or transportation infrastructure would be reclaimed to the greatest extent feasible. Direct and indirect impacts of construction from the proposed transportation infrastructure (widening of A1A) would be similar to those for the proposed plant; the proposed span to be widened includes mostly mangrove and smaller areas of upper hardwood forest, as some residential and commercial service areas among other uses.

Development of the conceptual transmission corridor incorporated the most direct route where possible, while considering potential conflicts with natural or man-made areas where important environmental resources were located, and avoiding populated areas and residences to the extent possible. Whenever possible, the new line was routed along existing transmission rights-of-way. The use of lands that are forested would be altered. Trees removed for construction would be replaced by low-growth types of ground cover such as grass. The new transmission corridor would not be expected to preclude agricultural activities near the eventual rights-of-way, but has the potential to affect a number of residents along the right-of-way. The land use in the

region (i.e., outside the coastal developments along the new transmission corridors) is generally rural, sparsely populated, and primarily used for agricultural activities. The St. Lucie site is within the Florida Coastal Zone; therefore, FPL would need to seek coastal zone certification to demonstrate that plant and transmission line construction activities are consistent with the requirements of the Coastal Zone Management Act [16 USC 1456(c)(3)(A)] (NUREG-1437, Supplement 11).

Table 9.3-16 includes estimates of the potentially affected area(s) of each land cover type (based on GIS FLUCCS Level III data analysis) for the St. Lucie site, including both onsite and offsite components (i.e., access road, and transmission corridors). It also further breaks out the land cover types along the assumed conceptual transmission corridor only, given the significant acreage this corridor encompasses (77 percent of the total area). As noted previously, regarding the offsite linear features associated with the projects, the estimated acreage requirements assume corridor widths for transmission which may exceed the area that would actually be disturbed during project construction and operation. These estimates are intended to provide the basis for an updated and consistent environmental comparison of alternative sites.

The proposed project would be a change from current land use. Operational impacts to site land use would include a permanent change in land use for approximately 623 acres of land for the power plant site and highway access corridor, including over 400 acres of mangrove swamps – that would be generally unavailable for other purposes. This area would be permanently altered for the estimated 60-year life of the AP power units (WEC 2007).

Operational impacts to the site and immediate vicinity also would include maintenance operations on project structures that would be small and temporary in nature.

Operational impacts of transmission lines result primarily from line maintenance, and include right-of-way vegetation clearing and control, transmission line maintenance, and other normal access activities. Additional right-of-way acquisition and development would not normally be required as part of plant operational activities. Maintenance activities would be limited to the immediate right-of-way and would be minimal. New transmission corridors would not be expected to preclude agricultural activities near the eventual rights-of-way. Corridor vegetation management and line maintenance procedures would be established by the transmission service provider.

Other offsite land use impacts as a result of plant operational activities would be minimal, temporary, and limited in the area impacted. Such activities could include primarily road maintenance and auxiliary building maintenance.

For the purpose of this analysis, land use impacts are considered small if less than 3000 acres are disturbed (including plant footprint, rights-of-way, and corridors) and there are no major

changes to land use. Based on the land disturbance totals (potentially affected area of 2828 acres of which 2187 acres is within the conceptual transmission corridor), the existing industrial use, land use impacts associated with site preparation, construction, and operation of the proposed nuclear plant at the St. Lucie site and the conceptual transmission corridor would be SMALL.

9.3.3.4.2 Air Quality

St. Lucie County (the St. Lucie nuclear plant site is in St. Lucie County) is part of the Southeast Florida Intrastate Air Quality Control Region. St. Lucie County, along with the entire state of Florida, is designated as attainment or unclassifiable with respect to the NAAQS (40 CFR 81.310). The nearest non-attainment area is in Georgia, several hundred miles north northwest of the St. Lucie site (40 CFR 81.311).

Criteria pollutant emissions from construction and operation of the proposed nuclear plant at the St. Lucie site would be comparable to the emissions generated at the Turkey Point site as described in Subsections 4.4.1.2 and 5.8.1.2, respectively. Construction impacts would be temporary and would be similar to those for any large-scale construction project. Particulate emissions in the form of dust from disturbed land, roads, and construction activities would be generated. Mitigation measures similar to those described in Subsection 4.4.1.2 would be applied as necessary. Criteria pollutants would also be generated from onsite fossil-fueled construction equipment and construction vehicles, and from commuter and delivery vehicles that travel to activities would be small compared to other emissions in the region. It is assumed unlikely that construction-related emissions would cause any violation of the NAAQS.

The project would include standby diesel generators and diesel-driven fire pumps. Annual emissions from these sources are listed in Table 3.6-4. It is expected that standby diesel generators and auxiliary power systems would see limited use and, when used, would operate for a short-time interval. The pollutant emissions generated by these systems (nonradiological) would be regulated by the FDEP in accordance with the air rules published under FAC Chapter 62. These rules cover general air pollution control provisions, stationary source requirements, preconstruction review, emission standards, air monitoring requirements, and other rules for control of air pollutant emissions. Airborne release of criteria pollutant and hazardous air pollutant emissions would be small and would comply with FDEP rules (FDEP 2008a).

Nonradiological emissions can potentially affect regional visibility, and visibility is an important feature at Federal Class I areas. The Federal Class I area nearest to the St. Lucie site is the Everglades National Park more than 100 miles to the south. Because the distance is large, and because the anticipated emission levels would be small, pollutant emissions attributable to operation of the new nuclear units would have a negligible impact on visibility at a Federal Class I area. Unfavorable psychometric conditions can result in visible vapor plumes from the cooling

tower operations. These plumes may be visible for several miles, but would not impact visibility or scenic vistas at any Federal Class I area.

Air quality impacts are considered small if the increase in regional pollutant concentrations attributable to the source (1) would not appreciably alter visibility, (2) would not exceed EPA significant impact levels, and (3) would not cause a violation of the most restrictive ambient air quality standards. Based on this evaluation metric, it is anticipated that the impacts to air quality from construction and operation would be SMALL.

9.3.3.4.3 Hydrology, Water Use, and Water Quality

The state of Florida is divided into five watershed management areas. The St. Lucie site is in the Kissimmee-Everglades watershed and falls under the jurisdiction of the SFWMD. This watershed region spans more than 16 counties and is logically divided into several river basins: Kissimmee River, Upper East Coast, Lower East Coast (which includes the entire southeast coast and the Everglades), and Lower West Coast (which includes the Big Cypress and Caloosahatchee Rivers). This region is the largest watershed region in the state of Florida and is home to 40 percent of Florida's population. The region also contains the Everglades (the largest subtropical wetland in the United States) and Lake Okeechobee, the second largest freshwater lake in the United States. This lake is of national importance, as its water has diverse usage and a large number of people depend on it for agricultural and domestic purposes (University of Florida Jun 2007).

Water quality and ecological health of Lake Okeechobee are adversely affected by excessive nutrient loading, extreme high and low water levels, and the proliferation of exotic species. To address restoration goals for the lake, the SFWMD, in coordination with the FDEP and the Florida Department of Agricultural and Consumer Services, has developed the Lake Okeechobee Watershed Construction Project Technical Plan. The plan was developed in response to the *Northern Everglades and Estuaries Protection Program* that the Florida Legislature signed into law in 2007. Primary components of the plan include the implementation of agricultural management practices, construction of treatment wetlands to clean water flows into the lake, and the creation of 900,000 to 1.3 million acre-feet of water storage north of the lake (SFWMD 2008)

The entire state of Florida, and portions of southern Alabama, southeastern Georgia, and southern South Carolina, are atop the Floridan aquifer. This aquifer covers some 100,000 square miles and is one of the most productive aquifers in the world. The Floridan aquifer system provides water for several large cities, such as Savannah and Brunswick in Georgia; and Jacksonville, Tallahassee, Orlando, Tampa Bay, and St. Petersburg in Florida. In addition, the aquifer system provides water for hundreds of thousands of people in smaller communities and

rural areas. The Floridan aquifer is intensively pumped for industrial and irrigation supplies (USGS Jul 1980).

Land subsidence related to karst terrain is not anticipated at the site. The site is in karst Area II where the surface cover is reported to be 30 to 200 feet thick. In such areas, sinkholes are reported to be few, shallow, of small diameter, and develop gradually (Sinclair, et al., 1985).

For the year 2000, water withdrawals in the region included both groundwater and surface water. Average daily surface water withdrawals were 1677 million gallons. Approximately 11.1 percent (198.9 million gallons) of this was freshwater and 88.9 percent (1478 million gallons) was saltwater. Average daily groundwater withdrawals were approximately 80.8 million gallons, and 100 percent of this was freshwater. The average total daily withdrawal in the county was 1758 million gallons per day, and approximately 84.1 percent was from saltwater sources (USGS Dec 2004).

St. Lucie Units 1 & 2 receive water from the city of Fort Pierce and the Fort Pierce Utilities Authority for potable and service uses at the plant. This freshwater is derived from groundwater sources on the mainland, and plant operations do not involve any additional groundwater withdrawal. Average potable water usage at the plant is approximately 131,500 gallons per day with no restrictions on supply (NUREG-1437, Supplement 11). It is anticipated that the addition of two more power units would nominally double this daily potable water requirement.

Water is withdrawn from the Atlantic Ocean in a once-through arrangement to cool St. Lucie Units 1 & 2 (NUREG-1437, Supplement 11). It is anticipated that a closed loop, tower-cooled system would be developed for the new nuclear power units, whereby consumptive losses are replaced from the Atlantic Ocean and blowdown water is routed to the Atlantic Ocean. As shown in Subsection 4.2.2.1, the peak construction water demand is estimated at 565 gpm which is slightly greater than 1 cubic foot per second, and the peak estimated potable water demand for operations is 2553 gpm (Table 3.3-1). Municipal potable water from St. Lucie County could easily satisfy these demands. As described in Subsection 5.2.1, an estimated 200 cfs of saltwater would be needed to support plant operations. The Atlantic Ocean is a virtually unlimited water source and could easily provide the estimated 200 cfs of saltwater needed to replace consumptive water use associated with operation of the proposed nuclear power units.

Water use impacts are considered small when water sources are readily available to meet demand. Therefore, because adequate water sources are available nearby, the impact on regional water use for both construction and operation would be SMALL.

Water quality impacts are considered small when changes in water quality do not affect or minimally affect aquatic biota and water uses (NUREG-1437, Supplement 11). The depth to the water table near the site is less than 5 feet below ground level. Therefore, it is expected that

dewatering would be required during the construction phase. This may require construction of temporary retention ponds to allow sediment-laden waters to settle before discharge to surface waters. Dewatering activities would be subject to NPDES permit requirements to avoid adverse impacts on surface waters.

Construction and operation activities at the St. Lucie site would be performed under the authorization of an NPDES permit issued by the FDEP (FDEP 2008b). As authorized by the Clean Water Act, the NPDES permit program regulates discharges into waters of the United States to control water pollution. Industrial, municipal, and other facilities must obtain permits if their discharges go directly to surface waters. NPDES permits describe (1) the limits on what can be discharged, (2) requirements to monitor and report discharges, and (3) other provisions to ensure that the discharge does not harm water quality. Any releases from the plant as result of construction or operation would be regulated by the FDEP through the NPDES permit process to ensure that water quality is protected. To ensure that wetlands and streams are not harmed by petroleum products or other industrial chemicals, FPL would restrict certain activities (e.g., transfer and filling operations) that involve the use of petroleum products and solvents to designated areas, such as laydown, fabrication, and shop areas. In addition, construction activities would be guided by a stormwater pollution prevention plan and a construction-phase spill prevention, control, and countermeasures plan similar to those proposed for the Turkey Point site, as described in Section 4.2. Therefore, any impacts to surface water during plant construction would be SMALL and would not warrant mitigation beyond best management practices required by the permits. The impacts to water quality during operations would also be SMALL because the NPDES permit requirements would ensure that adequate measures are applied to protect water quality.

9.3.3.4.4 Terrestrial Resources and Protected Species

Table 9.3-16 includes estimates of the potentially affected area(s) of each land cover type within the project area for both onsite and offsite components, including any natural vegetation and wetland areas. The nominal site elevation of the St. Lucie site is 0 to 5 feet above sea level, which falls within the 100-year floodplain. The most prominent topographic feature of the site is the grade for SR A1A, which passes through the eastern portion of the FPL property. Between the dunes and SR A1A, the principal feature is a series of mangrove-dominated mosquito impoundments interspersed with islands of natural coastal strand vegetation. St. Lucie Units 1 & 2 are on the west side of SR A1A in a relatively flat, sheltered area of the island. West of the facility, the land gradually slopes downward to a mangrove fringe bordering the intertidal shoreline of the Indian River Lagoon. East of the facility, land rises from the ocean shore to form dunes and ridges approximately 15 feet above mean low water (FPL Nov 2001).

As shown in Table 9.3-16, there are approximately 405 acres of wetlands within the project area, excluding the conceptual transmission corridor which could be directly impacted from project

construction. All of the wetland areas include mangrove habitat which serves as important habitat for wildlife. Any wetland functions that are impacted during construction would be replaced or restored. The footprint of the new facilities, excluding the assumed conceptual transmission corridor but including other offsite components such as the widening of A1A, would cover approximately 641 acres.

There are no designated critical terrestrial habitats for endangered species in the vicinity of St. Lucie Units 1 & 2 and the transmission corridor associated with the plant. The beach and dunes, mangrove, and tropical hammock habitats are important, however, in that they represent important coastal ecosystems that have been reduced by development. Also, these habitats support a variety of animal species (FPL Nov 2001).

At the St. Lucie Units 1 & 2 site, the beach and dune habitat consists of a narrow band along the Atlantic Ocean shoreline and is subject to considerable wave erosion. The seaward side of the dunes currently has no vegetation. Vegetation on the inland side of the dunes includes sea oats (*Uniola paniculata*), sea grape (*Coccoloba uvifera*), salt marsh hay (*Spartina patens*), Australian pine (*Casuarina equisetifolia*), marsh ox-eye (*Borrichia frutescens*), beach sunflower (*Helianthus debilis*), marsh elder (*Iva frutescens*), bay bean (*Canavalia rosea*), and railroad vine (*Ipomoea pes-caprae*) (FPL Nov 2001).

The mangrove habitat has been considerably altered from its former natural state. In the 1930s and 1940s, the mangrove forest was destroyed by trenching, diking, and flooding with seawater as part of a Work Progress Administration mosquito control program. Many trees were killed by hydrologic alterations, particularly the black mangrove (*Avicennia germinans*). Since that time there has been partial restoration, particularly of red mangrove (*Rhizophora mangle*), which tends to grow in lower, wetter portions of mangrove forests. Some black and white mangrove (*Laguncularia racemosa*), coin vine (*Dalbergia ecastaphyllum*), and giant leather fern (*Acrostichum danaeifolium*) have since been established at higher elevations. The mangrove stands suffered freeze damage in 1989, and revegetation has not occurred in some areas. Currently the mangrove areas are either inundated or intertidal, and function as mud flat habitats for wildlife (FPL Nov 2001).

The tropical hammock habitat exists east of SR A1A. The largest area of occurrence is amid the mangrove stands north of the St. Lucie Units 1 & 2 Discharge Canal. Prominent species include gumbo-limbo (*Bursera simaruba*), paradise tree (*Simarouba glauca*), white and Spanish stoppers (*Eugenia axillaris and E. foetida*), wild lime (*Zanthoxylum fagara*), white indigo berry (*Randia aculeata*), mastic (*Mastichodendron foetidissimum*), and snow berry (*Chiococca alba*). The existence of tropical hammocks with a distinct assemblage of tropical species this far north on the Atlantic coast is unusual (FPL Nov 2001). Based on the conceptual site layout for St. Lucie, part of this area would be impacted by plant construction and road widening activities for SR A1A.

Hutchinson Island habitats support a variety of animal species. FPL reported 24 species of mammals in Hutchinson Island, of which the Virginia opossum (*Didelphis virginiana*), raccoon (*Procyon lotor*), and beach mouse (*Peromyscus polionotus*) were most common. Nearly 160 bird species were reported to use Hutchinson Island, at least during part of their life cycles. Abundant resident species were typified by water-associated birds such as great egret (*Casmerodius albus*), American coot (*Fulica americana*), ring-billed gull (*Larus delawarensis*), and fish crow (*Corvus ossifragus*). Many migratory species pass through the area such as warblers [e.g., black and white warbler (*Mniotilta varia*)], spotted sandpiper (*Actitis macularia*), and Forster's tern (*Sterna forsteri*). Gopher tortoises (*Gopherus polyphemus*) are present on the site and have active burrows in areas of soft soils that are not subject to flooding (FPL Nov 2001).

Threatened, endangered, and/or species of special concern that exist in St. Lucie County are listed in Table 9.3-17. Certain species, such as the least tern (*Sterna antillarum*), black skimmer (*Rynchops niger*), American oystercatcher (*Haematopus palliateus*), several species of sea turtle, gopher tortoise (*Gopherus polyphemus*), and the Florida manatee (*Trichechus manatus latirostris*) have been documented at the St. Lucie Units 1 & 2 site. A number of the protected bird species listed in Table 9.3-17 have been seen on Hutchinson Island, including least tern, brown pelican (*Pelacanus occidentalis*), bald eagle (*Haliaeetus leucocephalus*), peregrine falcon (*Falco peregrinus*), wood stork (*Mycteria americana*), little blue heron (*Egretta caerulea*), snowy egret (*Egretta thula*), reddish egret (*Egretta rufescens*), and Louisiana heron (*Egretta tricolor*). The latter five species nest in mangroves. The least tern, a state threatened species, and the black skimmer, a state species of special concern, nest on the canal berms and building rooftops within the St. Lucie Units 1 & 2 property boundary. The American oystercatcher, a state species of special concern, also nests on the canal berms. The brown pelican, white ibis (*Eudocimus albus*), little blue heron, and the southeastern American kestrel (*Falco sparverius paulus*) were observed on site in recent surveys. Two protected plant species were also observed in recent surveys, inkberry (*Scaevola plumieri*) and common prickly pear (*Opuntia stricta*) (FPL Nov 2001).

Further field surveys would be conducted for federally listed and state protected species as part of the permitting process before any clearing or construction activities at the site or along associated transmission corridors. Land clearing associated with construction of the plant and transmission lines would be conducted according to federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices (e.g., directed drainage ditches, silt fencing) (FPL Dec 2006).

As described in Subsection 9.3.3.4.1, FPL assumed that a 63-mile conceptual transmission corridor, varying in width between 200 and 660 feet would extend from the site to the existing FPL transmission system via the Corbett Substation in Palm Beach County. The conceptual transmission corridor generally followed the most direct route between terminations, while consideration was also given to avoiding possible conflicts with natural areas where important environmental resources are located.

As shown in Table 9.3-16, there are approximately 512 acres of wetlands found within the conceptual transmission corridor; approximately 119 acres are forested wetlands and considered to be high quality. Any wetland functions that are impacted during construction would be replaced or restored. Construction of the new transmission lines would potentially impact approximately 2187 acres within the conceptual transmission corridor. However, the estimated acreage requirements for the transmission corridor assume corridor widths which may exceed the area that would actually be disturbed during project construction and operation. These estimates are used to provide the basis for an updated and consistent environmental comparison of alternative sites.

For the purpose of this analysis, impacts to terrestrial resources are considered small if no sensitive habitats, including wetlands, are disturbed and no important species are affected. St. Lucie County has a low number of sensitive species, although several have been observed in the site vicinity. Over 400 acres of mangrove habitat would be permanently lost from plant construction and the widening of SR A1A, which may serve as important habitat for wildlife. In addition, the proposed conceptual transmission corridor would potentially affect an additional 2187 acres of land, although existing transmission corridor has been used to the extent possible. The presence of additional structures could increase bird collisions but this affect would be minimal.

Because land clearing associated with construction of the plant and transmission lines would be conducted according to federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices, impacts to terrestrial resources, including endangered and threatened species, from construction of nuclear power facilities at the St. Lucie site would be minimized. However, because of the known presence of endangered species at the site, the permanent filling of over 400 acres of mangrove habitat, and potential impacts to an additional 2187 acres within the conceptual transmission corridor, the impact from construction would be considered MODERATE.

The most likely aquatic impact from nuclear operations at the St. Lucie site would be from drift from cooling tower operations. Cooling tower operations can generate vapor plumes that drift downwind. Salt and mineral deposits in the vapor plume have the potential to adversely impact sensitive plant and animal communities through changes in water and soil chemistry. Because the St. Lucie site would likely use ocean water for power plant heat rejection, the salt and mineral levels in the water would be high. The use of drift eliminators, along with proper tower design and operation, would help reduce these potential impacts. In addition, the surrounding ecosystem has already adapted to higher salinity levels given its coastal location. Therefore, the anticipated terrestrial impacts from operation of two nuclear units would be SMALL.

9.3.3.4.5 Aquatic Resources and Protected Species

The St. Lucie site is on Hutchinson Island in St. Lucie County and is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west. Existing Units 1 & 2 are cooled by a once-through system that withdraws water from the Atlantic Ocean and then discharges the heated water back into the Atlantic Ocean. Water canals channel the intake water to the west side of the plant. The intake canal spans approximately 4920 feet and has a trapezoidal cross section that is 180 feet wide and 30 feet deep. The discharge canal is approximately 2200 feet long with cross-sectional dimensions similar to those of the intake canal (NUREG-1437, Supplement 11). FPL assumed that the proposed new units at the St. Lucie site would use a closed loop, tower-cooled system for power cycle waste heat rejection, whereby consumptive losses are replaced from the Atlantic Ocean and blowdown water is routed to the Atlantic Ocean.

The near shore area of the Atlantic Ocean has no reef structures, grass beds, or rock outcroppings. Seaward, the ocean floor consists of unconsolidated sediments composed of quartz and calcareous sands, broken shell fragments, and negligible amounts of silts and clays. The sea floor gently slopes into a trough with a maximum depth of approximately 39 feet at approximately 1 nautical mile offshore. Continuing offshore, the sea floor rises to form the Pierce Shoal at approximately 2 miles (FPL Nov 2001).

Baseline monitoring before the construction of St. Lucie Units 1 & 2 established that there were three subtidal microhabitats offshore of the plant: shallow beach terrace, offshore shoal, and a deeper trough in between the two. Sediment composition differed among these zones. The biological composition of macroinvertebrate communities is largely influenced by sediment composition. Because of the sediment heterogeneity, the trough supports the most abundant fauna. It was characterized by high diversity and relatively rapid turnover of less abundant and more transient species. In the intertidal zone, the worm reef community provided yet another distinct habitat for macroinvertebrates. Patterns of fish abundance and diversity were also largely aligned along microhabitat boundaries. In addition to the habitats identified above, the surf zone harbored yet another distinct assemblage of fish (FPL Nov 2001).

Baseline studies identified 127 species of arthropods and nearly 300 species of mollusks. The diverse makeup of these groups, and to some extent their seasonal variability, was attributed to the transitional temperate, subtropical, and tropical mix of climate and water masses in the general vicinity of Hutchinson Island. Some estuarine affinities were also noted and attributed to water mass intrusions from the Indian River Lagoon by way of St. Lucie Inlet and prevailing northerly coastal currents. Among species of direct commercial value, the calico scallop was the only mollusk recorded. Arthropods of potential commercial value included penaeid shrimp and the blue crab. However, these species were generally collected in small numbers and infrequently (FPL Nov 2001).

The fish communities offshore are transitional assemblages of temperate and tropical forms. Since oceanic icthyofauna are most diverse and abundant near reefs and other hard-bottom areas, FPL sited intake and discharge structures for St. Lucie Units 1 & 2 in areas devoid of these habitats (FPL Nov 2001). FPL would anticipate the same strategy for the new units at St. Lucie.

Commercial and recreational fishing are important activities in the vicinity of St. Lucie Units 1 & 2. Three of the most abundant species in commercial catches are the bluefish, Spanish mackerel, and king mackerel (*Scomberomorus cavalla*). All three species are highly migratory, spawn in coastal waters from late summer into winter (depending on species), and migrate northward along the East Coast during the warmer seasons. Several other species are quite abundant, including tilefish (e.g., *Caulolatilus* spp.) and swordfish (*Xiphias gladius*) (FPL Nov 2001).

The Indian River Lagoon is a productive estuary that adjoins the western edge of the St. Lucie Units 1 & 2 property. The Lagoon is characterized by extensive growths of manatee grass (*Syringodium filiforme*) and red algae such as the dominant form *Gracilaria*. In turn, the grass and algae are inhabited by a variety of gammarids, shrimp, isopods, crabs, and juvenile fish. A variety of microscopic organisms are supported by this vegetative community, including diatoms attached to the plant leaves. Benthic organisms are also abundant and include tube-dwelling worms and crustaceans, the latter including larger shellfish such as shrimp and blue crabs. A diverse and abundant fish community of more than 300 species has been identified in the southern portion of the Indian River Lagoon. Red drum (*Sciaenops ocellatus*), spotted seatrout (*Cynoscion nebulosus*), common snook (*Centropomus undecimalus*), sheepshead (*Archosargus probatocephalus*), and gray snapper (*Lutjanus griseus*) were commonly reported (FPL Nov 2001). Several species of sea turtle, gopher tortoise (*Gopherus polyphemus*), and the Florida manatee (*Trichechus manatus latirostris*) have been documented at the St. Lucie Units 1 & 2 site. Five species of sea turtle have been reported from Hutchinson Island. The federally threatened loggerhead sea turtle (*Caretta caretta*) has historically been most common. Between 5000 and 8000 loggerhead nests have been reported on Hutchinson Island over the last 10 years. The endangered green sea turtle (*Chelonia mydas*) also nests on Hutchinson Island, but these nests are less abundant than those of the loggerhead. Juveniles of both species use the area near the St. Lucie Units 1 & 2 site as a developmental area. The endangered leatherback sea turtle (*Dermochelys coriacea*) infrequently nests on Hutchinson Island. The endangered Kemp's Ridley sea turtle (*Lepidochelys kempii*) and hawksbill sea turtle (*Eretmochelys imbricata*) do not nest on Hutchinson Island and have only infrequently been reported from the area (FPL Nov 2001).

For the purpose of this analysis, impacts to aquatic resources are considered small if no sensitive habitats are disturbed and no important species are affected. Water from the Atlantic Ocean would cool the new nuclear units constructed at the St. Lucie site. Field surveys would be conducted for federally listed and state protected aquatic species as part of the permitting process before any clearing or construction activities at the site or along associated transmission corridors. Because of this, and because land clearing associated with construction of the plant

and transmission lines would be conducted according to federal and state regulations, permit conditions, existing FPL procedures, good construction practices, and established best management practices, impacts to aquatic resources, including endangered and threatened species, from construction of nuclear power facilities at the St. Lucie site would be minimized. However, because of the known presence of endangered species at the site and the permanent filling of mangrove habitat, the impact from construction would be considered MODERATE.

The most likely aquatic impact from nuclear operations at the St. Lucie site would be entrainment and impingement of aquatic organisms from the Atlantic Ocean. Because the EPA requires facilities to meet criteria designed to protect organisms from entrainment and impingement, the potential for environmental impacts to aquatic resources, including endangered and threatened species, from nuclear power facility operations at the St. Lucie site would be minimized. The addition of two nuclear units would not be expected to entrain more turtles, fish, or cause more takes. Therefore, impacts would be SMALL.

9.3.3.4.6 Socioeconomics

This subsection evaluates the social and economic impacts to the region from construction and operation of a nuclear plant at the St. Lucie site. Much of the socioeconomic analysis relies on census data gathered by the USCB. The USCB performs an extensive census every 10 years. The most recent decennial U.S. census was performed in year 2000. The USCB assembles the decennial census data into a wide range of reports that can be used to characterize socioeconomic conditions of a region. In addition, the NRC sponsored development of a computer program called SECPOP2000 that enables an analyst to quickly assemble and quantify customized regional socioeconomic information; however, this program does not produce results for years later than 2000 (U.S. NRC Aug 2003). For years that fall between each decennial census, the USCB issues estimates based on surveys and statistical models; however, the types of data collected and assembled for intermediate years is less extensive than for years when a decennial census is performed; therefore, the decennial census provides the most comprehensive information.

Because the decennial census provides the most comprehensive information, and because the NRC software tool, SECPOP2000, is not available for intermediate years, information from the 2000 census was chosen as a common baseline for socioeconomic comparison for this analysis. Published census data for later years, if available, is presented as supplemental information.

9.3.3.4.6.1 Physical Impacts

Construction activities can cause temporary localized physical impacts such as noise, odor, fugitive dust, vehicle exhaust emissions, ground vibration, and shock from blast activities. The use of public roadways would be necessary to transport construction materials and equipment to

the site. It is expected that most major plant footprint associated construction activities would occur within the boundaries of the St. Lucie site. However, a significant stretch of SR A1A would be widened to four lanes to the north, south and immediately adjacent to the site that would result in temporary impacts to local residents and commercial business located along the route. In addition, the conceptual site layout developed for the site includes construction of a 63-mile conceptual transmission corridor that would include offsite impacts. Other offsite areas that would support construction activities (for example, borrow pits, quarries, and disposal sites) would be expected to be already permitted and operational. Impacts on those facilities from construction of the new plant would be small incremental impacts associated with their normal operations.

Potential impacts from power plant operations include noise, odors, exhausts, thermal emissions, and visual intrusions. Operational noise would be generated by pumps, fans, transformers, turbines, generators, onsite traffic, and switchyard equipment. Noise levels attenuate rapidly with distance so that ambient noise levels (attributable to power plant operations) would be minimal at the site boundary. The St. Lucie site is on an industrial segment of Hutchinson Island. Commuter traffic on SR A1A would be controlled by speed limits. Good road conditions and appropriate speed limits would minimize the dust and noise level generated by the delivery trucks and site workers that travel to and from the site.

The project would have standby diesel generators and auxiliary power systems. Air quality permits obtained for this equipment would ensure that air emissions comply with regulations. In addition, the generators would be operated on a limited, short-term basis. Normal plant operations would not use a quantity of chemicals that could generate odors that exceed odor threshold values.

Physical impacts are considered small when offsite areas are not affected or only minimally or temporarily affected by noise, odor, dust, emissions, vibration, or shock. In summary, construction activities would be temporary and would occur mainly within the boundaries of the St. Lucie site. Offsite impacts would represent small incremental changes to offsite services that support construction activities. During station operations, ambient noise levels would be minimal at nearby receptors. Air quality permits would be required for the diesel generators to ensure emissions comply with regulatory guidelines, and chemical use would be limited, which should limit odors. Therefore, the physical impacts of construction and operation of the new units at the St. Lucie site would be SMALL.

9.3.3.4.6.2 Demography

The St. Lucie site is in St. Lucie County on Hutchinson Island off the eastern coast of Florida. Coterminous counties include Indian River to the north, Okeechobee to the west, and Martin to the south. The nearest population centers larger than 25,000 residents are Port St. Lucie approximately 4.5 miles west and Fort Pierce approximately 7 miles northwest.

Based on the NRC (NUREG-1437, Supplement 11) approximately 97 percent of the St. Lucie site workforce lives in a four-county region that includes St. Lucie, Martin, Indian River, and Palm Beach Counties. Of the workforce in that lives in these counties, the percentage distribution is 47.4, 38.2, 8.2, and 6.2 percent, respectively. Based on this known workforce demographic, these same counties are selected to represent the ROI for the St. Lucie site.

Based on the 2000 census, the total population in the ROI was 1,563,557 which included 112,947 in Indian River County; 126,731 in Martin County; 1,131,184 in Palm Beach County; and 192,695 in St. Lucie County (USCB 2000). Census estimates for year 2007 show an ROI population of 1,798,409 people, which included 131,837 in Indian River County, 139,182 in Martin County, 1,266,451 in Palm Beach County, and 260,939 in St. Lucie County (USCB 2009).

NRC guidelines have been established to assess the demographic sparseness and proximity of a proposed site. Sparseness is a combined measure of (1) the population density within 20 miles of the site, and (2) the relative population of the nearest metropolitan area within 20 miles of the site. Proximity is a combined measure of (1) the population density within 50 miles of the site, and (2) the relative population of the nearest metropolitan area within 50 miles of the site. Based on the sparseness-proximity evaluation, a site is categorized as low, medium, or high (NUREG-1437, Supplement 11).

The land area within 20 miles of the St. Lucie site (i.e., excluding water bodies such as the Atlantic Ocean) is 553.1 square miles, and based on 2000 census data, the population of this area was 326,647 (NUREG-1437, Supplement 11). This yields a population density of 590.57 people per square mile, based on land area. Based on this metric, the sparseness level is 4 (population density greater than 120 people per square mile over a 20-mile radius) (NUREG-1437, Supplement 11).

Similarly, the land area within 50 miles of the St. Lucie site is 3551.9 square miles, and the population of this area was 1,003,699 (U.S. NRC Aug 2003). This yields a population density of 282.58 people per square mile. Based on this metric, the proximity level is 4 (population density greater than 190 people per square mile over a 50-mile radius). Therefore, the St. Lucie site has a sparseness-proximity measure of 4.4, which is categorized as high (NUREG-1437, Supplement 11).

Based on FPL estimates, the peak construction workforce for the project would be 3548 construction workers. Operations would overlap with peak construction activity for a period of time; therefore, in addition to the construction workforce, there would be a small number (99) of operations workers on the site during the peak construction period, and these workers would also relocate to the area. Because of the location of the St. Lucie site relative to population centers, FPL assumed that 50 percent of the construction and operation workers would relocate from outside the ROI. FPL further assumed that 70 percent of construction workforce and 100 percent

of operation workforce that moved to the area would bring their families. Based on these assumptions, a total of 1824 construction and operation workers would relocate to the area in the project construction phase, and 1291 would bring their families. Based on an average household size of 3.25 people (BMI Apr 1981), the total increase in population attributable to construction at the St. Lucie site would be 4729 people. An influx of 4729 people represents a 0.3 percent increase in the ROI population of 1,563,557 people. Impacts are considered small if plant-related population growth is less than 5 percent of the area's total population (NUREG-1437, Supplement 11). This would pose a SMALL impact on population for the ROI.

At the county level, if the demographic distribution of the construction workforce follows that of the St. Lucie plant workforce, the addition of the construction workforce employees and their families would increase the population in Indian River, Martin, Palm Beach, and St. Lucie Counties by 0.3 percent, 1.4 percent, 0.03 percent, and 1.2 percent, respectively. Therefore, these represent SMALL increases in the county population levels.

FPL estimated the total onsite operations workforce to be 806 workers, and that 50 percent of these workers (403) would relocate from outside the ROI. For the purpose of this analysis, FPL assumed that each operations worker who relocated would bring their family. Based on an average household size of 3.25 people, the total population increase attributable to project operations is 1310 people. This represents a 0.1 percent increase in the four-county ROI population. At the county level, if the demographic distribution of the operations workforce follows that of the workforce at the St. Lucie plant workforce, the addition of the operations workforce employees and their families would increase the population in Indian River, Martin, Palm Beach, and St. Lucie Counties by 0.1 percent, 0.4 percent, 0.01 percent, and 0.3 percent, respectively. These represent SMALL increases in the county population levels.

In summary, the population increase in the ROI would pose a SMALL impact. Likewise, it is anticipated that the population increase in each of the four counties would pose a SMALL impact.

9.3.3.4.6.3 Economy

Based on 2000 census data, Indian River County had a civilian labor force of 47,627 people and an unemployment rate of 4.5 percent; Martin County had a civilian labor force of 53,301 people and an unemployment rate of 4.2 percent; Palm Beach County had a civilian labor force of 510,046 people and an unemployment rate of 5.0 percent; and St. Lucie County had a civilian labor force of 82,070 people and an unemployment rate of 5.2 percent (USCB 2000). For the entire ROI, 99.9 percent of the labor force was part of the civilian labor force and 0.1 percent was in the armed forces. Of the civilian labor force, 95.1 percent were employed and 4.9 percent were unemployed. The overall unemployment rate for the four-county ROI is slightly lower than that of the state, which is 5.6 percent (USCB 2000).

The principal economies of the counties in the ROI are the same, dominated mainly by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force in the four-county ROI resides in Palm Beach County (USCB 2000).

An influx of 1824 construction and operation workers from outside the region would have positive economic impacts in the four-county region. Based on a multiplier of 1.7136 jobs (direct and indirect) for every construction job and 2.2500 for every operation job (BEA Aug 2009), an influx of 1824 workers would create 1354 indirect jobs, for a total of 3178 new jobs in the ROI. The creation of such a large number of direct and indirect jobs could reduce unemployment and would create business opportunities for goods and service-related industries and the housing industry. Workers generally spend most of their employment income in the county of permanent residence. The maximum impact on any single county would occur if 100 percent of the construction workforce settled there, and the minimum impact would occur if no construction workers settle there. Economic impacts attributable to project construction are considered beneficial and therefore require no mitigation. Economic effects are considered small if peak employment accounts for less than 5 percent of area employment (NUREG-1437, Supplement 11). The number of new jobs created would represent only a 0.5 percent increase in jobs within the ROI; therefore, the economic impacts would be SMALL.

An estimated 806 workers would be required for the operation of two nuclear power facilities at the St. Lucie site (U.S. DOE May 2004), and FPL assumed that 50 percent of these employees would migrate into the region. Based on a multiplier of 2.2500 jobs (direct and indirect) for every operations job at the new units (BEA Aug 2009), an influx of 403 operations workers would create 504 indirect jobs for a total of 907 new jobs in the region. FPL concluded that the impacts of operation of two nuclear power facilities on the economy would be beneficial and SMALL in the ROI and mitigation would not be warranted.

9.3.3.4.6.4 Taxes

Taxes collected as a result of construction and operation of the new nuclear units at the St. Lucie site would benefit the state and local tax authorities. FPL would pay property taxes to each taxing authorities whose boundaries contained the plant. Tax payments would be based on the assessed valuation of the plant and local tax rates. If the plant site straddled a jurisdictional boundary, FPL would pay taxes to both entities based on the assessed valuation within each entity.

As described in Subsection 4.4.2.2.2, it is not clear whether FPL corporate income taxes would increase as a result of construction of the new units at the St. Lucie site, because the units would not generate revenues until they became operational. However, once the units were placed in

service, St. Lucie County property taxes would begin and would continue for the 60-year operational life of the facility.

FPL assumed that annual property tax payments at St. Lucie site would be similar those paid by the nuclear units at Turkey Point plant. In 2006, the annual tax payment for the two units at the Turkey Point nuclear power plant was $6,902,670. For fiscal year 2006, St. Lucie County had property tax revenues of $134,254,911 (State of Florida, Mar 2007).

With respect to the school districts in Florida, local revenue for the school districts is derived almost entirely from property taxes levied by Florida's 67 counties, each of which constitutes a school district (Florida Department of Education 2008). As described in Subsection 2.5.2.3.5, the state of Florida has an established equalized funding program that reallocates tax base funds from counties that have a high economic tax base to counties that have a low economic tax base. The Florida Education Finance Program is the primary mechanism to fund the operational costs of Florida school districts. Funding is based on the number of full-time equivalent students, and considers variations in several factors to determine funding for each district: local property tax bases, education program costs, costs of living, and costs for equivalent educational programs because of the density and distribution of the student population.

It should be noted that school property tax payments would be based on the location of the plant and not necessarily on the district(s) attended by the workers' children. Therefore, it is not possible to assess the direct impact of the plant on the school district. In addition, the impact of plant construction and operation on the special tax districts is not assessed here because most of the property tax payment from the plant would go to the county and the school district(s).

The benefits of taxes are considered small when new tax payments by the nuclear plant constitute less than 10 percent of total revenues for local jurisdictions and large when new tax payments represent more than 20 percent of total revenues (NUREG-1437, Supplement 11). Therefore, based on the county portion of the FPL property tax payment for the new units, 8 percent of the 2006 property tax revenues for St. Lucie County would be provided by FPL and constitute a SMALL positive impact.

9.3.3.4.6.5 Transportation

The only road access to the St. Lucie site would be SR A1A (a two-lane road) which spans in the north-south orientation along the eastern site boundary. SR A1A intersects with U.S. Highway 1 in both directions. U.S. Interstate 95 spans parallel to U.S. Highway 1 and can be reached by numerous routes. Commuters from most cities in the region (Boynton Beach, Indiantown, Palm City, Port St Lucie, West Palm Beach) would travel northbound on SR A1A to reach the site. Commuters from Fort Pierce, Palm Bay and Vero Beach would travel southbound along SR A1A to reach the site.

FDOT reports the AADT count at two locations along SR A1A, one at one-half mile south of the site, and one 6 miles north of the site. The AADT count and directional peak hour volume of the southern location is 4700 vehicles per day and 273 vehicles per hour (FDOT 2008). This directional peak hour volume classifies this southern portion of the roadway as a LOS of C (FDOT 2007), and the remaining peak hour capacity is 147 vehicles. The northern location has an AADT count and directional peak hour volume of 3700 vehicles per day and 215 vehicles per hour (FDOT 2008). This peak hour volume classifies this northern portion of the roadway as a LOS of B (FDOT 2007), and the remaining peak hour capacity is 205 vehicles.

Based on the existing workforce at the St. Lucie site, FPL assumed that most of the workforce would likely travel along the southern portion of SR A1A and that a smaller amount of the workforce would travel along the northern portion. Also, the traffic attributable to construction material deliveries could cause additional congestion on SR A1A during certain times of the day. Based on the methodology presented in Subsection 4.4.2.2.4, FPL determined that construction at the St. Lucie site would add 1507 and 623 vehicles during the peak hour to the respective southern and northern portions of SR A1A. This would cause the road to exceed capacity and drop the southern and northern roadway to LOS classifications of E and F, respectively.

Based on this analysis, it is likely that the additional traffic would pose delays along SR A1A. To facilitate the additional traffic, SR A1A could be widened to a four-lane highway, and acceleration/deceleration lanes could be added to facilitate commuter traffic. These roadway modifications would be needed along SR A1A between Seaway Drive to the north and NE Causeway Boulevard to the south, particularly in the vicinity of the St. Lucie site. NRC applied significance levels to the LOS classifications that were projected to result from the additional traffic associated with refurbishment activities at nuclear plants (NUREG-1437, Supplement 11). FPL considers this approach to be appropriate for construction of a nuclear plant since both plant refurbishment and new plant construction would be large construction projects. NRC associates small impacts with LOS A and B, moderate impacts with LOS C and D, and large impacts with LOS E and F. It is therefore anticipated that the impact of the construction workforce on transportation would be LARGE.

Operations at the St. Lucie site would add approximately 332 and 137 more vehicles to the southern and northern portions of SR A1A during the hour of peak traffic, respectively. The roadway modifications to the southern part of SR A1A (mentioned above) would raise the roadway peak hour capacity sufficiently to accommodate the additional traffic from operations. Shift changes could be also be staggered so that the traffic increase would be less likely to cause congestion. However, based on the NRC LOS significance levels in the absence of road modifications that increase road capacity, the impact of the operations workforce on transportation would be MODERATE.

9.3.3.4.6.6 Aesthetics and Recreation

The St. Lucie site consists of 1130 acres of developed land on the widest section of Hutchinson Island in St. Lucie County. A portion of the site is occupied by St. Lucie Units 1 & 2 nuclear power generation facilities. The site is on a flat barrier island at elevations that range from 0 to 5 feet above MSL (USGS 1948) and within the Flatwoods physiographic province (USGS 2008).

Construction of the new units at the St. Lucie site could be viewed from offsite at certain locations, but the addition of two nuclear facilities would not substantially change the viewscape which results from the current nuclear generation facilities. Operation of the new nuclear units would have visual impacts similar to those of the St. Lucie Units 1 & 2, with occasional visible vapor plumes associated with cooling tower operations. Visibility of the plumes would depend on weather conditions and the location of the viewer in the area. Impacts on aesthetic resources are considered small if there is no potential for diminution in the enjoyment of the physical environment and no measurable impact on socioeconomic institutions and processes. Therefore, impacts of construction and operation of the new units on aesthetics would be SMALL and would not warrant mitigation.

The Indian River Lagoon is a long, shallow, tidally-influenced estuary that stretches along the central-east coast of Florida between the mainland and a series of offshore islands. At the St. Lucie site, the Indian River Lagoon is approximately 7200 feet wide and bounds the site to the west. Blind Creek Park and Big Mud Creek Park, inlets off Indian River Lagoon, are adjacent to the site. The stretch of lagoon adjacent to the site is designated as the Jensen Beach to Jupiter Inlet Aquatic Preserve. The North Fork St. Lucie River Aquatic Preserve is on the north fork of the St. Lucie River at Port St. Lucie. The St. Lucie Canal connects the St. Lucie site with Lake Okeechobee.

Fort Pierce Inlet State Recreation Area is approximately 9 miles north of the St. Lucie site and immediately north of the Fort Pierce Inlet. Recreational area activities include beach activities, swimming, picnicking, camping, and hiking. Other state recreational areas include Avalon, Savannas, and Pepper Beach. The Savannas State Preserve, a freshwater lagoon, is on the mainland approximately 2 miles west of the St. Lucie site and offers fishing, hiking, picnicking, and other outdoor-related activities (NUREG-1437, Supplement 11).

Three National Wildlife Refuges are within 50 miles of the St. Lucie site and include Hobe Sound, Pelican Island, and Arthur R. Marshall Loxahatchee National Wildlife Refuges. Hobe Sound is approximately 22 miles south of the site and occupies approximately 1035 acres of the most productive sea turtle nesting areas on the Florida east coast (USFWS 2008c). Pelican Island is approximately 32 miles north of the site and consists of a 5413-acre bird rookery island (USFWS 2008d). Loxahatchee is approximately 48 miles south of the site and consists of more than 221 square miles of Everglades habitat (USFWS 2008e).

Other prominent features within 50 miles of the St. Lucie site include Lake Okeechobee, Blue Cypress Lake, Jonathan Dickinson State Park, the DuPuis and J.W. Corbett Wildlife Management Areas, and a portion of the Seminole Brighton Indian Reservation (NUREG-1437).

Because the St. Lucie site already hosts a power plant with tall structures and transmission towers, the construction and operation of two nuclear power units and associated transmission lines would not pose an appreciable change to the viewscape. Therefore, visual impacts on the region would be SMALL.

During plant operations, some employees and their families would use the regional recreational facilities; however, the increase attributable to plant operations would be small compared to overall use of these facilities. Impacts on tourism and recreation are considered small if current facilities are adequate to handle local levels of demand. Therefore, impacts of facility construction and operation on tourism and recreation would be SMALL.

9.3.3.4.6.7 Housing

FPL estimated that 1824 construction and operation workers would move from outside the ROI to the counties in the ROI. These 1824 workers would need housing. Some of the workers would seek permanent residence, generally owner-occupied; some would choose to rent; and others would choose a transitional residence such as a hotel, a room in private home, or a camper or mobile home.

Based on 2000 census data, within the four-county ROI, there were 771,063 housing units of which 115,530 were vacant (15.0 percent). At the county level, the number of vacant housing units was 8765 in Indian River County (15.1 percent), 10,183 (15.6 percent) in Martin County, 82,253 (14.8 percent) in Palm Beach County, and 14,329 (15.7 percent) in St. Lucie County. This includes housing that is designated as seasonal, recreational, or occasional use (USCB 2000).

Based on absolute numbers, FPL estimated that the available housing would be sufficient to house the construction workforce. Workers who relocated could secure housing from the existing stock in any of the four counties within the region, have new homes constructed, or bring their own residence (mobile home or trailer) to the region. The influx of 1824 construction workers represents 1.6 percent of the 115,530 vacant housing units in the ROI. At the county level, if the construction workforce follows workforce housing patterns at the St. Lucie plant, then the percentage of vacant housing required in each county would be 1.7 percent, 6.8 percent, 0.1 percent, and 6 percent for Indian River, Martin, Palm Beach, and St. Lucie Counties, respectively. Impacts on housing are considered to be small when a small and not easily discernable change in housing availability occurs (NUREG-1437, Supplement 11). In summary, FPL concluded that the impacts on housing in the ROI and for any individual county would be SMALL and mitigation would not be warranted.

FPL estimated that 806 workers would be needed for operation of two nuclear power facilities at the St. Lucie site (U.S. DOE May 2004). An estimated 50 percent of these workers (403) would come from within the ROI, and 50 percent (403) would relocate to the area. An influx of 403 workers would represent less than 1 percent of the vacant housing in the ROI. At the county level, if the construction workforce followed workforce housing patterns at the St. Lucie plant, then the percentage of vacant housing required in each county would be 0.4 percent, 1.5 percent, 0.03 percent, and 1.3 percent for Indian River, Martin, Palm Beach, and St. Lucie Counties, respectively. In summary, FPL concluded that the impacts on housing in the ROI and for any individual county would be SMALL and that mitigation would not be warranted.

9.3.3.4.6.8 Public Services

Public services in the ROI include water supply and wastewater treatment facilities, law enforcement, fire, and medical facilities, and social services. Construction or operations employees who relocated from outside the region would most likely live in residentially developed areas where adequate water supply and wastewater treatment facilities already exist. The medical facilities in the four-county ROI provide medical care to much of the population in the 50-mile region, and therefore the small increases in the regional population would not materially impact the availability of medical services. Although the workers and their families would pose an additional overall demand on other public services, it is anticipated that the current capacity of public services within the four-county ROI would be adequate to accommodate the increased demand. Therefore, the impact would be SMALL.

The new nuclear plant and the associated population influx would likely pose an economic benefit for the disadvantaged population served by the Florida Department of Children and Families. Direct jobs created by the project would bring indirect jobs that could be filled by currently unemployed workers and therefore remove them from the care of social services.

The ratio of residents-to-law enforcement officers in Indian River, Martin, Palm Beach, and St. Lucie Counties was 562:1, 466:1, 928:1, and 722:1, respectively (FBI 2008). In the four-county ROI, the ratio was 798:1. For the state of Florida, the resident-to-law enforcement officer ratio was 851:1. Ratios are partly dependent on population density. In general, fewer law enforcement safety officers are necessary for the same population if the population resides in a smaller area. In the ROI, if no additional law enforcement officers were hired, the population increase attributable to project construction at the St. Lucie site would increase the resident-to-law enforcement officer ratio by 0.3 percent to 801:1. This is a small increase and would still yield a lower resident-to-law enforcement officer ratio than the average for the state of Florida. Similarly, the increase in the resident-to-law enforcement officer ratio attributable to operations would yield less than a 0.1 percent increase.

The ratio of residents to firefighters for these counties was 411:1, 363:1, 519:1 and 563:1, respectively (USFA 2009). In the ROI, the ratio was 497:1, and for the state of Florida, the resident-to-firefighter ratio was 1,230:1 (USFA 2009). As described above in the description of law enforcement officers, ratios are partly dependent on population density. In general, fewer firefighters are necessary for the same population if the population resides in a smaller area. In the ROI, if no additional firefighters were hired, the population increase attributable to project construction at the St. Lucie site would increase the resident-to-firefighter ratio by 0.3 percent to 498:1. This is a small increase and would still yield a lower resident-to-firefighter ratio than the average for the state of Florida. Similarly, the increase in the resident-to-firefighter ratio attributable to operations would yield less than a 0.1 percent increase.

Impacts on public services are considered small if there is little or no need for additional personnel. Impacts are considered moderate if some permanent additions or some new capital equipment purchases are needed (NUREG-1437, Supplement 11). The population increase in the four-county region attributable to construction or operation of the new power units could pose a need to hire additional emergency personnel; however, any additional need would be small, and increased tax revenues would be adequate to pay the salaries of any additional emergency personnel hired. Therefore, it is not expected that public services would be materially impacted by new construction or operations employees that relocate from outside the region. Impacts are therefore considered SMALL, and mitigation would not be warranted.

9.3.3.4.6.9 Education

Based on data for the 2006-2007 school year, Indian River County had 28 prekindergarten through 12 (PK–12) schools with a total enrollment of 17,611 students; Martin County had 36 PK–12 schools with a total enrollment of 18,239 students; Palm Beach County had 264 PK–12 schools with a total enrollment of 171,431 students; and St. Lucie County had 46 PK–12 schools with a total enrollment of 38,793 students (NCES 2009). In the four-county ROI, there were 374 PK–12 schools with a total enrollment of 246,074 students.

FPL estimated that 1824 construction and operation workers would migrate to the area, and that 1291 of these would bring a family. This would yield a total population increase of 4729 people. Based on an estimate of 0.8 school-aged children per family, an estimated 1033 of the 4729 people who relocated to the four-county area would be school-aged children. This would yield a 0.4 percent increased in the student population in the ROI.

Based on the demographic distribution of the St. Lucie plant workforce, an increase of 1033 students would increase the student populations in Indian River, Martin, Palm Beach, and St. Lucie Counties by 0.5 percent, 2.2 percent, 0.04 percent, and 1.3 percent, respectively. Small impacts are generally associated with project-related enrollment increases are less than 3 percent and moderate impacts on local school systems are generally associated with project-

related enrollment increases of 3 to 8 percent (NUREG-1437). Therefore, projected increases in the student populations for the ROI and for each individual county are expected to be SMALL. The quickest mitigation would be to hire additional teachers and move modular classrooms to existing schools. Increased property and special option sales tax revenues as a result of the increased population would fund additional teachers and facilities. No additional mitigation would be warranted.

FPL assumed that 403 operations workers and their families would relocate from outside the region, and that the total population increase would be 1310 people. This would include an estimated 322 children in the PK–12 school range. This influx of students would increase the student population in the ROI by 0.1 percent. Based on the demographic distribution of the St. Lucie plant workforce, an increase of 322 students would increase the student populations in Indian River, Martin, Palm Beach, and St. Lucie Counties by 0.2 percent, 0.7 percent, 0.01 percent, and 0.4 percent, respectively. Therefore, projected increases in the student populations for the ROI and for each individual county are expected to be SMALL, and mitigation would not be warranted.

9.3.3.4.7 Historic and Cultural Resources

FPL conducted historical and archaeological records searches on the National Park Service NRIS and reviewed information on historic and archeological sites provided in the NRC *Final Report: Generic Environmental Impact Statement (GEIS) for License Renewal of Nuclear Plants, Supplement 11, St. Lucie Units 1 and 2* (NUREG-1437, Supplement 11).

The GEIS Supplement 11 for the St. Lucie Units 1 & 2 indicates that in 2001 FPL submitted a letter to the Florida SHPO to request comments on the St. Lucie Units 1 & 2 license renewal process. In the letter, FPL determined that the continued operation of St. Lucie would have no impact on historic properties. In response, the Florida SHPO cautioned that there was a moderate to high likelihood for the presence of significant prehistoric archaeological sites in the currently undeveloped portions of the St. Lucie site, as evidenced by the presence of the archeological remains along Blind Creek at the northern end of the site boundary (NUREG-1437, Supplement 11).

The NRHP identifies 124 sites in the four-county ROI; including 70 sites in Palm Beach County, 12 sites in Martin County, 16 sites in St. Lucie County, and 26 sites in Indian River County. Fifteen of these properties are within 10 miles of the St. Lucie site (NPS 2008e).

Siting the proposed nuclear plant at the St. Lucie site would require a formal cultural resources survey be conducted so that no archeological or historic resources would be damaged during construction. Sites are considered to have small impacts to historic and cultural resources if the SHPO identifies no significant resources on or near the site or determines they would not be

affected by plant construction or operation. Sites are considered to have large impacts if historic or cultural resources would be disturbed or otherwise have their historic character altered by construction. Because of the moderate to high likelihood of significant prehistoric archaeological sites, the impacts to cultural resources from construction or operation of the new units at the St. Lucie site would be considered MODERATE. Mitigation measures would be applied to prevent any permanent damage.

Construction activities at the St. Lucie site could be viewed from the historic and cultural sites 10 miles from the site, but the addition of two nuclear power facilities would not substantially change the view. Operation of the new units probably would have visual impacts similar to those of the existing FPL St. Lucie power plant, with the addition of cooling tower plumes. Therefore, visual impacts of construction and operation of the St. Lucie site relative to historic and culture sites would be SMALL and would not warrant mitigation.

9.3.3.4.8 Environmental Justice

Environmental justice refers to a federal policy under which each federal agency identifies and addresses, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority or low-income populations. The NRC has a policy on the treatment of environmental justice matters in licensing actions (69 FR 52040) and guidance (U.S. NRC May 2004). Subsection 2.5.4.1 describes the methodology FPL used to establish locations of minority and low-income populations.

The 2000 census block groups were used to ascertain minority and low-income population distributions in the area. There are 590 block groups within 50 miles of the St. Lucie site. The census data for Florida characterizes 14.6 percent of the population as black, 0.3 percent American Indian or Alaskan Native, 1.7 percent Asian, 0.1 percent Native Hawaiian or other Pacific Islander, 3.0 percent as other single minorities, 2.4 percent multiracial, 22.0 percent aggregate of minority races, and 16.8 percent Hispanic ethnicity. If any block group percentage exceeded the state percentage by more than 20 percent or was greater than 50 percent, then the block group was considered to have a significant minority population.

Significant black minority populations exist in 86 block groups, significant American Indian or Alaskan Native populations exist in 1 block group, significant other race minority populations exist in 5 block groups, significant aggregate of minority races populations exist in 96 block groups, and significant Hispanic ethnicity populations exist in 30 block groups. There are no block groups containing significant Asian, Native Hawaiian or other Pacific Islander, multiracial minority populations within 50 miles of the St. Lucie site.

A portion of the Brighton Seminole Indian Reservation is 50 miles west-southwest of the St. Lucie site. As described in Subsection 9.3.3.1.8, the reservation offers several tourist attractions

including Indian arts and crafts shops, the Seminole Casino Brighton, a rodeo arena, the Brighton Citrus Grove, and the Brighton Seminole Campground. Today, most Seminole Tribal members are afforded modern housing and health care. In fact, today the Seminole Indians live much the same way as those who live outside Seminole County (Seminole Tribe of Florida 2008).

The locations of the minority populations within 50 miles of the St. Lucie site and the Brighton Indian Reservation are shown in Figure 9.3-18.

The census data characterizes 11.7 percent of Florida households as low income. Based on the more than 20 percent criterion, 37 block groups out of a possible 590 contain a significant number of low-income household. The locations of the low-income populations within 50 miles of the St. Lucie site are shown in Figure 9.3-19.

The closest minority and low-income block groups are in Fort Pierce approximately 10 miles north-northwest of the St. Lucie site. Construction activities (noise, fugitive dust, and air emissions) would be contained within site boundaries and would not impact minority populations. In fact, minority and low-income populations would most likely benefit from construction activities through an increase in construction-related jobs. Operation of the new units at the St. Lucie site is also unlikely to have disproportionate impacts on minority or low-income populations.

FPL concludes that construction and operation of the proposed nuclear plant at the St. Lucie site would not disproportionately impact minority or low-income populations and that mitigation would not be warranted, and the impacts to these populations would be SMALL.

9.3.3.4.9 Other Projects in the Vicinity of the St. Lucie Site

The cumulative impacts of past, present, and reasonably foreseeable federal (e.g. USCOE, USGS), non-federal (e.g. FDEP, FDOT, county), and private projects within a 50-mile radius of the St. Lucie site, excluding Brownfield and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) sites, that could have cumulative impacts with the proposed action are described in Table 9.3-18. These projects have either requested an air or water permit/license or had an environmental impact statement complete. Projects included in Table 9.3-18 are within the 50-mile radius of the St. Lucie site and the appropriate timeframe for construction and operation of the new units (Figure 9.3-17) from 2013 to 2063 (based on a construction start date of 2013, a Unit 7 in-service date of 2023, and a 40-year operating license). Nuclear power projects within 100 miles of the St. Lucie site (i.e., St. Lucie Units 1 & 2) are also described in Table 9.3-18. The Turkey Point site is more than 130 miles from the St. Lucie site and is therefore not included in the table. The only other nuclear power plant currently operating in Florida, Crystal River, is more than 180 miles from the St. Lucie site and therefore is also not included the table. The proposed nuclear power plant in Levy County is approximately the same distance as the Crystal River site and is not included in the table. It should be noted that this list is

not intended to be exhaustive and should not be used to imply that no other past, present or reasonably foreseeable projects exist that could contribute to cumulative impacts within each alternative site project area.

The impacts to land use that would have a cumulative impact on alternative sites would generally be characterized as a change to the land use designation from “agriculture” to “industrial.” A positive land-use impact, for example, would be the CERP projects. These projects are within the 50-mile radius would redevelop, reuse, or develop additional land for conservation. The cumulative impacts to hydrology and water use would be minimally negative due to the restrictions placed on all surface water and groundwater use, also beneficial impact due to the large scale CERP projects for reservoir and storage areas which would provide additional water to the southern Everglades Agricultural Area, reestablish wetland hydropatterns and improve water quality in several different watersheds by treating excessive discharge. The cumulative impacts for terrestrial/aquatic resources would be associated with the minimal loss of wetlands, which is offset by the restoration of developed lands for conservation and restoration of native species through CERP projects. The cumulative impacts for socioeconomics for the St. Lucie site would appear as beneficial impacts to taxes and adverse impacts on transportation. Also, there would not be any disproportionate impact to low-income or minority populations by the activities at the St. Lucie site.

9.3.4 SUMMARY AND CONCLUSIONS

The decision to locate two additional nuclear power units at the Turkey Point site was based on a comparison of four alternative sites: a greenfield site in south-central Glades County, a greenfield site in southern Okeechobee County, an FPL-owned fossil power plant site in western Martin County, and an FPL-owned nuclear power plant site in eastern St. Lucie County. The FPL evaluation sought to determine whether any of the alternative sites are environmentally preferable to the Turkey Point site to site a pair of new nuclear power units to increase grid capacity in south Florida.

The evaluation process was consistent with the special case noted in NUREG-1555, Section 9.3(III)(8), and considered the advantages already present at existing nuclear facilities within the ROI. As described in Section 9.2, based on FPL knowledge and experience, 23 potential sites were initially identified for consideration (12 greenfield sites, 2 existing nuclear power plant sites, and 9 existing non-nuclear power plant sites). A parallel site identification process involving a GIS regional screening analysis was also conducted, and 6 additional potential greenfield sites were identified. These sites were then evaluated based on a range of performance criteria and weighted scores. After three successive stages of qualitative and quantitative evaluation, 24 sites were determined to be less favorable, and the top five sites were identified. Taking into consideration the results of each evaluation conducted (including satisfying the overall business objectives for the FPL COL project), the Turkey Point site was selected as the proposed site for

FPL's new nuclear power generation project, and the Glades, Martin, Okeechobee 2, and St. Lucie sites were identified as the top alternative sites. Turkey Point is reviewed at length in other sections of the ER. This section, Subsection 9.3.3, describes the evaluation of the alternative sites based on reconnaissance level information.

A comparison of the environmental impacts from construction and operation for the proposed site and each of the top alternative sites is presented in Tables 9.3-19 and 9.3-20. The impact summaries presented in these tables indicate that environmental impacts at the Glades, Okeechobee 2, and St. Lucie sites would, in general, be higher than those at the Turkey Point and Martin sites. The magnitude of estimated impacts at Martin and Turkey Point are similar, with each site having MODERATE versus SMALL impacts in one or two of the resource areas evaluated, with Turkey Point having an advantage (SMALL to MODERATE versus LARGE) in the Transportation resource area. Overall, especially given the reconnaissance level information used in developing these estimates, neither Turkey Point nor Martin would be expected to have significantly less environmental impact. Therefore, based on these analyses, FPL concludes that no alternative site is environmentally preferable to the proposed Turkey Point site; accordingly, no alternative site is obviously superior to Turkey Point as the proposed site for its new two-unit nuclear power plant.

Table 9.3-1 (Sheet 1 of 2)
Regional Screening Criteria

Criterion	Mapped Data	Mapping Criteria	Effect on Candidate Area Identification	Data Source(s)	Comments/Rationale
Cooling Water Availability (Surface Water)	Water sources (major rivers/ canals, existing lakes/reservoirs, coastal areas)	Rivers/canals within the FPL ROI for which the annual mean flow > 500 cfs (approximately 5 times the new plant cooling water requirement[(a)]) and the Atlantic Ocean and Gulf of Mexico	Excluded areas greater than 10 miles from qualifying rivers and 10 miles from the Atlantic Ocean and the Gulf of Mexico	USGS Water-Data Reports	Rivers for which more than 20% of the average flow will be required for makeup water may present permitting or operational water supply problems. The Atlantic Ocean and the Gulf of Mexico were assumed to be a viable source for cooling water makeup. Pumping makeup water more than 10 miles from rivers and the Atlantic Ocean/Gulf of Mexico may impose significant construction and operational costs and can result in operational risks.
Cooling Water Availability (Reclaimed Water)	Wastewater treatment plants	Wastewater treatment plants with an effluent flow rate of at least 20 Mgal/day (one-third the assumed makeup water requirement[(a)])	Excluded areas greater than 10 miles from qualifying wastewater treatment plants	FDEP Reuse Inventory Database and Annual Report	Wastewater treatment plants with a flow of at least one-third of the total makeup requirement (~20 Mgal/day) were identified as potential cooling water sources. Wastewater treatment plants unable to supply the total cooling water requirement would be supplemental sources of cooling water only. Wastewater treatment plants unable to supply at least one-third of the total cooling water requirement were assumed to be uneconomical as makeup water sources.
Population	Population Density	Census block groups where population density > 300 persons/ mi^2	Excluded	2000 Census, updated as available	Areas with > 300 persons/mi^2 likely have multiple imbedded areas > 500 persons/mi^2. Siting outside of these areas would more likely result in a population density less than the NRC guideline of 500 persons/mi^2 within a 20-mile radius of a site.
Dedicated Lands	Lands designated as National Parks, National Wildlife Refuges, National Marine Sanctuary Areas, military installations, Indian lands, and Florida state parks	Boundaries of dedicated lands identified	Excluded	Federal and state agency web sites (see Appendix A).	None.

Table 9.3-1 (Sheet 2 of 2)
Regional Screening Criteria

Criterion	Mapped Data	Mapping Criteria	Effect on Candidate Area Identification	Data Source(s)	Comments/Rationale
Ecological Features mapped on a regional basis	Mapped critical habitat for identified species (see comments column at right)	Areal extent of identified features	Not considered as favorable areas for identification of additional potential sites	U.S. Fish and Wildlife Service (USFWS) Digitized Critical Habitat Data	Regional screening included critical habitat for species for which the USFWS website provided GIS shape files (digital data).This included critical habitat for the following species: American Crocodile, Cape Sable Seaside Sparrow, Choctawhatchee Beach Mouse, Everglade Snail Kite, Frosted Flatwoods Salamander, Gulf Sturgeon, Johnson's Seagrass, Perdido Key Beach Mouse, Piping Plover, Purple Bankclimber, Rice Rat, Right Whale, St. Andrew Beach Mouse.

(a) Assumed makeup water requirements (two units, closed cycle) = 42.000 gpm,~ 100 cfs; ~ 60 Mgal/day).

Table 9.3-2 (Sheet 1 of 2)
Candidate Area Siting Suitability Characteristics

Candidate Area	Siting Suitability Characteristics
CA-1	A significant portion of the western half of the candidate area is covered in wetlands; these areas were avoided for potential site selection.
CA-2	A significant portion of the southern half of the candidate area is covered in wetlands; these areas were avoided for potential site selection. Potential sites in CA-2 were located in the central/southern portion of the candidate area to minimize the distance from the Miami load center and environmental impacts associated with construction of transmission and transportation infrastructure.
CA-3	The northeastern portion of the candidate area is located nearer areas of large population and does not offer any perceived advantages over other sites within the candidate area.
CA-4	The northern portion of the candidate area is located farther from the Miami load center than other sites in the candidate area and does not offer any perceived advantages over other sites within the candidate area.
CA-5	The southern and western portion of the candidate area is covered in wetlands; these areas were avoided for potential site selection.
CA-6 through CA-10	These candidate areas are located in the northern portion of FPL's service territory and are farther from the primary load center in the Miami area. Sites in these candidate areas will be disadvantaged due to the increased environmental impacts associated with construction of transmission infrastructure. These candidate areas do not offer any perceived advantages that would outweigh the increased environmental impacts associated with construction of transmission infrastructure. Additionally, significant portions of CA-6, CA-7, CA-9, and CA-10 are covered in wetlands.
CA-11	The majority of this candidate area is covered in wetlands; these areas were avoided for potential site selection. Additionally, the candidate area is surrounded by areas of large population.
CA-12	The candidate area contains pockets of larger population and is surrounded by areas of large population. Additionally, the wastewater treatment plant in the area can only supply a portion of the cooling water requirement, and access to other sources may be limited.
CA-13	The majority of this candidate area is covered in wetlands; these areas were avoided for potential site selection. The areas not covered in wetlands are developed and closer to areas of large population. During the process of canvassing the candidate areas to identify potential sites, FPL examined areas in southern Florida to attempt to identify potential sites that could potentially use the reuse water from the south Miami area. However, due to population and environmental constraints present in these candidate areas, FPL did not identify any potential sites other than Turkey Point that were located near viable sources of reclaimed water.
CA-14	The majority of the candidate area is populated and surrounded by areas of large population. The candidate area was examined closely to identify any potential sites that could take advantage of reclaimed water in the south Miami area, but no potential sites beyond Turkey Point were identified.

Table 9.3-2 (Sheet 2 of 2)
Candidate Area Siting Suitability Characteristics

Candidate Area	Siting Suitability Characteristics
CA-15	The majority of the candidate area is covered in wetlands. Aside from the area surrounding the St. Lucie nuclear power plant, no viable siting areas were identified in the candidate area.
CA-16	With the exception of the central portion, the majority of the candidate area is covered in wetlands; these areas were avoided for potential site selection. Additionally, pipeline access to the Gulf of Mexico could be complicated by area development, large population, and environmental concerns (e.g., estuarine/marine habitat).

Table 9.3-3 (Sheet 1 of 4)
Screening Evaluation Criteria

Criterion Number	Criterion	Measure of Suitability	
		Metric	**Rating Rationale**
P1	Cooling Water Supply	Composite ratings were based on an average of ratings for the following four aspects: **Flow** – Surface water: Annual mean flow for the period of record as reported by USGS. [http://waterdata.usgs.gov/fl/nwis/current/?type=flow]. Reclaimed water: WWTP flow reported by FDEP. [http://www.dep.state.fl.us/water/reuse/inventory.htm]. Groundwater: Flow estimated based on FPL familiarity with Floridan aquifer, where feasible. Lake Okeechobee: Conservatively estimated to be at least the lower of the low daily mean flow reported for the C44 and C43 canals (360 cfs).	Assumes only 20% of river/canal/lake flows are available for permit/withdrawal. 5 = No practical restriction 4 = Availability greater than 5 times the requirement 3 = Availability 3-5 times the requirement 2 = Availability less than 3 times the requirement 1 = Insufficient flow
		Flexibility – Number of source(s) of water present and capable of providing substantial portion of required flow.	Assumes groundwater only available as an augmentation source (data sources for groundwater availability on an areal basis throughout the ROI were not available). 5 = Multiple sources each capable of full flow required 4 = Additional sources capable of providing substantial portion of flow 3 = One source capable of providing full flow 2 = Multiple sources each capable of providing substantial portion of flow with no single source providing full flow requirements 1 = Insufficient flow regardless of number of sources

Table 9.3-3 (Sheet 2 of 4)
Screening Evaluation Criteria

Criterion Number	Criterion	Measure of Suitability	
		Metric	**Rating Rationale**
		Risk – Associated with flow variability, longer pumping distances and/or other reliability aspects of water supply.	5= All aspects favorable 4= Some favorable aspects 3= Neutral 2= Some risk 1= Substantial risk
		Regulatory Challenge – Known areas with elevated competition for water resources, a high number of water users, difficult supply conditions or challenging compliance situation are ranked lower than those without such challenges, based on knowledge and insights of the FPL siting team.	5= All aspects favorable 4= Some favorable aspects 3= Neutral 2= Some challenges 1= Substantial challenges
P2	Flooding	Flood potential considering difference between mean site elevation and surface water body elevation, proximity to swamp areas, and proximity to flood prone areas (100-year flood zone).	5 = Low flood potential, elevation difference greater than 20 feet, plant site can be located outside of swamp areas and outside of 100-year flood zone. 4 = Moderately low flood potential, elevation difference greater than 10 feet, plant site can be located outside of 100-year flood zone, swamp areas may be encountered. 3 = Moderate flood potential, elevation difference greater than 5 feet, plant site located on border of 100-year flood zone, swamp areas may be encountered. 2 = Moderately high flood potential, elevation difference less than 5 feet, plant site located within 500-year flood zone, swamp areas likely to be encountered. 1 = High flood potential, elevation difference less than 5 feet, plant site located within 100-year flood zone, base flood elevations above site elevation, swamp areas likely to be encountered.

Table 9.3-3 (Sheet 3 of 4)
Screening Evaluation Criteria

Criterion Number	Criterion	Measure of Suitability	
		Metric	**Rating Rationale**
P3	Population	Composite ratings were based on an average of ratings based on the following two conditions: (1) Distance to nearest population center (high density); and (2) Population density of host county (based on 2000 census). In addition, a rating point was deducted or added if the site is or is not in a particularly densely populated area. Population centers are defined as the nearest "place" or "concentration of population" as defined by the U.S. Census Bureau, where a place is either legally incorporated under the laws of its respective state, or a statistical equivalent that the Census Bureau treats as a Census Designated Place (CDP).	5 = No population centers within 20 miles 4 = Population centers between 20 and 15 miles 3 = Population centers between 15 and 10 miles 2 = Population centers between 10 and 5 miles 1= Population centers within 5 miles County Population Density Ratings: 5 = Less than 50 persons per square mile (psm) 4 = Between 250 psm and 50 psm 3 = Between 350 psm and 250 psm 2 = Between 500 psm and 350 psm 1 = Greater than 500 psm A point was added if no densely populated area is found within 40 miles of the site; a point deducted if a densely populated area is found within 15 miles of the site or if a large grouping of densely populated areas are located within 15-40 miles of the site.
P4	Hazardous Land Uses	Number of airports, pipelines, and other known hazardous industrial facilities (including Air Force Bases and Kennedy Space Center/ Cape Canaveral), as determined from publicly available data.	5 = No major airport, city or county airport, military base, or rail within 10 miles [small air fields/landing strips are allowed if no more than 2 within 5 miles] 4 = No major airport (or Air Force Base) within 10 miles, no rail, pipeline small city or county airport within 5 miles [1-2 small air fields/landings strips are ok] 3 = Rail and small airports (multiple) < 5 miles 2 = Major airport or Air Force Base < 10 miles 1 = Major airport or Air Force Base < 10 miles, rail and multiple small airports < 5 miles, and existing plant location
P5	Ecology	Number of Federal Threatened, Endangered and Rare Species in County [aquatic and terrestrial]	5 = 0 species 4 = 1-10 species 3 = 11-20 species 2 = 21-30 species 1 = over 30 species
P6	Wetlands	Number of mapped wetland acres within a 5000 acre nominal site area*, excluding riverine, existing reservoirs, and deepwater marine areas. Note: The use of the term "wetlands" is used solely as a descriptive term and is not used as a regulatory or jurisdictional term.	5 = 0 acres 4 = Between 0 acres and 250 acres, or ≤ 5% of land area 3 = Between 250 acres and 500 acres, or ≤ 10% of land area 2 = Between 500 acres and 1500 acres, or ≤ 30% of land area 1 = Greater than 1500 acres, or > 30% of land area

Table 9.3-3 (Sheet 4 of 4)
Screening Evaluation Criteria

Criterion Number	Criterion	Measure of Suitability	
		Metric	**Rating Rationale**
P7	Railroad Access	Estimated cost of constructing a rail spur to the site, based on distance in miles to the nearest in-service rail line.	Ratings computed by scaling costs from lowest (rating = 5) to highest (rating = 1). 1 = More than 15 miles 2 = Between 15 miles and 10 miles 3 = Between 10 miles and 5 miles 4 = Between 5 miles and 2 miles 5 = Fewer than 2 miles Note: Ratings may be adjusted if barge access is located in the immediate vicinity in lieu of railroad access.
P8	Transmission Access	Transmission access is evaluated in the preliminary screening in terms of distance to the load center in the greater Miami area (Palm Beach, Broward, and Miami-Dade Counties) and amount of new right-of-way that would have to be acquired.	Ratings computed by measuring distances to greater Miami Area Load Center and considering high-level evaluation of transmission issues. 1 = More than 200 miles 2 = Between 200 miles and 100 miles 3 = Between 100 miles and 70 miles 4 = Between 70 miles and 50 miles 5 = Fewer than 50 miles Ratings points adjusted based on amount of new right-of-way that must be acquired and the relative difficulty of acquisition. The plant switchyard is assumed to be the same for all sites.
P9	Land Acquisition	Estimated cost of acquiring land (nominally 3000 acres per site where FPL does not own**), based on the following cost/acre assumptions: – very remote areas - $8000 - $12,000 [used $10,000] – farm areas - $15,000 - $20,000 per acre [used $17,500] – land near population centers - $30,000 - $40,000 per acre [used $35,000]	Ratings computed by scaling costs from lowest to highest as follows: 2 = FPL does not own; site near large population/highest cost 3 = FPL does not own; site in farm area/moderate cost 4 = FPL does not own; site in very remote area/lowest cost 5 = FPL owns sufficient land In instances where FPL owns some land but would need to acquire additional land to accommodate nuclear development, rating based on total cost compared to other greenfield sites, (total acres to be acquired X estimated cost per acre based on metric).

* To provide a consistent basis for site evaluation and comparison across sites in the screening phase wetlands evaluation, each potential site was initially identified as a 5000-acre area, nominally a circle centered on a site centerpoint. The 5000-acre general area provided a general characterization of the presence of wetlands and flexibility in the eventual plant layout. It is also consistent with the upper bound of the Desired Owner Buffer Area as identified by FPL for the site selection study.

** The lower bound of the Desired Owner Buffer Area (i.e., 3000 acres), as identified by FPL for the site selection study, was used for the land acquisition criterion evaluation as the basis for comparing sites according to the need to acquire land and the associated land costs at sites FPL does not already own (or owns but has determined holdings are insufficient for development of two new nuclear units).

Listed Species Documented or Reported in Glades County
August 2011

Scientific Name	Common Name	Federal Status	State Status
Reptiles			
Alligator mississippiensis	American Alligator	SAT	LS
Crocodylus acutus	American Crocodile	LT	LE
Drymarchon couperi	Eastern Indigo Snake	LT	LT
Gopherus polyphemus	Gopher Tortoise	N	LT

FEDERAL STATUS

LE Endangered: species in danger of extinction throughout a significant portion of its range.

LT Threatened: species likely to become Endangered within the foreseeable future throughout a significant portion of its range.

SAT Treated as threatened because of similarity of appearance to a species that is federally listed so that enforcement personnel have difficulty in attempting to differentiate between the listed and unlisted species.

XN Nonessential experimental population.

N Not currently listed, nor currently being considered for listing as Endangered or Threatened.

STATE LEGAL STATUS

LE Endangered: species, subspecies, or isolated population so few or depleted in number or so restricted in range that it is in imminent danger of extinction.

LT Threatened: species, subspecies, or isolated population facing a very high risk of extinction in the future.

LS Species of Special Concern is a species, subspecies, or isolated population which is facing a moderate risk of extinction in the future.

Table 9.3-9 (Sheet 1 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Energy Projects				
Charlotte County Solid Waste Management Facility - Landfill Gas to Energy Project	Two-unit, 3.2-MW landfill gas-fired plant	49 miles west of the Glades Site	Proposed. Air construction permit issued November 2009.	FDEP Nov 2009a
Desoto County Energy Park	Two-unit, 340-MW gas- and oil-fired plant	48 miles northwest of the Glades Site	Operational	FDEP Jan 2008a
Florida Gas Transmission - Phase VIII Expansion Project	Construction and operation of 483.2 miles of pipeline facilities, including an 89.8-mile long natural gas pipeline in a new right-of-way that runs from DeSoto County through Highlands and Okeechobee Counties to the FPL Martin Plant site.	DeSoto, Highlands, Okeechobee, and Martin Counties	Proposed. Final EIS issued September 2009.	FERC Sep 2009
Floridian Natural Gas Storage Company - Natural Gas Storage Facility	Liquefied natural gas storage, liquefaction, and vaporization facility with storage capacity of eight billion cubic feet of natural gas	43 miles northeast of the Glades Site	Proposed. Final EIS issued July 2008.	FERC Jul 2008
FPL - DeSoto Next Generation Solar Energy Center	25-MW solar photovoltaic plant	50 miles northwest of the Glades Site	Operational	FPL Feb 2010
FPL - Fort Myers Plant	Two-unit, 2503-MW gas- and oil-fired plant	39 miles southwest of the Glades Site	Operational	FDEP Jan 2008b
FPL - Martin Next Generation Solar Energy Center	75-MW solar thermal plant	40 miles northwest of the Glades Site	Proposed. Currently under construction, expected completion 3Q 2010.	FPL May 2008
FPL - Martin Plant	Five-unit, 3734-MW gas- and oil-fired plant	45 miles northwest of the Glades Site	Operational	FDEP Nov 2009b
FPL - West County Energy Center	Two-unit, 2500-MW gas-fired plant	50 miles southeast of the Glades Site	Operational	FDEP Jul 2008a
FPL - West County Energy Center, Unit 3	Single-unit, 1250-MW gas-fired plant	50 miles southeast of the Glades Site	Proposed. Unit 3 under construction, expected completion in 2011.	FDEP Jul 2008a
FPL - St. Lucie Plant	Two-unit, 1680-MW nuclear plant	67 miles northeast of the Glades Site	Operational	FPL Dec 2007
FPL - St. Lucie Uprate Project	The project will increase the net electrical generation for Units 1 & 2 by 104-MW each.	67 miles northeast of the Glades Site	Proposed. Site Certification Application approved by FPSC in 2008.	FPL Dec 2007
Highlands Ethanol Facility	39.4-MGPY cellulosic ethanol refinery	20 miles northeast of the Glades Site	Proposed. Air Construction Permit issued March 2010.	FDEP Mar 2010a

Table 9.3-9 (Sheet 2 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Indiantown Cogeneration Plant	Single-unit, 330-MW coal-fired plant with 2 gas-fired auxiliary boilers.	43 miles northeast of the Glades Site	Operational	FDEP Jan 2010
Lee County Resource Recovery Facility	Three-unit, 60-MW municipal solid waste (MSW)-fired plant	40 miles southwest of the Glades Site	Operational	FDEP Jul 2009
New Hope Power Company - Okeelanta Cogeneration Plant	Three-unit, 140-MW biomass-fired plant	31 miles southeast of the Glades Site	Operational	FDEP May 2005
Okeechobee Landfill - Landfill Gas to Energy Project	Four- unit, 25.5-MW landfill gas-fired plant	46 miles northeast of the Glades Site	Proposed. Air construction permit issued April 2010.	FDEP Apr 2010
Southeastern Renewable Fuels Biorefinery and Cogeneration Plant	22 MGPY cellulosic ethanol refinery and a 30-MW biomass-fired power plant	20 miles southeast of the Glades Site	Proposed. Application for air construction permit submitted March 2010.	Golder Mar 2010
Tampa Electric Company - J.H. Phillips Station	Two-unit, 42-MW oil-fired plant	44 miles northwest of the Glades Site	Operational	FDEP May 2009
Transportation Projects				
Arcadia Municipal Airport	General aviation airport	48 miles northwest of the Glades Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Immokalee Regional Airport	Air cargo and general aviation airport	30 miles southwest of the Glades Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Indiantown Airport	General aviation airport	47 miles northeast of the Glades Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Okeechobee County Airport	General aviation airport	36 miles northeast of the Glades Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Page Field Airport	General aviation and reliever airport for Southwest Florida International	46 miles southwest of the Glades Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009

Table 9.3-9 (Sheet 3 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Palm Beach County Glades Airport	General aviation airport	29 miles east of the Glades Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Sebring Regional Airport	General aviation airport. The old runway system is now Sebring International Raceway.	45 miles north of the Glades Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Shell Creek Airpark	General aviation airport	47 miles west of the Glades Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Southwest Florida International Airport	Full service airport - commercial airlines, air cargo, and general aviation	41 miles southwest of the Glades Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Tampa - Orlando - Miami High-Speed Intercity Passenger Rail	This project would provide high-speed rail service from Tampa to Miami (through Orlando) with stops in West Palm Beach and Ft. Lauderdale. The termini for the Orlando -Miami corridor are the Orlando International Airport (OIA) and the Miami Intermodal Center at the Miami Airport (MIA).	Route follows the Florida Turnpike corridor from Orange County through Osceola, Okeechobee, St. Lucie, Martin and Palm Beach Counties	Proposed. Phase 1 (Tampa-Orlando corridor) is ongoing. Project development for Phase 2 (Orlando-Miami corridor) began in May 2010.	FDOT May 2010
Parks and Nature Preserve Facilities				
Archbold Biological Station	An independent, non-profit research facility, devoted to long-term ecological research and conservation. The Station owns and manages a 5,000-acre preserve that is a matrix of pristine native vegetation, including oak and rosemary scrubs, pine flatwoods, and cutthroat seeps and seasonal wetlands. The station also manages the 10,500-acre MacArthur Agro-ecology Research Center (MAERC) at Buck Island Ranch.	27 miles northwest of the Glades Site	Development likely limited within this area	ABS Feb 2004
Arthur R. Marshall Loxahatchee National Wildlife Refuge	Management of species and habitats to enhance the native biodiversity and integrity of the Everglades ecosystem. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	47 miles southeast of the Glades Site	Additional land acquisition and expansion of visitor facilities are planned. Other development would be limited within this refuge.	USFWS Sep 2000

Table 9.3-9 (Sheet 4 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Babcock Ranch Preserve	The 73,239-acre state conservation activities include cattle ranching, silviculture tenant farming, horticultural debris disposal, ecotourism, and natural resource based recreation such as hiking, hunting, and fishing.	25 miles west of the Glades Site	Addition of hiking, biking, and horse trails and camping facilities is planned. Other development would be limited.	FFWCC Jul 2008
Barley Barber Swamp	A one-mile boardwalk runs through a cypress swamp. On FLP owned Martin site land. Public access requires advance reservation.	36 miles northeast of the Glades Site	Development likely limited within this refuge	FFWCC Jul 2010
Big Cypress National Preserve	Over 729,000 acres of valuable habitat for a variety of threatened and endangered species, including the Florida panther, West Indian manatee, red cockaded woodpecker, and wood storks. Public recreational activities include bird watching, camping, canoeing, bicycling, off road vehicles, hunting, hiking, and wildlife observation.	41 miles south of the Glades Site	Additional facilities to further accommodate public use such as hunting, hiking, boat, and van tours are planned. Other development likely limited within property.	NPS Jun 2009
Big Water Heritage Trail	Scenic auto route circling Lake Okeechobee passing though five counties and going by multiple natural and historic sites.	2 miles east of the Glades Site	Development likely limited at specific points along the trail.	SWFRPC 2009
Dinner Island Ranch Wildlife Management Area	The 21,667-acre property was purchased as part of the Panther Glades Florida Forever Land Acquisition Project to protect and manage significant natural habitat of exotic plant and animals.	23 miles south of the Glades Site	Additional land acquisition is planned. Development likely limited within property.	FFWCC Jun 2005
DuPuis Wildlife and Environmental Area	21,875 acres managed to conserve and protect water resources as well as protect and restore land resources to its natural state. Recreation activities include hunting, fishing, horseback and bicycle riding, canoeing, camping, and hiking.	36 miles east of the Glades Site	Development likely limited within this refuge.	SFWMD Jun 2008
Estero Bay Preserve State Park	10,405 acres managed to protect Estero Bay's water quality, and its native plants and animals. Recreational opportunities include bicycling, hiking, bird watching, and nature appreciation.	Closest parcel of land is 50 miles southwest of the Glades Site	Additional land acquisition is planned. Development likely limited within property.	FDEP Dec 2004
Fisheating Creek Wildlife Management Area	The 18,272-acre property is used for conservation and protection of the natural communities along the shores of Fisheating Creek. Contains natural summer roosts for endangered swallowtail kites.	6 miles northwest of the Glades Site	Development limited within property.	FFWCC Feb 2003

Table 9.3-9 (Sheet 5 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Florida National Scenic Trail	Scenic hiking trail stretches over 1400 miles across the state and traverses nearly all of Florida's unique habitats and includes the Lake Okeechobee Scenic Trail. Portions of the trail are accessible for bicycling, horseback riding, or inline skating.	2 miles east of the Glades Site	Development likely limited at specific points along the trail.	USDAFS Feb 2006
Florida Panther National Wildlife Refuge	Home to one of the last populations of the endangered Florida panther. Established to conserve fish, wildlife, and plants which are listed as endangered or threatened species. Recreational activities are limited to hiking and wildlife viewing.	43 miles south of the Glades Site	Development likely to be minor and limited within this refuge.	USFWS Oct 1998
Highlands Hammock State Park	One of Florida's first state parks. Public outdoor recreation and conservation is the designated single use of the 9251 acre property. Recreation activities include camping, picnicking, hiking, horse and bicycle riding,	45 miles northwest of the Glades Site	Development includes, refurbishing of existing facilities, and creating an additional day use area.	FDEP Feb 2007
Hungryland Wildlife and Environmental Area	The 10,294-acre property was purchased to conserve and protect environmentally unique and irreplaceable lands including relatively undisturbed, high quality pine flatwoods. Recreation activities include hiking, horseback riding, hunting, and fishing.	47 miles east of the Glades Site	Development likely limited within this property.	FFWCC Feb 2002
J.W. Corbett Wildlife Management Area	Management of unique tropical hardwood hammocks and slash pine flatwoods habitat of the South Florida systems and recovery of the endangered and threatened species that occur there. The vast majority of the 60,288-acre property is used for wildlife management and public hunting.	41 miles east of the Glades Site	Additional land acquisition is planned. Planned public uses will include hunting, fishing, and horseback riding.	FFWCC Apr 2003
Kissimmee Prairie Preserve State Park	Public outdoor recreation and conservation is the single use of the 53,760-acre property. Recreation activities include hiking, biking and horse riding trails, camping, picnicking, and interpretive programs.	47 north of the Glades Site	Development of new visitor center is planned. Other development likely limited within this property	FDEP Apr 2005a
Koreshan State Historic Site	The site is comprised of a 142-acre historic district that contains natural landscapes and the remains of a utopian pioneer settlement dating to the 1890's, and 52 acres of mangrove community located at the mouth of the Estero River. Recreation activities include picnicking, fishing, camping, nature study and boating.	50 miles southwest of the Glades Site	Development likely limited within this property	FDEP Aug 2003

Table 9.3-9 (Sheet 6 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Lake June in Winter Scrub State Park	Some of the finest remnants of scrub habitat found in peninsular Florida and supports a significant population of Florida scrub jays and five listed plant species. The primary recreation activities focus on the shoreline of the lake.	34 miles northwest of the Glades Site	Development likely limited within this property	FDEP Feb 2004
Lake Okeechobee	Lake Okeechobee is the second largest freshwater lake within the continental United States and is a nationally recognized bass and pan fishing resource. The lake offers other recreational amenities as well. Air boat and swamp buggy rides, bike riding, hiking, picnicking, camping, and nature interpretation are popular land-based recreation activities in the region.	5 miles northeast of the Glades Site	Development likely limited within this area	FDEP Jun 2010
Lake Okeechobee Scenic Trail	A 110 mile long hiking trail circling Lake Okeechobee atop the Herbert Hoover Dike offers scenic views of lakeside and agricultural landscapes. The trail provides opportunities for hiking, bicycle and horseback riding, bird watching, and fishing.	2 miles east of the Glades Site	Development likely limited at specific points along the trail.	FDEP Jun 2010
Lake Wales Ridge National Wildlife Refuge	Management of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	Closest parcel of land is 24 miles northwest of the Glades Site	Additional land acquisition is planned. Development likely limited within this area.	USFWS Apr 2010
Lake Wales Ridge Wildlife and Environmental Area	Management and restoration of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	Closest parcel of land is 24 miles northwest of the Glades Site	Development likely limited within this area.	FFWCC Sep 2002
Okaloacoochee Slough Wildlife Management Area	A 2,923-acre property managed to maintain and restore the Okaloacoochee Slough sawgrass marsh unique lands and threatened and endangered species associated with it. Public activities include hunting, fishing, bird watching, horseback riding, hiking, nature study, wildlife viewing, picnicking, and primitive camping. Access limited to eastern side of property.	17 miles southwest of the Glades Site	Additional acquisition is planned of surrounding land. Development likely limited within this area.	FFWCC Dec 2001

Table 9.3-9 (Sheet 7 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Spirit of the Wild Wildlife Management Area	This 7487-acre property is managed to protect existing slough or "river grass" natural community which forms an important habitat for numerous species of special concern, as well as form a hydrological connection with protected lands to the east and south. Public recreation activities include hunting, fishing, horseback riding, hiking, nature study, wildlife viewing, picnicking, and primitive camping.	20 miles southwest of the Glades Site	Additional acquisition is planned. Development likely limited within this area.	FFWCC Sep 2006
Comprehensive Everglades Restoration Plan Projects				
C-43 Basin Aquifer Storage and Recovery	The project will consist of aquifer storage and recovery wells with a capacity of approximately 220 million gallons per day in order to capture C-43 Basin runoff and releases from Lake Okeechobee.	24 miles southwest of the Glades Site	Currently in pre-construction design. Pilot plant in operation.	USACE Undated
Caloosahatchee River (C-43) West Basin Storage	Project to establish in Hendry County, a large storage reservoir along the Caloosahatchee River to capture and store stormwater runoff from the C-43 basin and reduce excess water flow to the Caloosahatchee Estuary. It will also capture and store regulatory releases from Lake Okeechobee, reducing discharges to coastal estuaries.	21 miles southwest of the Glades Site	Proposed. Test cell completed. Construction scheduled to begin in 2011.	SFWMD Jun 2010, USACE Nov 2009
C-44 Reservoir and Storage and Treatment Area	A component of the Indian River Lagoon - South Project consisting of a 3,400-acre reservoir and 6200 acres of emergent vegetation.	49 miles east of the Glades Site	Design and land acquisition for this project is completed. Construction is anticipated to begin in 2011.	SFWMD Feb 2006, USACE Feb 2010
Everglades Agricultural Area Storage Reservoirs - Phase 1	Project consists of a large above-ground storage reservoir on former farmlands designed to provide significant additional water in the southern region of the Everglades Agricultural Area.	32 miles southeast of the Glades Site	Construction of the A-1 Reservoir was initiated in 2006, but has been subsequently suspended in since 2008 due to litigation.	SFWMD Jun 2010, USACE Nov 2009
Flows to Northwest and Central Water Conservation Areas 3A	Project will increase depths, extend wetland hydropatterns, and increase water supply availability in the northwest corner and west-central portions of WCA 3A.	43 miles southeast of the Glades Site	Proposed. Project design underway.	USACE Undated

Table 9.3-9 (Sheet 8 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Indian River Lagoon - South Project	The project includes construction of several above-ground reservoirs and stormwater treatment areas. The project will use constructed wetlands and muck removal to improve surface water management and water quality of several canal basins, as well as, improve habitat in the St. Lucie Estuary and Indian River Lagoon.	41 miles northeast of the Glades Site	Proposed. Project is scheduled to begin in 2010.	SFWMD Jun 2010, USACE Nov 2009, USACE Feb 2010
Lake Okeechobee Aquifer Storage and Recovery	Project proposes to increase regional storage while reducing both evaporation losses and the amount of land removed from current land use. This will be accomplished by a series of aquifer storage and recovery wells adjacent to Lake Okechobee with a capacity of one billion gallons per day and the associated pre- and post-water quality treatment facilities.	2 miles east of the Glades Site	Five separate ASR pilot projects have been constructed around Lake Okeechobee and have provided five years of field data. Two more pilot systems began cycle testing in 2008.	USACE Undated, USACE Jun 2008
Lake Okeechobee Watershed Project	Construction of a 1984-acre reservoir and 3975-acre treatment area in the Taylor Creek/Nubbin Slough basin; a 10,281-acre reservoir in the Kissimmee River basin; a 5416-acre reservoir and 8044-acre treatment area in the Lake Istokpoga basin, and a 3730-acre wetland restoration site in Paradise Run in order to increase aquatic and wildlife habitat, regulate lake staging, reduce phosphorus loading, and reduce damaging releases to the surrounding estuaries.	Various locations in Okeechobee County	Proposed. Project is scheduled to begin in 2019.	USACE Undated, USACE Nov 2009
Melaleuca Eradication and other Exotic Plants	Project enhances efforts to control invasive exotic species in south Florida through mass clearing and controlled release of biological agents throughout the region.	Throughout the region	Proposed. Project is scheduled to begin in 2011.	USACE Nov 2009
Miccosukee Tribal Water Management Plan	Project includes providing water storage capacity and water quality enhancement for Miccosukee Tribe's reservation discharge waters and conversion of 900 acres tribally owned cattle pasture into a managed wetland retention/detention area.	43 miles southeast of the Glades Site	Currently in pre-construction design.	USACE Undated
Modify Holey Land Wildlife Management Area Operation Plan	Modifications to the current operating plan for Holey Land WMA will implement rain-driven operations as needed and will be made to improve the timing and location of water depths.	35 miles southeast of the Glades Site	Project in planning stage.	USACE Undated

Table 9.3-9 (Sheet 9 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Modify Rotenberger Wildlife Management Area Operation Plan	Modifications to the current operating plan for the Rotenberger WMA will implement rain-driven operations as needed and will be made to improve the timing and location of water depths.	32 miles south of the Glades Site	Project in planning stage.	USACE Undated
North Palm Beach County - Part 1	Part 1 of this project includes portions of seven basins that will capture, store and treat excess water that is currently discharged to the Lake Worth Lagoon and use that water to enhance the Loxahatchee River, Loxahatchee Slough, and West Palm Beach Water Catchment Area.	46 miles east of the Glades Site	Project in pre-construction, engineering, and design phase. Part 1 construction is estimated to be completed in 2014.	USACE Undated, USACE May 2005
Central and Southern Florida (C&SF) Projects				
Herbert Hoover Dike Rehabilitation	Project to strengthen the 143-mile dike that surrounds Lake Okeechobee.	2 miles east of the Glades Site	Construction is underway on the southeast section of the dike. Completion of the project is anticipated in 2025.	USACE Nov 2009
Southern Corkscrew Regional Ecosystem Watershed (CREW)	Project consists of 28,540 acres of predominantly swale and strand swamp communities to be restored to native conditions. Public recreation activities include hiking, horseback riding, primitive camping, hunting, fishing, and nature appreciation.	44 miles southwest of the Glades Site	Project will continue to improve and restore the hydrology and ecology of the project area (along with resulting benefits to upstream and downstream lands. Additional land acquisition required to reach target goals.	SFWMD May 2006
Other Ecosystem Restoration Projects				
Kissimmee River Restoration Project	Project to restore over 40 square miles of river and floodplain ecosystem, including 43 miles of meandering river channel and 27,000 acres of wetlands. The project will reestablish a favorable environment for the flora and fauna that existed in the area prior to the 1960s, when the river was altered to provide flood protection.	Closest parcel 39 miles north of the Glades Site	Restoration efforts are underway and are expected to be completed in 2013.	USACE Nov 2009
Lakes Park Restoration	Project to improve water quality at Lakes Park in Lee County through a three-phased approach. Phases I and II have been completed. Phase III involves creating a 40-acre flow-way marsh, which will act as a natural filter cleansing nutrients from the lakes. Reduced nutrients and proper water elevations will aid in the control of aquatic and upland exotic plant species and improve native habitat.	48 miles southwest of the Glades Site	Proposed. Construction of the filter marsh and flow-way are anticipated to begin in 2011.	SFWMD Jun 2010

Table 9.3-9 (Sheet 10 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Lakeside Ranch Storage and Treatment Area	Construction of a 2700-acre wetland in western Martin County that will use emergent vegetation to remove phosphorus from stormwater runoff in the Taylor Creek/ Nubbin Slough basin before it enters Lake Okeechobee. The project has been divided into two phases, STA North and STA South.	37 miles northeast of the Glades Site	Construction of STA North began in 2009. Final design of STA South is scheduled to be completed in 2010, and construction is scheduled to begin in 2011.	SFWMD Jun 2010, USACE Nov 2009
Seminole Big Cypress Water Conservation Plan	Water management system designed to reduce flood damage and promote water conservation on the Seminole Tribe's Big Cypress Basin Reservation, the Big Cypress National Preserve, and the Everglades Protection Area. Includes construction of conveyance canals, water storage cells, and a new pump station.	34 miles south of the Glades Site	Construction expected to be completed in 2010.	USACE Nov 2009
Mining Projects				
Babcock Mine	Crushed stone mine	37 miles west of the Glades Site	Operational	USGS 2005
Bonita Pit	Crushed stone mine	48 miles southwest of the Glades Site	Operational	USGS 2005
Charlotte County Shell Quarry	Crushed stone mine	38 miles northwest of the Glades Site	Operational	USGS 2005
Coral Rock Quarry	Crushed stone mine	37 miles west of the Glades Site	Operational	USGS 2005
Florida Rock Industries, Inc. Alico Rock Quarry	Crushed stone mine	38 miles southwest of the Glades Site	Operational	USGS 2005
Lake Point Mine	Development of a 959-acre commercial limestone quarry in Martin County	37 miles northeast of the Glades Site	Proposed. CWA Section 404 permit application submitted April 2010.	
Ortona Mine & Plant	Sand and gravel mine	9 miles west of the Glades Site	Operational	USGS 2005
Ortona Sand Mine Expansion	154-acre expansion of sand mining operation in Glades County	8 miles west of the Glades Site	Proposed. CWA Section 404 permit application submitted March 2010.	ACOE Apr 2010b
Palmdale Sand	Sand and gravel mine	13 miles northwest of the Glades Site	Operational	USGS 2005
Rinker Materials Corp. - Alico Road Quarry	Crushed stone mine	42 miles southwest of the Glades Site	Operational	USGS 2005
RMC South Florida	Crushed stone mine	49 miles southwest of the Glades Site	Operational	USGS 2005

Table 9.3-9 (Sheet 11 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Sebring Tu-Co Peat Operation	Peat mine	46 miles northwest of the Glades Site	Operational	USGS 2005
Southwest Aggregates	Crushed stone mine	50 miles west of the Glades Site	Operational	USGS 2005
Star Pit	Crushed stone mine	31 miles southeast of the Glades Site	Operational	USGS 2005
Witherspoon Sand Plant	Sand and gravel mine	8 miles west of the Glades Site	Operational	USGS 2005
Other Actions/Projects				
Central and Southern Florida Flood Control Project	The C&SF Flood Control Project was authorized by Congress in 1948 to provide flood control, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources. Today the CS&F project includes 1000 miles of canals, 720 miles of levees, and almost 200 water control structures. It covers 16 counties over an 18,000-square-mile area from Orlando to the Florida Reef Tract. The existing project provides water supply, flood protection, water management and other benefits to South Florida. However, the project has had unintended negative effects on the Everglades.	Throughout the region.	Operational	HRA Jun 2006
Action Craft	Fiberglass boat manufacturer	50 miles west of the Glades Site	Operational	FDEP May 2007a
Alpha General Services, Inc.	Fiberglass tank manufacturer	48 miles northeast of the Glades Site	Operational	FDEP Sep 2006
Atlantic Sugar Association	Sugar manufacturer	34 miles southeast of the Glades Site	Operational	FDEP Jun 2007
E-Stone USA Corp	Cultured granite reinforced plastics manufacturer	45 miles north of the Glades Site	Operational	FDEP Nov 2009c
Everglades Sugar Refinery Inc.	Sugar manufacturer	32 miles southeast of the Glades Site	Operational	FDEP Aug 2000
Louis Dreyfus Citrus Inc. - Indiantown Citrus Processing Plant	Food Manufacturer	45 miles northeast of the Glades Site	Operational	FDEP Jul 2008b
Munters Corporation	Paper and polyvinyl chloride filter manufacturer	46 miles southwest of the Glades Site	Operational	FDEP Mar 2007a

Table 9.3-9 (Sheet 12 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Glades Alternative Site

Project Name	Summary of Project	Location	Status	Reference
Okeelanta Corporation	Sugar manufacturer	31 miles southeast of the Glades Site	Operational	FDEP Jan 2001
Osceola Farms Co	Sugar manufacturer	38 miles east of the Glades Site	Operational	FDEP Mar 2010b
Pall Aeropower Corporation	Filter element manufacturer	46 miles southwest of the Glades Site	Operational	FDEP Mar 2007b
Sebring International Raceway	A road course auto racing facility with three track configurations: the 12-hour Grand Prix Course, the Old Club Course, and the New Club Course.	45 miles northwest of the Glades Site	Operational	NAMP Jun 2007
Southern Gardens Citrus Processing Corp. - Clewiston Plant	Food manufacturer	6 miles southeast of the Glades Site	Operational	FDEP May 2010a
Sugar Cane Growers Cooperative of Florida	Sugar manufacturer	33 miles southeast of the Glades Site	Operational	FDEP Aug 2006
U.S. Sugar Corp. - Clewiston Mill	Sugar manufacturer	15 miles southeast of the Glades Site	Operational	FDEP Feb 2010
Water Reclamation and Wastewater Treatment Plants	Numerous plants	Within 50-mile radius of the Site.	Operational	FDEP Aug 2010a FDEP Aug 2010b
Future Urbanization	Construction of housing units and associated commercial buildings; roads, bridges and rail; construction of water and/or wastewater treatment facilities and associated pipelines.	Throughout the region.	Construction would occur in the future, as described in state and local land-use planning documents.	—
Various hospitals and industrial facilities that use radioactive materials	Medical and other isotopes	Within 50-mile radius of the Site.	Operational	—

Drymarchon couperi	Eastern Indigo Snake	LT	LT
Eretmochelys mbricate	Hawksbill	LE	LE
Gopherus polyphemus	Gopher Tortoise	N	LT

FEDERAL STATUS
LE Endangered: species in danger of extinction throughout a significant portion of its range.
LT Threatened: species likely to become Endangered within the foreseeable future throughout a significant portion of its range.
SAT Treated as threatened because of similarity of appearance to a species that is federally listed so that enforcement personnel have difficulty in attempting to differentiate between the listed and unlisted species.
C Candidate species for which federal listing agencies have sufficient information on biological vulnerability and threats to support proposing to list the species as Endangered or Threatened.
XN Nonessential experimental population.
SC Not currently listed, but considered a "species of concern" to USFWS.

STATE LEGAL STATUS
LE Endangered: species, subspecies, or isolated population so few or depleted in number or so restricted in range that it is in imminent danger of extinction.
LT Threatened: species, subspecies, or isolated population facing a very high risk of extinction in the future.
LS Species of Special Concern is a species, subspecies, or isolated population which is facing a moderate risk of extinction in the future.
N Not currently listed, nor currently being considered for listing.

Table 9.3-12 (Sheet 1 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Energy Projects				
City of Vero Beach Municipal Utilities	Five-unit, 155-MW gas- and oil-fired plant	41 miles northeast of the Martin Site	Operational	FDEP Jan 2008c
Florida Gas Transmission - Phase VIII Expansion Project	Construction and operation of 483.2 miles of pipeline facilities, including an 89.8-mile long natural gas pipeline in a new right-of-way that runs from DeSoto County through Highlands and Okeechobee Counties to the FPL Martin Plant site.	DeSoto, Highlands, Okeechobee, and Martin Counties. Terminus collocated at the Martin Site.	Proposed. Final EIS issued September 2009.	FERC Sep 2009
Florida Gas Transmission - Station #20	Compressor station consisting of 5 internal combustion engines.	28 miles northeast of the Martin Site	Operational	FDEP May 2008
Florida Municipal Power Agency - Treasure Coast Energy Center	Single-unit, 300-MW gas-fired plant	25 miles northeast of the Martin Site	Operational	FDEP May 2010b
Floridian Natural Gas Storage Company - Natural Gas Storage Facility	Liquefied natural gas storage, liquefaction, and vaporization facility with storage capacity of eight billion cubic feet of natural gas	2 miles southeast of the Martin Site	Proposed. Final EIS issued July 2008.	FERC Jul 2008
Fort Pierce Utilities Authority - H. D. King Power Plant	Four-unit, 136-MW gas- and oil-fired plant	31 miles northeast of the Martin Site	Operational	FDEP Jan 2008d
FPL - Martin Next Generation Solar Energy Center	75-MW solar thermal plant	Collocated at the Martin Site	Proposed. Currently under construction, expected completion 3Q 2010.	FPL May 2008
FPL - Martin Plant	Five-unit, 3734-MW gas- and oil-fired plant	Collocated at the Martin Site	Operational	FDEP Nov 2009b
FPL - Riviera Plant	Two-unit, 580-MW oil- and gas-fired plant	36 miles southeast of the Martin Site	Operational. Would be replaced by the Riviera Plant Repowering Project	FDEP Jan 2009
FPL - Riviera Plant Repowering Project	A single-unit, 1250-MW gas-fired combined-cycle plant would replace the two existing boilers at the site.	36 miles southeast of the Martin Site	Proposed. Air Construction Permit issued June 2009.	FDEP Jun 2009
FPL - St. Lucie Plant	Two-unit, 1680-MW nuclear plant	27 miles northeast of the Martin Site	Operational.	FPL Dec 2007
FPL - St. Lucie Uprate Project	The project will increase the net electrical generation for Units 1 & 2 by 104-MW each.	27 miles northeast of the Martin Site	Proposed. Site Certification Application approved by FPSC in 2008.	FPL Dec 2007
FPL - West County Energy Center	Two-unit, 2500-MW gas-fired plant	27 miles southeast of the Martin Site	Operational	FDEP Jul 2008a

Table 9.3-12 (Sheet 2 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
FPL - West County Energy Center, Unit 3	Single-unit, 1250-MW gas-fired plant	27 miles southeast of the Martin Site	Proposed. Unit 3 under construction, expected completion in 2011.	FDEP Jul 2008a
Highlands Ethanol Facility	39.4-MGPY cellulosic ethanol refinery	35 miles northwest of the Martin Site	Proposed. Air Construction Permit issued March 2010.	FDEP Mar 2010a
Indiantown Cogeneration Plant	Single-unit, 330-MW coal-fired plant with 2 gas-fired auxiliary boilers.	25 miles northeast of the Martin Site	Operational	FDEP Jan 2010
INEOS New Planet Indian River County BioEnergy Facility	8-MGPY cellulosic ethanol refinery and a 5-MW biomass-fired power plant	37 miles north of the Martin Site	Proposed. Application for air construction permit submitted February 2010.	INEOS Feb 2010
Lake Worth Utilities - Tom G. Smith Power Plant	Three-unit, 105-MW gas- and oil-fired plant	42 miles southeast of the Martin Site	Operational	FDEP Jan 2008e
New Hope Power Company - Okeelanta Cogeneration Plant	Three-unit, 140-MW biomass-fired plant	31 miles southwest of the Martin Site	Operational	FDEP May 2005
Okeechobee Landfill - Landfill Gas to Energy Project	Four- unit, 25.5-MW landfill gas-fired plant.	22 miles northwest of the Martin Site	Proposed. Air construction permit issued April 2010.	FDEP Apr 2010
Solid Waste Authority of Palm Beach County - Palm Beach Renewable Energy Facility No. 1	Two-unit, 62-MW municipal solid waste (MSW)-fired plant	31 miles southeast of the Martin Site	Operational	FDEP Jul 2006
Solid Waste Authority of Palm Beach County - Palm Beach Renewable Energy Facility No. 2	Three-unit, 100-MW MSW-fired plant	31 miles southeast of the Martin Site	Proposed. Application for air construction permit submitted May 2010.	SWAPBC May 2010
Southeastern Renewable Fuels Biorefinery and Cogeneration Plant	22 MGPY cellulosic ethanol refinery and a 30-MW biomass-fired power plant	42 miles southwest of the Martin Site	Proposed. Application for air construction permit submitted March 2010.	Golder Mar 2010
Transportation Projects				
Indiantown Airport	General aviation airport.	7 miles southeast of the Martin Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
North Palm Beach County Airport	General aviation and reliever airport for Palm Beach International	25.6 miles southeast of the Martin Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009

Table 9.3-12 (Sheet 3 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Okeechobee County Airport	General aviation airport.	23 miles northwest of the Martin Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach County Glades Airport	General aviation airport.	20 miles southwest of the Martin Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach County Park Airport	General aviation and reliever airport for Palm Beach International	43 miles southeast of the Martin Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach International Airport	Full service airport - commercial airlines, air cargo, and general aviation.	39 miles southeast of the Martin Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
St Lucie County International Airport	General aviation airport.	32 miles northeast of the Martin Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Vero Beach Municipal Airport	Commercial and general aviation airport.	42 miles northeast of the Martin Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Witham Field Airport	General aviation airport.	22 miles northeast of the Martin Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Port of Fort Pierce	99-acre deepwater seaport with public and private cargo terminals. Current annual cargo throughput of 0.358 million tons.	32 miles northeast of the Martin Site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010

Table 9.3-12 (Sheet 4 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Port of Palm Beach	Large full-service deepwater seaport. Current annual cargo throughput of 2.3 million tons. Cruise terminal serves 349,000 passengers annually.	37 miles southeast of the Martin Site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010
Tampa - Orlando - Miami High-Speed Intercity Passenger Rail	This project would provide high-speed rail service from Tampa to Miami (through Orlando) with stops in West Palm Beach and Ft. Lauderdale. The termini for the Orlando -Miami corridor are the Orlando International Airport (OIA) and the Miami Intermodal Center at the Miami Airport (MIA).	Route follows the Florida Turnpike corridor from Orange County through Osceola, Okeechobee, St. Lucie, Martin and Palm Beach Counties	Proposed. Phase 1 (Tampa-Orlando corridor) is ongoing. Project development for Phase 2 (Orlando-Miami corridor) began in May 2010.	FDOT May 2010
Parks and Nature Preserve Facilities				
Archbold Biological Station	An independent, non-profit research facility, devoted to long-term ecological research and conservation. The Station owns and manages a 5000-acre preserve that is a matrix of pristine native vegetation, including oak and rosemary scrubs, pine flatwoods, and cutthroat seeps and seasonal wetlands. The station also manages the 10,500-acre MacArthur Agro-ecology Research Center (MAERC) at Buck Island Ranch.	50 miles northwest of the Martin Site	Development likely limited within this area	ABS Feb 2004
Arthur R. Marshall Loxahatchee National Wildlife Refuge	Management of species and habitats to enhance the native biodiversity and integrity of the Everglades ecosystem. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	29 miles southeast of the Martin Site	Additional land acquisition and expansion of visitor facilities are planned. Other development would be limited within this refuge.	USFWS Sep 2000
Atlantic Ridge Preserve State Park	The preserve has not yet opened to the public due to the lack of a public access road. Once the constructed the preserve will be available for passive recreational including hiking, horseback riding, picnicking, wildlife observation, and birding.	20 miles east of the Martin Site	Development likely limited within this refuge	FDEP Dec 2005
Avalon State Park	Supports intact examples of coastal and wetland communities including a large stand of undeveloped maritime hammock. Recreational activities focus on the 6000 feet of Atlantic shoreline and include swimming, fishing, and surfing.	36 miles northeast of the Martin Site	Trail development likely within this park. Other development would be limited.	FDEP Aug 2002
Barley Barber Swamp	A one-mile boardwalk runs through a cypress swamp. On FLP owned Martin site land. Public access requires advance reservation.	Collocated at the Martin Site	Development likely limited within this refuge.	FFWCC Jul 2010

Table 9.3-12 (Sheet 5 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Big Water Heritage Trail	Scenic auto route circling Lake Okeechobee passing though five counties and going by multiple natural and historic sites.	5 miles west of the Martin Site	Development likely limited at specific points along the trail.	SWFRPC 2009
DuPuis Wildlife and Environmental Area	21,875 acres managed to conserve and protect water resources as well as protect and restore land resources to its natural state. Recreation activities include hunting, fishing, horseback and bicycle riding, canoeing, camping, and hiking.	3 miles south of the Martin Site	Development likely limited within this refuge.	SFWMD Jun 2008
Fisheating Creek Wildlife Management Area	The 18,272-acre property is used for conservation and protection of the natural communities along the shores of Fisheating Creek. Contains natural summer roosts for endangered swallowtail kites.	35 miles west of the Martin Site	Development limited within property.	FFWCC Feb 2003
Florida National Scenic Trail	Scenic hiking trail stretches over 1400 miles across the state and traverses nearly all of Florida's unique habitats and includes the Lake Okeechobee Scenic Trail. Portions of the trail are accessible for bicycling, horseback riding, or inline skating.	5 miles west of the Martin Site	Development likely limited at specific points along the trail.	USDAFS Feb 2006
Fort Pierce Inlet State Park	Beaches used as nesting grounds for loggerhead sea turtles. Recreation activities include fishing, swimming, surfing, boating, biking, hiking, and wildlife viewing.	33 miles northeast of the Martin Site	Additional facilities for canoe access, picnicking staff housing needs, and securing reliable access to the island are planned.	FDEP Dec 2006
Hobe Sound National Wildlife Refuge	An important example of pre-contact Florida ecological environments. Sand dunes and associated lagoons are habitats for rare and threatened species as manatees, scrub jays, and leatherback sea turtles. Hiking and swimming available to public.	26 miles east of the Martin Site	Upgrades to existing beach facilities are planned.	USFWS Dec 2006
Hungryland Wildlife and Environmental Area	The 10,294-acre property was purchased to conserve and protect environmentally unique and irreplaceable lands including relatively undisturbed, high quality pine flatwoods. Recreation activities include hiking, horseback riding, hunting, and fishing.	10 miles southeast of the Martin Site	Development likely limited within this property.	FFWCC Feb 2002
Indian River County Public Shooting Range	Provides public outdoor recreation facility and a training site for hunter education students, volunteers, and law enforcement personnel.	50 miles north of the Martin Site	Development likely limited within this property.	FFWCC Aug 2008

Table 9.3-12 (Sheet 6 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
J.W. Corbett Wildlife Management Area	Management of unique tropical hardwood hammocks and slash pine flatwoods habitat of the South Florida systems and recovery of the endangered and threatened species that occur there. The vast majority of the 60,288-acre property is used for wildlife management and public hunting.	8 miles southeast of the Martin Site	Additional land acquisition is planned. Planned public uses will include hunting, fishing, and horseback riding.	FFWCC Apr 2003
John D. MacArthur Beach State Park	Park protects a unique cross section of coastal Florida landscape including 121 acres of tropical maritime hammock, the largest remaining example in the county. Nine designated plant and 20 animal species occupy the natural habitats preserved by this park. The 7000-ft sand beach and dune community attracts a large number of nesting loggerhead, green, and leatherback sea turtles. Recreation activities include swimming, snorkeling, canoeing, fishing, and bird watching.	35 miles southeast of the Martin Site	Development likely limited within this property.	FDEP Apr 2005b
Jonathan Dickenson State Park	The 11,471-acre park supports many unique natural features and significant cultural resources. Contains one the last remaining coastal sand pine scrub plant communities along the southeast coast, a 2600-acre wilderness preserve, and most of the Loxahatchee National Wild and Scenic River. Recreation activities include hiking, biking, camping, picnicking, canoe/ kayaking, and interpretive programs.	24 miles east of the Martin Site	Development likely limited within this property.	FDEP Feb 2000
Kissimmee Prairie Preserve State Park	Public outdoor recreation and conservation is the single use of the 53,760-acre property. Recreation activities include hiking, biking and horse riding trails, camping, picnicking, and interpretive programs.	40 miles northwest of the Martin Site	Development of new visitor center is planned. Other development likely limited within this property.	FDEP Apr 2005a
Koreshan State Historic Site	The site is comprised of a 142-acre historic district that contains natural landscapes and the remains of a utopian pioneer settlement dating to the 1890's, and 52 acres of mangrove community located at the mouth of the Estero River. Recreation activities include picnicking, fishing, camping, nature study and boating.	50 SW G	Development likely limited within this property.	FDEP Aug 2003

Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Lake Okeechobee	Lake Okeechobee is the second largest freshwater lake within the continental United States and is a nationally recognized bass and pan fishing resource. The Lake offers other recreational amenities as well. Air boat and swamp buggy rides, bike riding, hiking, picnicking, camping, and nature interpretation are popular land-based recreation activities in the region.	5 miles west of the Martin Site	Development likely limited within this area.	FDEP Jun 2010
Lake Okeechobee Scenic Trail	A 110-mile-long hiking trail circling Lake Okeechobee atop the Herbert Hoover Dike offers scenic views of lakeside and agricultural landscapes. The trail provides opportunities for hiking, bicycle and horseback riding, bird watching, and fishing.	5 miles west of the Martin Site	Development likely limited at specific points along the trail.	FDEP Jun 2010
Lake Wales Ridge National Wildlife Refuge	Management of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	47 miles west of the Martin Site	Additional land acquisition is planned. Development likely limited within this area.	USFWS Apr 2010
Lake Wales Ridge Wildlife and Environmental Area	Management and restoration of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	49 miles west of the Martin Site	Development likely limited within this area.	FFWCC Sep 2002
Pelican Island National Wildlife Refuge	Management of habitats to sustain abundant populations of native species and to help recover threatened and endangered species. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	50 miles north of the Martin Site	Expansion of visitor facilities is planned. Other development would be limited within this refuge.	USFWS Sep 2006
Savannas Preserve State Park	Property (5227 acres) encompasses portions of the Atlantic Costal Ridge and the flatwoods and savanna-like wetlands associated with it. It harbors a unique set of natural communities that include sand pine scrub, flatwoods, marsh, and wet prairies. Public recreation activities include hiking, bicycle and horseback riding, canoe/kayaking, picnicking, wildlife viewing and environmental education.	24 miles northeast of the Martin Site	Development of facilities for public use likely limited within this area.	FDEP Jun 2003
Seabranch Inlet State Park	Management of 913 acres of various different natural communities including a rare and important baygall, beach dune, and scrub communities. The park in only open to the public for hiking and nature appreciation.	24 miles east of the Martin Site	Development likely limited within this area.	FDEP Oct 2002a

Table 9.3-12 (Sheet 8 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
St. Lucie Inlet Preserve State Park	Accessible only by private boat and provides 4786 acres consisting of mangrove swamps, maritime hammock and undeveloped beach. Public recreation activities include swimming, snorkeling, scuba diving, sunbathing, fishing, primitive camping, picnicking, hiking, and nature appreciation.	25 miles east of the Martin Site	Development likely limited within this park.	FDEP Oct 2002b
St. Sebastian River Preserve State Park	Twenty archaeological sites and twenty-two distinct natural communities have been mapped in the 21,748-acre park including mesic flatwoods, prairie hammock, sandhill, scrubby flatwoods, and upland hardwood forests. Recreation activities include fishing, canoe/ kayaking, horseback riding, hiking, primitive camping, and nature appreciation.	49 miles north of the Martin Site	Development likely limited within this area.	FDEP Oct 2005
Comprehensive Everglades Restoration Plan Projects				
Acme Basin B	Project will improve Everglades water quality by diverting urban stormwater runoff into the C-51 canal and then to STA-1E for treatment. The project includes construction of two new pump stations and improvements to the C-1 canal, which will increase conveyance capacity and provide connection to the C-51 canal.	35 miles southeast of the Martin Site	Proposed. Phase 1, which includes the C-51 pump station installations and C-1 canal improvements, is complete. Phase 2, involving design of the Section 24 Impoundment, is ongoing.	SFWMD Jun 2010, USACE Oct 2003
C-44 Reservoir and Storage and Treatment Area	A component of the Indian River Lagoon – South Project consisting of a 3400-acre reservoir and 6200 acres of emergent vegetation.	9 miles east of the Martin Site	Design and land acquisition for this project is completed. Construction is anticipated to begin in 2011.	SFWMD Feb 2006, USACE Feb 2010
Everglades Agricultural Area Storage Reservoirs - Phase 1	Project consists of a large above-ground storage reservoir on former farmlands designed to provide significant additional water in the southern region of the Everglades Agricultural Area.	40 miles south of the Martin Site	Construction of the A-1 Reservoir was initiated in 2006, but has been subsequently suspended in since 2008 due to litigation.	SFWMD Jun 2010, USACE Nov 2009
Flows to Northwest and Central Water Conservation Areas 3A	Project will increase depths, extend wetland hydropatterns, and increase water supply availability in the northwest corner and west-central portions of WCA 3A.	50 miles south of the Martin Site	Proposed. Project design underway.	USACE Undated

Table 9.3-12 (Sheet 9 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Fran Reich Preserve (Site 1 Impoundment)	Construction of a 1600-acre impoundment to capture and store the excess surface water runoff from the Hillsboro Watershed and reduce water storage demands on the Arthur R. Marshall Loxahatchee National Wildlife Refuge and Lake Okeechobee.	50 miles south of the Martin Site	Proposed. Project design underway.	SFWMD Jun 2010, USACE Nov 2009
Indian River Lagoon-South Project	The project includes construction of several above-ground reservoirs and stormwater treatment areas. The project will use constructed wetlands and muck removal to improve surface water management and water quality of several canal basins, as well as, improve habitat in the St. Lucie Estuary and Indian River Lagoon.	2 miles north of the Martin Site	Proposed. Project is scheduled to begin in 2010.	SFWMD Jun 2010, USACE Nov 2009, USACE Feb 2010
Lake Okeechobee Aquifer Storage and Recovery (ASR)	Project proposes to increase regional storage while reducing both evaporation losses and the amount of land removed from current land use. This will be accomplished by a series of aquifer storage and recovery wells adjacent to Lake Okechobee with a capacity of one billion gallons per day and the associated pre- and post- water quality treatment facilities.	Nearest parcel is 4 miles west of the Martin Site	Five separate ASR pilot projects have been constructed around Lake Okeechobee and have provided five years of field data. Two more pilot systems began cycle testing in 2008.	USACE Undated, USACE Jun 2008
Lake Okeechobee Watershed Project	Construction of a 1984-acre reservoir and 3975-acre treatment area in the Taylor Creek/Nubbin Slough basin; a 10,281-acre reservoir in the Kissimmee River basin; a 5416-acre reservoir and 8,044-acre treatment area in the Lake Istokpoga basin, and a 3730-acre wetland restoration site in Paradise Run in order to increase aquatic and wildlife habitat, regulate lake staging, reduce phosphorus loading, and reduce damaging releases to the surrounding estuaries.	Various locations in Okeechobee County	Proposed. Project is scheduled to begin in 2019.	USACE Undated, USACE Nov 2009
Loxahatchee National Wildlife Refuge Internal Canal Structures	The purpose of this project is to improve the timing and location of water depths within the Refuge. It would consist of two water control structures in the northern ends of the perimeter canals encircling the Refuge.	28 miles northwest of the Martin Site	Currently in pre-construction design.	USACE Undated
Melaleuca Eradication and other Exotic Plants	Project enhances efforts to control invasive exotic species in south Florida through mass rearing and controlled release of biological agents throughout the region.	Throughout the region	Proposed. Project is scheduled to begin in 2011.	USACE Nov 2009

Table 9.3-12 (Sheet 10 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Modify Holey Land Wildlife Management Area (WMA) Operation Plan	Modifications to the current operating plan for Holey Land WMA will implement rain-driven operations as needed and will be made to improve the timing and location of water depths.	43 miles south of the Martin Site	Project in planning stage.	USACE Undated
Modify Rotenberger Wildlife Management Area Operation Plan	Modification to the current operating plan for the Rotenberger WMA will implement rain-driven operations as needed and will be made to improve the timing and location of water depths.	48 miles southwest of the Martin Site	Project in planning stage.	USACE Undated
North Palm Beach County - Part 1	Part 1 of this project includes portions of seven basins that will capture, store and treat excess water that is currently discharged to the Lake Worth Lagoon and use that water to enhance the Loxahatchee River, Loxahatchee Slough, and West Palm Beach Water Catchment Area.	8 miles southeast of the Martin Site	Project in pre-construction, engineering, and design phase. Part 1 construction is estimated to be completed in 2014.	USACE Undated, USACE May 2005
North Palm Beach County - Part 2	Part 2 includes an ASR with a capacity of 220 million gallons per day.	39 miles southeast of the Martin Site	Project in pre-construction, engineering, and design phase.	USACE Undated
Palm Beach County (PBC) Agriculture Reserve Aquifer Storage and Recovery and Reservoir	The project will supplement water supplies for central and southern Palm Beach County by capturing and storing excess water currently discharged to the Lake Worth Lagoon. The project includes 15 aquifer storage and recovery well clusters and an above-ground reservoir.	42 miles southeast of the Martin Site	Project in pre-construction, engineering, and design phase.	USACE Undated
Strazzula Wetlands	Project will provide hydrological and ecological connectivity of the Loxahatchee National Wildlife Refuge (NWR) and act as a buffer between higher water stages to the west and urban lands to the east. The increase in spatial extent of protected natural areas provides habitat connectivity for species that require large unfragmented tracts of land for survival. The area also contains rare and important cypress habitat and sawgrass marshes in the eastern Everglades area.	36 miles southeast of the Martin Site	Project in pre-construction, engineering, and design phase.	USACE Undated, USACE Nov 2003
Central and Southern Florida (C&SF) Projects				
Herbert Hoover Dike Rehabilitation	Project to strengthen the 143-mile dike that surrounds Lake Okeechobee.	5 miles west of the Martin Site	Construction is underway on the southeast section of the dike. Completion of the project is anticipated in 2025.	USACE Nov 2009

Table 9.3-12 (Sheet 11 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
West Palm Beach Canal/ Stormwater Treatment Area - 1E	Project provides flood control, water quality and water supply to the C-51 basin in Palm Beach County.	30 miles southeast of the Martin Site	Construction is underway. Completion of the project is expected in 2010.	USACE Nov 2009
Other Ecosystem Restoration Projects				
Kissimmee River Restoration Project	Project to restore over 40 square miles of river and floodplain ecosystem, including 43 miles of meandering river channel and 27,000 acres of wetlands. The project will reestablish a favorable environment for the flora and fauna that existed in the area prior to the 1960s, when the river was altered to provide flood protection.	47 miles northwest of the Martin Site	Restoration efforts are underway and are expected to be completed in 2013.	USACE Nov 2009
Lakeside Ranch Storage and Treatment Area	Construction of a 2700-acre wetland in western Martin County that will use emergent vegetation to remove phosphorus from stormwater runoff in the Taylor Creek/ Nubbin Slough basin before it enters Lake Okeechobee. The project has been divided into two phases, STA North and STA South.	19 miles northwest of the Martin Site	Construction of STA North began in 2009. Final design of STA South is scheduled to be completed in 2010, and construction is scheduled to begin in 2011.	SFWMD Jun 2010, USACE Nov 2009
Mining Projects				
Brown Ranch Mine	Crushed stone mine	34 miles northeast of the Martin Site	Operational	USGS 2005
Capron Trails Mine	Sand and gravel mine	21 miles northeast of the Martin Site	Operational	USGS 2005
Fort Pierce Quarry	Crushed stone mine	13 miles north of the Martin Site	Operational	USGS 2005
John's Pit	Sand and gravel mine	40 miles southeast of the Martin Site	Operational	USGS 2005
Lake Point Mine	Development of a 959-acre commercial limestone quarry in Martin County	5 miles southwest of the Martin Site	Proposed. CWA Section 404 permit application submitted April 2010.	ACOE Apr 2010a
Mecca-Ryan Operation	Sand and gravel mine	23 miles southeast of the Martin Site	Operational	USGS 2005
Ortona Sand Mine Expansion	154-acre expansion of sand mining operation in Glades County	49 miles southwest of the Martin Site	Proposed. CWA Section 404 permit application submitted March 2010.	ACOE Apr 2010b
Palm Beach Mine	Crushed stone mine	28 miles southeast of the Martin Site	Operational	USGS 2005
Palmdale Sand	Sand and gravel mine	47 miles southwest of the Martin Site	Operational	USGS 2005

Table 9.3-12 (Sheet 12 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
St. Lucie Mine	Sand and gravel mine	16 miles northeast of the Martin Site	Operational	USGS 2005
Star Pit	Crushed stone mine	32 miles southwest of the Martin Site	Operational	USGS 2005
United Dredging Corp. Operation	Sand and gravel mine	46 miles southeast of the Martin Site	Operational	USGS 2005
Witherspoon Sand Plant	Sand and gravel mine	49 miles southwest of the Martin Site	Operational	USGS 2005
Other Actions/Projects				
Central and Southern Florida (C&SF) Flood Control Project	The C&SF Flood Control Project was authorized by Congress in 1948 to provide flood control, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources. Today the C&SF project includes 1000 miles of canals, 720 miles of levees, and almost 200 water control structures. It covers 16 counties over an 18,000-square-mile area from Orlando to the Florida Reef Tract. The existing project provides water supply, flood protection, water management and other benefits to South Florida. However, the project has had unintended negative effects on the Everglades and the entire south Florida ecosystem.	Throughout the region.	Operational	HRA Jun 2006
Arch Mirror South	Glass mirror manufacturer	30 miles northeast of the Martin Site	Operational	FDEP Oct 2007
Atlantic Sugar Association	Sugar manufacturer	27 miles southeast of the Martin Site	Operational	FDEP Jun 2007
Louis Dreyfus Citrus Inc. - Indiantown Citrus Processing Plant	Food Manufacturer	5 miles southeast of the Martin Site	Operational	FDEP Jul 2008b
Macho Products Inc	Protective equipment manufacturer	50 miles north of the Martin Site	Operational	FDEP May 2007b
Maverick Boat Company	Fiberglass boat manufacturer	32 miles north of the Martin Site	Operational	FDEP Jan 2006
Okeelanta Corporation	Sugar manufacturer	35 miles southwest of the Martin Site	Operational	FDEP Jan 2001
Osceola Farms Co	Sugar manufacturer	15 miles south of the Martin Site	Operational	FDEP Mar 2010b

Table 9.3-12 (Sheet 13 of 13)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of Martin Site

Project Name	Summary of Project	Location	Status	Reference
Pratt & Whitney - Area C12 & C14	Engineering, manufacturing, and testing of gas turbine and rocket engines	15 miles southeast of the Martin Site	Operational	PBCHD Jul 2004
S2 Yachts Inc. Pursuit Division	Fiberglass boat manufacturer	32 miles north of the Martin Site	Operational	FDEP Mar 2008
Southern Gardens Citrus Processing Corp. - Clewiston Plant	Food manufacturer	42 miles southwest of the Martin Site	Operational	FDEP May 2010a
Sugar Cane Growers Cooperative of Florida	Sugar manufacturer	24 miles southwest of the Martin Site	Operational	FDEP Aug 2006
Tropicana Products, Inc. - Fort Pierce Facility	Citrus product and animal feed manufacturer	24 miles northeast of the Martin Site	Operational	FDEP Oct 2006
Twin Vee Catamarans	Fiberglass boat manufacturer	28 miles northeast of the Martin Site	Operational	FDEP Oct 2008
U.S. Sugar Corp. - Clewiston Mill	Sugar manufacturer	33 miles southwest of the Martin Site	Operational	FDEP Feb 2010
Venture Marine Inc.	Fiberglass boat manufacturer	35 miles southeast of the Martin Site	Operational	PBHCD Dec 2007
Water Reclamation and Wastewater Treatment Plants	Numerous plants	Within 50-mile radius of the Site.	Operational	FDEP Aug 2010a FDEP Aug 2010b
Future Urbanization	Construction of housing units and associated commercial buildings; roads, bridges and rail; construction of water and/or wastewater treatment facilities and associated pipelines.	Throughout the region.	Construction would occur in the future, as described in state and local land-use planning documents.	—
Various hospitals and industrial facilities that use radioactive materials	Medical and other isotopes	Within 50-mile radius of the Site.	Operational	—

Listed Species Documented or Reported in Okeechobee County
August 2011

Scientific Name	Common Name	Federal Status	State Status
Amphibians			
Rana capito	Gopher Frog	N	LS
Birds			
Ammodramus savannarum floridanus	Florida Grasshopper Sparrow	LE	LE
Aphelocoma coerulescens	Florida Scrub-jay	LT	LT
Aramus guarauna	Limpkin	N	LS
Athene cunicularia floridana	Florida Burrowing Owl	N	LS
Campephilus principalis	Ivory-billed Woodpecker	LE	—
Caracara cheriway	Crested Caracara	LT	LT
Egretta caerulea	Little Blue Heron	N	LS
Egretta thula	Snowy Egret	N	LS
Egretta tricolor	Tricolored Heron	N	LS
Eudocimus albus	White Ibis	N	LS
Falco sparverius paulus	Southeastern American Kestrel	N	LT
Grus americana	Whooping Crane	XN	—
Grus mbricate pratensis	Florida Sandhill Crane	N	LT
Mycteria americana	Wood Stork	LE	LE
Picoides borealis	Red-cockaded Woodpecker	LE	—
Polyborus plancus audubonii	Audubon's Crested Caracara	LT	—
Rostrhamus sociabilis plumbeus	Snail Kite	LE	LE
Sterna antillarum	Least Tern	N	LT
Mammals			
Eumops floridanus	Florida Bonneted Bat	C	—
Puma concolor coryi	Florida Panther	LE	LE
Puma concolor (all subsp. Except coryi)	Puma (Mountain Lion)	SAT	—
Sciurus niger shermani	Sherman's Fox Squirrel	N	LS
Trichechus manatus	Manatee	LE	LE
Plants and Lichens			
Calopogon multiflorus	Many-flowered Grass-pink	N	LE
Conradina grandiflora	Large-flowered Rosemary	N	LT
Lechea divaricata	Pine Pinweed	N	LE
Nemastylis floridana	Celestial Lily	N	LE
Nolina atopocarpa	Florida Beargrass	N	LT
Ophioglossum palmatum	Hand Fern	N	LE
Panicum abscissum	Cutthroat Grass	N	LE
Pteroglossaspis ecristata	Giant Orchid	N	LT
Reptiles			
Alligator mississippiensis	American Alligator	SAT	LS

Table 9.3-14 (Sheet 2 of 2)
Listed Species Documented or Reported in Okeechobee County
August 2011

Scientific Name	Common Name	Federal Status	State Status
Drymarchon couperi	Eastern Indigo Snake	LT	LT
Gopherus polyphemus	Gopher Tortoise	N	LT

FEDERAL STATUS

LE Endangered: species in danger of extinction throughout a significant portion of its range.

LT Threatened: species likely to become Endangered within the foreseeable future throughout a significant portion of its range.

SAT Treated as threatened because of similarity of appearance to a species that is federally listed so that enforcement personnel have difficulty in attempting to differentiate between the listed and unlisted species.

XN Nonessential experimental population.

N Not currently listed, nor currently being considered for listing as Endangered or Threatened.

STATE LEGAL STATUS

LE Endangered: species, subspecies, or isolated population so few or depleted in number or so restricted in range that it is in imminent danger of extinction.

LT Threatened: species, subspecies, or isolated population facing a very high risk of extinction in the future.

LS Species of Special Concern is a species, subspecies, or isolated population which is facing a moderate risk of extinction in the future.

USFWS, Feb 2010

Table 9.3-15 (Sheet 1 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Energy Projects				
City of Vero Beach Municipal Utilities	Five-unit, 155-MW gas- and oil-fired plant	34 miles northwest of the Okeechobee 2 Site	Operational	FDEP Jan 2008c
Florida Gas Transmission - Phase VIII Expansion Project	Construction and operation of 483.2 miles of pipeline facilities, including an 89.8-mile-long natural gas pipeline in a new right-of-way that runs from DeSoto County through Highlands and Okeechobee Counties to the FPL Martin Plant site.	DeSoto, Highlands, Okeechobee, and Martin Counties	Proposed. Final EIS issued September 2009.	FERC Sep 2009
Florida Gas Transmission - Station #20	Compressor station consisting of 5 internal combustion engines.	35 miles northeast of the Okeechobee 2 Site	Operational	FDEP May 2008
Florida Municipal Power Agency - Treasure Coast Energy Center	Single-unit, 300-MW gas-fired plant	36 miles northeast of the Okeechobee 2 Site	Operational	FDEP May 2010b
Progress Energy - Avon Park Steam Plant	Two-unit, 64-MW gas- and oil-fired plant	41 miles northwest of the Okeechobee 2 Site	Operational	FDEP Jan 2008f
Floridian Natural Gas Storage Company - Natural Gas Storage Facility	Liquefied natural gas storage, liquefaction, and vaporization facility with storage capacity of eight billion cubic feet of natural gas	30 miles southeast of the Okeechobee 2 Site	Proposed. Final EIS issued July 2008.	FERC Jul 2008
Fort Pierce Utilities Authority - H. D. King Power Plant	Four-unit, 136-MW gas- and oil-fired plant	40 miles northeast of the Okeechobee 2 Site	Operational	FDEP Jan 2008d
FPL - Martin Next Generation Solar Energy Center	75-MW solar thermal plant	26 miles southeast of the Okeechobee 2 Site	Proposed. Currently under construction, expected completion 3Q 2010.	FPL May 2008
FPL - Martin Plant	Five-unit, 3734-MW gas- and oil-fired plant	33 miles southeast of the Okeechobee 2 Site	Operational	FDEP Nov 2009b
FPL - St. Lucie Plant	Two-unit, 1680-MW nuclear plant	43 miles east of the Okeechobee 2 Site	Operational	FPL Dec 2007
FPL - St. Lucie Uprate Project	The project will increase the net electrical generation for Units 1 & 2 by 104-MW each.	43 miles east of the Okeechobee 2 Site	Proposed. Site Certification Application approved by FPSC in 2008.	FPL Dec 2007
Geoplasma-St. Lucie, LLC - St. Lucie Plasma Gasification Project	24-MW plasma arc gasification waste-to-energy (WTE) plant	35 miles northeast of the Okeechobee 2 Site	Proposed. Draft Air Construction Permit issued May 2010.	FDEP May 2010c
Highlands Ethanol Facility	39.4-MGPY cellulosic ethanol refinery	8 miles west of the Okeechobee 2 Site	Proposed. Air Construction Permit issued March 2010.	FDEP Mar 2010a
Indiantown Cogeneration Plant	Single-unit, 330-MW coal-fired plant with 2 gas-fired auxiliary boilers.	30 miles southeast of the Okeechobee 2 Site	Operational	FDEP Jan 2010

Table 9.3-15 (Sheet 2 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
INEOS New Planet Indian River County BioEnergy Facility	8-MGPY cellulosic ethanol refinery and a 5-MW biomass-fired power plant	36 miles northwest of the Okeechobee 2 Site	Proposed. Application for air construction permit submitted February 2010.	INEOS Feb 2010
New Hope Power Company - Okeelanta Cogeneration Plant	Three-unit, 140-MW biomass-fired plant	45 miles southeast of the Okeechobee 2 Site	Operational	FDEP May 2005
Okeechobee Landfill - Landfill Gas to Energy Project	Four-unit, 25.5-MW landfill gas-fired plant.	16 miles northeast of the Okeechobee 2 Site	Proposed. Air construction permit issued April 2010.	FDEP Apr 2010
Southeastern Renewable Fuels Biorefinery and Cogeneration Plant	22 MGPY cellulosic ethanol refinery and a 30-MW biomass-fired power plant	46 miles south of the Okeechobee 2 Site	Proposed. Application for air construction permit submitted March 2010.	Golder Mar 2010
Tampa Electric Company - Dinner Lake Station	Single-unit, 12.65-MW gas- and oil-fired plant	35 miles northwest of the Okeechobee 2 Site	Permanently closed	FDEP Apr 1999
Tampa Electric Company - J.H. Phillips Station	Two-unit, 42-MW oil-fired plant	29 miles northwest of the Okeechobee 2 Site	Operational	FDEP May 2009
Transportation Projects				
Avon Park Executive Airport	General aviation airport.	43 miles northwest of the Okeechobee 2 Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Indiantown Airport	General aviation airport.	34 miles southeast of the Okeechobee 2 Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Okeechobee County Airport	General aviation airport.	6 miles northeast of the Okeechobee 2 Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach County Glades Airport	General aviation airport.	35 miles southeast of the Okeechobee 2 Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Sebring Regional Airport	General aviation airport.	28 miles northwest of the Okeechobee 2 Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009

Table 9.3-15 (Sheet 3 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
St Lucie County International Airport	General aviation airport.	39 miles northeast of the Okeechobee 2 Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Vero Beach Municipal Airport	Commercial and general aviation airport.	42 miles northeast of the Okeechobee 2 Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Witham Field Airport	General aviation airport.	44 miles southeast of the Okeechobee 2 Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Port of Fort Pierce	99-acre deepwater seaport with public and private cargo terminals. Current annual cargo throughput of 0.358 million tons.	41 miles northeast of the Okeechobee 2 Site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010
Tampa - Orlando - Miami High-Speed Intercity Passenger Rail	This project would provide high-speed rail service from Tampa to Miami (through Orlando) with stops in West Palm Beach and Ft. Lauderdale. The termini for the Orlando -Miami corridor are the Orlando International Airport (OIA) and the Miami Intermodal Center at the Miami Airport (MIA).	Route follows the Florida Turnpike corridor from Orange County through Osceola, Okeechobee, St. Lucie, Martin and Palm Beach Counties	Proposed. Phase 1 (Tampa-Orlando corridor) is ongoing. Project development for Phase 2 (Orlando-Miami corridor) began in May 2010.	FDOT May 2010
Parks and Nature Preserve Facilities				
Archbold Biological Station	An independent, non-profit research facility, devoted to long-term ecological research and conservation. The Station owns and manages a 5000-acre preserve that is a matrix of pristine native vegetation, including oak and rosemary scrubs, pine flatwoods, and cutthroat seeps and seasonal wetlands. The station also manages the 10,500-acre MacArthur Agro-ecology Research Center (MAERC) at Buck Island Ranch.	25 miles southwest of the Okeechobee 2 Site	Development likely limited within this area.	ABS Feb 2004

Table 9.3-15 (Sheet 4 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Archie Carr National Wildlife Refuge	Home to the largest nesting population of endangered loggerhead, leatherback, and green sea turtles in the U.S. Recreational activities include fishing, canoeing, swimming, and wildlife viewing. 195,000 visitors in 2006.	49 miles northeast of the Okeechobee 2 Site	Development likely limited within this refuge.	USFWS Nov 2008
Atlantic Ridge Preserve State Park	The preserve has not yet opened to the public due to the lack of a public access road. Once the constructed the preserve will be available for passive recreational including hiking, horseback riding, picnicking, wildlife observation, and birding.	43 miles southeast of the Okeechobee 2 Site	Development likely limited within this refuge.	FDEP Dec 2005
Avalon State Park	Supports intact examples of coastal and wetland communities including a large stand of undeveloped maritime hammock. Recreational activities focus on the 6000 feet of Atlantic shoreline and include swimming, fishing, and surfing.	42 miles northeast of the Okeechobee 2 Site	Trail development likely within this park. Other development would be limited.	FDEP Aug 2002
Babcock Ranch Preserve	The 73,239-acre property was purchased by the state of Florida and Lee County in 2006 and is the largest purchase of conservation land in the state's history. The property is preserved as-is with operations including cattle ranching, silviculture tenant farming, horticultural debris disposal, ecotourism, and natural resource based recreation (such as hiking, hunting, and fishing).	44 miles southwest of the Okeechobee 2 Site	Addition of hiking, biking, and horse trails and camping facilities is planned. Other development would be limited.	FFWCC Jul 2008
Barley Barber Swamp	A one-mile boardwalk runs through a cypress swamp. On FLP owned Martin site land. Public access requires advance reservation.	25 miles southeast of the Okeechobee 2 Site	Development likely limited within this refuge.	FFWCC Jul 2010
Big Water Heritage Trail	Scenic auto route circling Lake Okeechobee passing though five counties and going by multiple natural and historic sites.	7 miles southeast of the Okeechobee 2 Site	Development likely limited at specific points along the trail.	SWFRPC 2009
DuPuis Wildlife and Environmental Area	21,875 acres managed to conserve and protect water resources as well as protect and restore land resources to its natural state. Recreation activities include hunting, fishing, horseback and bicycle riding, canoeing, camping, and hiking.	28 miles southeast of the Okeechobee 2 Site	Development likely limited within this refuge.	SFWMD Jun 2008
Fisheating Creek Wildlife Management Area	The 18,272-acre property is used for conservation and protection of the natural communities along the shores of Fisheating Creek. Contains natural summer roosts for endangered swallowtail kites.	23 miles southwest of the Okeechobee 2 Site	Development limited within property.	FFWCC Feb 2003

Table 9.3-15 (Sheet 5 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Florida National Scenic Trail	Scenic hiking trail stretches over 1400 miles across the state, traverses nearly all of Florida's unique habitats, and includes the Lake Okeechobee Scenic Trail. Portions of the trail are accessible for bicycling, horseback riding, or inline skating.	2 miles south of the Okeechobee 2 Site	Development likely limited at specific points along the trail.	USDAFS Feb 2006
Fort Pierce Inlet State Park	Beaches used as nesting grounds for loggerhead sea turtles. Recreation activities include fishing, swimming, surfing, boating, biking, hiking, and wildlife viewing.	41 miles northeast of the Okeechobee 2 Site	Additional facilities for canoe access, picnicking staff housing needs, and securing reliable access to the island are planned.	FDEP Dec 2006
Highlands Hammock State Park	One of Florida's first state parks. Public outdoor recreation and conservation is the designated single use of the 9251-acre property. Recreation activities include camping, picnicking, hiking, horse and bicycle riding,	36 miles northwest of the Okeechobee 2 Site	Development includes, refurbishing of existing facilities, and creating an additional day use area.	FDEP Feb 2007
Hobe Sound National Wildlife Refuge	An important example of pre-contact Florida ecological environments. Sand dunes and associated lagoons are habitats for rare and threatened species such as manatees, scrub jays, and leatherback sea turtles. Hiking and swimming available to public.	49 miles east of the Okeechobee 2 Site	Upgrades to existing beach facilities are planned.	USFWS Dec 2006
Hungryland Wildlife and Environmental Area	The 10,294-acre property was purchased to conserve and protect environmentally unique and irreplaceable lands including relatively undisturbed, high-quality pine flatwoods. Recreation activities include hiking, horseback riding, hunting, and fishing.	37 miles southeast of the Okeechobee 2 Site	Development likely limited within this property.	FFWCC Feb 2002
Indian River County Public Shooting Range	Provides public outdoor recreation facility and a training site for hunter education students, volunteers, and law enforcement personnel.	44 miles northeast of the Okeechobee 2 Site	Development likely limited within this property.	FFWCC Aug 2008
J.W. Corbett Wildlife Management Area	Management of unique tropical hardwood hammocks and slash pine flatwoods habitat of the South Florida systems and recovery of the endangered and threatened species that occur there. The vast majority of the 60,288-acre property is used for wildlife management and public hunting.	35 miles southeast of the Okeechobee 2 Site	Additional land acquisition is planned. Planned public uses will include hunting, fishing, and horseback riding.	FFWCC Apr 2003

Table 9.3-15 (Sheet 6 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Jonathan Dickenson State Park	The 11,471-acre park supports many unique natural features and significant cultural resources. Contains one the last remaining coastal sand pine scrub plant communities along the southeast coast, a 2600-acre wilderness preserve, and most of the Loxahatchee National Wild and Scenic River. Recreation activities include hiking, biking, camping, picnicking, canoe/ kayaking, and interpretive programs.	49 miles east of the Okeechobee 2 Site	Development likely limited within this property.	FDEP Feb 2000
Kissimmee Prairie Preserve State Park	Public outdoor recreation and conservation is the single use of the 53,760-acre property. Recreation activities include hiking, biking and horse riding trails, camping, picnicking, and interpretive programs.	20 miles north of the Okeechobee 2 Site	Development of new visitor center is planned. Other development likely limited within this property.	FDEP Apr 2005a
Lake June in Winter Scrub State Park	Some of the finest remnants of scrub habitat found in peninsular Florida and supports a significant population of Florida scrub jays and five listed plant species. The primary recreation activities focus on the shoreline of the lake.	29 miles west of the Okeechobee 2 Site	Development likely limited within this property.	FDEP Feb 2004
Lake Okeechobee	Lake Okeechobee is the second largest freshwater lake within the continental United States and is a nationally recognized bass and pan fishing resource. The lake offers other recreational amenities as well. Air boat and swamp buggy rides, bike riding, hiking, picnicking, camping, and nature interpretation are popular land-based recreation activities in the region.	7 miles southeast of the Okeechobee 2 Site	Development likely limited within this area.	FDEP Jun 2010
Lake Okeechobee Scenic Trail	A 110-mile-long hiking trail circling Lake Okeechobee atop the Herbert Hoover Dike offers scenic views of lakeside and agricultural landscapes. The trail provides opportunities for hiking, bicycle and horseback riding, bird watching, and fishing.	2 miles south of the Okeechobee 2 Site	Development likely limited at specific points along the trail.	FDEP Jun 2010
Lake Wales Ridge National Wildlife Refuge	Management of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	23 miles west of the Okeechobee 2 Site	Additional land acquisition is planned. Development likely limited within this area.	USFWS Apr 2010
Lake Wales Ridge Wildlife and Environmental Area	Management and restoration of unique scrub habitat of the Central Florida ridge systems and recovery of the endangered and threatened species that occur there. Public access to refuge is limited to guided tours only.	23 miles west of the Okeechobee 2 Site	Development likely limited within this area.	FFWCC Sep 2002

Table 9.3-15 (Sheet 7 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Okaloacoochee Slough Wildlife Management Area	A 2923-acre property managed to maintain and restore the Okalacoochee Slough sawgrass marsh unique lands and threatened and endangered species associated with it. Public activities include hunting, fishing, bird watching, horseback riding, hiking, nature study, wildlife viewing, picnicking, and primitive camping. Access limited to eastern side of property.	47 miles southwest of the Okeechobee 2 Site	Additional acquisition is planned of surrounding land. Development likely limited within this area.	FFWCC Dec 2001
Pelican Island National Wildlife Refuge	Management of habitats to sustain abundant populations of native species and to help recover threatened and endangered species. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	48 miles northeast of the Okeechobee 2 Site	Expansion of visitor facilities is planned. Other development would be limited within this refuge.	USFWS Sep 2006
Savannas Preserve State Park	Property (5227 acres) encompasses portions of the Atlantic Costal Ridge and the flatwoods and savanna-like wetlands associated with it. It harbors a unique set of natural communities that include sand pine scrub, flatwoods, marsh, and wet prairies. Public recreation activities include hiking, bicycle and horseback riding, canoe/kayaking, picnicking, wildlife viewing and environmental education.	39 miles east of the Okeechobee 2 Site	Development of facilities for public use likely limited within this area.	FDEP Jun 2003
Seabranch Inlet State Park	Management of 913 acres of various different natural communities including a rare and important baygall, beach dune, and scrub communities. The park in only open to the public for hiking and nature appreciation.	47 miles east of the Okeechobee 2 Site	Development likely limited within this area.	FDEP Oct 2002a
Spirit of the Wild Wildlife Management Area	This 7486-acre property is managed to protect existing swale or “river grass” natural community which forms an important habitat for numerous species of special concern, as well as forms a hydrological connection with protected lands to the east and south. Public recreation activities include hunting, fishing, horseback riding, hiking, nature study, wildlife viewing, picnicking, and primitive camping	50 miles southwest of the Okeechobee 2 Site	Additional acquisition is planned. Development likely limited within this area.	FFWCC Sep 2006
St. Lucie Inlet Preserve State Park	Accessible only by private boat and provides 4786 acres consisting of mangrove swamps, maritime hammock and undeveloped beach. Public recreation activities include swimming, snorkeling, scuba diving, sunbathing, fishing, primitive camping, picnicking, hiking, and nature appreciation.	47 miles east of the Okeechobee 2 Site	Development likely limited within this park.	FDEP Oct 2002b

Table 9.3-15 (Sheet 8 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
St. Sebastian River Preserve State Park	Twenty archaeological sites and twenty-two distinct natural communities have been mapped in the 21,748-acre park including mesic flatwoods, prairie hammock, sandhill, scrubby flatwoods, and upland hardwood forests. Recreation activities include fishing, canoe/ kayaking, horseback riding, hiking, primitive camping, and nature appreciation.	42 miles northeast of the Okeechobee 2 Site	Development likely limited within this area	FDEP Oct 2005
Three Lakes Wildlife Management Area	A 50,889-acre property managed to provide environmental protection of extensive prairie, lake, and hammock habitats and maintain biodiversity while allowing compatible use by man. Recreation activities include hunting, fishing, horseback riding, hiking, canoeing, boating, wildlife viewing, picnicking, and camping.	40 miles north of the Okeechobee 2 Site	Additional acquisition is planned. Development likely limited within this area	FFWCC Jan 2001
Comprehensive Everglades Restoration Plan Projects				
C-44 Reservoir and Storage and Treatment Area	A component of the Indian River Lagoon - South Project consisting of a 3400-acre reservoir and 6200 acres of emergent vegetation.	34 miles southeast of the Okeechobee 2 Site	Design and land acquisition for this project is completed. Construction is anticipated to begin in 2011.	SFWMD Feb 2006, USACE Feb 2010
Indian River Lagoon - South Project	The project includes construction of several above-ground reservoirs and stormwater treatment areas. The project will use constructed wetlands and muck removal to improve surface water management and water quality of several canal basins, as well as improve habitat in the St. Lucie Estuary and Indian River Lagoon.	22 miles east of the Okeechobee 2 Site	Proposed. Project is scheduled to begin in 2010.	SFWMD Jun 2010, USACE Nov 2009, USACE Feb 2010
Lake Okeechobee Aquifer Storage and Recovery	Project proposes to increase regional storage while reducing both evaporation losses and the amount of land removed from current land use. This will be accomplished by a series of aquifer storage and recovery wells adjacent to Lake Okechobee with a capacity of one billion gallons per day and the associated pre- and post-water quality treatment facilities.	6 miles southeast of the Okeechobee 2 Site	Five separate ASR pilot projects have been constructed around Lake Okeechobee and have provided five years of field data. Two more pilot systems began cycle testing in 2008.	USACE Undated, USACE Jun 2008

Table 9.3-15 (Sheet 9 of 12)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Lake Okeechobee Watershed Project	Construction of a 1984-acre reservoir and 3975-acre treatment area in the Taylor Creek/Nubbin Slough basin; a 10,281-acre reservoir in the Kissimmee River basin; a 5416-acre reservoir and 8044-acre treatment area in the Lake Istokpoga basin, and a 3730-acre wetland restoration site in Paradise Run in order to increase aquatic and wildlife habitat, regulate lake staging, reduce phosphorus loading, and reduce damaging releases to the surrounding estuaries.	Various locations in Okeechobee County	Proposed. Project is scheduled to begin in 2019.	USACE Undated, USACE Nov 2009
Melaleuca Eradication and other Exotic Plants	Project enhances efforts to control invasive exotic species in south Florida through mass rearing and controlled release of biological agents throughout the region.	Throughout the region	Proposed. Project is scheduled to begin in 2011.	USACE Nov 2009
North Palm Beach County - Part 1	Part 1 of this project includes portions of seven basins that will capture, store and treat excess water that is currently discharged to the Lake Worth Lagoon and use that water to enhance the Loxahatchee River, Loxahatchee Slough, and West Palm Beach Water Catchment Area.	35 miles southeast of the Okeechobee 2 Site	Project in pre-construction, engineering, and design phase. Part 1 construction is estimated to be completed in 2014.	USACE Undated, USACE May 2005
Central and Southern Florida (C&SF) Projects				
Herbert Hoover Dike Rehabilitation	Project to strengthen the 143-mile dike that surrounds Lake Okeechobee.	7 miles southeast of the Okeechobee 2 Site	Construction is underway on the southeast section of the dike. Completion of the project is anticipated in 2025.	USACE Nov 2009
Other Ecosystem Restoration Projects				
Kissimmee River Restoration Project	Project to restore over 40 square miles of river and floodplain ecosystem, including 43 miles of meandering river channel and 27,000 acres of wetlands. The project will reestablish a favorable environment for the flora and fauna that existed in the area prior to the 1960s, when the river was altered to provide flood protection.	22 miles northwest of the Okeechobee 2 Site	Restoration efforts are underway and are expected to be completed in 2013.	USACE Nov 2009
Lakeside Ranch Storage and Treatment Area	Construction of a 2700-acre wetland in western Martin County that will use emergent vegetation to remove phosphorus from stormwater runoff in the Taylor Creek/ Nubbin Slough basin before it enters Lake Okeechobee. The project has been divided into two phases, STA North and STA South.	9 miles east of the Okeechobee 2 Site	Construction of STA North began in 2009. Final design of STA South is scheduled to be completed in 2010, and construction is scheduled to begin in 2011.	SFWMD Jun 2010, USACE Nov 2009

Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the Okeechobee 2 Site

Project Name	Summary of Project	Location	Status	Reference
Other Actions/Projects				
Central and Southern Florida Flood Control Project	The C&SF Flood Control Project was authorized by Congress in 1948 to provide flood control, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources. Today the CS&F project includes 1000 miles of canals, 720 miles of levees, and almost 200 water control structures. It covers 16 counties over an 18,000-square-mile area from Orlando to the Florida Reef Tract. The existing project provides water supply, flood protection, water management and other benefits to South Florida. However, the project has had unintended negative effects on the Everglades and the entire south Florida ecosystem.	Throughout the region.	Operational	HRA Jun 2006
Alpha General Services, Inc.	Fiberglass tank manufacturer	34 miles northwest of the Okeechobee 2 Site	Operational	FDEP Sep 2006
Arch Mirror South	Glass mirror manufacturer	36 miles northeast of the Okeechobee 2 Site	Operational	FDEP Oct 2007
Atlantic Sugar Association	Sugar manufacturer	44 miles southeast of the Okeechobee 2 Site	Operational	FDEP Jun 2007
Avon Park Air Force Range	106,000-acre bombing and gunnery range and air-ground training complex. Approximately 82,000 acres are open for public access on a regular basis for hiking, hunting, fishing, camping, and other related activities.	25 miles northwest of the Okeechobee 2 Site	Operational	Global Security undated
Cargill Juice America, Inc. - Avon Park Citrus Processing Facility	Citrus juice products and animal feed manufacturer	45 miles northwest of the Okeechobee 2 Site	Operational	FDEP May 2007c
Cargill Juice America, Inc. - Frostproof Plant	Food manufacturer	49 miles northwest of the Okeechobee 2 Site	Operational	FDEP Apr 2006
E-Stone USA Corp	Cultured granite reinforced plastics manufacturer	29 miles northwest of the Okeechobee 2 Site	Operational	FDEP Nov 2009c
Genpak LLC	Polystyrene foam packaging materials manufacturer	37 miles northwest of the Okeechobee 2 Site	Operational	FDEP Jul 2005
Louis Dreyfus Citrus Inc. - Indiantown Citrus Processing Plant	Food manufacturer	33 miles southeast of the Okeechobee 2 Site	Operational	FDEP Jul 2008b
Macho Products Inc	Protective equipment manufacturer	44 miles northeast of the Okeechobee 2 Site	Operational	FDEP May 2007b

Listed Species Documented or Reported in St. Lucie County
August 2011

Scientific Name	Common Name	Federal Status	State Status
Glandularia maritima	Coastal Vervain	N	LE
Halophila johnsonii	Johnson's Seagrass	LT	N
Harrisia fragrans	Fragrant Prickly Apple	LE	LE
Lechea cernua	Nodding Pinweed	N	LT
Okenia hypogaea	Burrowing Four-o'clock	N	LE
Peperomia obtusifolia	Blunt-leaved Peperomia	N	LE
Polygala smallii	Tiny Polygala	LE	LE
Pteroglossaspis ecristata	Giant Orchid	N	LT
Schizachyrium niveum	Scrub Bluestem	N	LE
Tephrosia angustissima var. curtissii	Coastal Hoary-pea	N	LE
Reptiles			
Alligator mississippiensis	American Alligator	SAT	LT (S/A)
Caretta caretta	Loggerhead	LT	LT
Chelonia mydas	Green Turtle	LE	LE
Crocodylus acutus	American Crocodile (FL population)	LT	—
Dermochelys coriacea	Leatherback	LE	LE
Drymarchon couperi	Eastern Indigo Snake	LT	LT
Eretmochelys mbricate	Hawksbill	LE	LE
Gopherus polyphemus	Gopher Tortoise	N	LT
Lepidochelys kempii	Kemp's Ridley	LE	LE
Pituophis melanoleucus mugitus	Florida Pine Snake	N	LS

FEDERAL STATUS

LE Endangered: species in danger of extinction throughout a significant portion of its range.

LT Threatened: species likely to become Endangered within the foreseeable future throughout a significant portion of its range.

SAT Treated as threatened because of similarity of appearance to a species that is federally listed so that enforcement personnel have difficulty in attempting to differentiate between the listed and unlisted species.

C Candidate species for which federal listing agencies have sufficient information on biological vulnerability and threats to support proposing to list the species as Endangered or Threatened.

XN Nonessential experimental population.

SC Not currently listed, but considered a "species of concern" to USFWS.

N Not currently listed, nor currently being considered for listing as Endangered or Threatened.

STATE LEGAL STATUS

LE Endangered: species, subspecies, or isolated population so few or depleted in number or so restricted in range that it is in imminent danger of extinction.

LT Threatened: species, subspecies, or isolated population facing a very high risk of extinction in the future.

LS Species of Special Concern is a species, subspecies, or isolated population which is facing a moderate risk of extinction in the future.

N Not currently listed, nor currently being considered for listing.

Table 9.3-18 (Sheet 1 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Energy Projects				
City of Vero Beach Municipal Utilities	Five-unit, 155-MW gas- and oil-fired plant	21 miles northwest of the St. Lucie Site	Operational	FDEP Jan 2008c
Florida Gas Transmission - Phase VIII Expansion Project	Construction and operation of 483.2 miles of pipeline facilities, including an 89.8-mile long natural gas pipeline in a new right-of-way that runs from DeSoto County through Highlands and Okeechobee Counties to the FPL Martin Plant site.	DeSoto, Highlands, Okeechobee, and Martin Counties	Proposed. Final EIS issued September 2009.	FERC Sep 2009
Florida Gas Transmission - Station #20	Compressor station consisting of 5 internal combustion engines.	12 miles northwest of the St. Lucie Site	Operational	FDEP May 2008
Florida Municipal Power Agency - Treasure Coast Energy Center	Single-unit, 300-MW gas-fired plant	8 miles northwest of the St. Lucie Site	Operational	FDEP May 2010b
Floridian Natural Gas Storage Company - Natural Gas Storage Facility	Liquefied natural gas storage, liquefaction, and vaporization facility with storage capacity of eight billion cubic feet of natural gas	26 miles southwest of the St. Lucie Site	Proposed. Final EIS issued July 2008.	FERC Jul 2008
Fort Pierce Utilities Authority - H. D. King Power Plant	Four-unit, 136-MW gas- and oil-fired plant	9 miles northwest of the St. Lucie Site	Operational	FDEP Jan 2008d
FPL - Martin Next Generation Solar Energy Center	75-MW solar thermal plant	28 miles southwest of the St. Lucie Site	Proposed. Currently under construction, expected completion 3Q 2010.	FPL May 2008
FPL - Martin Plant	Five-unit, 3734-MW gas- and oil-fired plant	26 miles southwest of the St. Lucie Site	Operational	FDEP Nov 2009b
FPL - Riviera Plant	Two-unit, 580-MW oil- and gas-fired plant	42 miles southeast of the St. Lucie Site	Operational. Would be replaced by the Riviera Plant Repowering Project	FDEP Jan 2009
FPL - Riviera Plant Repowering Project	A single-unit, 1250-MW gas-fired combined-cycle plant would replace the two existing boilers at the site.	42 miles southeast of the St. Lucie Site	Proposed. Air Construction Permit issued June 2009.	FDEP Jun 2009
FPL - St. Lucie Plant	Two-unit, 1680-MW nuclear plant	Collocated with existing units at the St. Lucie Site	Operational	FPL Dec 2007
FPL - St. Lucie Uprate Project	The project will increase the net electrical generation for Units 1 & 2 by 104-MW each.	Collocated with existing units at the St. Lucie Site	Proposed. Site Certification Application approved by FPSC in 2008.	FPL Dec 2007
FPL - West County Energy Center	Two-unit, 2500-MW gas-fired plant	45 miles southwest of the St. Lucie Site	Operational	FDEP Jul 2008a

Table 9.3-18 (Sheet 2 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
FPL - West County Energy Center, Unit 3	Single-unit, 1250-MW gas-fired plant	45 miles southwest of the St. Lucie Site	Proposed. Unit 3 under construction, expected completion in 2011.	FDEP Jul 2008a
Geoplasma-St. Lucie, LLC - St. Lucie Plasma Gasification Project	24-MW plasma arc gasification waste-to-energy (WTE) plant	9 miles northwest of the St. Lucie Site	Proposed. Draft Air Construction Permit issued May 2010.	FDEP May 2010c
Indiantown Cogeneration Plant	Single-unit, 330-MW coal-fired plant with 2 gas-fired auxiliary boilers.	26 miles southwest of the St. Lucie Site	Operational	FDEP Jan 2010
INEOS New Planet Indian River County BioEnergy Facility	8-MGPY cellulosic ethanol refinery and a 5-MW biomass-fired power plant	22 miles northwest of the St. Lucie Site	Proposed. Application for air construction permit submitted February 2010.	INEOS Feb 2010
Okeechobee Landfill - Landfill Gas to Energy Project	Four- unit, 25.5-MW landfill gas-fired plant.	27 miles west of the St. Lucie Site	Proposed. Air construction permit issued April 2010.	FDEP Apr 2010
Sea Gen St. Lucie Hydroelectric Project	Installation, 25 miles off shore near St. Lucie County, of 20 to 40 submerged hydrokinetic generating units with a total capacity of 20- to 40-MW	31 miles east of the St. Lucie Site	Proposed. Preliminary permit issued February 2005.	FERC Feb 2005a
Sea Gen St. Sebastian Hydroelectric Project	Installation, 25 miles off shore near Indian River County, of 20 to 40 submerged hydrokinetic generating units with a total capacity of 20- to 40-MW	41 miles northeast of the St. Lucie Site	Proposed. Preliminary permit issued February 2005.	FERC Feb 2005b
Solid Waste Authority of Palm Beach County - Palm Beach Renewable Energy Facility No. 1	Two-unit, 62-MW municipal solid waste (MSW)-fired plant	39 miles southeast of the St. Lucie Site	Operational	FDEP Jul 2006
Solid Waste Authority of Palm Beach County - Palm Beach Renewable Energy Facility No. 2	Three-unit, 100-MW MSW-fired plant	39 miles southeast of the St. Lucie Site	Proposed. Application for air construction permit submitted May 2010.	SWAPBC May 2010
Transportation Projects				
Indiantown Airport	General aviation airport.	25 miles northwest of the St. Lucie Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
North Palm Beach County Airport	General aviation and reliever airport for Palm Beach International	34 miles south of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009

Table 9.3-18 (Sheet 3 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Okeechobee County Airport	General aviation airport.	37 miles southwest of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach County Glades Airport	General aviation airport.	47 miles southwest of the St. Lucie Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Palm Beach International Airport	Full service airport - commercial airlines, air cargo, and general aviation	46 miles south of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
St Lucie County International Airport	General aviation airport.	12 miles northwest of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Valkaria Airport	General aviation airport.	46 miles northwest of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Vero Beach Municipal Airport	Commercial and general aviation airport.	23 miles northwest of the St. Lucie Site	Operational. Expansion and construction would occur in the future, as described in state and local planning documents.	FDOT 2009
Witham Field Airport	General aviation airport.	12 miles south of the St. Lucie Site	Operational. Limited expansion would occur in the future, as described in state and local planning documents.	FDOT 2009
Port of Fort Pierce	99-acre deepwater seaport with public and private cargo terminals. Current annual cargo throughput of 0.358 million tons.	9 miles northwest of the St. Lucie Site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010

Table 9.3-18 (Sheet 4 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Port of Palm Beach	Large full-service deepwater seaport. Current annual cargo throughput of 2.3 million tons. Cruise terminal serves 349,000 passengers annually.	42 miles southeast of the St. Lucie Site	Operational. Port expansion, dredging, and construction would occur in the future, as described in state and local planning documents.	FSTEDC Mar 2010
Tampa - Orlando - Miami High-Speed Intercity Passenger Rail	This project would provide high-speed rail service from Tampa to Miami (through Orlando) with stops in West Palm Beach and Ft. Lauderdale. The termini for the Orlando -Miami corridor are the Orlando International Airport (OIA) and the Miami Intermodal Center at the Miami Airport (MIA).	Route follows the Florida Turnpike corridor from Orange County through Osceola, Okeechobee, St. Lucie, Martin and Palm Beach Counties	Proposed. Phase 1 (Tampa-Orlando corridor) is ongoing. Project development for Phase 2 (Orlando-Miami corridor) began in May 2010.	FDOT May 2010
Parks and Nature Preserve Facilities				
Archie Carr National Wildlife Refuge	Home to the largest nesting population of endangered loggerhead, leatherback, and green sea turtles in the U.S. Recreational activities include fishing, canoeing, swimming, and wildlife viewing. 195,000 visitors in 2006.	31 miles northeast of the St. Lucie Site	Development likely limited within this refuge.	USFWS Nov 2008
Arthur R. Marshall Loxahatchee National Wildlife Refuge	Management of species and habitats to enhance the native biodiversity and integrity of the Everglades ecosystem. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	46 miles south of the St. Lucie Site	Additional land acquisition and expansion of visitor facilities are planned. Other development would be limited within this refuge.	USFWS Sep 2000
Atlantic Ridge Preserve State Park	The preserve has not yet opened to the public due to the lack of a public access road. Once the road is constructed, the preserve will be available for passive recreational activities including hiking, horseback riding, picnicking, wildlife observation, and birding.	16 miles south of the St. Lucie Site	Development likely limited within this refuge.	FDEP Dec 2005
Avalon State Park	Supports intact examples of coastal and wetland communities including a large stand of undeveloped maritime hammock. Recreational activities focus on the 6,000 feet of Atlantic shoreline and include swimming, fishing, and surfing.	14 miles northwest of the St. Lucie Site	Trail development likely within this park. Other development would be limited.	FDEP Aug 2002
Barley Barber Swamp	A one-mile boardwalk runs through a cypress swamp. On FLP owned Martin site land. Public access requires advance reservation.	29 miles southwest of the St. Lucie Site	Development likely limited within this refuge.	FFWCC Jul 2010
Big Water Heritage Trail	Scenic auto route circling Lake Okeechobee passing though five counties and going by multiple natural and historic sites.	30 miles southwest of the St. Lucie Site	Development likely limited at specific points along the trail.	SWFRPC 2009

Table 9.3-18 (Sheet 5 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
DuPuis Wildlife and Environmental Area	21,875 acres managed to conserve and protect water resources as well as protect and restore land resources to its natural state. Recreation activities include hunting, fishing, horseback and bicycle riding, canoeing, camping, and hiking.	29 miles southwest of the St. Lucie Site	Development likely limited within this refuge.	SFWMD Jun 2008
Florida National Scenic Trail	Scenic hiking trail stretches over 1400 miles across the state and traverses nearly all of Florida's unique habitats and includes the Lake Okeechobee Scenic Trail. Portions of the trail are accessible for bicycling, horseback riding, or inline skating.	22 miles south of the St. Lucie Site	Development likely limited at specific points along the trail.	USDAFS Feb 2006
Fort Pierce Inlet State Park	Beaches used as nesting grounds for loggerhead sea turtles. Recreation activities include fishing, swimming, surfing, boating, biking, hiking, and wildlife viewing.	9 miles north of the St. Lucie Site	Additional facilities for canoe access, picnicking staff housing needs, and securing reliable access to the island are planned.	FDEP Dec 2006
Hobe Sound National Wildlife Refuge	An important example of pre-contact Florida ecological environments. Sand dunes and associated lagoons are habitats for rare and threatened species such as manatees, scrub jays, and leatherback sea turtles. Hiking and swimming available to public.	17 miles southeast of the St. Lucie Site	Upgrades to existing beach facilities are planned.	USFWS Dec 2006
Hungryland Wildlife and Environmental Area	The 10,294-acre property was purchased to conserve and protect environmentally unique and irreplaceable lands including relatively undisturbed, high quality pine flatwoods. Recreation activities include hiking, horseback riding, hunting, and fishing.	24 miles south of the St. Lucie Site	Development likely limited within this property.	FFWCC Feb 2002
Indian River County Public Shooting Range	Provides public outdoor recreation facility and a training site for hunter education students, volunteers, and law enforcement personnel.	35 miles northwest of the St. Lucie Site	Development likely limited within this property.	FFWCC Aug 2008
Indian River Lagoon State Park	Two miles of undeveloped frontage (402 acres) along the Indian River Lagoon purchased to preserve and improve the aquatic natural communities. A third of the country's manatee population lives in the Indian River Lagoon. Public use limited to picnicking, hiking, bank fishing, and camping at undeveloped sites.	42 miles north of the St. Lucie Site	31 acres of additional land acquisition is planned. Development likely limited within this property.	FDEP Jan 2004

Table 9.3-18 (Sheet 6 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
J.W. Corbett Wildlife Management Area	Management of unique tropical hardwood hammocks and slash pine flatwoods habitat of the South Florida systems and recovery of the endangered and threatened species that occur there. The vast majority of the 60,288-acre property is used for wildlife management and public hunting.	28 miles south of the St. Lucie Site	Additional land acquisition is planned. Planned public uses will include hunting, fishing, and horseback riding.	FFWCC Apr 2003
John D. MacArthur Beach State Park	Park protects a unique cross section of coastal Florida landscape including 121 acres of tropical maritime hammock, the largest remaining example in the county. Nine designated plant and 20 animal species occupy the natural habitats preserved by this park. The 7,000-ft sand beach and dune community attracts a large number of nesting loggerhead, green, and leatherback sea turtles. Recreation activities include swimming, snorkeling, canoeing, fishing, and bird watching.	37 miles south of the St. Lucie Site	Development likely limited within this property	FDEP Apr 2005b
Jonathan Dickenson State Park	The 11,471-acre park supports many unique natural features and significant cultural resources. Contains one the last remaining coastal sand pine scrub plant communities along the southeast coast, a 2600-acre wilderness preserve, and most of the Loxahatchee National Wild and Scenic River. Recreation activities include hiking, biking, camping, picnicking, canoe/ kayaking, and interpretive programs.	22 miles south of the St. Lucie Site	Development likely limited within this property	FDEP Feb 2000
Kissimmee Prairie Preserve State Park	Public outdoor recreation and conservation is the single use of the 53,760-acre property. Recreation activities include hiking, biking and horse riding trails, camping, picnicking, and interpretive programs.	44 miles west of the St. Lucie Site	Development of new visitor center is planned. Other development likely limited within this property.	FDEP Apr 2005a
Lake Okeechobee	Lake Okeechobee is the second largest freshwater lake within the continental United States and is a nationally recognized bass and pan fishing resource. The lake offers other recreational amenities as well. Air boat and swamp buggy rides, bike riding, hiking, picnicking, camping, and nature interpretation are popular land-based recreation activities in the region.	31 miles southwest of the St. Lucie Site	Development likely limited within this area.	FDEP Jun 2010

Table 9.3-18 (Sheet 7 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Lake Okeechobee Scenic Trail	A 110-mile-long hiking trail circling Lake Okeechobee atop the Herbert Hoover Dike offers scenic views of lakeside and agricultural landscapes. The trail provides opportunities for hiking, bicycle and horseback riding, bird watching, and fishing.	31 miles southwest of the St. Lucie Site	Development likely limited at specific points along the trail.	FDEP Jun 2010
Pelican Island National Wildlife Refuge	Management of habitats to sustain abundant populations of native species and to help recover threatened and endangered species. Recreational activities include hunting, fishing, canoeing, boating, and wildlife viewing.	31 miles north of the St. Lucie Site	Expansion of visitor facilities is planned. Other development would be limited within this refuge.	USFWS Sep 2006
Savannas Preserve State Park	Property (5227 acres) encompasses portions of the Atlantic Costal Ridge and the flatwoods and savanna-like wetlands associated with it. It harbors a unique set of natural communities that include sand pine scrub, flatwoods, marsh, and wet prairies. Public recreation activities include hiking, bicycle and horseback riding, canoe/kayaking, picnicking, wildlife viewing and environmental education.	2 miles west of the St. Lucie Site	Development of facilities for public use likely limited within this area.	FDEP Jun 2003
Seabranch Inlet State Park	Management of 913 acres of various different natural communities including a rare and important baygall, beach dune, and scrub communities. The park in only open to the public for hiking and nature appreciation.	14 miles south of the St. Lucie Site	Development likely limited within this area.	FDEP Oct 2002a
Sebastian Inlet State Park	This 971-acre park provides the typical recreational resources of Florida's coastal barrier islands with beach frontage on the Atlantic Ocean. Public recreation activities include hiking, biking, picnicking, camping, and bird watching in the upland communities.	35 miles north of the St. Lucie Site	Development likely limited within this area.	FDEP Dec 2008
St. Lucie Inlet Preserve State Park	Accessible only by private boat and provides 4786 acres consisting of mangrove swamps, maritime hammock, and undeveloped beach. Public recreation activities include swimming, snorkeling, scuba diving, sunbathing, fishing, primitive camping, picnicking, hiking, and nature appreciation.	14 miles south of the St. Lucie Site	Development likely limited within this park.	FDEP Oct 2002b

Table 9.3-18 (Sheet 8 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
St. Sebastian River Preserve State Park	Twenty archaeological sites and twenty-two distinct natural communities have been mapped in the 21,748-acre park including mesic flatwoods, prairie hammock, sandhill, scrubby flatwoods, and upland hardwood forests. Recreation activities include fishing, canoe/ kayaking, horseback riding, hiking, primitive camping, and nature appreciation.	33 miles northwest of the St. Lucie Site	Development likely limited within this area.	FDEP Oct 2005
Comprehensive Everglades Restoration Plan Projects				
C-44 Reservoir and Storage and Treatment Area	A component of the Indian River Lagoon - South Project consisting of a 3400-acre reservoir and 6200 acres of emergent vegetation.	20 miles south of the St. Lucie Site	Design and land acquisition for this project is completed. Construction is anticipated to begin in 2011.	SFWMD Feb 2006, USACE Feb 2010
Indian River Lagoon - South Project	The project includes construction of several above-ground reservoirs and stormwater treatment areas. The project will use constructed wetlands and muck removal to improve surface water management and water quality of several canal basins, as well as improve habitat in the St. Lucie Estuary and Indian River Lagoon.	16 miles southwest of the St. Lucie Site	Proposed. Project is scheduled to begin in 2010.	SFWMD Jun 2010, USACE Nov 2009, USACE Feb 2010
Lake Okeechobee Aquifer Storage and Recovery	Project proposes to increase regional storage while reducing both evaporation losses and the amount of land removed from current land use. This will be accomplished by a series of aquifer storage and recovery wells adjacent to Lake Okechobee with a capacity of one billion gallons per day and the associated pre- and post-water quality treatment facilities.	30 miles southwest of the St. Lucie Site	Five separate ASR pilot projects have been constructed around Lake Okeechobee and have provided five years of field data. Two more pilot systems began cycle testing in 2008.	USACE Undated, USACE Jun 2008
Lake Okeechobee Watershed Project	Construction of a 1984-acre reservoir and 3975-acre treatment area in the Taylor Creek/Nubbin Slough basin; a 10,281-acre reservoir in the Kissimmee River basin; a 5416-acre reservoir and 8044-acre treatment area in the Lake Istokpoga basin, and a 3730-acre wetland restoration site in Paradise Run in order to increase aquatic and wildlife habitat, regulate lake staging, reduce phosphorus loading, and reduce damaging releases to the surrounding estuaries.	Various locations in Okeechobee County	Proposed. Project is scheduled to begin in 2019.	USACE Undated, USACE Nov 2009

Table 9.3-18 (Sheet 9 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Melaleuca Eradication and other Exotic Plants	Project enhances efforts to control invasive exotic species in south Florida through mass rearing and controlled release of biological agents throughout the region.	Throughout the region	Proposed. Project is scheduled to begin in 2011.	USACE Nov 2009
North Palm Beach County - Part 1	Part 1 of this project includes portions of seven basins that will capture, store and treat excess water that is currently discharged to the Lake Worth Lagoon and use that water to enhance the Loxahatchee River, Loxahatchee Slough, and West Palm Beach Water Catchment Area.	26 miles south of the St. Lucie Site	Project in pre-construction, engineering, and design phase. Part 1 construction is estimated to be completed in 2014.	USACE Undated, USACE May 2005
North Palm Beach County - Part 2	Part 2 includes aquifer storage and recovery (ASR) with a capacity of 220 million gallons per day.	47 miles south of the St. Lucie Site	Project in pre-construction, engineering, and design phase.	USACE Undated
Central and Southern Florida (C&SF) Projects				
Herbert Hoover Dike Rehabilitation	Project to strengthen the 143-mile dike that surrounds Lake Okeechobee.	30.4 miles southwest of the St. Lucie Site	Construction is underway on the southeast section of the dike. Completion of the project is anticipated in 2025.	USACE Nov 2009
West Palm Beach Canal/ Stormwater Treatment Area - 1E	Project provides flood control, water quality and water supply to the C-51 basin in Palm Beach County.	45 miles south of the St. Lucie Site	Construction is underway. Completion of the project is expected in 2010.	USACE Nov 2009
Other Ecosystem Restoration Projects				
Lakeside Ranch Storage and Treatment Area	Construction of a 2700-acre wetland in western Martin County that will use emergent vegetation to remove phosphorus from stormwater runoff in the Taylor Creek/ Nubbin Slough basin before it enters Lake Okeechobee. The project has been divided into two phases, STA North and STA South.	37 miles west of the St. Lucie Site	Construction of STA North began in 2009. Final design of STA South is scheduled to be completed in 2010, and construction is scheduled to begin in 2011.	SFWMD Jun 2010, USACE Nov 2009
Mining Projects				
Brown Ranch Mine	Crushed stone mine	15 miles northwest of the St. Lucie Site	Operational	USGS 2005
Capron Trails Mine	Sand and gravel mine	12 miles south of the St. Lucie Site	Operational	USGS 2005
Fort Pierce Quarry	Crushed stone mine	18 miles southwest of the St. Lucie Site	Operational	USGS 2005

Table 9.3-18 (Sheet 10 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
Lake Point Mine	Development of a 959-acre commercial limestone quarry in Martin County	32 miles southwest of the St. Lucie Site	Proposed. CWA Section 404 permit application submitted April 2010.	ACOE Apr 2010a
Mecca-Ryan Operation	Sand and gravel mine	37 miles south of the St. Lucie Site	Operational	USGS 2005
Palm Beach Mine	Crushed stone mine	46 miles southwest of the St. Lucie Site	Operational	USGS 2005
St. Lucie Mine	Sand and gravel mine	12 miles southwest of the St. Lucie Site	Operational	USGS 2005
Other Actions/Projects				
Central and Southern Florida Flood Control Project	The C&SF Flood Control Project was authorized by Congress in 1948 to provide flood control, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources. Today the CS&F project includes 1000 miles of canals, 720 miles of levees, and almost 200 water control structures. It covers 16 counties over an 18,000-square-mile area from Orlando to the Florida Reef Tract. The existing project provides water supply, flood protection, water management and other benefits to South Florida. However, the project has had unintended negative effects on the Everglades and the entire south Florida ecosystem.	Throughout the region.	Operational	HRA Jun 2006
Arch Mirror South	Glass mirror manufacturer	13 miles northwest of the St. Lucie Site	Operational	FDEP Oct 2007
Louis Dreyfus Citrus Inc. - Indiantown Citrus Processing Plant	Food Manufacturer	26 miles southwest of the St. Lucie Site	Operational	FDEP Jul 2008b
Macho Products Inc	Protective equipment manufacturer	35 miles northeast of the St. Lucie Site	Operational	FDEP May 2007b
Maverick Boat Company	Fiberglass boat manufacturer	12 miles northeast of the St. Lucie Site	Operational	FDEP Jan 2006
Osceola Farms Co	Sugar manufacturer	40 miles southwest of the St. Lucie Site	Operational	FDEP Mar 2010b
Pratt & Whitney - Area C12 & C14	Engineering, manufacturing, and testing of gas turbine and rocket engines	29 miles south of the St. Lucie Site	Operational	PBCHD Jul 2004

Table 9.3-18 (Sheet 11 of 11)
Past, Present, and Reasonably Foreseeable Projects and Other Actions in the Vicinity of the St. Lucie Site

Project Name	Summary of Project	Location	Status	Reference
S2 Yachts Inc. Pursuit Division	Fiberglass boat manufacturer	12 miles northwest of the St. Lucie Site	Operational	FDEP Mar 2008
Sugar Cane Growers Cooperative of Florida	Sugar manufacturer	50 miles southwest of the St. Lucie Site	Operational	FDEP Aug 2006
Tropicana Products, Inc. - Fort Pierce Facility	Citrus product and animal feed manufacturer	9 miles northwest of the St. Lucie Site	Operational	FDEP Oct 2006
Twin Vee Catamarans	Fiberglass boat manufacturer	7 miles northwest of the St. Lucie Site	Operational	FDEP Oct 2008
Venture Marine Inc.	Fiberglass boat manufacturer	41 miles southeast of the St. Lucie Site	Operational	PBHCD Dec 2007
Water Reclamation and Wastewater Treatment Plants	Numerous plants	Within 50-mile radius of the Site.	Operational	FDEP Aug 2010a FDEP Aug 2010b
Future Urbanization	Construction of housing units and associated commercial buildings; roads, bridges and rail; construction of water and/or wastewater treatment facilities and associated pipelines.	Throughout the region.	Construction would occur in the future, as described in state and local land-use planning documents.	—
Various hospitals and industrial facilities that use radioactive materials	Medical and other isotopes	Within 50-mile radius of the Site.	Operational	—

9.4 ALTERNATIVE PLANT AND TRANSMISSION SYSTEMS

This section provides an analysis of alternative plant and transmission systems in relation to the proposed Units 6 & 7 in order to provide a determination as to whether any of these alternatives are environmentally equivalent or environmentally preferable to the proposed system. An environmental screening process was conducted for each potential alternative. Potential alternatives that were considered feasible for construction and operation at the proposed plant site that (1) are not prohibited by federal, state, regional, or local regulations, or Native American tribal agreements, (2) are consistent with any findings of the Federal Water Pollution Control Act, and (3) can be judged as practical from a technical standpoint with respect to the proposed dates of plant construction and operation were further evaluated to determine whether any of the potential plant and transmission system alternatives were environmentally preferable to the proposed system. If any of the potential alternatives are deemed to be environmentally preferable with the proposed system, a benefit-cost basis is provided to determine if any such system should be considered as a preferred alternative to the proposed system.

Subsection 9.4.1 evaluates alternative heat dissipation systems, Subsection 9.4.2 evaluates alternative circulating water systems, and Subsection 9.4.3 evaluates alternative transmission systems for comparison with the proposed plant and transmission systems. The proposed heat dissipation system for the Units 6 & 7 site is the round mechanical draft cooling tower. Water pumped from radial collector wells and/or a reclaimed water treatment plant (Subsection 9.4.2.1.1) is the proposed water supply for makeup water. The makeup water replaces water lost by evaporation, drift, and blowdown from the cooling towers. The proposed water discharge system for blowdown water is to the Boulder Zone of the Lower Floridan aquifer at a depth of approximately 2800–3450 feet (Subsection 9.4.2.2).

9.4.1 HEAT DISSIPATION SYSTEMS

9.4.1.1 Screening of Alternative Heat Dissipation Systems

This subsection presents alternatives to the proposed heat dissipation system (Section 3.4) based on the guidance provided in NUREG-1555. Alternatives considered are those generally included in the broad categories of once-through and closed-cycle systems. This subsection includes evaluation of alternatives, in comparison with the proposed system, to identify those systems that are environmentally preferable to the proposed system. In addition to once through cooling, the following closed-cycle category heat dissipation systems were considered:

- Cooling ponds
- Spray ponds
- Dry cooling towers

- Wet and Hybrid (Wet/Dry) Cooling Towers
    - — Natural draft
    - — Mechanical draft
    - — Fan-assisted natural draft
    - — Hybrid

An initial environmental screening of the alternative designs was done to eliminate those systems that are obviously unsuitable for use at the Units 6 & 7 site. In accordance with NUREG-1555, factors such as the following were considered in the initial screening process:

- — Land use (e.g., site size and terrain)
- — Water use (e.g., availability of cooling water)
- — Legislative restrictions

This initial screen is described in the following paragraphs.

9.4.1.1.1 Proposed Heat Dissipation System

For comparison, the round mechanical draft cooling tower is the proposed heat dissipation system for the Units 6 & 7 site. As presented in Section 3.4, six mechanical draft cooling towers would be required to dissipate a maximum waste heat load of up to 1.53E10 Btu/hour from the two units, would operate with approximately a 7.1°F approach temperature, and provide a less than 91°F return temperature at design ambient conditions. The circulating water system cooling towers will be octagonal and would rise approximately 67 feet above the top of the basin curb. Heat dissipation with wet cooling towers relies on evaporation for heat transfer. The water from the cooling system lost to the atmosphere through evaporation must be replaced. In addition, this evaporation would result in an increase in the concentration of solids in the circulating water. To control solids, a portion of the recirculated water must be removed, blown down, and replaced with make-up water from the raw water system. In addition to the blowndown and evaporative losses, a small percentage of water in the form of droplets (drift) is lost from the cooling towers.

9.4.1.1.2 Alternative Heat Dissipation Systems

9.4.1.1.2.1 Once-Through Cooling

The water requirements for a once-through cooling system for an AP1000 unit would be 850,000 gpm (WEC 2003). Once-through water requirements for both Units 6 & 7 would be 1,700,000

gpm, or about 3790 cubic feet per second. This withdrawal rate is approximately 44 times and 20 times the average makeup water withdrawal rate of 38,400 gpm and 86,400 gpm under normal operating conditions, with a reclaimed water and a marine water source; respectively, for the proposed system. The only water body in the vicinity of Units 6 & 7 that could supply this quantity of water is the Biscayne Bay, which is designated as an aquatic preserve.

In addition, once-through cooling water would pose risks of thermal effects and damage to aquatic organisms because of changes in water quality, impingement, and entrainment. Compliance with Section 316(a) of the Clean Water Act would apply and would prove difficult to attain.

9.4.1.1.2.2 Cooling Ponds

Turkey Point Units 1 through 4 currently operate with 5900-acre cooling canals. A pond of similar size would be required to support Units 6 & 7. The amount of land required for a cooling pond is not available at the proposed site. For this reason, cooling ponds were eliminated from further consideration.

9.4.1.1.2.3 Spray Ponds

This alternative is similar to cooling ponds because it involves creating new surface water bodies. Assuming sufficient heat dissipation could be achieved with a spray pond size of approximately 1 acre per 15 MWe (AEC 1973), Units 6 & 7 would require approximately 160 acres of spray pond. However efficiency may be lower due to the local climate. Spray modules promote evaporative cooling in the pond that reduces the land requirement relative to cooling ponds; however, this advantage is offset by higher operating and maintenance costs. This alternative would not reduce the environmental impacts relative to the proposed system. For these reasons, cooling ponds were eliminated from further consideration.

9.4.1.1.2.4 Dry Cooling Towers

This alternative is not suitable for the reasons described in the EPA's preamble to the final rule addressing cooling water intake structures for new facilities (66 FR 65256; December 18, 2001). Dry cooling carries high capital and operating and maintenance costs that are sufficient to pose a barrier to entry to the marketplace for some facilities. In addition, dry cooling has a detrimental effect on electricity production by reducing the efficiency of steam turbines. Dry cooling tower performance is dependent on the ambient dry bulb temperature. Thermal performance limitations under high ambient air temperature conditions would result in a very large dry tower array and the plant efficiency may be significantly reduced due to high circulating water temperature which increases steam turbine backpressure. The higher humidity in the area would also impact tower performance and cost. Dry cooling towers cause the facility to generate less energy than would be generated with wet cooling towers. This energy penalty is significant in the warmer southern

regions during summer months when the demand for electricity is at its peak and would result in an increase in environmental impacts as replacement generating capacity would be needed to offset the loss in efficiency from dry cooling. Therefore, dry cooling towers at the Units 6 & 7 site do not warrant further consideration.

9.4.1.1.2.5 Wet and Hybrid (Wet/Dry) Cooling Towers

Wet and wet-dry hybrid cooling towers are potential alternate heat dissipation systems for the Units 6 & 7 and are described below:

Natural Draft Cooling Tower

This design is the most commonly used cooling tower in nuclear power plants in the United States. Favorable features include the absence of fans, which provides for very low operating cost, low auxiliary power requirements, and minimal noise impact. Natural draft towers are very tall and may have negative public perception because the towers and plume are visible from a great distance. However, the height can be favorable in terms of environmental impact because the drift is dispersed at such a great height that the concentration that accumulates around the tower is lower than other tower designs. Traditional natural draft cooling towers cannot be used at the Units 6 & 7 site because of a site permit height restriction of 350 feet (MDC 2007), therefore, natural draft cooling towers are eliminated from further consideration.

Mechanical Draft Cooling Tower

Mechanical draft cooling towers are often the cooling tower design for power applications and the relatively low profile makes these a good choice when aesthetics are a major concern. This type of tower is in widespread use in industry, and many cooling tower vendors would be able to supply mechanical draft cooling towers. If necessary, this type of tower could be designed to be plume abated. Plume abatement should be considered when towers are located so that the plume will visually disturb surrounding communities or if the plume can settle on roadways, causing dangerous fogging and icing conditions. The use of traditional rectilinear mechanical draft cooling towers is not feasible because the area needed for the arrangement (spacing) of these towers to prevent recirculation and interference of moist hot air exiting the towers is not available at the Units 6 & 7 site versus the round mechanical draft cooling towers, the proposed heat dissipation system, that require less footprint.

Fan-Assisted Natural Draft Cooling Tower

The hyperbolic shell of the fan-assisted natural draft cooling tower achieves a natural draft effect which supports the fans arranged around the circumference of the cooling tower shell. Advantages of this design include reduced power consumption, favorable space requirements, minimized recirculation effects, optimum operational behavior for saltwater application, and

aesthetics. However, the extra section of fans results in a high auxiliary power load and makes this design taller than a rectilinear tower. The round design minimizes required spacing in between the towers. This type of tower is a feasible alternative for Units 6 & 7.

Hybrid (Wet-Dry) Cooling Tower

In this design, the circulating water flows in series first through a dry tower and then through a round forced draft cooling tower. This system provides the important benefit of water savings because when the dry tower is used, the duty on the round tower is lowered, decreasing evaporation. However, the dry tower component of the hybrid design is very large, requiring additional fans and resulting in higher overall power consumption. This design has the highest capital costs. The water usage of a hybrid system is generally one-third to one-half that for wet cooling towers. However, the comparative cost increases of the hybrid systems to the wet cooling systems do not outweigh water use savings of approximately one-half to two-thirds (U.S. EPA 2001a). Additionally, the EPA does not consider hybrid cooling towers as a candidate for best available technology for heat dissipation at new generating plants of the size proposed for the Units 6 & 7 site. Reasons include the lack of adequate demonstration of this technology's use at similar sized power plants. The EPA does note, however, that there is distinct potential for the use of hybrid cooling systems, especially in cases where plume abatement is concerned (U.S. EPA 2001b). Since most advantages to be gained by hybrid cooling towers are in areas of reduced fogging and icing and neither of these problems is of sufficient magnitude at Units 6 & 7 and because this system is not considered a best available technology by the EPA, this cooling tower is precluded from further analysis.

9.4.1.2 Feasible Alternatives

The results of the initial environmental screening process indicate that the round mechanical draft and fan-assisted natural draft cooling towers are suitable heat dissipation system alternatives for Units 6 & 7. The round mechanical draft cooling tower is the proposed primary heat dissipation system (Subsections 3.4.1 and 5.3.3.1). In accordance with NUREG-1555, the fan-assisted natural draft alternative cooling tower design is evaluated for land use, water use, and other environmental requirements for comparison with the proposed heat dissipation system (Table 9.4-1).

9.4.1.3 Summary

Table 9.4-1 offers a summary comparison of the relative environmental impacts and regulatory considerations for the base case and the identified potential alternative heat dissipation system for Units 6 & 7. The results of the evaluation indicate that the alternate design (fan-assisted natural draft cooling tower) is not environmentally equivalent or preferable to the proposed design

(round mechanical draft cooling towers). It should be noted that a cost comparison has not been included since no alternate was found to be environmentally preferable to the primary design.

9.4.2 CIRCULATING WATER SYSTEMS

In accordance with NUREG-1555, this subsection considers alternatives to the plant circulating water system in order to identify systems that are environmentally preferable or environmentally equivalent to the proposed system. The review includes an investigation of the following plant circulating water systems:

- Intake systems
- Discharge systems
- Water supply
- Water treatment

NUREG-1555 indicates that the applicant should consider only those alternatives that are applicable at the proposed site and are compatible with the proposed heat dissipation system. As described in Subsection 9.4.1, the round mechanical draft cooling tower is the proposed heat dissipation system for the Units 6 & 7 site. An initial environmental screening was performed for each alternative of the component of the circulating water system to eliminate those systems or components that are unsuitable for use at the proposed site. Those systems or components that were determined to be feasible after the initial screening process were analyzed further to determine if they are environmentally preferable or equivalent to the proposed system. That analysis is described below.

9.4.2.1 Intake Systems

9.4.2.1.1 Screening of Alternate Intake Systems

The most important elements of the intake system are its location and configuration. The following factors were considered in siting the alternate intake systems:

- Water availability
- Water quality
- Intake hydraulics
- Constructability and cost

- Maintenance and dredging
- Operation and maintenance

Water availability and water quality considerations are addressed in Subsection 9.4.2.3.

The results of this analysis indicate that in addition to the proposed intake system from the selected water sources—reclaimed water and/or saltwater supplied by radial collector wells, there are two alternate water sources which were found feasible for operation at Units 6 & 7: the Lower Floridan aquifer (Boulder Zone, a groundwater source), and the Card Sound Canal (a surface water source). Two different types of intake systems are conceptualized to withdraw water from the Card Sound Canal. These intake systems are conventional shoreline intake structures with active screens, and intake with passive panel-type screens equipped with air back flush. The proposed circulating water intake system and the three alternative intake systems (two alternatives for Card Sound Canal and one for the Lower Floridan aquifer Boulder Zone production wells) are presented below.

9.4.2.1.2 Proposed Intake System

The proposed raw water for the circulating water system would be supplied from two different sources, reclaimed water and saltwater. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, additional makeup water would be saltwater supplied from radial collector wells. Reclaimed water would be provided from the Miami-Dade Water and Sewer District (MDWASD) with further water treatment provided at an FPL reclaimed water treatment facility. The treated reclaimed water would be supplied to and stored in the makeup water reservoir. Pumps for each unit would provide the required makeup water by transferring treated reclaimed water from the makeup water reservoir to the circulating water system.

The saltwater would be supplied by radial collector wells. A radial collector well consists of a central reinforced concrete caisson, extending below the ground to target depth. The conceptual design for a radial collector well is further presented in Subsection 3.4.2.1.1.2. The wells would be recharged from the marine environment (Biscayne Bay), combining the desirable features of extremely high well yields with induced seabed filtration of suspended particulates. This improves the raw water quality and simplifies the treatment process.

The proposed conceptual design for Units 6 & 7 consists of four 33 1/3 percent radial collector wells with a capacity of 30,000 gpm per well. Three wells would meet the makeup water requirements for the circulating water systems; the fourth would be an installed spare. Two 50 percent pumps (15,000 gpm capacity per pump) in each well caisson would transfer the saltwater to the circulating water system.

Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The design for a typical radial collector well is illustrated in Figure 3.4-2. The wells would be designed and located to induce recharge from Biscayne Bay.

These two proposed raw water makeup sources do not require any cooling water intake structures as defined by 40 CFR 125.83. Because the proposed raw water makeup sources do not require a cooling water intake structure as defined by 40 CFR 125.83, there would be no construction-related, aquatic ecology, threatened or endangered species, and minimal water use impacts as a result of constructing/operating a cooling water intake structure. As described in Chapter 4, the environmental impacts of constructing the reclaimed water pipeline and radial collector wells would be SMALL.

9.4.2.1.3 Alternate Intake Systems

9.4.2.1.3.1 Lower Floridan Aquifer Boulder Zone

As described in Subsection 9.4.2.3, deep groundwater from the Boulder Zone in the Lower Floridan aquifer could alternatively supply the cooling water for Units 6 & 7. The conceptual design for a Boulder Zone cooling water supply system consists of a groundwater production well field adjacent to the nuclear island and shown in Figure 9.4-1. The well field would consist of approximately 15 wells, each capable of producing 10 mgd. At any time, two wells would operate in standby mode and act as reserve wells in the event of unplanned well outages or scheduled maintenance events. Because of the very high Boulder Zone transmissivities, projected drawdown is insignificant, and there is significant flexibility in selecting final well location placement and spacing. Production wells would be constructed with telescoping steel casings to protect drinking water resources in the overlying Upper Floridan and surficial (Biscayne) aquifers from cross-contamination with the Boulder Zone groundwater. The well boreholes would extend past the bottom of the final lower casing to ensure adequate communication between the open borehole and the cavernous water producing intervals of the Boulder Zone. Well casings would be cemented in place from top to bottom with sulfate/corrosion resistant cement.

The Boulder Zone production wells are not considered a cooling water intake structure as defined by 40 CFR 125.83. There would be no aquatic ecology, threatened or endangered species, or water use impacts of construction and operation. There would be no costs associated with intake construction and operating a cooling water intake structure, and Section 316(b) of the Clean Water Act would not apply. It is unknown at this time if use of the Boulder Zone as a source of makeup water for Units 6 & 7 and as a discharge location for regional wastewater and Units 6 & 7 would impact water quality and affect long-term plant operations.

9.4.2.1.3.2 Card Sound Canal

Card Sound Canal is a canal that runs from the southern end of the Turkey Point Units 1 through 4 cooling canals to Card Sound. Card Sound Canal is not hydraulically connected to the Units 1 through 4 cooling canals; however, it is connected to Card Sound. Card Sound Canal was created to serve as the cooling water discharge canal for Units 1, 2, 3, and 4 as part of an open-cycle cooling system. This cooling system was subsequently abandoned, leaving a 1-mile reach of abandoned canal in hydraulic connection with Card Sound, which is approximately 4 miles south of the site. The canal is 200 feet wide and 20 feet deep. Makeup water to Units 6 & 7 could be supplied from an intake located in the northernmost end of the canal where it meets the cooling canals for Units 1 through 4. A pipeline would connect the intake to Units 6 & 7. Figure 9.4-2 is a conceptual layout of the pipeline and intake structures.

There are two alternative intake structures proposed to withdraw water from Card Sound Canal:

- Conventional shoreline intake structure
- Intake with passive panel type screens equipped with air back flush

Conventional Shoreline Intake Structure on Card Sound Canal

The conventional shoreline pump intake would be located on the east bank of the canal on an existing wetland and convey water to the site by pipeline routed by the east side of the canal. The intake system would consist of a trash rack and a raking system, traveling water screens and screen wash pumps, baffle blocks and curtain walls, and pumping systems. Three 50-percent pumps along with two 50-percent traveling screens are considered for each unit with a common forebay for the two units. The conceptual plan view and sectional view of the intake system are shown in Figures 9.4-3 and 9.4-4. A canal width of 200 feet and a canal bottom elevation of –20 feet NAVD 88 are considered in developing the conceptual design.

Conventional shoreline-type intake systems with traveling screens are widely used in power plant applications and their performance behavior is well documented. In order to comply with the Clean Water Act Article 316(b), fine mesh screens with a velocity less than 0.5 feet per second and with fish return capability would be used. The intake system would meet the requirements of Article 316(b) of the Clean Water Act relating to impingement, entrainment, and aquatic monitoring.

Passive Panel-Type Screens with Air Flush on Card Sound Canal

An alternate intake system on Card Sound Canal would consist of passive panel screens with polyhedron-shaped screens supported on a stainless steel frame and an air backwash unit. The polyhedron sides that are directed to the water surface are equipped with the screen panels

made with special cling-free elements. The sides that are directed to the canal bed remain closed to avoid debris (sediment) ingress from the bed and for the optimum performance of air backwash. Air spray nozzles are arranged inside the polyhedron enabling a particularly effective screen backwash by pressurized air pulses. A compressor generates the air pressure pulses. The system is suitable for brackish or ocean environment because of its screen element types and polyhedron shape that have been optimized to respond to the fouling topology in surface water. The system is also considered superior over the traditional cylindrical wedge wire screens where fouling tends to develop over the screen drum surface and inside the drum. The number and size of the polyhedron are designed based on the required flow rate and available minimum water depth. The modular structure of the panel screen system would facilitate maintenance of the screens.

The polyhedron screen system conveys water to a wet well onshore, which is then pumped to the site. Flow to the wet well is controlled by the difference in hydraulic head between the well and the canal. Operating the air backwash system would be automated based on the pressure difference between the polyhedron and the wet well representing debris accumulation on the screen as well as on a timer, which is typically two to three times a day. Because the polyhedron is closed at the bottom, air backwash is more effective in removing debris from the screen surfaces compared to the traditional wedge wire screen where the air flush is outside the screen drum.

Although the panel-type intake system is a relatively new technology compared to the cylindrical wedge wire screens such as Johnson screens, its operation would be advantageous in reducing debris, biofouling, and ease of maintenance in a marine environment. In addition, passive screens are considered superior in minimizing impingement and entrainment, and would be environmentally preferable over traditional shoreline intake with active screens. Use of passive screens also eliminates the need for a fish return capability and the associated impacts on fish. The plan view and sectional view of the conceptual panel type intake system are shown in Figures 9.4-5 and 9.4-6.

9.4.2.1.4 Feasible Alternatives

The results of the initial environmental screening process indicate that alternate intake structures in the Boulder Zone and Card Sound Canal (conventional and passive intake structures) may be suitable for Units 6 & 7. In accordance with NUREG-1555, the feasible alternative intake structures are evaluated for comparison with the proposed intake structure system. The details of that evaluation are presented in Table 9.4-2.

9.4.2.1.5 Summary

A comparison of these alternative circulating water intake structures for Units 6 & 7 for construction-related, aquatic ecology, threatened or endangered species, and water use impacts is provided Table 9.4-2. Based on the analysis, the alternate intake structures (Boulder Zone and Card Sound Canal) are not environmentally preferable to the proposed intake structures. Therefore, no cost comparison has been provided. The proposed intakes would have minimal impact on ecological resources when compared to the alternate surface water intakes. The Boulder Zone intake alternative would be considered as environmentally equivalent as the proposed alternatives. However, it is unknown at this time if use of the Boulder Zone as a source of makeup water for Units 6 & 7 and as a discharge location for regional wastewater and Units 6 & 7 would impact water quality and affect long-term plant operations.

9.4.2.2 Discharge Systems

9.4.2.2.1 Screening of Alternative Discharge Systems

This subsection describes potential alternatives for discharge from the circulating water system and compares these alternatives to the proposed system. Alternatives for the discharge of blowdown from the circulating water system were identified. The potential blowdown receiving water bodies were selected from those within proximity of Units 6 & 7. The following discharge alternatives were considered. The initial screen is described in the following paragraphs.

9.4.2.2.1.1 Proposed Discharge System

The proposed circulating water system for Units 6 & 7 would discharge to the Boulder Zone of the Lower Floridan aquifer. Blowdown from the cooling tower would be injected into deep wells onsite. Subsection 2.3.1.2 provided details on subsurface injection in south Florida.

Class I injection wells would be developed in the proposed Units 6 & 7 power block area (Figure 3.1-3). Individual Class I injection wells would be designed and constructed to maintain an injection rate of approximately 6750 gpm. Injection wells would be located so that they would be separated from adjacent injection wells by at least 150 feet. However, the high Boulder Zone permeability allows significant flexibility in selecting the final well location placement in the event that suitable land availability is an issue.

Twelve wells would be installed for the proposed intake system for discharge to the Boulder Zone. Ten of the twelve wells would be used to accommodate 57,600 gpm of projected blowdown, and two wells would be used as backup. The injection zone, or interval, would be accessed via an open borehole spanning the entire vertical extent of the Boulder Zone. At the Units 6 & 7 site, this interval lies at an approximate elevation 2900 feet MSL and is presumed to be approximately 200 feet thick. A 24-inch-diameter injection casing with an 18-inch diameter

liner pipe would convey the blowdown to the top of the Boulder Zone. Class I injection wells would be constructed with telescoping steel casings cemented in place from top to bottom with sulfate, heat, and corrosion resistant cement. Figure 3.4-3 presents a schematic cross-sectional view of the conceptual design for a Class I injection well constructed in the Boulder Zone. Preliminary design showing operational characteristics and details of the Boulder Zone injection wells are provided in Subsection 2.3.2.

9.4.2.2.1.2 Alternate Discharge Systems

9.4.2.2.1.2.1 Biscayne Bay

Blowdown from the circulating water system would be discharged to Biscayne Bay using a shoreline or offshore diffuser. Construction of either type of diffuser would require alteration of, or construction on, the seabed. Rule 62-4.242, Florida Administrative Code prohibits activities, such as the dredging required to construct a shoreline or offshore diffuser that would degrade water quality of Outstanding Florida Waters. Therefore, this discharge system is eliminated from further consideration.

9.4.2.2.1.2.2 Card Sound

Blowdown from the circulating water system would be discharged to Card Sound using a shoreline or offshore diffuser. Construction of either type of diffuser would require alteration of, or construction on, the seabed and is therefore eliminated from further consideration.

9.4.2.2.1.2.3 Atlantic Ocean

Blowdown from the circulating water system would be discharged to the Atlantic Ocean via an offshore diffuser located outside the boundary of the Florida Keys National Marine Sanctuary, a distance of about 14.5 miles from the proposed plant site. Construction of the pipeline conveying blowdown from the circulating water system to the offshore diffuser would require dredging and burial of the pipe in the seafloor, or directional drilling or tunneling beneath the seabed to avoid disturbance of the seabed within park or sanctuary boundaries and is therefore eliminated from further consideration.

9.4.2.2.1.2.4 Card Sound Canal

Blowdown from the circulating water system would be discharged to Card Sound Canal using a shoreline discharge structure or a diffuser at the canal bed located at the north end of the canal. This blowdown discharge alternative could not be used in conjunction with the Card Sound Canal makeup water supply alternative due to the potential for recirculating the concentrated, dissolved constituents in the blowdown back to the makeup water intake.

9.4.2.2.1.2.5 Turning Basin

Blowdown from the circulating water system would be discharged to the turning basin using a shoreline discharge structure located at the southwest end of the basin. This blowdown water discharge alternative could not be used in conjunction with the turning basin makeup water supply alternative due to the potential for recirculating the concentrated, dissolved constituents in the blowdown back to the makeup water intake. Extensive construction and/or dredging within the canal would be required along with resulting thermal impacts; this alternative is therefore eliminated from further consideration.

9.4.2.2.1.2.6 Wastewater Treatment Plant

Blowdown water from the Units 6 & 7 cooling towers could be returned to the MDWASD for disposal via their existing effluent disposal wells as an alternate circulating water discharge. The same pipeline route for the conveyance of makeup water supply would be used to return the blowdown water discharge. The location the MDWASD is shown in Figure 9.4-7 along with the FPL right-of-way.

Water quality acceptance criteria and capacity restrictions on wastewater treatment plant discharges by deep well injection could restrict the use of this option for blowdown discharge if the makeup water for the circulating water system is supplied from a saltwater source such as radial collector wells, Boulder Zone, or the Card Sound Canal.

9.4.2.2.1.2.7 Cooling Canals

The onsite cooling canals are part of the closed-cycle circulating water system for Units 1 through 4. Because the temperature of the discharge water from the new Units 6 & 7 would be lower than the temperature of the existing (Units 1 through 4) circulating water discharges, the cooling canals could be used as an option for blowdown discharge.

The cooling canals are considered viable only when the makeup water supply is obtained from the MDWASD. Use of reclaimed water would allow higher cycles of concentration in the cooling tower resulting in a smaller blowdown discharge rate. Even at four cycles of concentration, the salinity of the blowdown (on the order of 4000 milligram/liter (mg/L) total dissolved solids) would be significantly less than the current salinity of the cooling canals (approximately 55,000 mg/L total dissolved solids). The blowdown water would be released to the discharge (hot) side of the existing cooling canals to initiate maximum mixing. The conceptual designs of the blowdown pipeline route and diffuser details are shown in Figures 9.4-8 and 9.4-9.

When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, additional makeup water would be saltwater supplied from radial

collector wells. The proposed backup water supply source provides saltwater, thus a backup discharge option (i.e. Boulder Zone discharge) would also be necessary.

9.4.2.2.1.2.8 Wetlands Rehydration

One of the alternatives of the Biscayne Bay Coastal Wetlands Restoration project requires a source of fresh water to rehydrate wetlands in the vicinity of Units 6 & 7. This blowdown discharge alternative entails conveying cooling tower blowdown via canals or pipelines to the wetlands north and west of Units 6 & 7 to rehydrate these wetlands. Because fresh water is required for rehydration purposes, any makeup water supply alternative using brackish or saltwater sources would be precluded for this blowdown discharge alternative. Also, the need to apply water to the wetlands exists only during the dry months of the year. During wet periods, water would need to be discharged to a different receiving water body. Additionally, the blowdown discharge may need to be treated to a level suitable for use in the restoration project. For these reasons, this alternative is eliminated from further consideration.

9.4.2.2.2 Feasible Alternatives

A screening analysis of the potential blowdown discharge alternatives was conducted to identify the feasible blowdown discharge alternatives. The objective of the screening analysis was to identify the feasible blowdown discharge alternatives to be considered for further environmental assessment. The results of the initial environmental screening process indicate that three were determined to be feasible. The three feasible alternative wastewater discharge systems were identified for Units 6 & 7 as follows:

- Cooling Canals
- Card Sound Canal
- Wastewater treatment plant

In accordance with NUREG-1555, the three feasible alternatives are evaluated for comparison with the proposed discharge system (Table 9.4-3). A comparison of these alternative circulating water discharge structures for Units 6 & 7 for construction-related, aquatic ecology, threatened or endangered species, and water use impacts is provided in Table 9.4-3. Based on the comparison, no discharge alternative was found to be environmentally equivalent or preferable to the proposed alternative; therefore no cost comparison has been provided. The proposed discharge structure would have minimal impact on ecological resources when compared to the alternative discharge structures.

9.4.2.2.3 Summary

Table 9.4-3 offers a summary comparison of the relative environmental impacts and regulatory considerations for the proposed discharge system and the alternative discharge systems for Units 6 & 7. The results of the evaluation indicate that the alternate discharge systems are not environmentally preferable to the proposed discharge system. Thus, a cost comparison has not been included.

9.4.2.3 Water Supply

9.4.2.3.1 Screening of Alternative Water Supply Systems

This subsection presents potential alternatives for water supply to the circulating water system and compares these alternatives to the proposed system. The proposed water supply for Units 6 & 7 will use reclaimed water from the MDWASD South District Wastewater Treatment Plant as makeup water for the circulating water system. Another fully operational water supply system will be saltwater supplied from radial collector wells. The circulating water system will be designed to accommodate 100 percent supply from reclaimed water, saltwater, or a combination of the two sources, based on operation of the units. The ratio of water supplied by the two makeup water sources will vary based on the availability of reclaimed water from the MDWASD South District Wastewater Treatment Plant.

Potential sources were identified and organized into five categories based on the original source of the makeup water supply. These identified potential alternative makeup water sources are those water bodies or water sources within proximity to the proposed plant site that are capable of supplying the makeup water needs of the units. The categories of the makeup water supply sources identified the following:

- Marine source
- Groundwater source
- Reclaimed water source
- Onsite surface water source
- Offsite surface water source

An initial environmental screening of the alternative designs was done to eliminate those systems that are unsuitable for use at the Units 6 & 7 site. The initial screen is described in the following paragraphs.

9.4.2.3.2 Proposed Water Supply System

Each of the two proposed water supplies to the circulating water system is described below:

Reclaimed Water — Proposed Raw Water System

Reclaimed water would be from the MDWASD South District Wastewater Treatment Plant, which is located approximately 9 miles north of the site.

Conceptually, the supply water would be conveyed from the MDWASD South District Wastewater Treatment Plant to the site by a pipeline that would be generally follow an existing FPL right-of-way. Locating the MDWASD South District Wastewater Treatment Plant and the right-of-way is shown in Figure 9.4-10.

There are no known current or future restrictions on use of this water for this application. However, to ensure uninterrupted water supply for plant operation, water supply from a backup source is highly desirable. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, additional makeup water would be saltwater supplied from radial collector wells.

Radial Collector Well — Proposed Raw Water System

As presented in Subsection 2.3.1, water derived from a radial collector well—a substratum collector of saltwater—from the geological formations underlying Biscayne Bay will supply the required backup cooling water for Units 6 & 7. The water bearing units of interest include the Pleistocene Miami Oolite and Fort Thompson formation. Water in these formations is saltwater at the proposed plant site, with salinity concentrations transitioning to freshwater levels several miles west of the site. The water bearing formations extend from approximately –5.0 feet to –115 feet below MSL NAVD 88. Transmissivities of these formations have been estimated to range from 4.8E04 square feet per day to greater than 2.0E06 square feet per day.

Saltwater cooling water sources in the Pleistocene Miami Oolite and Fort Thompson formation would be supplied by a series of radial collector wells (see Subsection 2.3.1 for details of the radial collector wells). A radial collector well consist of a central reinforced concrete caisson, approximately 25 feet inside diameter, extending below the ground to the target depth. Well screens project laterally outward into the surrounding earth materials in a radial pattern at the target depth. The well screen typically ranges from 12 to 30 inches in diameter and typically extends as far from the caisson as horizontal drilling conditions allow. In seawater applications, the caisson is constructed in an above grade watertight fashion and completed with a pump house.

There are no present or known future restrictions on use of water from the radial collector wells. Projected yield for the radial collector wells is provided in Subsection 2.3.1.

9.4.2.3.3 Marine Sources

Biscayne Bay

The Biscayne Bay is a shallow coastal lagoon that lies immediately east of the proposed Units 6 & 7 site. The bay is bounded on the west by the mainland and on the east by a series of barrier islands including Elliott Key that forms the northern limit of Florida Keys. In the vicinity of the plant site, the bay is about 6 miles in width and relatively shallow, having a maximum depth of about 9 feet.

The bay adjacent to the Units 6 & 7 site is within the boundary of Biscayne National Park. This portion of the bay also serves as part of the Intracoastal Waterway. Makeup water would be supplied from either a shoreline or offshore intake. Due to the shallowness of the bay, a shoreline intake would require dredging a channel in the seafloor to ensure sufficient capacity and is therefore eliminated from further consideration.

Card Sound

Card Sound is located south of Biscayne Bay and south-southeast of the proposed plant site for Units 6 & 7, and is part of the Biscayne Bay Aquatic Preserve. Card Sound is about 3.5 miles wide, bounded on the northwest by the mainland and on the southeast by Key Largo, and relatively shallow with a maximum depth of approximately 11 feet. A portion of the Intracoastal Waterway traverses the entire length of Card Sound. Makeup water for the circulating water system would be supplied from either a shoreline or offshore intake. Due to the shallowness of the bay, a shoreline intake would require dredging a channel in the seafloor to ensure sufficient capacity and is therefore eliminated from further consideration.

Atlantic Ocean

The portion of the Atlantic Ocean considered as a potential makeup water supply alternative for the circulating water system (CWS) lies approximately 14.5 miles east of the proposed plant site and outside the eastern boundary of the Florida Keys National Marine Sanctuary, which is defined by the 300-foot isobath. Makeup water would be supplied by an offshore intake.

The 14.5-mile-long pipeline conveying makeup water from the offshore intake to the plant site would traverse the 13-mile width of Biscayne National Park and a 1.5-mile-wide portion of the Florida Keys National Marine Sanctuary. Construction of the pipeline would require dredging and burial of the pipe in the seafloor, or directional drilling or tunneling beneath the seabed to avoid

disturbance of the seabed within park or sanctuary boundaries and is therefore eliminated from further consideration.

Card Sound Canal

Card Sound Canal was originally intended to serve as the cooling water discharge canal for Turkey Point Units 1, 2, 3, and 4 as part of an open-cycle cooling system. This cooling system was subsequently abandoned, leaving an approximately 1-mile reach of remnant canal in hydraulic connection with Card Sound. The canal is located about 4 miles south of the site and lies within FPL property. The canal is 200 feet wide and 20 feet deep. Makeup water for the circulating water system would be supplied from an intake located in the northernmost end of the canal where it dead ends.

Since Card Sound Canal is in hydrological connection with Card Sound, Biscayne Bay, and ultimately the Atlantic Ocean, there is plentiful marine water supply for Units 6 & 7 makeup to the cooling towers and there are no present or future water restrictions on use of water from this source.

Turning Basin

The turning basin is about 0.5 miles northeast of the proposed Units 6 & 7 and in hydraulic connection with Biscayne Bay. The basin lies within FPL property and is about 0.3 mile in length. Makeup water for the CWS would be supplied from an intake located in the southwestern end of the basin. Construction and/or maintenance dredging within the basin could be required and is therefore eliminated from further consideration.

9.4.2.3.4 Groundwater Sources

Biscayne Aquifer

The Biscayne aquifer is a shallow, unconfined aquifer consisting of highly permeable limestone and less permeable sandstone and sand. The area of the aquifer is approximately 4000 square miles, and is the principal water source for Dade and Broward counties and the southeastern part of Palm Beach County.

The quality of water in Biscayne aquifer is classified as fresh, however, in the vicinity of the plant site and beneath Biscayne Bay, groundwater contained in the hydrogeologic units equivalent to the Biscayne aquifer increases in salinity approaching the bay. The salinity of the groundwater adjacent to and underlying the bay is roughly equal to that of seawater.

At the site, the water bearing zone extends from slightly below ground surface to about 115 feet below sea level. Being in direct hydraulic connection with the ocean, the quality of water produced from these units underlying the bay would be saltwater. The portion of the Biscayne

aquifer that is designated as an EPA “sole source aquifer” is by definition the fresh (potable) portion of the aquifer. Circulating water system makeup water from the freshwater portion of the Biscayne aquifer would be derived from an inland well field of vertical water supply wells. Miami-Dade County Resolution Z-56-07, condition 4 requires that FPL shall not apply for any water withdrawals from the Biscayne Aquifer as a source of cooling water for the proposed facilities and is therefore eliminated from further consideration.

Upper Floridan Aquifer

The Upper Floridan aquifer underlies the Biscayne aquifer. It is comprised of a thick sequence of carbonate rocks (limestone and dolomite) generally 500 to 600 feet thick and consisting of several thin water-bearing zones of high permeability interlaid with thick zones of low permeability.

The most transmissive permeable zone is found at the top of the Upper Floridan aquifer and is associated with the unconformity at the top of the rocks of Eocene age. The quality of water produced from the Upper Floridan aquifer is classified as brackish. Makeup water for the circulating water system would be obtained from an onsite well field. Miami-Dade County Resolution Z-56-07, Condition 5 requires that any withdrawals from the Floridan aquifer will not interfere with current legal users of that source and meet the substantive requirements of Section 24-43.2 of the Code. An aquifer performance test would be required to demonstrate that no legal users of the aquifer would be affected and another water supply source would likely be required to supplement that supplied from the Floridan aquifer and therefore this water source is eliminated from further consideration

Lower Floridan Aquifer (Boulder Zone)

Deep groundwater from the Boulder Zone in the Lower Floridan aquifer is an alternative water supply for cooling water to Units 6 & 7. The Boulder Zone consists of a deeply buried zone of highly transmissive, cavernous limestone, and dolomites of the lower Eocene Oldsmar Formation. The Boulder Zone occurs under confined conditions. Transmissivities of greater than 3E06 square feet per day are typically reported. The Boulder Zone underlies a 13-county area in southern Florida and lies at a depth of approximately 2800 feet to 3450 feet at the Turkey Point site. Average dissolved solids concentration of Boulder Zone groundwater is approximately 37,000 mg/L total dissolved solids.

The conceptual design for a Boulder Zone cooling water supply consists of a groundwater production well field adjacent to the nuclear island (Figure 9.4-1). Details of the well field are described above with intake structures.

There are no permitted users, other than FPL of the Floridan aquifer within approximately 5 miles of Units 6 & 7. The cavernous nature of this formation suggests that this source could provide

100 percent of the cooling tower makeup water demand for Units 6 & 7. However, aquifer pumping tests would be required to characterize the hydrogeologic properties of the Boulder Zone and finalize the well and production well designs. This information is also needed to support groundwater modeling. Sampling and analysis of the Boulder Zone groundwater would be necessary to characterize the water quality, evaluate whether water pretreatment may be needed and to support any treatment system design, if needed. Initial evaluations indicate a strong possibility for recirculation of wastewater into the cooling water supply if the Boulder Zone were to be used for discharge of cooling tower blowdown. However, aquifer testing and groundwater modeling have not been conducted to determine exact aquifer yield since this water supply is not environmentally equivalent to using reclaimed water/radial collector well water.

9.4.2.3.5 Onsite Surface Water Sources

Cooling Canals

The hypersaline surface water currently in the cooling canals would be used as makeup for the circulating water system via direct withdrawal. This withdrawal would necessarily increase the volume of groundwater that infiltrates into the cooling canals from the surficial aquifer. The increased groundwater infiltration to the cooling canals would decrease the fresh water groundwater inflow to the Biscayne Bay. The impacts of the reduced inflow to Biscayne Bay may not be acceptable and is therefore eliminated from further consideration.

Deepened Cooling Canals

This alternative would entail deepening a portion of the cooling canals to increase the hydraulic connectivity between the surface water in the cooling canals and the groundwater in the surficial aquifer. The hypersaline surface water in the cooling canals would be used as makeup for the circulating water system via direct withdrawal, which would necessarily increase the volume of groundwater that infiltrates into the cooling canals. The increased groundwater infiltration to the cooling canals would decrease the fresh water groundwater inflow to the Biscayne Bay. The impacts of the reduced inflow to Biscayne Bay may not be acceptable and is therefore eliminated from further consideration.

9.4.2.3.6 Offsite Water Sources

Comprehensive Everglades Restoration Plan

The Biscayne Bay Coastal Wetlands preferred plan, Alternative O, includes plans to rehydrate wetlands in the vicinity of the proposed plant site. Fresh water would be obtained by building a new reservoir or expanding the Florida City Canal in an area northwest of the proposed plant site. In either case, the water would be used jointly by the South Florida Water Management District and Units 6 & 7, with makeup water being obtained from an intake at the shoreline of the

reservoir and conveyed to the circulating water system. However, because South Florida Water Management District plans and Comprehensive Everglades Restoration Projects require use of fresh water for public water supply and environmental restoration projects, it is unlikely that the required makeup water supply would be permitted for industrial use and is therefore eliminated from further consideration.

Private Property Reservoir

Fresh water would be provided by expanding an existing surface water reservoir located about 7 miles west of the proposed plant site, or by constructing a new reservoir on private property in an undetermined location. Makeup water would be withdrawn from reservoir using an intake at the shoreline of the reservoir, and conveyed to the circulating water system by pipeline. However, because South Florida Water Management District plans and Comprehensive Everglades Restoration Projects require use of fresh water for public water supply and environmental restoration projects, it is unlikely that the required makeup water supply would be permitted for industrial use and is therefore eliminated from further consideration.

9.4.2.3.7 Feasible Water Supply Systems

A screening analysis of the potential water supply system alternatives was conducted to identify the feasible water supply alternatives. The objective of the screening analysis was to identify the feasible water supply alternatives to be considered for further environmental assessment. The results of the initial environmental screening process indicate that two alternatives were determined to be feasible. In addition to the proposed water supplies, the two feasible alternative water supply systems were identified for Units 6 & 7 as follows:

- Boulder Zone Groundwater Source (saltwater)
- Card Sound Canal Marine Source (saltwater)

9.4.2.3.8 Summary

Table 9.4-4 summarizes the details of the evaluation of the proposed and alternative water supplies. The results of the evaluation indicate that the alternative water supplies are not environmentally preferable to the proposed water supply. Thus, a cost comparison has not been included.

9.4.2.4 Water Treatment

Evaporating water from cooling towers leads to an increase in chemical and solids concentrations in the circulating water, which in turn increases the scaling tendencies of the water. The circulating water system for Units 6 & 7 would be operated so that the concentration of

solids in the circulating water would be approximately four to one-and-a-half times the concentration of solids in the makeup (e.g., four to one-and-a-half cycles of concentration). The cooling tower would be operated at a maximum of four cycles of concentration when 100 percent of the makeup water is MDWASD South District Wastewater Treatment Plant reclaimed water and operated at a minimum of one-and-a-half cycles of concentration when 100 percent of the makeup water is from the radial collector wells. When makeup is a mixture of MDWASD South District Wastewater Treatment Plant reclaimed wastewater and radial collector wells, the cooling tower would operate at cycle of concentrations required for proper water chemistry determined by the makeup water quality of the mixture of the two sources of water.

As described in Subsection 3.3.2.1, reclaimed water from the MDWASD would be treated at the FPL reclaimed water treatment facility and used as circulating water system cooling tower makeup. The makeup water for the circulating water cooling towers will receive treatment to prevent biofouling in the intake structure and raw water supply piping to the circulating water cooling towers. The Miami-Dade potable water supply will provide water for the service water cooling towers, potable water system, fire protection system, demineralized water system, and other miscellaneous water users. The makeup water for the service water cooling towers will receive treatment to prevent biofouling in the intake structure and raw water supply piping to the service water cooling towers.

Additional treatment for biofouling, scaling, and suspended matter with biocides, antiscalants, and dispersants, respectively, will be performed at the water treatment facility as needed for the circulating water system. This treatment normally occurs through injecting chemicals into the system piping during circulation of the water withdrawn from the basins through the circulating water and service water systems. The cooling tower cycles of concentration would be adjusted to prevent scale formation or deposition from affecting tower performance.

Sodium hypochlorite would be used to control biological growth in the circulating water system for Units 6 & 7. Alternative biocides could include hydrogen peroxide or ozone. The final choice of water treatment chemicals or combination of chemicals is dictated by makeup water conditions, technical feasibility, economics, and discharge permit requirements. If alternative treatment chemicals are to be used to improve the conditions of the makeup water, they would have to be chosen from those that can be approved by the EPA or the state of Florida, and the volume and concentration of each chemical constituent discharged to the environment would meet the requirements established in the applicable permits. The anticipated aquatic impacts of alternative chemical use would be environmentally equivalent to those resulting from the use of the proposed chemicals described in Subsection 3.3.2. Since all blowdown from the circulating water system will be discharged to the Boulder Zone (proposed method of discharge), there would be minimal-to-no environmental impacts. Mechanical treatment and other non-chemical treatment such as ultraviolet are not viable options due to the large quantity of water requiring treatment, and, hence the large scale water treatment system necessary for the plant’s cooling system. No

further alternatives are proposed since it is unlikely that any other water treatment alternatives would be preferable when compared against the proposed treatment system.

9.4.3 TRANSMISSION SYSTEMS

As specified in the guidelines in NUREG-1555, ESRP 9.4.3, this summary discussion identifies the feasible and legislatively compliant alternative transmission systems. Detailed descriptions of the transmission line system are described in Subsection 2.2.2 and Section 3.7, and associated environmental impacts are described in Chapters 4 and 5. Corridors are defined as transmission line routes of variable widths, which are sufficient to contain the eventual rights-of-way (NUREG-1555, Section 3.7.I, Note (a)). New transmission line corridors will be required to integrate Units 6 & 7 to the Florida electrical grid system, as described in Subsection 2.2.2 and Section 3.7.

Approval of transmission line corridors is under authority of the Florida Power Plant Siting Act, §403.501-518, F.S. A route study and corridor selection process was performed for the new lines under the requirements of this Act. The results of these analyses are presented in the following paragraphs.

9.4.3.1 Alternatives to the Proposed Transmission System Design

FPL has performed an interconnection and integration study that examined multiple alternatives for integrating Units 6 & 7 into the FPL transmission system. The study incorporated the latest data provided for the Units 6 & 7 project. Models used for the analysis were based on the latest available load forecasts, generation expansion plan, and system plans for 10 years into the future. As the load forecasts and system plans are updated (e.g., topological changes, generation retirements, or additions) in the coming years, the performance of the system will be reviewed as part of the normal transmission system assessment to ensure compliance with the North American Electric Reliability Corporation (NERC) and Florida Reliability Coordinating Council (FRCC) reliability standards and the effectiveness of the proposed transmission plan. To the extent necessary, adjustments to the results of this study may be warranted. In such circumstances, adjustments will be communicated to the relevant stakeholders, including the NERC and FRCC.

The evaluation process used to develop the transmission-related requirements for the Units 6 & 7 interconnection and integration plan considers factors associated with planning, construction, and operating the electric system. The process began with an evaluation team, including engineers from transmission and substation planning, operations, engineering, project management, permitting, and siting, who together performed the evaluation and developed a transmission interconnection and integration plan. The evaluation process considers many factors, as outlined below, in order to develop an effective transmission plan. The resultant plan is in compliance with NERC and FRCC reliability standards.

Generally, the process was to evaluate the proposed generating plant site location to determine its proximity to existing transmission facilities. To the extent there are existing transmission facilities nearby, those facilities are assessed to determine their capabilities for reliably interconnecting and integrating the proposed new generation into the transmission system as a firm FPL generation resource. Other factors, such as those listed below are considered (as applicable):

- Amount of generation (MW) being added at the new generation site, and the dispatch profile of the new generation resource relative to FPL's other generation resources in serving FPL's load
- Capabilities to upgrade existing facilities
- Capability of transmission lines needed, right-of-way requirements, existing right-of-way capabilities, siting of new right-of-way, permitting requirements, and expected time frame to acquire right-of-way and necessary permits
- Ability to transmit power efficiently
- Existing and new substation requirements, capabilities, and availability
- Impact on existing facilities
- Constructability
- Overall compatibility with the system (e.g., do the new facilities require new material stocking requirements or the need for new tools to maintain?)
- Compliance with NERC and FRCC reliability standards
- Operating considerations (e.g., what are the maintenance requirements of the proposed interconnection and integration facilities and how will they impact the ongoing operation of the system)
- Expected in-service testing and commercial operations dates for new generation (e.g., which transmission facilities necessary for interconnection and integration need to be in-service before the commercial operation in-service date for testing)
- Material adverse impact on third party transmission owner(s)
- Initial and recurring costs of facilities and operations

Taking into account these factors, a feasible interconnection and integration plan was developed and power flow studies for a proposed plan were performed. These power flow studies were used to evaluate the performance of the system and to converge on specific new system facilities and upgrades that would be needed to interconnect and integrate the new generation into the transmission system.

9.4.3.1.1 Assumptions

The project consisted of two nuclear generating units each with a total net summer continuous capability of 1100 MW, with June 2018 and June 2020 in-service dates. The proposed plan tested for interconnecting and integrating the Units 6 & 7 to the FPL network was connecting the units to a new 500/230 kV substation known as Clear Sky substation.

The latest available peak case model for the summer of 2017 from the 2007 FRCC databank with firm long-term contractual obligations was used to create a base case model for the power flow analysis. The model was modified to reflect the 2020 load forecasts for FPL. The model was also updated to include the most up-to-date information on the FPL system (e.g., planned new transmission facilities and upgrades, committed new generation, confirmed transmission service obligations, etc.). The resulting model is the reference base case.

The study case was derived from the aforementioned base case while also modeling Units 6 & 7, which were modeled as two generating units with a total net generating capacity of approximately 2200 MWe.

9.4.3.1.2 Acceptance Criteria

The study was performed by conducting a single contingency power flow analysis. Studied contingencies include each generating unit outage (including the largest generating unit), and each transmission line outage (including the most critical transmission line outage). The performance of the system must meet NERC reliability standards for normal and single contingency operation. Overloads greater than 100 percent of a facility rating (and not evident before Units 6 & 7) that were materially aggravated (more than 3 percent) when compared to the reference case, for the same contingency, were attributed to the new units. Similarly, low voltages that were materially lower (more than 1.5 percent) when compared to the reference case, for the same contingency, are attributed to Units 6 & 7.

9.4.3.1.3 Interconnection and Integration Study Results

The tested interconnection and integration plan for Units 6 & 7 would require constructing a new Clear Sky substation with two 500/230 kV autotransformers. Two new 500 kV lines, approximately 43 miles long, will be constructed to connect the Clear Sky substation to the Levee 500 kV substation. A new 230 kV line will be constructed between the Clear Sky substation and

the Davis 230 kV substation, continuing on to the Miami substation. A second new 230 kV line will be constructed between the Clear Sky substation and Pennsuco 230 kV substation. A new line will also be constructed to the Turkey Point substation from Clear Sky. The results are summarized below:

Transmission Line (kV)	Termination Point	Length (miles)
Clear Sky-Levee # 1 (500 kV)	Levee 500 kV	43
Clear Sky-Levee # 2 (500 kV)	Levee 500 kV	43
Clear Sky-Davis (230 kV)	Davis 230 kV	19
Davis-Miami (230 kV)	Miami 230 kV	18
Clear Sky-Pennsuco (230 kV)	Pennsuco 230 kV	52
Clear Sky-Turkey Point (230 kV)	Turkey Point	0.4

9.4.3.2 Corridor Selection

Turkey Point Units 6 & 7 will require new transmission facilities to reliably interconnect and integrate the project into FPL's transmission system, as described in Subsection 9.4.3.1. The requirement to add transmission facilities is the result of the necessity to deliver approximately 2200 MWe net capacity of new generation from the site to FPL's load centers. It should be noted that the Clear Sky substation is on the Units 6 & 7 plant area and therefore is not further considered in the selection process.

The preferred corridors for the Turkey Point project were selected by a multidisciplinary transmission line siting team consisting of experts in land use, engineering, and the environment.

The objective of the corridor selection study was to select certifiable corridors that balance land use, socioeconomic, environmental, engineering, and cost considerations. Corridor selection methods were designed to be:

- Integrative of multidisciplinary siting criteria
- Rational and objective in decision making
- Sensitive to social and environmental conditions
- Responsive to regulatory requirements
- Reflective of community concerns and issues
- Capable of accurate documentation and verification

The corridor selection process consisted of four major tasks:

- Transmission study area definition
- Resource mapping and alternative route delineation
- Evaluating alternative routes and selecting the preferred corridors
- Community outreach

A summary describing each of these major tasks is presented in the following subsections. The transmission line siting team was assisted throughout this process by members of the public who participated in a public outreach program developed specifically for this transmission line routing study.

Transmission Study Area Definition

As presented in Subsection 9.4.3.1, FPL determined the best option to integrate this power to the FPL transmission system was to build a new onsite substation (Clear Sky) and new transmission lines to the existing Davis, Miami, Levee, and Pennsuco substations. The Clear Sky to Levee and Pennsuco substations corridor is known as the West Preferred Corridor. The Clear Sky to Davis and Miami substations corridor is known as the East Preferred Corridor. The following paragraphs discuss the transmission corridor selection.

West Preferred Corridor

The corridor selection process was based primarily on the geographic location of the starting and ending substations. A study area was first selected that incorporated the Clear Sky, Levee, and Pennsuco substations and FPL's existing transmission lines into those substations. Since much of the west study area is dominated by low-density residential development, agricultural and nursery operations, conservation lands, mining activities, and relatively few existing linear features (roads, other transmission lines) with which to collocate, there were immediately only a few obvious choices for routes. FPL has an existing 230 kV transmission line on a 330-foot-wide right-of-way leaving the Turkey Point site and intersecting with a 138 kV line which continues west and north for several miles. A portion of this available right-of-way, which was acquired by FPL in the 1960s and early 1970s, traverses what became the Everglades National Park (ENP) expansion area. From the Levee substation, there are also existing transmission lines and roads that provide potential routes to the Pennsuco substation.

East Preferred Corridor

The corridor selection process was based primarily on the geographic configuration of the starting and ending substations. A study area was first selected that incorporated the Clear Sky, Turkey Point, Davis, and Miami substations and FPL's existing transmission lines into those

substations. Since much of the east study area is dominated by high-density residential development, there are several existing linear features (roads, railroads, other transmission lines) with which to collocate. FPL has existing 230 kV transmission lines on a 330-foot-wide right-of-way leaving the Turkey Point site all the way to the Davis substation. From there, FPL has available transmission line, roadway, railway, or other linear features to follow to the Miami substation.

Resource Mapping and Alternative Route Delineation

FPL first evaluated the study areas for all such opportunities and constraints in a regional screening mapping exercise. Resource mapping information was obtained from available information sources, including local, state, and federal agency data files, particularly Miami-Dade County's geographic information system (GIS); the Florida Geographic Data Library (FGDL); the Florida Natural Areas Inventory (FNAI); SFWMD; and other commercial non-agency databases. FPL used a technique of overlay mapping through the use of computer mapping software programs such as AutoCAD® and ArcView®. Use of computer mapping allowed flexibility in adding new information as it became available and modifying coverage to analyze certain constraints or opportunities. Table 9.4-5 provides a listing of the types of resources mapped. Once those resources were mapped, the team developed alternative routes that attempted to best avoid or minimize certain constraints and take advantage of certain opportunities. Figures 9.4-11 and 9.4-12 depict the west and east alternative routes studied, respectively.

Then using predetermined route selection guidelines summarized in Table 9.4-6, FPL developed several alternative route segments that when combined could connect the substations.

Based on the results of the alternative route identification, 34 route segments were identified, comprising 99 potential alternative route alignments between the Clear Sky substation and the existing Levee and Pennsuco substations.

Thirty five route segments were identified, comprising 134 potential alternative route alignments between the Clear Sky substation site and the existing Davis and Miami substations.

Finally, using predetermined route selection guidelines contained in Table 9.4-6, FPL developed several alternative route segments that when combined could connect these substations.

Alternative Route Evaluation and Preferred Corridor Selection

The objective of this task was to evaluate, in detail, the routes identified and ultimately select a West and East Preferred Corridor.

The first step of the alternative route evaluation process was to perform a systematic, quantitative evaluation of each route alternative using environmental, land use, cost, and engineering criteria.

Table 9.4-7 presents the criteria used in this evaluation. These criteria are based on application of accepted transmission line siting factors used on projects across Florida.

Data used to apply these criteria came from the regional screening map data, recent digital aerial photography for the study area, input from agencies and local governments, ground surveys of routes, and input from the community outreach program. Each segment was then analyzed for each of the criteria listed in Table 9.4-7, and the value for each criterion was recorded by segment.

The relative weight (importance) of each criterion to be used in the alternative route evaluation was then established by the multidisciplinary transmission line siting team. These criteria and weights were validated through input from the community obtained as part of the community outreach program, discussed in Subsection 9.4.3.4.

The routes were ranked according to their weighted composite score on all criteria. This score represented a route's potential for impacting a combination of all the relevant resources (Table 9.4-7), with the lowest score being the most favorable.

Recognizing that the quantitative evaluation alone does not provide a true indication of the potential suitability of the routes, the transmission line siting team then began evaluation of the alternatives with a qualitative assessment of more site-specific conditions. This evaluation included analyses of site-specific siting issues and opportunities, additional ground and aerial surveys, and feedback and comments received at agency meetings, the nine community open houses, and individual meetings with area residents and property owners. Table 9.4-8 depicts a list of the types of criteria evaluated at this stage.

After evaluation of all the identified route alignments and significant public input throughout the route selection process, the West Preferred, West Secondary and East Preferred routes were selected (see Figures 9.4-13 and 9.4-14).

Finally, corridor boundaries were delineated along the West and East routes. The West/East Preferred Corridors are of variable width, being wider in certain areas to give FPL an appropriate amount of flexibility in accommodating site-specific conditions or taking advantage of certain opportunities, and narrower in other areas to avoid existing siting constraints or to utilize existing FPL rights-of-way.

9.4.3.3 Preferred Corridors

Based on the results of the first three tasks discussed above, East and West Preferred Corridors were selected. The corridors are depicted on Figures 9.4-13 and 9.4-14. The following paragraphs discuss the preferred corridors selected.

West Preferred Corridor Description

The proposed corridor width varies from a minimum of 170 feet to a maximum of 3700 feet along the length of the West Preferred Corridor. This allows FPL the ability to maximize use of existing FPL rights-of-way, avoid constraints in some areas, and provide FPL the necessary flexibility to locate a right-of-way consistent with local conditions and landowner and agency input. Once a corridor is certified, FPL expects to use a combination of existing and relocated right-of-way of approximately 330 feet in width from Clear Sky to Levee and then use an existing right-of-way of approximately 170-feet minimum width between the Levee and Pennsuco substations. The total length of the West Preferred Corridor is approximately 52 miles; between Clear Sky and Levee is about 44 miles, and between Levee and Pennsuco is about 8 miles.

West Preferred Corridor from Clear Sky Substation to Levee Substation

The West Preferred Corridor begins within the Turkey Point plant property at the boundary of the Units 6 & 7 plant area. The proposed location of the West Preferred Corridor is on FPL's Turkey Point plant property for a distance of approximately 3.2 miles. For the first mile, the corridor is 3700 ft wide. The remainder of the corridor on the Turkey Point plant property is approximately 500 ft wide.

FPL has an existing approximately 330- to 370-ft-wide right-of-way running west from the Turkey Point plant property for several miles. There is currently one single-pole, 230-kV line in that right-of-way that runs for a distance of approximately 4.5 miles. The West Preferred Corridor is collocated with this existing transmission right-of-way. The two 500-kV lines and the 230-kV line can be constructed within this available right-of-way alongside the existing 230-kV line. Therefore, the corridor is limited to FPL's existing right-of-way boundaries in this location, and no additional property will be necessary.

The West Preferred Corridor continues to run due west for another approximately 4.25 miles following FPL's existing right-of-way containing a 138-kV line. Just west of SW 202nd Avenue, the West Preferred Corridor and existing 138-kV line turn to the north and then run due north for approximately 14.5 miles to SW 136th Street where the 138-kV line turns due east and departs the West Preferred Corridor. The West Preferred Corridor then continues for approximately 1 mile to SW 120th Street.

The width of the West Preferred Corridor in this area remains 330 to 370 feet, collocated with FPL's existing right-of-way. Adjacent to the Miami-Dade County Natural Forest Community (NFC) north of SW 304th Street, the corridor is expanded by 50 feet to the west to allow flexibility in accessing the transmission line within the NFC.

Although FPL currently owns sufficient right-of-way in fee or by easement for this project through the ENP and the Water Conservation Area 3B (WCA-3B), FPL has been working cooperatively

with multiple federal and state agencies to relocate this portion of the right-of-way to outside the ENP. To that end, these agencies have entered into agreements with FPL to implement the relocation. This land exchange has been authorized by the federal Omnibus Public Land Management Act of 2009. As a result of relocating the 7.4-mile portion of the right-of-way now within the ENP Expansion Area to outside the ENP, contiguous portions of the existing right-of-way to the north and south must also be relocated to provide a continuous right-of-way. FPL is agreeable to the proposed right-of-way exchange in this area if this can be accomplished in a timely manner and is therefore proposing the relocated right-of-way as its West Preferred Corridor.

At SW 120th Street, the West Preferred Corridor turns due east and continues to the SFWMD L-31N Canal right-of-way and is approximately 900 to 1000 feet wide. This alignment will allow FPL to locate the proposed transmission lines at the periphery of the ENP and provide the opportunity to use the existing SFWMD L-31N levee as an access road.

The West Preferred Corridor continues to follow the L-31N Canal right-of-way for several miles, crossing U.S. Highway 41/Tamiami Trail, and then runs parallel to the L-30 Canal right-of-way. In this area, the West Preferred Corridor is approximately 900 to 1000 feet wide and provides the opportunity to use the existing SFWMD L-30N levee as an access road.

Approximately 3 miles north of U.S. Highway 41/Tamiami Trail, the West Preferred Corridor turns due east along an existing FPL right-of-way (at approximately NW 41st Street) and proceeds to the Levee substation. In this area, the West Preferred Corridor is limited to the existing FPL 330- to 1100-foot-wide right-of-way. At the Levee substation, the two 500-kV lines terminate, but the corridor expands around the substation to approximately 1750 feet (to accommodate the proposed Clear Sky-Pennsuco 230-kV line bypassing the substation) and lies entirely within FPL property.

From Clear Sky to Levee, the West Preferred Corridor crosses the jurisdictions of Miami-Dade County and Florida City.

West Preferred Corridor from Levee to Pennsuco

Beginning at the existing Levee substation area, the West Preferred Corridor exits the substation property heading east approximately 4.4 miles within an existing FPL right-of-way along NW 41st Street between NW 147th Avenue and NW 137th Avenue and NW 50th Street between NW 137th Avenue and NW 107th Avenue. The right-of-way within this portion of the West Preferred Corridor, which ranges from approximately 170 to 1750 feet (exiting the Levee substation) wide, currently accommodates multiple transmission lines and has room to accommodate the new 230-kV line.

At NW 107th Avenue, the corridor turns due north and follows the existing FPL right-of-way paralleling NW 107th Avenue approximately 4 miles to the existing Pennsuco substation. The West Preferred Corridor paralleling NW 107th Avenue averages 170 feet wide and is wholly located within FPL's existing right-of-way.

From the Levee substation to Pennsuco substation, the West Preferred Corridor crosses the jurisdictions of Miami-Dade County, Doral, and Medley.

West Secondary Corridor

FPL is proposing one alternate corridor to its West Preferred Corridor, which is referred to as the "West Secondary Corridor."

The West Secondary Corridor is an alternate for the West Preferred Corridor in the ENP and WCA-3B areas. The West Secondary Corridor deviates from the West Preferred Corridor at SW 120th Street in the 8.5 SMA and continues to follow FPL's existing right-of-way directly northward through the ENP Expansion Area for approximately 7.4 miles to U.S. Highway 41/Tamiami Trail. There, the West Secondary Corridor crosses U.S. Highway 41/Tamiami Trail and then turns northeastward along FPL's existing right-of-way to its intersection with the West Preferred Corridor along Krome Avenue. The West Secondary Corridor is approximately 330 to 370 feet wide and is wholly located within existing FPL right-of-way. The total length of FPL's West Secondary Corridor is approximately 51 miles; the length where it differs from the West Preferred Corridor is 12 miles.

The West Secondary Corridor is being proposed as an alternative option in the event the previously described proposed right-of-way exchange is not completed on a timely basis.

East Preferred Corridor

The proposed corridor width varies from approximately 150 to a maximum of 2200 feet along the length of the East Preferred Corridor. This allows FPL the ability to maximize use of existing FPL rights-of-way, avoid constraints in some areas, and provide the necessary flexibility to locate a right-of-way consistent with local conditions and landowner and agency input. Once a corridor is certified, FPL expects to use an existing FPL 330-foot-wide right-of-way from the Turkey Point plant property to the Davis substation. From the Davis substation FPL proposes to use an existing FPL right-of-way of variable width north and east to U.S. Highway 1. After reaching U.S. Highway 1, FPL generally plans to locate within an existing transportation right-of-way of variable width northeast to the vicinity where Interstate 95 (I-95) and Metrorail diverge. The corridor is expanded, however, around the Metrorail stations (Dadeland South, Dadeland North, Douglas Road, Coconut Grove, Vizcaya, and Brickell). This is to provide flexibility in locating the right-of-way at these congested areas, while also maintaining the ability to accommodate potential future development associated with these mass transit stations. In the vicinity where

I-95 and Metrorail diverge, the corridor expands to provide flexibility in locating the right-of-way as it approaches the Miami substation. The total length of the East Preferred Corridor is approximately 36.7 miles; between Clear Sky and Davis is about 19 miles, and between Davis and Miami is about 18 miles.

East Preferred Corridor from Clear Sky to Davis

The East Preferred Corridor begins within the Turkey Point plant property at the boundary of the Units 6 & 7 plant area. The first 1.8 miles of the East Preferred Corridor is entirely within the Turkey Point plant property and will accommodate both the Clear Sky-Turkey Point 230-kV and Clear Sky-Davis 230-kV transmission lines. In this area, the corridor varies from 330 to 800 feet in width. FPL has a multi-circuit transmission line right-of-way running north from the Turkey Point substation for approximately 17 miles to the Davis substation. North of the Turkey Point plant property, the East Preferred Corridor is limited to that existing transmission line right-of-way, which is approximately 330 feet in width, and will accommodate the Clear Sky-Davis 230-kV transmission line.

After exiting the Turkey Point plant property, the corridor continues due north for several miles and then turns west along SW 261st Street until the corridor crosses Florida's Turnpike (Homestead Extension) and turns northwestward to U.S. Highway 1. After crossing U.S. Highway 1, the corridor again proceeds due north to approximately SW 212th Street, where it turns northwest to SW 208th Street and then north again. It continues due north to approximately SW 164th Street, where it turns northeast to the Davis substation. At this point, the corridor includes the entire FPL property surrounding Davis substation. The corridor from Clear Sky to Davis is within the jurisdiction of Miami-Dade County.

East Preferred Corridor from Davis to Miami

North of the Davis substation along SW 131st Street, the corridor turns eastward along an existing FPL multi-circuit transmission line easement of varying widths for about 4.4 miles to U.S. Highway 1. At this point, FPL's existing easement and two transmission lines cross U.S. Highway 1 and continue east, while FPL's East Preferred Corridor heads northeastward along U.S. Highway 1.

Along U.S. Highway 1, the corridor encompasses the U.S. Highway 1/Busway right-of-way and is generally widened to include an additional 30 feet on either side of this transportation corridor. It is FPL's intent to locate its right-of-way along the Busway right-of-way immediately west of the U.S. Highway 1 right-of-way. However, since the authority to place the new line within the Busway right-of-way has not yet been secured, and to provide flexibility in a relatively congested siting area, the East Preferred Corridor is approximately 260 feet wide in this portion of the route.

Along the east side of U.S. Highway 1, the corridor includes a narrow strip of the jurisdictions of Palmetto Bay and Pinecrest.

When the corridor reaches the Palmetto Expressway/Dadeland area, it is widened to approximately 2200 feet. The east corridor boundary in this area remains generally 30 feet east of the U.S. Highway 1 right-of-way. The west corridor boundary expands to approximately 30 feet west of the SW 77th Avenue right-of-way. After crossing Kendall Drive, the boundary turns east approximately 30 feet north of the Kendall Drive right-of-way and then turns north approximately 30 feet west of the Palmetto Expressway right-of-way. When the west corridor boundary reaches the middle of the Snapper Creek Canal, it turns back to the east following the centerline of the Snapper Creek Canal (parallel to Dadeland Mall Road) to the Florida East Coast (FEC) right-of-way located along SW 70th Avenue. The corridor boundary then proceeds north approximately 30 feet west of the FEC right-of-way to the centerline of SW 80th Street and then proceeds east back to 30 feet west of the U.S. Highway 1/Metrorail right-of-way. The widening of the corridor in this area will provide flexibility in siting the transmission line in a heavily congested area.

Proceeding northeastward along U.S. Highway 1 from the Dadeland area, the corridor generally includes the area from 30 feet east of the east right-of-way boundary of U.S. Highway 1 to 30 feet west of the west boundary of the Metrorail right-of-way. The corridor crosses the jurisdiction of South Miami at this point. The corridor varies in width depending on the widths of those transportation rights-of-way. FPL also expands the corridor to include the centerline of Ponce de Leon Boulevard beginning at SW 57th Avenue/Red Road northeast to Ruiz Avenue. This expansion of the corridor will provide the opportunity to collocate the new transmission line with the existing 138-kV transmission line on the east side of Ponce de Leon Boulevard. This area crosses the jurisdiction of Coral Gables.

The corridor is further expanded to accommodate siting constraints around the Douglas Road Metrorail station and provide the opportunity to incorporate other transmission improvements planned independent of the Units 6 & 7 project, thereby avoiding another transmission line segment in this area. The west corridor boundary in this area expands to include approximately 30 feet north of Ruiz Avenue, approximately 30 feet west of SW 38th Avenue, and approximately 100 feet north of Bird Road/SW 40th Street until it reaches a point approximately 30 feet west of the Metrorail/U.S. Highway 1 right-of-way. From this location to the Miami substation, the East Preferred Corridor lies within the jurisdiction of the City of Miami.

Further north, the corridor is again expanded at the Coconut Grove Metrorail station both to the north and south of the U.S. Highway 1/Metrorail transportation corridor to provide flexibility in a relatively congested area. In this area, the west corridor boundary proceeds approximately 30 feet west of the SW 29th Avenue right-of-way, approximately 30 feet north of the SW 27th Terrace right-of-way and then approximately 250 feet east of the SW 27th Avenue right-of-way until the boundary reaches 30 feet north of the Metrorail/U.S. Highway 1 transportation corridor,

at which point it again proceeds approximately 30 feet west of the Metrorail right-of-way boundary. South of U.S. Highway 1 in this location, the corridor boundary proceeds approximately 30 feet south of the SW 28th Terrace right-of-way, approximately 30 feet east of the SW 27th Avenue right-of-way, approximately 30 feet south of the SW 28th Street right-of-way, and then approximately 30 feet east of the SW 26th Avenue right-of-way until the boundary reaches 30 feet south of the U.S. Highway 1 right-of-way.

Proceeding northeastward, the corridor is again expanded in the vicinity of the Vizcaya Metrorail station to provide flexibility around the station. The corridor is expanded to include a short stretch of SW 1st Avenue and the Metrorail parking lot on the north (west) side of U.S. Highway 1.

Just north of the Vizcaya Metrorail station, I-95 intersects the East Preferred Corridor. Here the west (north) corridor boundary widens to proceed approximately 30 feet north (west) of the SW 1st Avenue right-of-way and to a point approximately 30 feet west of the intersection with the I-95 right-of-way. The east (south) corridor boundary in this area proceeds approximately 30 feet south of the U.S. Highway 1 right-of-way, and then turns east approximately 30 feet east of the South Miami Avenue right-of-way. Approximately 30 feet north (east) of the SW 26th Road right-of-way, the east corridor boundary proceeds west to approximately 30 feet east of the I-95 right-of-way. The east corridor boundary then proceeds north (east) approximately 30 feet east of the I-95 right-of-way boundary. In the area of SW 19th Road, I-95 and the east corridor boundary turn to the west. The east corridor boundary then proceeds north (east) approximately 30 feet south of the Metrorail right-of-way.

Where I-95 crosses over to the west side of Metrorail, the East Preferred Corridor is again widened to allow flexibility in the approach to the Miami substation. The west edge of the corridor crosses I-95 from west to east and borders the east right-of-way boundary of I-95 north to SW 5th Street. From there, the west edge of the corridor turns northeast across the Miami River into the Miami substation property.

Along the east side of the corridor in this area, the corridor boundary extends approximately 30 feet east of the Metrorail right-of-way past Simpson Park and then east approximately 30 feet south of the SW 15th Road right-of-way to 30 feet east of the SW 1st Avenue right-of-way, where it turns north to SW 7th Street. The corridor boundary then turns northeast for a short distance along the east road right-of-way of South Miami Avenue, then turns north to the west of South Miami Place, and then turns northwest to cross the river. This alignment continues due north along the east boundary of the Metrorail property north of the Miami River and then to the Miami substation.

The East Preferred Corridor in this area of Miami allows flexibility in siting an overhead route to the Miami River, the crossing of which is at present proposed to be subaqueous.

The total length of the East Preferred Corridor is approximately 37 miles.

9.4.3.4 Community Outreach Program

FPL extended considerable effort to inform and involve the public during the route selection process that produced the preferred corridors. FPL used direct mail, a community e-survey, nine open houses, a newspaper advertisement, a project Web page, two agency workshops, meetings with local governments and regional and state agencies, a project e-mail address, and a toll free telephone number to share information and provide an opportunity for interested persons to learn more about the project and express their views.

Initially, using the Miami-Dade County Property Appraisers' and FPL customer databases, more than 260,000 letters were sent to FPL customers and property owners within 0.5 mile from the potential routes that were under consideration. This letter was sent in English and Spanish, introduced the transmission line improvement project, and invited people to attend upcoming open houses. Enclosed with the letter was a map of Miami-Dade County showing the potential routes being studied and a list of the locations, dates, and times for the nine open houses.

Prior to the open houses, the team was able to identify from the FPL database those customers within a half mile of the routes who have provided their e-mail addresses and allow unsolicited e-mail. These 64,000 customer accounts were sent an e-survey that asked people which of the selection criteria the respondents thought were more important. These surveys generated results that validated the route selection criteria used.

Nine open houses were held in November and December 2008 with the intent of spreading them out to different geographical sites along the potential routes. More than 350 people attended these open houses. During the open houses, visitors were able to talk directly, informally, and one-on-one with FPL project team members. They could learn about the project and the routes being considered, view maps and aerial photographs of the routes being evaluated, and specifically identify on Google Earth® their home or property in relation to the alternative routes under consideration. Engineers, biologists, land use planners and other FPL representatives in attendance were there to answer questions and review information provided about the project and FPL on display boards and in brochures. Attendees could express their views and provide feedback to FPL for consideration in the route selection process.

Two agency workshops were held with local, regional, and state government staff at the initiation of the route selection process and after the open houses as the team began to narrow their focus. The staff personnel provided valuable input regarding special features and community values of their jurisdiction, future plans for development, and ways to communicate with their constituents.

Additional one-on-one meetings and contacts with local, regional, and state governments were held throughout the selection process, not only to collect relevant data and maps, but to also

seek input on route selection issues. Agencies and local governments provided important information about the routes FPL was studying, as well as individuals and groups who might have specific interest in the project. Some of the agencies and local government representatives proposed alternate routes that were considered and studied by FPL.

FPL representatives were also available to meet with community groups, homeowner associations, and property owners upon request to discuss the project route selection and route selection process, as well as the Florida Electrical Power Plant Siting Act (PPSA) process.

The FPL project team incorporated what they learned through the community outreach program into the preferred corridor selection decision. Members of the public and governmental agencies who participated through the various components of the program were able to suggest the following to the team:

- Places to consider or avoid in routing.
- Other linear facilities to consider for collocation with the proposed line.
- Which evaluation criteria should be considered as more important.
- Specific routes to evaluate.
- Unique or important study area features or characteristics that should be given consideration in route selection.
- Areas under consideration for future development that could potentially affect a route.
- Existing operational considerations for land uses on or near the rights-of-way.
- Preferences on structure design for the 500 kV lines.
- Ways to effectively communicate with the public regarding the project.

Table 9.4-1 (Sheet 1 of 2)
Analysis of Heat Dissipation System Alternatives

Factors Affecting System Selection	Round Mechanical Draft Cooling Towers — Proposed	Fan-Assisted Natural Draft Towers — Alternate
Land Use		
Onsite land requirements	The round mechanical draft would require approximately 30 acres to support 2 AP1000 units.	The fan-assisted natural draft would require approximately 30 acres to support 2 AP1000 units.
Terrain considerations	Terrain features of the Units 6 & 7 site are suitable for the round mechanical draft.	Terrain features of the Units 6 & 7 site are suitable for a fan-assisted natural draft system.
Floodplain Alterations	The round mechanical draft cooling tower would not result in modifications of the floodplain (site will be raised to elevation above floodplain).	The fan-assisted natural draft cooling tower would not result in modifications of the floodplain (site will be raised to elevation above floodplain).
Wetlands or Critical Habitat Issues	The Units 6 & 7 site is a critical non-nesting habitat for the American crocodile so constructing the round mechanical draft would disturb approximately 30 acres of critical habitat land during construction and slightly less during operation.	The Units 6 & 7 site is a critical non-nesting habitat for the American crocodile so constructing the fan-assisted natural draft would disturb approximately 30 acres of critical habitat land during construction and slightly less during operation.
Terrestrial Biota	Impacts to terrestrial biota are presented in Subsection 4.3.1.	Impacts to terrestrial biota are described in Subsection 4.3.1. Impacts from constructing and operating the fan-assisted natural draft would be similar to impacts from constructing and operating the round mechanical draft.
Water Use	Intake requirements for round mechanical draft would be for makeup water and would consist of pumps, piping, and valves. There are no foreseen impacts to aquatic biota associated with constructing or operating the saltwater wells (radial collector wells) or the reclaimed water source. Circulating water makeup quantity (to replace water lost by evaporation and drift) for the proposed system is provided in Table 3.3-1. The discharge water quality is provided in Section 3.6 and the quantity is provided in Table 3.3-1.	Intake requirements for the fan-assisted natural draft would be for makeup water and would consist of pumps, piping and valves. There are no foreseen impacts to aquatic biota associated with constructing or operating the saltwater wells (radial collector wells) or the reclaimed water source. Circulating water makeup and discharge quantity for the fan-assisted natural drafts expected to be approximately the same or less than the proposed round mechanical draft system. The discharge water quality for the fan-assisted natural draft is expected to be the same as for the proposed round mechanical draft.

Table 9.4-1 (Sheet 2 of 2)
Analysis of Heat Dissipation System Alternatives

Factors Affecting System Selection	Round Mechanical Draft Cooling Towers — Proposed	Fan-Assisted Natural Draft Towers — Alternate
Atmospheric Effects	The round mechanical draft system would emit water droplets (drift) and intermittently produce a visible vapor plume. As provided in Subsection 5.3.3, the drift droplets would be a minor source of particulate matter and salt deposits. The water vapor plume would result in minimal additional fogging but no icing conditions on local road systems.	Similar to the round mechanical draft system, fan-assisted natural draft would emit water droplets (drift) and intermittently produce a visible vapor plume. It is expected that, similar to the round mechanical draft, the drift droplets would be a minor source of particulate matter and salt deposits. The water vapor plume would result in minimal additional fogging but no icing conditions on local road systems.
Thermal and Physical Effects	The discharge to the Boulder Zone of the Lower Floridan aquifer would meet the requirement of Florida's Department of Environment Deep Well Injection Control, Chapter 62-528.	The discharge to the Boulder Zone of the Lower Floridan aquifer would meet the requirement of Florida's Department of Environment Deep Well Injection Control, Chapter 62-528.
Noise Levels	Sound pressure level is estimated at 85 decibels adjusted (dBA) at 3 feet from the tower.	Sound pressure level is estimated at 97 dBA at 3 feet from the tower.
Aesthetic and Recreational Benefits	Aesthetic impacts from the visible plume would be small. There are no recreational benefits to the round mechanical draft cooling tower.	Aesthetic impacts from the visible plume would be small. There are no recreational benefits to the fan-assisted natural draft cooling tower.
Operating and Maintenance Experience	Established technology in the U.S. with highly reliable experience with operation and maintenance and plentiful installations throughout the U.S.	Considered an emerging technology in the U.S.; however, there is successful operation and maintenance experience outside the U.S.
Generating Efficiency (per AP1000 unit)	Total Fan Auxiliary Power Requirement (MW): 6.7 Total Pump Auxiliary Power Requirement (MW): 16.5.	Total Fan Auxiliary Power Requirement (MW): 8.0 Total Pump Auxiliary Power Requirement (MW): 24.7.
Legislative Restrictions	The proposed raw water makeup sources (reclaimed and radial collector well) do not require an intake system as defined by 40 CFR 125.83 so there would be no construction-related, aquatic ecology, threatened or endangered species, or water use impacts and Section 316(b) of the Clean Water Act does not apply. Cooling tower blowdown would discharge to the Boulder Zone of the Lower Floridan aquifer and, therefore not impact aquatic biota. The regulatory restrictions would not negatively impact applying this heat dissipation system.	The proposed raw water makeup sources (reclaimed and radial collector wells) do not require an intake system as defined by 40 CFR 125.83 so there would be no construction-related, aquatic ecology, threatened or endangered species, or water use impacts and Section 316(b) of the Clean Water Act does not apply. Cooling tower blowdown, which may be less than the preferred alternative, would discharge to the Boulder Zone of the Lower Floridan aquifer and therefore, not impact aquatic biota. The regulatory restrictions would not negatively impact applying this heat dissipation system.
Is this a suitable alternative for the Units 6 & 7 site?	Yes.	Yes.

Table 9.4-2
Comparison of Proposed Water Intake Alternatives

Impact	MDWASD Reclaimed Water — Proposed Raw Water System	Biscayne Aquifer (Radial Collector Well) — Proposed Raw Water System	Lower Floridan Aquifer (Boulder Zone) — Alternate System	Card Sound Canal Conventional Intake — Alternate System	Card Sound Canal Passive Screen Intake — Alternate System
Construction Impacts	No intake system is required. There would be no construction impacts related to intake structures. However, construction impacts would include land disturbance along the pipeline route.	A cooling water intake structure as defined by 40 CFR 125.83 does not exist for this alternative; however, construction impacts include land disturbance and associated ecological impacts in the vicinity of the caissons and along pipeline route to plant site. Construction impacts would be low.	No intake system is required. There would be no construction impacts related to intake structures. However, construction impacts of this system would be limited to localized land disturbance.	Construction impacts include land disturbance on east bank of canal at intake location and along pipeline route. Construction impacts would be low.	Construction impacts include land disturbance on east bank of canal at intake location and along pipeline route to plant site (about 4 miles), and canal bed disturbance in area of passive screens. Construction impacts would be low.
Aquatic Impacts	No intake system is required. There would be no aquatic impacts.	Operation would induce flow from Biscayne Bay into the seabed. Induced flow would be distributed over a very large area. Aquatic impacts are not foreseen.	No intake system is required. There would be no aquatic impacts.	Aquatic impacts include impingement and entrainment. Use of a closed-cycle cooling system and compliance with EPA 316(b) cooling water intake structure requirements would mitigate aquatic impacts to low levels.	Aquatic impacts include impingement and entrainment. Use of a closed-cycle cooling system and compliance with EPA 316(b) cooling water intake structure requirements would mitigate aquatic impacts to low levels.
Water-Use Impacts	No intake system is required. There would be no water-use impacts.	There are no other consumptive water uses and operation would not interfere with non-consumptive uses. There would be no water-use impacts.	No intake system is required. There could be water use impacts from Boulder zone discharge option if used simultaneously with this option from recirculation effects.	There are no other consumptive or nonconsumption water uses of Card Sound Canal. There would be no water use impacts.	There are no other consumptive or nonconsumption water uses of Card Sound Canal. There would be no water use impacts.
Compliance with Regulations	Not applicable.	Not applicable.	Not applicable.	The intake would need to comply with Article 316(b) of the Clean Water Act as applied to new facilities.	The intake would need to comply with Article 316(b) of the Clean Water Act as applied to new facilities.

Table 9.4-3
Comparison of Water Discharge Alternatives

Impact	Lower Floridan Aquifer (Boulder Zone) — Proposed System	MDWASD Wastewater Treatment Plant — Alternate System	Cooling Canals — Alternate System	Card Sound Canal — Alternate System
Construction Impacts	Construction impacts limited to localized land disturbance in the vicinity of the deep injection wells and along the discharge pipeline route. Construction impacts would be low.	Construction impacts include land and traffic disturbance along the pipeline route (Approx. 9 miles of public right-of-way in urbanized areas or FPL transmission corridors). Construction impacts would be moderate.	Construction impacts limited to the short pipeline route between the plant site and the discharge side of the existing cooling canals. Construction impacts would be low.	Construction impacts include land disturbance on canal bank at discharge location and along pipeline route to plant site (about 4 miles). Construction impacts would be low.
Aquatic Impacts	The Boulder Zone is a deep saltwater aquifer that has no interaction with aquatic systems. There would be no aquatic impacts.	There would be no site-related aquatic impacts.	Temperature and salinity of blowdown would be less than the ambient levels in cooling canals. Assuming that blowdown discharge would be treated for nutrient limits, aquatic impacts would be low, although pollutants unique to reclaimed water may require consideration.	Water temperatures would be elevated as a result of discharging blowdown, but within thermal compliance limits at the point of discharge to Card Sound. Water quality of the blowdown is less saline than ambient levels. Aquatic impacts would be low.
Water-Use Impacts	Other than potentially Units 6 & 7, there are no other water users in the region. There would be no water use impacts.	Currently, the wastewater treatment plants do not have the capacity to accept blowdown from Units 6 & 7. However, if reclaimed water is used for water supply, the blowdown could be returned to the wastewater treatment plant for disposal. Water quality acceptance criteria and capacity restrictions on wastewater plant discharges could restrict the use of this option. Also, returning water to the MDWASD would deprive other potential users of the beneficial use of this water (e.g., for wetlands rehydration).	Turkey Point Units 1 through 4 are the sole users of the cooling canals. The additional flow would supplement their supply. There would be no water use impacts.	There are no other consumptive or non-consumptive water uses of the Card Sound Canal. There would be no water-use impacts.
Compliance with Regulations	Discharge must comply with Class I injection well concentration limits. Compliance monitoring required.	Water returned to the MDWASD for disposal would need to meet the requirements of their pretreatment.	The current industrial wastewater permit would require modification to accept blowdown from Units 6 & 7.	The discharge of blowdown from a recirculated cooling water system would need to comply with Rule 62-4.242, F.A.C.

Table 9.4-4
Comparison of Water Supply Alternatives

Impacts	Reclaimed Water — Proposed Supply	Radial Collector Wells — Proposed Supply	Boulder Zone — Alternate Supply	Card Sound Canal — Alternate Supply
Construction Impacts	Construction impacts include land and traffic disturbance along the pipeline route (Approx. 9 miles of public right-of-way in urbanized areas or FPL transmission corridors) and land disturbance at the MDWASD where new treatment facilities would be constructed. Given that the pipeline would follow a majority of an existing corridor, clearing of new corridors and /or expansion of existing corridors would include use of best management practices to reduce impacts to sensitive habitats. Therefore, impacts would be low.	Construction impacts include land disturbance in the vicinity of the caissons and along pipeline route to plant site. Construction impacts would be low.	Construction impacts limited to localized land disturbance in the vicinity of the supply wells and along pipeline route to plant site. Construction impacts would be low.	Construction impacts include land disturbance on east bank of canal at intake location and along pipeline route to plant site (about 4 miles), and canal bed disturbance in area of passive screens. Construction impacts would be low.
Aquatic Impacts	There would be no adverse aquatic impacts associated with the use of reclaimed water. Using reclaimed water would eliminate the volume of treated effluent discharged by ocean outfall and positively impact those receiving water bodies.	Operation would induce flow from Biscayne Bay or Card Sound into the seabed. Induced flow would be distributed over a very large area. Aquatic impacts would be low.	The Boulder Zone is a deep saltwater aquifer that has no interaction with aquatic systems. There would be no aquatic impacts.	Aquatic impacts include impingement and entrainment. Use of a closed-cycle cooling system and compliance with EPA 316(b) cooling water intake structure requirements would mitigate aquatic impacts to low levels.
Water-Use Impacts	Reclaimed water use would allow MDWASD to meet a portion of its water reuse requirements while supplying the plant site with makeup water. There would be no consumptive water-use impacts.	There are no other consumptive water users and operation would not interfere with nonconsumptive uses. There would be no water use impacts.	The Boulder Zone is a saltwater aquifer that is not used for water supply. There would be no consumptive or nonconsumptive water use impacts. There could be re-circulation impacts if Boulder Zone discharge option used simultaneously.	There are no other consumptive or nonconsumptive water uses of Card Sound Canal. There would be no water use impacts.
Compliance with Regulations	The use of reclaimed water used in open cooling towers would need to comply with Rule 62-610.668, F.A.C.	The water supply system would not need to comply with Article 316(b) of the Clean Water Act as applied to new facilities.	Not Applicable	The cooling water intake system would need to comply with Article 316(b) of the Clean Water Act as applied to new facilities.

Table 9.4-5
Area Resources Mapped

Category	Resource
Base map information	• Highways, roads, streets • County boundaries • City boundaries • Railroads, airports, heliports • Existing and proposed FPL substations • Existing FPL transmission lines • Existing FPL properties, rights-of-way, and easements • Water bodies, rivers, streams, canals
Land use information	• Existing and proposed development for which local approvals are pending • Planned unit developments and developments of regional impact • Property boundaries • Existing school properties • National parks, wildlife refuges, estuarine sanctuaries, landmarks, or historical sites • State parks, preserves, proposed and existing Florida Forever lands, • Areas of Critical State Concern, Conservation and Recreation Lands, Save Our Rivers lands, aquatic preserves • SFMWD-owned lands • Miami-Dade County lands, parks, recreation areas, and mitigation lands • Native American lands • Private designated wetland mitigation areas • Privately owned environmental preserves/sanctuaries • Military properties
Environmental information	• Listed federal and state species and unique habitats, U.S. Fish and Wildlife Service (USFWS)-designated critical habitats • Wetlands as delineated on USFWS national wetlands inventory maps

Table 9.4-6
Alternative Route Identification

• Maximize collocation with certain linear features (existing FPL transmission lines, easements, or rights-of-way, roads, canals, etc.)
• Follow parcel or section lines where practicable and when other collocation opportunities do not exist
• Minimize crossing of constraints identified as a result of regional screening (e.g., environmentally sensitive lands, existing development, and proposed development for which local approvals are pending)
• Avoid known airports and private airstrips consistent with Federal Aviation Administration and other applicable regulations
• Follow disturbed alignments (ditches, roads) through wetlands, where practicable
• Minimize crossing of existing transmission lines

Table 9.4-7
Alternate Route Evaluation Criteria — West/East Routes

- Number of buildings in proximity
- Number of school properties in proximity
- Number of non-FPL parcels/lots crossed
- Length of route not following FPL-owned right-of-way or other transmission line easements
- Length of route not following other linear features (roads, railroads, canals, etc.)
- Length of route through existing parks/recreation areas/designated conservation lands
- Length of forested wetlands crossed
- Length of non-forested wetlands crossed
- Number of eagle nests/wading bird colonies in proximity
- Engineering costs

Table 9.4-8 (Sheet 1 of 2)
Qualitative Criteria Used to Evaluate — West/East Alternate Routes

West Alternate Routes
• Available space within existing FPL rights-of-way, easements, or fee-owned property
• Available right-of-way along roads, transmission lines, and railroads
• Road plans (new roads, extensions, widening)
• Proposed development plans
• Proximity of existing development to collocation rights-of-way
• Types of development in proximity
• Proximity and orientation of public airports and private airstrips
• Ingress to substations
• Bridge crossings
• Constructability
• Acquisition status of existing and proposed conservation lands and/or greenways
• Availability of multi-agency land exchange
• Ability to avoid or minimize wetland impacts
• Ability to avoid or minimize impacts to parks, recreation, and conservation lands
• Proximity to historical districts, roads, and/or structures
• Review of potential underground scenarios where overhead is not feasible
• Potential listed species presence
• Crossing of Native American lands
• Potential use of local access roads/trails
• Proximity to known archaeological sites
• Vegetative landscapes along streets (tall trees)

Table 9.4-8 (Sheet 2 of 2)
Qualitative Criteria Used to Evaluate — West/East Alternate Routes

East Alternate Routes
• Available space within existing FPL rights-of-way, easements, or fee-owned property
• Available right-of-way along roads, transmission lines, and railroads
• Road plans (new roads, extensions, widening)
• Proposed development plans
• Proximity of existing development to collocation rights-of-way
• Types of development in proximity
• Proximity and orientation of public airports and private airstrips
• Ingress to Miami substation and crossing the Miami River
• Bridge crossings
• Constructability
• Acquisition status of existing and proposed conservation lands and/or greenways
• Ability to avoid or minimize wetland impacts
• Ability to avoid or minimize impacts to parks, recreation, and conservation lands
• Proximity to historical districts, roads, and/or structures
• Review of potential underground scenarios where overhead is not feasible
• Potential listed species presence
• Crossing of Native American lands
• Potential use of local access roads/trails
• Proximity to known archaeological sites
• Miami-Dade Metrorail and/or Busway right-of-way availability and use
• Vegetative landscapes along streets (tall trees)

CHAPTER 10 LIST OF TABLES

Number	Title
10.1-1	Construction-Related Unavoidable Adverse Environmental Impacts
10.1-2	Operations-Related Unavoidable Adverse Environmental Impacts
10.2-1	Material Quantities Required for Construction of Units 6 & 7
10.4-1	Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7
10.4-2	Turkey Point Nuclear Units 6 & 7 Cost Estimate Range

CHAPTER 10 ENVIRONMENTAL CONSEQUENCES OF THE PROPOSED ACTION

In accordance with NUREG-1555, this chapter presents the potential environmental consequences from construction and operation of Units 6 & 7. This chapter describes the environmental consequences in four major subsections:

- Unavoidable adverse environmental impacts of construction and operations (10.1)
- Irreversible and irretrievable commitments of resources (10.2)
- Relationship between short-term uses and long-term productivity of the human environment (10.3)
- Benefit-cost balance (10.4)

Environmental impacts are quantified to the maximum extent practical and further categorized on a three-level standard of significance—SMALL, MODERATE, or LARGE. This standard of significance was developed based on the Council on Environmental Quality guidelines set forth in the footnotes to Table B-1 of 10 CFR Part 51, Subpart A, Appendix B, as shown below:

- **SMALL** — Environmental effects are not detectable or are so minor they will neither destabilize nor noticeably alter any important attribute of the resource.
- **MODERATE** — Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
- **LARGE** — Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

10.1 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS

Unavoidable adverse impacts are predicted adverse environmental impacts that cannot be avoided and for which there are no practical means of mitigation. This section considers unavoidable adverse impacts from construction and operation of Units 6 & 7 and associated facilities and offsite facilities such as transmission corridors, potable and reclaimed water pipelines, FPL-owned fill source, and access roads.

10.1.1 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS OF CONSTRUCTION

This subsection and Table 10.1-1 are based on the details of construction impacts presented in Chapter 4, focusing on unavoidable adverse impacts. Full and detailed descriptions of impacts

are presented by resource area in Chapter 4, which include both positive and adverse impacts as well as applicable mitigation measures. Table 4.6-1 summarizes the impacts and mitigation measures by section. The impacts of segregation of construction activities, as summarized in Table 4.6-2, are not considered here since this is considered a subset of the activities and mitigation measured summarized in Table 4.6-1. Table 10.1-1 summarizes the predicted adverse impacts associated with construction, grouping the impacts by the impact categories of land use, hydrological and water use, terrestrial and aquatic ecological, socioeconomic, radiological, atmospheric and meteorological, and environmental justice as provided for by NUREG-1555. For each predicted adverse impact, Table 10.1-1 presents a brief statement(s) of actions that would be taken to mitigate the impacts and finally identifies and quantifies, when practical, those adverse impacts that would remain even after the effective implementation of the mitigation measures.

Construction of Units 6 & 7 and associated facilities on the plant property, along with the new transmission lines, reclaimed and potable water pipelines, access roads, and FPL-owned fill source would produce unavoidable adverse impacts. Construction impacts would be limited to Miami-Dade County. Areas affected by construction of new transmission lines, reclaimed and potable water pipelines, access roads, and FPL-owned fill source could experience temporary localized impacts such as loss of natural habitat, loss or displacement of wildlife, and temporary increased noise and pollutant emissions (fugitive dust and equipment exhaust).

Selection of the transmission corridors was guided by a corridor selection process and is consistent with the requirements of the Florida Power Plant Siting Act. The objective of the corridor selection process was to select certifiable corridors that balance land use/ socioeconomic, environmental, engineering and cost considerations.

Adverse impacts attributable to construction activities would generally be SMALL. Exceptions are a MODERATE ecological impact as a result of construction activities and traffic near American crocodile habitat including construction of transmission lines across the cooling canals of the industrial wastewater facility, a MODERATE ecological impact on wetlands habitat, both on the Turkey Point plant property and at offsite construction locations, a MODERATE visual impact on aethestics from construction within transmission corridors and a MODERATE transportation impact on local roadways as a result of additional commuter traffic and material delivery vehicles once new road improvements are available. Based on the road improvements being completed, the traffic impacts would be temporary and MODERATE.

10.1.2 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS OF OPERATIONS

This subsection is based on the details of operation impacts presented in Chapter 5, focusing on unavoidable adverse impacts. Full and detailed descriptions of impacts are presented by resource area in Chapter 5, which includes both positive and adverse impacts and potentially

applicable mitigation measures. Table 5.10-1 summarizes the impacts and mitigation measures by section.

Table 10.1-2 summarizes the predicted adverse impacts associated with operation of Units 6 & 7, grouping the impacts by the impact categories of land use, hydrological and water use, terrestrial and aquatic ecological, socioeconomic, radiological, atmospheric and meteorological, and environmental justice as provided for by NUREG 1555. For each predicted adverse impact, Table 10.1-2 presents a brief statement(s) of actions that could be taken to mitigate the impacts and finally identifies and quantifies, when practical, those adverse impacts that would remain even after the effective implementation of the mitigation measures. Unavoidable adverse impacts from the operation of Units 6 & 7 include

- Permanent dedication of land
- Withdrawal of water from beneath Biscayne Bay to provide makeup water for the cooling system
- Disturbance of terrestrial ecosystems from permanent land dedication
- Salt deposits and noise from operation of the cooling towers
- Radiological and air pollutant emissions
- Radioactive and nonradioactive waste that requires disposal
- Increased demands on public infrastructure from population increase and plant water needs
- Increases in local traffic volume
- Visual impacts on the landscape from industrial structures

Operation of Units 6 & 7 and associated facilities on the plant property, along with the new transmission lines, reclaimed and potable water pipelines, and access roads would produce unavoidable adverse impacts. Operation impacts would be limited to Miami-Dade County. Areas affected by operation of new transmission lines, reclaimed and potable water pipelines, and access roads could experience localized permanent impacts such as loss of natural habitat.

Unavoidable adverse impacts attributable to operation activities would generally be SMALL. Exceptions include a SMALL to MODERATE impact on terrestrial ecosystems, and a MODERATE transportation impact on traffic levels for local roadways.

Table 10.1-1 (Sheet 1 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Land Use	Earth would be disturbed on Turkey Point plant property, transmission corridors, reclaimed and potable water pipelines, access roads, and FPL-owned fill source.	Environmental controls such as stormwater management systems; construction practices including erosion control and dust control; control plant access for personnel and vehicular traffic; and restrict construction activities to specified areas to would be used to minimize impacts. Procedures to address inadvertent discovery of historic, archaeological, or paleontological resource would be developed.	Disturbance of acreage including wetlands that are mitigated through regional mitigation opportunities, disturbance of land for fill materials, additional acreage for transmission lines and pipelines rights-of-way.
	Construction activities on Turkey Point plant property, transmission corridors, reclaimed and potable water pipelines, access roads, FPL-owned fill source in and near wetlands would impact wetlands.	Turkey Point Plant Property and offsite areas: Wetland impacts would be avoided and minimized to the extent practicable, for the transmission lines (to the extent practicable, existing corridors would be used), reclaimed and potable water pipelines, access roads, FPL-owned fill source, and by restricting construction activities to specified areas. Use environmental best management practices for clearing and construction to minimize impacts. Use equipment that minimizes environmental impacts such as erosion-control devices, mattings, and wide-track vehicles when crossing wetlands. Conduct restoration activities where necessary after construction. Offset the potential loss of any disturbed wetlands with regional mitigation opportunities.	Though wetland impacts are unavoidable, losses would be offset with regional mitigation opportunities.

Table 10.1-1 (Sheet 2 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Hydrological and Water Use	Hydrological alterations as a result of site preparation and construction activities including excavation, dewatering, filling, and elevating land surface as well as creation of a reservoir onsite.	Turkey Point plant property: water drainage from spoils areas, FPL reclaimed water treatment facility, nuclear administration and training buildings would be directed to the existing cooling canals of the industrial wastewater facility. Water drainage from the radial collector wells would be controlled by environmental best management practices. Also the berm east of the return canal would serve to mitigate impacts from construction activities within the Units 6 & 7 plant area. Access Roads: Existing roads would be used to the extent practicable. Ditches and the use of culverts would allow stormwater drainage to be maintained along the road route. During construction on Turkey Point plant property, stormwater runoff would be directed to retention basins or other erosion control devised before release to the cooling canals of the industrial wastewater facility. Should modification to the existing drainage ditches or drainage features be required, the impacts would be temporary and the disturbed areas could be returned to preconstruction conditions. Re-vegetation could be required. All work would be performed in accordance with site-obtained permits. Transmission lines and reclaimed/potable water pipelines: Standard construction industry practices would be used. A Stormwater Pollution Prevention Plan (SWPPP) for the proposed construction activities would be developed or the work would be performed under existing FPL permits/plans for these types of activities. FPL-owned fill source: Standard construction industry practices would be used. Surface water flow would be controlled through the use as such practices as berms, drainage ditches, and/or stormwater retention basins.	Hydrological alterations as a result of site preparation and construction activities including excavation, dewatering, filling, and elevating land surface as well as creation of a reservoir onsite.

Table 10.1-1 (Sheet 3 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Hydrological and Water Use (cont.)	Impacts to surface water and groundwater from sediment and pollutants as a result of site preparation and construction activities including excavation, dewatering, filling, and elevating land surface as well as creation of an onsite reservoir.	Develop an erosion, sedimentation, and pollution control plan. Implement environmental best management practices, including structural (i.e., erosion-control devices and detention ponds) and operational controls to prevent the movement of pollutants (including sediments) into wetlands and water bodies via stormwater runoff. Dewatering activities and enlargement of the equipment barge unloading area would include use of a slurry wall, and cutoff wall techniques, as appropriate. The water from dewatering activities would be directed to the cooling canals of the industrial wastewater facility.	None
	Installation of deep injection wells.	The deep injection wells and the required monitoring wells would be installed in accordance with a Florida Department of Environmental Protection (FDEP) injection well permit requirements and any local permit requirements. During the construction of the injection wells and delivery system, any stormwater runoff would be released to the cooling canals of the industrial wastewater facility.	None
	Accidental spills could adversely impact surface waters and groundwater.	Construction activities would be performed under a new SWPPP and associated spill prevention plan that could include oil and fuel containment. Any minor spills of diesel fuel, hydraulic fluid, lubricants, or other construction-related pollutants during construction of the project would be cleaned up quickly to prevent them from moving into the groundwater. This would also mitigate impacts to local surface water because spills would be quickly attended to and not allowed to flow to nearby surface water.	None

Table 10.1-1 (Sheet 4 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Terrestrial Ecological	Conversion of land, including wetlands for construction of Units 6 & 7 and supporting structures.	Restrict construction activities to specified areas. Loss of wetlands could be offset with the regional mitigation opportunities.	Construction activities for Units 6 & 7 would impact wetlands, primarily hypersaline mudflats.
	Crocodiles and listed species could be disturbed by site preparation and construction activities and traffic.	A project-specific management plan for crocodiles and other listed species was created for this construction activity. Mitigation measures may include creation of freshwater refugia on the berms for young crocodiles, vegetation management on the berms to promote a native plant community that is more conducive to crocodile use, use of warning signs and education material (for construction personnel) as to the presence and status of crocodiles and restrictions of nocturnal activities around the cooling canals of the industrial wastewater facility. Traffic on access road at the north end of the cooling canals of the industrial wastewater facility may pose a threat to crocodiles crossing this road and would be mitigated by installation of a wildlife corridor to provide pathways for crocodiles to travel between wetlands on either side of this road. Construction of transmission facilities within the cooling canals of the industrial wastewater facility would avoid known crocodile nests and be conducted between nesting seasons.	None
	Construction noise and vibration could displace some wildlife and tall structures and cranes and light pollution could affect birds.	Measures to reduce noise and vibration levels during construction may include staggering work activities, and use of noise dampeners and noise control equipment on vehicles and equipment. To the extent practicable, unnecessary lights would be turned off at night, lights turned downward or hooded (directing light downward), and lower-power lights used.	Some wildlife individuals would be displaced.

Table 10.1-1 (Sheet 5 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Terrestrial Ecological (cont.)	Transmission lines would be located within nine wood stork colonies' core foraging area.	Impacts to wetlands within the core foraging area would be mitigated as prescribed by regulatory agencies. To mitigate the potential for collisions or electrocutions, avian-friendly design features would be used as provided for in the FPL Avian Protection Plan.	None
Aquatic Ecological	Equipment barge unloading area enlargement activities, increased barge traffic, and dredging, if needed, could disturb manatees.	A management plan has been prepared to minimize impacts on manatees as a result of the expansion and increased use of the turning basin.	None
Socioeconomic Impacts	Exposure of construction workers to temporary elevated noise levels, fugitive dust and fine particulate matter emissions from construction activities, and other occupational hazards.	Construction activities would be conducted in accordance with Occupational Safety and Health Administration safety standards. Develop and implement a dust control plan, or similar planning document to minimize dust.	None
	Increased population and subsequent increased demand for public water, wastewater treatment, police and fire services, medical services, and increase in student population.	The construction workforce will gradually increase. Communication would be maintained with local and regional governmental officials about the Units 6 & 7 construction and its schedules, allowing local and regional officials opportunity to plan for the population influx. Increased property and sales/use tax revenues generated during construction could be used to fund additional law enforcement officers and firefighters. Communication would be maintained with local and regional nongovernmental organizations, including Department of Community and Economic Development, to disseminate project information in a timely manner. This would allow these organizations to be given the opportunity to plan accordingly.	Population increase in Miami-Dade County 5139. Number estimated to settle in Homestead-Florida City area 2199.
	Increased traffic in roads due to construction personnel and deliveries of borrow fill and materials.	Improvements would be made to local access roads, including existing road widening and the addition of turn lanes.	Additional vehicles would travel to Units 6 & 7 and result in moderate impacts to traffic once the new access road and other road improvements are available.
	Using public water supply for construction activities.	None	Peak construction activities would require an estimated 565 gpm of potable water from the Miami-Dade County.

Table 10.1-1 (Sheet 6 of 6)
Construction-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Radiological	Potential radiation exposure to Units 6 & 7 construction workers as a result of the operation of Units 3 & 4 and from Unit 6 after it becomes operational.	None	Potential radiation exposure from operating units.
Atmospheric and Meteorological	Temporary and localized noise, fugitive dust, and exhaust emissions during construction.	Measures to reduce noise and vibration levels during construction may include staggering work activities, and use of noise dampeners and noise control equipment on vehicles and equipment. Develop and implement a dust-control plan, or similar planning document to minimize dust.	Temporary and localized noise, fugitive dust, and exhaust emissions during construction.
Environmental Justice	No disproportionately high or adverse impacts to minority or low-income populations were identified.	None	None

Table 10.1-2 (Sheet 1 of 4)
Operations-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Land Use	Land use would be permanently dedicated to Units 6 & 7 and associated facilities until decommissioning.	None	Land dedicated to Units 6 & 7 and associated facilities.
	Land use for transmission lines and access roads would be dedicated to these uses, precluding the land from being developed as residential, industrial, or certain agricultural properties.	None	Land dedicated to transmission infrastructure that is not currently in FPL-owned rights-of-way.
	Deposits of low concentrations of salt from operation of the cooling towers.	None	Salt deposits would occur at the southern end of the plant area. Salt deposits of 10 kg/ha/month are generally confined to the plant property and in the cooling canals of the industrial wastewater facility, with the exception of the eastern and southeastern perimeters of the plant property.
	Generation of nonradiological and low-level radioactive waste that would require disposal in offsite permitted facilities.	Implement waste minimization plan.	Landfill space would be used for disposal of radioactive and nonradioactive wastes from Units 6 & 7 and not available for disposal of other wastes.
	Generation of spent fuel requiring disposal in a DOE facility licensed by NRC.	None	Disposal facility capacity would be used by disposal of spent fuel.
	Permanent commitment of land per year for each AP1000 due to the operations and processes associated with provision, utilization, and ultimate disposal of fuel.	None	Permanent commitment of 34 acres of land per year for fuel cycle operations and processes that would support Units 6 & 7.
Hydrological and Water Use	As a second 100 percent source of makeup water for the cooling system, water would be withdrawn from a saltwater aquifer beneath Biscayne Bay via radial collector wells.	Compliance with permit requirements.	Maximum of 86,400 gpm would be withdrawn when this source of makeup water is needed.
	Operation of the radial collector wells could impact the Biscayne aquifer and surface water (Biscayne Bay and the cooling canals).	Compliance with permit requirements as applicable and monitoring of local groundwater and surface water.	None
	Public potable water would be supplied to the site by Miami-Dade County for the operation of Units 6 & 7, except for use as cooling water.	None	Public water in the amount of 936 gpm (1.35 mgd) to 2553 gpm (3.68 mgd) would be supplied.
	Operation of the deep injection wells could impact the upper Floridan aquifer	Compliance with UIC permit requirements including monitoring at the plant area to ensure proper operation of the injections wells	None

Table 10.1-2 (Sheet 2 of 4)
Operations-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Hydrological and Water Use (cont.)	Some maintenance activities could involve earth moving and dewatering and could lead to temporary hydrological alterations and impacts to surface water and/or groundwater quality on the plant property and offsite areas.	Soil retention and erosion control measures such as silt barriers would be used to reduce impacts in accordance with an SWPPP developed for Units 6 & 7 and/or offsite facilities. Water from the dewatering process would be routed to the cooling canals of the industrial wastewater facility (if onsite) or handled by environmental best management practices and any applicable permits.	None
	Any contaminants (e.g., diesel fuel, hydraulic fluid, antifreeze, lubricants, or other pollutant) spilled during operations, and not contained or remediated, could affect the groundwater and surface water quality.	Operational activities would be performed under an SWPPP and a spill prevention plan. Any minor spills of diesel fuel, hydraulic fluid, lubricants, or other construction-related pollutants during operations Units 6 & 7 would be cleaned up quickly.	None
	Water consumption and discharges during fuel cycle activities.	None	Annual water use would be 2.95E10 gallons for both units.
Terrestrial Ecological	Salt deposits from operation of the cooling towers would not impact salinity levels of the cooling canals of the industrial wastewater facility significantly, which are critical habitat for the threatened American crocodile.	Continue FPL crocodile program that mitigates the impacts to American crocodile hatchlings from the existing elevated salinity levels.	None
	Potential impacts to wildlife from noise from the Units 6 & 7 cooling towers. Noise from cooling towers at greater than 200 feet would be less than the level known to startle or frighten some birds and small mammals.	None	None
	Maintenance activities would be conducted in transmission corridors and the reclaimed water pipelines rights-of-way potentially impacting soils and wetlands.	Environmental best management practices would be implemented to reduce soil erosion and sedimentation. FPL has right-of-way vegetation management programs and procedures intended to minimize impacts. The same procedure establishes strict guidelines for use of herbicides, application according to federal, state, and local regulations.	None

Table 10.1-2 (Sheet 3 of 4)
Operations-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Aquatic Ecological	Salt deposits from operation of the cooling towers would not impact salinity levels of the cooling canals of the industrial wastewater facility significantly.	None	None
	Maintenance activities would be conducted in transmission and the reclaimed and potable water pipelines corridors potentially at or near water bodies, wetlands, and the South Florida Water Management District (SFWMD) canals and could potentially impact water quality.	Vegetation management in forested wetlands will be in compliance with Florida Statute 403.814 General permits. Mangrove areas will be maintained below 14 feet. Herbicides approved for the site by federal and state rules will be used on exotic and incompatible species. Care will be taken to retain a cover of compatible species. Vegetation fuel loads will periodically be evaluated and mitigated to protect the reliability of the lines and surrounding private property. The same procedure establishes strict guidelines for use of herbicides, application according to federal, state, and local regulations.	None
Socioeconomics	Potential impact to members of the public from noise emitted by Units 6 & 7 cooling towers.	None	Noise levels beyond 400 feet from the cooling towers are estimated to be <65 decibels adjusted (dBA), a level characterized by NRC in NUREG-1555 as of small significance.
	New transmission lines may induce shock in objects beneath or near lines, could emit corona-induced noise at very low or inaudible levels, and would have visual impacts.	Build new transmission lines to the National Electrical Safety Code to limit shock from induced currents. Other impacts have no mitigation.	None
	Potential for occupational injuries and illnesses.	Implement existing Units 3 & 4 industrial safety program at Units 6 & 7.	None
	Increased population and subsequent increased demand for public water, wastewater treatment, police and fire services, medical services, and increase in student population.	Increased property, sales/use, and corporate tax revenues could be used to fund additional law enforcement officers and firefighters.	Population increase in Miami-Dade County 1310. Number estimated to settle in Homestead-Florida City area 559.
	Increased traffic on local roads used to access Turkey Point.	Road improvements would be developed for the construction traffic and these or a portion of these may remain in service during operations.	Traffic would increase due to additional operations and outage workers.
	Additional structures would be within the viewscape.	None	Additional structures would be within the viewscape.

Table 10.1-2 (Sheet 4 of 4)
Operations-Related Unavoidable Adverse Environmental Impacts

Category	Adverse Impact	Actions to Mitigate Impacts	Unavoidable Adverse Environmental Impact
Radiological	Potential health impacts to members of the public from exposure to radiological releases.	Conduct radiological monitoring program as required. Conduct meteorological monitoring.	Modeling using the design and operational parameters of Units 6 & 7 results in estimated doses to the public that are within the design objectives of 10 CFR Part 50 Appendix I and within regulatory limits of 40 CFR Part 190.
	Potential doses to biota from gaseous effluents would be less than the 100 millirad/day.	Conduct radiological monitoring program as required.	Potential doses to biota from Units 6 & 7 would be well within the 100 millirad/day guideline from the International Atomic Energy Agency.
	Potential health impacts to workers from radiation exposure.	Conduct radiological monitoring program as required.	Maximum annual occupational dose to operations workers of 67 person-rem per unit.
Atmospheric and Meteorological	Plumes from Units 6 & 7 cooling towers.	None	Plumes would remain primarily on site and minimal ground-level fogging and no icing was predicted.
	Air emissions due to intermittent operation of auxiliary systems such as emergency diesel generators.	Comply with state of Florida permit limits and regulations for operating air emission sources.	Small quantities of pollutants emitted during intermittent operation of auxiliary systems.
	Relatively small quantities of air pollutants would result from the uranium fuel cycle.	None	Potential impacts to air and water quality from uranium fuel cycle. Gaseous effluents would be less than 0.08 percent of all 2005 U.S. sulfur dioxide emissions and less than 0.02 percent of all 2006 U.S. nitrogen oxide emissions.
Environmental Justice	There would be no disproportionately high and adverse impacts to minority or low-income populations within 50 miles of the proposed site via soil, water, or air pathways that would affect the health and environment of populations.	None	None
	There would be no disproportionately high and adverse impacts to minority or low-income populations from operations-related activities with the exception of transportation.	None	Increased traffic could lead to impacts along the commuting routes.

10.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

This section describes the predicted irreversible and irretrievable environmental resource commitments that would result from construction and operation of Units 6 & 7. The term *irreversible commitments* of resources describes environmental resources that would be potentially changed by the construction or operation of Units 6 & 7 and that could not be restored at some later time to the condition present before construction or operation. Irretrievable commitments of resources are generally materials that would be used for Units 6 & 7 in such a way that they could not, by practical means, be recycled or restored for other uses.

10.2.1 IRREVERSIBLE COMMITMENTS OF RESOURCES

In addition to the materials used for the nuclear fuel, irreversible commitments of environmental resources associated with Units 6 & 7 are described in Subsections 10.2.1.1 through 10.2.1.7.

10.2.1.1 Land Use

Land designated for spent nuclear fuel storage and radioactive and nonradioactive waste disposal would be committed to those uses and could not be used for other purposes. When Units 6 & 7 cease operations and the plant is decommissioned in accordance with NRC requirements, the land that supports the power plant facilities could be returned to support other industrial or non-industrial uses. If the need for the transmission lines, substations, and access roads cease, the land occupied by these facilities could also be returned to support other industrial or non-industrial uses. Below grade structures such as the reclaimed water and potable water pipelines have little to no impact on land use. The FPL-owned fill source would become a water management area and hence serve as a beneficial long-term resource.

10.2.1.2 Hydrological and Water Use

Site preparation activities (e.g., excavation and filling, dewatering, land surface modifications) would pose hydrologic alterations; however, these impacts would be temporary and SMALL. All of the cooling water (reclaimed and saltwater) would be consumed either through cooling tower drift, evaporation, system blowdown, or disposal via deep injection wells. Additionally, potable water would be consumed during the construction and operation of Units 6 & 7. Because the use of these resources is entirely consumptive, they would not be available for other uses. The impact to the resource would be SMALL for the operational life of the plant, and impacts would cease when operations cease.

It is expected that normal releases of contaminants into the environment from Units 6 & 7 will have negligible effects on surface and groundwater uses and will be in compliance with an Underground Injection Control (UIC) permit issued by the Florida Department of Environmental Protection (FDEP). Sections 3.6 and 5.5 discuss the FDEP requirements for a UIC permit. This

permit will ensure that discharges are controlled from systems such as discharge lines, sewage treatment facilities, radwaste treatment systems, water treatment waste systems, and facility service water. The effect on water quality due to the operation of the Units 6 & 7 will be monitored to ensure compliance with the issued UIC permit for construction and operation.

10.2.1.3 Aquatic and Terrestrial Biota

Land preparation activities would include the removal of present ground surface materials and the import of fill material to elevate the Turkey Point plant area ground level above the current elevation. Land preparation and construction activities would displace some wildlife, and would temporarily and adversely affect the abundance and distribution of local flora and fauna at several locations on the Turkey Point plant property. Permanent replacement of mangrove habitats and aquatic habitats at several filled-in canals would occur. Adverse impacts to the American crocodile are not anticipated at the Turkey Point plant property since the mitigation programs already in place would continue.

Similar impacts would occur on the new transmission corridors, access roads, water supply pipeline corridors, and FPL-owned fill source. When construction is complete, flora and fauna would recover in areas that are not directly adjacent to or part of operations.

Impacts to aquatic and terrestrial Biota would be SMALL, with the exceptions as previously described.

10.2.1.4 Socioeconomic

Because five power generation units exist on the Turkey Point plant property, construction of Units 6 & 7 would pose only a slight alteration of the regional viewscape. The change in viewscape could be restored after plant operations cease and the facilities are decommissioned. The construction and operation of Units 6 & 7 would also create short-term and long-term changes in the population, the nature and character of the local community, and the local socioeconomic structure. Indirect or secondary growth and associated changes in the character of the socioeconomic structure would also occur. Some of the impacts on infrastructure and services are mitigated through property and worker taxes and payments made in lieu of taxes. Other changes such as noise and traffic congestion would only be partially mitigated.

10.2.1.5 Releases to Air and Surface Water

Vehicle and construction equipment operation would release GHGs and other air pollutants to the air from land preparation and other construction activities. Surface water runoff could increase sedimentation to local surface waters. These impacts would be localized and temporary. Operations would also produce low-quantity emissions (e.g., diesel generator exhaust and vehicle exhaust would release GHG emissions and other air pollutants). Very small quantities of

low-concentration radioactive gases and particulates would also be released to the air and surface water.

Water vapor from mechanical draft cooling towers would be the main constituent of emissions during operation. Under some weather conditions, water vapor from these towers could form a visible plume that would vary in size and opacity. The frequency of the occurrence and length of these visible plumes would generally be greatest in the winter months when the ambient air temperatures are cooler.

The release of treated hazardous and radioactive effluents would represent a SMALL adverse impact on water quality. The release of hazardous and radioactive air emissions would represent a SMALL adverse impact on air quality. Hazardous and radioactive air and water constituents would be monitored at their release points. All releases from Units 6 & 7 would comply with issued permits and are not expected to measurably affect the air and surface water resources

10.2.1.6 Disposal of Hazardous and Radioactively Contaminated Waste

Units 6 & 7 would generate radioactive, hazardous, and non-hazardous waste. Each waste type will require proper storage, on-site management, and disposal or treatment in accordance with applicable permits and regulations. Radioactive waste will be disposed in radioactive landfills in accordance with regulations governing radioactive waste. Final disposition of hazardous waste will be managed in accordance with the permit and regulatory requirements governing permitted hazardous waste treatment, storage, and disposal facilities. Non-hazardous waste will be beneficially used, recycled, or disposed of in accordance with applicable permits and regulations governing non-hazardous waste. Universal wastes generated by the facility may be recycled with an authorized universal waste handler in lieu of land disposal in a FDEP-permitted industrial landfill. Used oil may be recycled via permitted used-oil handlers. Land committed to the disposal of radioactive and hazardous waste is an irreversible impact because it is committed to that use and can be used for few other purposes.

10.2.1.7 Uranium Fuel Cycle

The uranium fuel cycle involves several stages, and each stage poses environmental impacts. At the uranium mine, uranium ore is extracted from the ground and typically milled. The product is then prepared into uranium hexafluoride and processed for isotopic enrichment. The enriched uranium product is then fabricated into fuel and loaded into a nuclear power plant. When the fuel is spent, it is removed from the reactor and stored on site. Each stage of the uranium fuel cycle generates various forms of low-level and high-level waste.

10.2.2 IRRETRIEVABLE COMMITMENTS OF RESOURCES

As shown in Table 10.2-1, large quantities of metals, concrete and other construction materials would be required to construct Units 6 & 7. Asbestos and other materials considered hazardous would generally not be used, or would be used in limited quantities and in accordance with safety regulations and practices. Some of the construction materials would ultimately become contaminated or irradiated over the life of power plant operations. Based on current technology, these materials could not be reused or recycled. Instead, these materials would, therefore, require isolation from the biosphere for hundreds or thousands of years, and would represent an irretrievable commitment of resources.

Although the total quantity of construction materials is large, use of such quantities in large-scale construction projects such as nuclear reactors, hydroelectric and coal-fired plants, and many large industrial facilities (e.g., refineries and manufacturing plants) represents a relatively small incremental increase in the overall use of such materials. Even if these materials are eventually routed for disposal, the impact would be SMALL with respect to the national or global consumption of these materials.

The primary resources that are irreversibly and irretrievably committed by operations would be the uranium used in fuel and the energy required to create the fuel. The estimated consumption of enriched uranium for Units 6 & 7 is 25.35 tons per year. The World Nuclear Association studies supply and demand of uranium and states that an 80-year supply of uranium is available based on known deposits and current usage. Exploration for uranium deposits has increased in recent years and it is expected to continue and lead to greater supplies as the demand increases (World Nuclear Association 2008). Therefore, the uranium that would be used to generate power by Units 6 & 7, although irretrievable, would have a SMALL impact with respect to the long-term availability of uranium worldwide.

Other irretrievable commitments of resources include materials used for the normal industrial operations of the plant that cannot be recovered or recycled or that are consumed or reduced to unrecoverable forms, such as elemental materials that would become radioactive.

Table 10.2-1
Material Quantities Required for Construction of Units 6 & 7

Materials	Quantity Required
Concrete	154,400 cubic yards
Rebar	20,000 tons
Structural steel	12,800 tons
Power cable	1,620,000 linear feet
Small bore pipe (less than 3-inch diameter)	460,000 linear feet
Large bore pipe (3-inch diameter or larger)	136,000 linear feet
Aluminum, boron, titanium, tungsten, and other natural resources	Small quantities

10.3 RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY OF THE HUMAN ENVIRONMENT

This environmental report has focused on the analyses and conclusions associated with the environmental and socioeconomic impacts from activities during the construction and operation of Units 6 & 7. These activities are considered to be short-term uses for purpose of this section. In this section, the long-term is considered to begin at the moment Units 6 & 7 have been decommissioned.

This section includes an evaluation of the extent to which the short-term uses preclude any options for future use of the Units 6 & 7 plant area and associated facilities. Construction and operation of an independent spent fuel storage installation (ISFSI) are not part of the proposed action and are therefore not discussed in this section. The ISFSI is described in Sections 4.7 and 5.11.

10.3.1 CONSTRUCTION OF UNITS 6 AND 7 AND LONG-TERM PRODUCTIVITY

Subsection 10.1.1 summarizes the potential unavoidable adverse environmental impacts of construction of Units 6 & 7 and the mitigative measures proposed to reduce those impacts. Some adverse environmental impacts would remain after all practical measures to avoid or mitigate the impacts have been applied. However, none of these impacts represent a long-term effect that would preclude any options for future use of land associated with Units 6 & 7. The acreage disturbed by construction activities would be larger than that required for the actual structures, associated facilities, and offsite facilities (e.g. FPL-owned fill source, transmission lines, access roads, reclaimed and potable water pipelines) because of the need for such facilities as construction laydown, support areas, and parking areas for the construction workforce. Clearing this acreage, in addition to the noise of the construction, would displace some wildlife and remove vegetation. Once the construction activities are completed, some disturbed areas could be restored. It is expected that wildlife would then return to the restored areas.

Noise generated by some construction activities would increase the ambient noise levels in the vicinity of the plant property. However, upon completion of these activities, the ambient levels would return to the levels comparable to the preconstruction ambient noise levels. The workforce would be protected by adherence to the 29 CFR 1910.95 requirements for occupational noise exposure. There would be no effects on the long-term productivity of Units 6 & 7 as a result of these impacts

Increased traffic volume as a result of construction personnel and material deliveries would increase congestion and traffic delays on local roadways. Additional traffic associated with plant operations would also contribute to congestion and traffic delays on local roadways, but at a lower level than construction.

Construction of Units 6 & 7 would be beneficial to the local area through the generation of new construction-related jobs, local purchases by the construction workforce, and payment of taxes to the area. Some socioeconomic impacts that occur as a result of increased population due to construction would cease once construction is complete and the workforce leaves the area. However, some changes incurred because of increased tax revenues would persist into the foreseeable future. In those cases, construction would have some positive impact on the long-term economic productivity of the area. Construction would not affect long-term productivity of the environment.

10.3.2 OPERATION OF UNITS 6 & 7 AND LONG-TERM PRODUCTIVITY

Subsection 10.1.2 summarizes the potential unavoidable adverse environmental impacts of operation of Units 6 & 7 and the measures proposed to reduce or eliminate those impacts. Some adverse environmental impacts could remain after all practical measures to avoid or mitigate them have been applied. However, none of these impacts would pose long-term effects that would preclude any options for future use of the Turkey Point plant property.

The Turkey Point plant property currently supports five large power generation facilities—two oil/gas-fired units, one combined-cycle unit, and two nuclear units. Therefore, operation of Units 6 & 7 would represent a continuation of the current and planned use of the land. However, once Units 6 & 7 cease to operate and the plant is decommissioned to NRC standards, the land would be available for other industrial or non-industrial uses.

Units 6 & 7 would require large volumes of water for heat rejection. This requirement would be satisfied by a combination of reclaimed water delivered from Miami-Dade County and saltwater withdrawn from radial collector wells under Biscayne Bay. All of this water would be consumed through cooling tower drift, evaporation, system blowdown, or disposal via deep injection wells. Additionally, potable water would be consumed during the construction and operation of Units 6 & 7. Because the use of these resources are entirely consumptive, they would not be available for other uses, and would therefore impact the availability of water for other uses. After Units 6 & 7 cease to operate and the plant is decommissioned, water withdrawals for Units 6 & 7 would cease.

The operation of Units 6 & 7 would slightly increase annual air emissions because of emergency diesel generators. These generators would be operated infrequently and usually for short duration. This equipment would be operated in accordance with applicable federal, state, and local regulations, and would not create any measurable impacts on regional air quality. In addition, as described in Subsection 5.3.3, precipitation and atmospheric dispersion would limit the accumulation of salt in the soil near the cooling towers. In addition, the salt deposition analysis has determined that salt deposit levels attributable to salt drift from the cooling towers would remain below levels at which ecological impacts might occur, and would therefore pose no

long-term ecological impacts. No future issues for the long-term uses of the site would result from the impacts of increased air emissions or salt deposits. Once the plant ceases to operate and is decommissioned, impacts to the air quality would cease.

The operation of the deep injection wells installed on Turkey Point plant property for effluent disposal and wastewater disposal into the Boulder Zone could potentially impact groundwater within the Boulder Zone over the life of the plant but would not impact the Biscayne aquifer. Well systems would be installed to monitor the impacts attributable to operation of the deep injection wells and the radial collector wells. Once the plant ceases to operate and is decommissioned, impacts to groundwater and surface waters would cease.

Impacts as a result of radiological emissions would be SMALL because the Units 6 & 7 would be operated in accordance with state and federal regulations and a program would be implemented to monitor radiological emissions and their impact of land, flora, fauna, and air. Data would be analyzed against previous results to identify concerns. Once the plant ceases to operate and is decommissioned, radiological releases would cease. No future issues associated with the radiological emissions from operation Units 6 & 7 would affect the long-term uses of the Turkey Point plant property.

Some socioeconomic changes associated with the operation of the plant would likely continue after the plant is decommissioned. Property taxes paid by FPL to Miami-Dade County would provide revenues to the county for the foreseeable future to sustain services that support the Miami-Dade County population.

Taxes paid by FPL to Miami-Dade County would have a long-term effect on the productivity of the county. Workers that establish residence in Miami-Dade County would not only spend a portion of their income in the county, but would also pay property, sales, and use taxes. Long-term tax revenues would depend on the number of operations personnel that remain in Miami-Dade County and their ability to obtain employment at the same pay level they received as plant operations employees. The economic impacts to Miami-Dade County from Units 6 & 7 would be considered a benefit.

10.3.3 SUMMARY OF RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

The impacts attributable to construction and operation of Units 6 & 7 would result in some adverse short-term impacts. The principal short-term benefit is the production of electrical energy. The economic benefit of Units 6 & 7 and the associated workforce is large compared with the economic benefit from other potential uses for the site. The economic benefit is expected to be the type that would continue even after Units 6 & 7 are decommissioned, such as the continuation of commercial establishments that arose as a result of Units 6 & 7 service of power production, the presence of retired and former workforce in the area, and the presence of a well-

trained and educated workforce for the benefit of subsequent employers. Because the plant would eventually be decommissioned and restored, there would be no impacts to long-term productivity of the site.

10.4 BENEFIT–COST BALANCE

This section provides the benefit-cost analysis for construction and operation of Units 6 & 7 on the Turkey Point plant property. Subsection 10.4.1 describes the benefits of constructing and operating new nuclear units. Subsection 10.4.2 describes costs of constructing and operating the units.Subsection 10.4.3 provides a high-level summary of the benefits and costs addressed in Subsections 10.4.1 and 10.4.2.

10.4.1 BENEFITS

10.4.1.1 Need for Power

As described in Chapter 8, FPL submitted its Petition to Determine Need for Units 6 & 7 Electrical Power Plant (FPL Oct 2007c) to the Florida Public Service Commission (FPSC) in October 2007. The FPSC granted FPL's petition by a final order in April 2008. The factors for consideration by the FPSC included: (1) the need for electric system reliability and integrity, (2) the need for fuel diversity and supply reliability, (3) the need for baseload generating capacity, (4) the need for adequate electricity at a reasonable cost, and (5) whether the proposed plant is the most cost-effective alternative available. The FPSC also annually reviews FPL's resource planning process, which is described in detail in FPL's annual Ten Year Power Plant Site Plan. The most current version was filed in April 2010 (FPL Apr 2010).

The Final Order Granting Petition for Determination of Need for Proposed Nuclear Power Plants includes the following:

- Florida has a well-defined, systematic, and comprehensive resource planning program that adequately reviews resources and growing demand for additional base load, eliminating the need for additional NRC review.

- FPL has the need for 8350 MW of additional capacity for the period 2011–2020 to meet its reserve margin criteria.

- The FPSC, statutorily charged by the state of Florida with determining whether Units 6 & 7 would be necessary, has reviewed the pertinent information and has determined a need for the proposed units. Further, the Florida Reliability Coordinating Council process for gathering need-for-power data provides further satisfaction of NRC criteria at the regional level.

- The integrated resource planning process gives NRC the assurance that the need for power is real and that the benefits of satisfying that need would be realized.

- The benefits to be derived from the addition of Units 6 & 7 include fuel savings, emissions avoidance, enhanced fuel diversity, and improved system reliability.

Also, a summary of the 2010 Ten Year Power Plant Site Plan and integrated resource plan indicates that FPL's need for power is further based on the following (FPL Apr 2010):

- Within FPL's service territory, the projected load growth for the summer peak is projected to increase to 25,785 MW by 2019 with an increase of 3434 MW over the 2009 actual summer peak.

- There are no other additional new generating units proposed that meet capacity needs in the 2015 through 2019 time period.

- FPL's resource plan reflects concern for maintaining and enhancing fuel diversity in the FPL system and maintaining a balance between load and generating capacity in Southeastern Florida. FPL recognizes that the addition of new nuclear units will result in significant system fuel savings, system emission savings (including CO_2), and gains in system fuel diversity. FPL has addressed the revised in-service dates for Turkey Point Units 6 & 7 for planning purposes in the May 3, 2010 nuclear cost recovery filing with the FPSC (FPL May 2010a).

10.4.1.2 Fuel Diversity

Fuel diversity is the key to affordable and reliable electricity. A diverse fuel mix protects electric companies and consumers from contingencies such as fuel unavailability, price fluctuations, and changes in regulatory practices (EEl Mar 2003). History teaches that it is risky to develop an over-reliance on any one energy source. Industry experience over the past 30 years has demonstrated that a balanced energy portfolio is the key to providing America with a growing supply of affordable electricity (NRRI Mar 2005).

An electric system that relies on one or two fuels to generate a significant portion of the electricity needed to meet its customers' demand, all else being equal, is less reliable than a system that uses a more balanced, fuel-diverse generation portfolio (FPL Oct 2007a). An over-reliance on a single fuel source is a potential vulnerability to the long-term security of the nation's energy supply (USDOE 2008).

The Florida legislature, as part of the 2006 Florida Energy Act, amended Florida statutes to explicitly require the FPSC to consider the need for fuel diversity when making its determination of need for new electricity generating capacity (FPL Oct 2007b). At the same time, the legislature directed the commission to establish alternative mechanisms for recovering nuclear power plant costs (FPL Oct 2007c), a change that helps ensure availability of nuclear power as an option in maintaining fuel diversity in Florida.

There are only a few technologies suited to providing baseload capacity in Florida today and in the foreseeable future: nuclear, gas-fired combined-cycle, and advanced, clean coal technology such as supercritical pulverized coal or integrated gasification combined-cycle (IGCC).

The FPSC denied FPL's request to construct advanced clean coal units. This action further limits the number of available technologies. In addition, IGCC continues to present many unanswered questions about its commercial viability and operational reliability. FPL today depends upon natural gas for most of its energy needs. This dependence is expected to grow to 70 percent by 2024 if FPL does not build Units 6 & 7 and, instead, adds an equivalent capacity of combined-cycle generation.

In summary, fuel diversity is recognized nationally and within Florida as critical to attaining a reliable electrical system. Nuclear power is the key to maintaining fuel diversity. The construction and operation of Units 6 & 7 would provide the benefit of fuel diversity to FPL and the state.

10.4.1.3 Avoided Emissions

Nuclear power generation results in significant local and national air quality benefits. Power plants that use natural gas and coal for electrical generation produce air emissions (e.g., nitrogen oxides, sulfur dioxide, and carbon dioxide). Of increasing concern is carbon dioxide due to its contribution as a greenhouse gas.

It is reasonably anticipated by most electric industry observers and others that there will be some form of greenhouse gas regulation. Whether it is federal, regional, or state, it is anticipated that such regulation will include requirements for significant greenhouse gas reductions within the timeframe that FPL must plan for additional capacity. The Florida governor, by executive order, has established aggressive greenhouse gas reduction targets (FPL Oct 2007d):

By 2017: Reduce greenhouse gas emissions to 2000 levels

By 2025: Reduce greenhouse emissions to 1990 levels

By 2050: Reduce greenhouse emissions to 80 percent of 1990 levels

Nuclear generation is generally considered a "non-emitting" technology because nuclear units emit no greenhouse gas as they operate to produce electricity (FPL Oct 2007e). Subsection 9.2.3.1 indicates that a coal-fired alternative to Units 6 & 7 would emit approximately 14 million tons of carbon dioxide per year and Subsection 9.2.3.2 indicates that the gas-fired alternative would emit approximately 6 million tons per year. In other words, a substantial benefit of Units 6 & 7, if constructed, is the avoidance of 6 to 14 million tons of greenhouse gas emission per year. However, there is no plausible scenario in which the state's greenhouse gas targets could be achieved in a cost-effective manner without new nuclear resources (FPL Oct 2007d).

10.4.1.4 Advantage of Nuclear Power

Concerns about greenhouse gases and global climate change make it reasonable to expect that, eventually, the United States may have to strictly curb emissions from fossil-fuel electric generation plants, conceivably to the point of displacing coal- and gas-fired electricity generation. (If environmental policies restrict carbon emissions in the future, the cost of building and operating fossil-fired plants could increase by 50 to 100 percent.) Nuclear power is the only technology currently available that is a viable alternative to fossil-fired plants for baseload generation. The long lead time required to bring a new nuclear power plant online to displace fossil fuel power is one of the reasons for national concern with maintaining a nuclear energy capability (UC Aug 2004).

10.4.1.5 Tax Payments

As described in Subsection 4.4.2.2, construction and operation-related activities would generate sales tax revenue. Corporate income taxes are a second source of revenue for the state, while property taxes are primarily paid to Miami-Dade County.

During the 123-month construction period, workers and their families would spend part of their income in the region on taxable items from restaurants, hotels, and retail shops, contributing to tax revenue. Increased sales and use tax could result from the purchase of taxable materials and services to construct Units 6 & 7. Sales and use tax collections from the construction and operation of Units 6 & 7 would contribute less than 1 percent to Florida sales tax revenue. Some of this revenue would be returned to the counties to help fund local services.

FPL would pay increased corporate income taxes to the state of Florida once Units 6 & 7 generate additional income by producing power. However, to the extent that FPL purchases goods and services in the state during the construction phase, this contributes to the earnings of other corporations. Similarly, the purchases made by the construction workforce and other households whose jobs are indirectly related to the construction activity would contribute toward corporate income. The Florida sales tax revenue collected from the construction of Units 6 & 7 would generate an estimated $175.1–$255.5 million to the state. Also the Miami-Dade County sales tax revenue collected during construction would generate an estimated $29.2–$42.6 million for the county.

As addressed in Subsection 5.8.2, several sources of tax revenue and public expenditure are related to the operation of Units 6 & 7. These include sales taxes, property taxes, and corporate income taxes. Sales taxes would be levied on materials purchased during operation of Units 6 & 7 as well as on goods and services purchased by workers. Sales taxes on such purchases would be a beneficial impact to the local economy. Similarly, there may be direct and indirect beneficial

economic impacts from sales tax revenue generated from goods and services purchased by workers who do not currently work in the region.

FPL would pay corporate income taxes on its increased net state income. However, as described in Subsection 4.4.2.2.2.1, any tax increase attributable to the increased income of Units 6 & 7 would be paid at the consolidated entity level. The Turkey Point property tax revenue would be generated from real property and tangible personal property of FPL.

10.4.1.6 Local and State Economy

In all, construction and operations workers during Units 6 & 7 construction period would earn a total of more than $709.3 million over the 123-month construction period. Depending on the proportion of wages spent, the creation of Units 6 & 7 jobs would inject approximately $1.3 billion into the economy during the life of the construction project. In addition, the injection of new income would create jobs in the economy and create business opportunities for housing and service-related industries. The construction of Units 6 & 7 would contribute positively to the regional economy through purchases of capital and materials that are produced in the region.

As described in Subsection 5.8.2, the operation workforce for Units 6 & 7 would consist of 806 employees, with an estimated 50 percent of the workers migrating into Miami-Dade County to support the operation of Units 6 & 7. FPL anticipates that 172 (43 percent of the 50 percent in-migrant workers) would migrate to the Homestead and Florida City area. The remaining 50 percent of the workers would be expected to be current residents in the area. In addition, in-migration of 403 workers would create additional indirect jobs in the region because of the multiplier effect. FPL estimates that the influx of 403 workers would create approximately 874 indirect jobs in Miami-Dade County for a total of 1277 new jobs.

Construction and operation workers are expected to live and spend most of their salaries within the local area and surrounding region. In addition, these workers are likely to spend some portion of their salaries in the local area for gasoline, beverages, food, and incidental items. Because construction workers would be at this location for some time, there would be a multiplier effect where money is spent and re-spent in the local area and later in the region. By patronizing local retail and service sector businesses, construction workers may temporarily increase sales. The economic multiplier effect is one way of measuring secondary effects and means that every dollar earned by in-migrant construction and operation worker results in the creation of an additional 1.5902 dollars in the regional economy.

10.4.1.7 Other Benefits

Section 10.3 describes the relationship between short-term uses and long-term productivity of the human environment. Additional benefits not described in Section 10.3 include:

- Reduced dependence on foreign energy supplies.
- Reduced foreign trade deficit.
- Reduced depletion of finite fossil fuel supplies.

10.4.1.8 Benefit Summary

Table 10.4-1 is a summary of the benefits of the proposed action. In Subsection 9.3.3, FPL evaluated environmental impacts of construction and operation of the proposed project at four alternative sites (Glades, Martin, Okeechobee 2, and St. Lucie). Table 10.4-1 also provides a comparison of the costs of construction and operation of the project as opposed to those at the four alternative sites.

10.4.2 COSTS

10.4.2.1 Internal Costs — Proposed Action

10.4.2.1.1 Introduction

Construction costs and operation costs are generally described using established cost information developed by several resources. There are many cost studies available in the literature with a wide range of cost estimates. While the Final Order Granting Petition for Determination of Need for Proposed Nuclear Power Plants confirms that the proposed action is the preferred alternative in nearly all future fuel cost and environmental compliance cost scenarios, the following is a sampling of studies that examines these costs:

- New Nuclear Power Plant Licensing Demonstration Project ABWR Cost/Schedule/COL Project at TVA's Bellefonte Site, Tennessee Valley Authority (TVA) (TVA Aug 2005)
- Nuclear Power's Role in Generating Electricity, Congressional Budget Office (CBO May 2008)
- Study of Projected Electricity Generating Costs, Organization for Economic Co-operation and Development, Nuclear Energy Agency (NEA) (NEA 2005)
- The Economic Future of Nuclear Power, University of Chicago (UC) (UC Aug 2004)
- The Future of Nuclear Power, an Interdisciplinary MIT Study, Massachusetts Institute of Technology (MIT) (MIT 2003)
- Annual Energy Outlook, Energy Information Administration (EIA) (EIA Jan 2004)

- Nuclear Power Joint Fact Finding, The Keystone Center (Keystone 2007)

- Power Plants: Characteristics and Costs, Congressional Research Service (CRS 2008)

The CBO, Chicago, MIT, and NEA studies are based on costs for plants recently constructed overseas and use input from the EIA. The TVA study was a bottom-up estimate based on materials and labor costs. The Congressional Research Service study was based on, when available, submittals to state public service commissions.

It is frequently difficult to compare study results because of differing assumptions and analytic approaches. In addition, studies do not always identify inputs that would facilitate explanation of the reason for differing results. As the Congressional Research Service states, published information on plant costs often do not clearly distinguish which components are included in an estimate, or different analysts may use different definitions (CRS 2008). Therefore, FPL relies most heavily on the estimate of Units 6 & 7 costs that it prepared for approval by the FPSC (FPL Oct 2007f for detail; FPL Oct 2007g for summary).

Commonly used terminology to explain the different cost includes:

- **Overnight cost** — Sometimes called “overnight capital cost,” this is a convention for expressing the cost of construction as if the plant could be built overnight. The cost is expressed as an absolute dollar value or a dollar value per unit of net (exclusive onsite use) electrical generation capacity, such as dollars per kilowatt or dollars per megawatt. The cost does not include escalation or interest costs during construction or during the time between estimate and assumed start of construction. The data are useful for comparing costs of alternative nuclear technologies and becomes the basis for broader cost estimates. Variables affecting interpretation of published information include whether basis is recent construction history or materials and labor costs buildup; inclusion of owner's costs (e.g., licensing, land, site preparation, cooling system, switchyard, transmission facilities, project management, and contingencies); economies of scale due to number of units to be built at site; and dollar-year of estimate.

- **Construction cost** — Sometimes called “all-in cost,” this adds to overnight cost escalation and interest during construction and during the time between a cost estimate and the start of construction. It is expressed in the same units as overnight cost and is useful for identifying total cost of construction and for determining the effects of construction delays. Variables affecting interpretation of published information include completeness of overnight cost estimate; assumptions on escalation and interest rates, debt/equity ratio, length of construction period, and contingencies; and dollar-year of estimate.

- **Levelized Cost** — Sometimes called “levelized annual cost,” this is the constant real wholesale price needed to recover construction and operation costs of the plant. The cost is expressed as cent or dollar value per amount of net electrical generation over time, such as cents per kW-hour. Levelized cost has been used in the past for comparing cost-competitiveness between alternative generation technologies (e.g., nuclear versus coal). Variables affecting interpretation of published information include completeness of intermediary cost estimates (overnight and construction), choices for discount rate, construction duration, plant life span, capacity factor, cost of debt and equity and split between debt and equity financing, depreciation time, tax rates, and premium for uncertainty. Estimates include decommissioning but, because of the effect of discounting a cost that would occur as much as 40 years in the future, decommissioning costs have relatively little effect on the levelized cost.

  For various reasons, levelized cost estimates are being recognized as an inadequate analytical approach to use in comparing competing resource options. Estimate methodologies historically have been based on the premise that construction cost recovery begins upon start of commercial operation. However, some states are beginning to allow recovery of construction costs as they are incurred to reduce overall project costs (by reducing carrying charges) and to reduce ratepayer “sticker shock” once operation begins. This change also means that cost recovery is not necessarily “levelized” in the traditional sense. Finally, such changes in state practices are not always consistent between alternative generation technologies, making cross-technologies estimates using traditional levelized cost methodologies even more problematic.

The studies report cost estimates for different years, such as $1800 in 2003 dollars. In order to compare estimates from different studies, FPL escalated or discounted all estimates to 2007 dollars.

10.4.2.1.2 Overnight Cost

The general studies present a range of overnight cost estimates from $2000 to almost $6000 per kW in 2007 dollars. As with a levelized cost approach on a per kW-hour basis, a comparison of overnight cost on a per kW-basis is an inadequate approach for comparing resource options. For example, there are two limitations to applying these overnight cost figures to Units 6 & 7. First, it is not clear how completely some of the studies incorporate the cost of land. It is reasonable to conclude that construction costs for completed reactors would include owner’s costs and that, therefore, EIA projections include owner’s costs. The FPL study expressly includes $0 for land cost because FPL would use a site of an existing power plant. The second limitation to the overnight cost information is that it does not include the cost of transmission facilities. It is noted that, while NRC has historically considered transmission costs to be internal costs, transmission costs might be excluded from estimates for publicly owned utilities. FPL would need to incur

internal cost for additional transmission lines, land within the transmission corridor, and any construction needed for substation expansion or renovation.

Total overnight cost would range from $7.9 to $11.4 billion, as shown in Table 10.4-2.

10.4.2.1.3 Construction Cost

FPL estimated the construction cost for Units 6 & 7 to range from $5823 to $8497 per kW in 2012 dollars as shown in Table 10.4-2. Total construction cost would range from $12.8 to $18.7 billion as shown in Table 10.4-2.

10.4.2.1.4 Levelized Cost

Overnight capital costs account for a third of the levelized cost, and interest costs on the overnight costs account for another 25 percent (UC Aug 2004). The general studies identified show a wide range of operation cost estimates. Levelized cost of electricity estimates range from $36 to $83 per megawatt hour (3.6 to 8.3 cents per kWh).

Due to the fundamental problems inherent in a levelized cost approach to comparing, the state of Florida and FPL did not use levelized cost in their evaluation of the need for Units 6 & 7 and an estimate has not been generated. Instead, FPL has modeled a number of economic scenarios that incorporate a range of potential fuel prices and possible environmental compliance costs, including a range of greenhouse gas emission reduction costs. As part of this analysis, a range of economic outcomes in which one fuel technology (nuclear or combined-cycle) is the cost-preferred solution relative to the other in reducing the capacity gap was identified. The results of the analysis were presented as a breakeven capital cost for each individual case.

10.4.2.2 Internal Costs — Generation Alternatives

NRC precedent has established that project cost information for alternatives is relevant only if the alternatives are environmentally preferable to the proposed action (NRC Feb 2009). As described in Section 9.2, FPL has concluded that coal- and gas-fired generation were not environmentally preferable alternatives to the proposed action. In keeping with NRC precedent, FPL has not included internal cost estimates for the generation alternatives.

10.4.2.3 External Costs

10.4.2.3.1 Land Use

Disturbance of land is one of the costs of constructing the new nuclear reactor units and appurtenant structures. Units 6 & 7 would be part of the Turkey Point plant property that is currently zoned by Miami-Dade County for permitted use for nuclear reactors. As described in Sections 4.1 and 5.1, locating the new reactors on the Turkey Point Plant Property is expected to

have SMALL adverse impacts. Appropriate best environmental management practices would be implemented to minimize the potential for land use impacts including erosion and sedimentation and any unavoidable impacts to wetlands would require mitigation.

10.4.2.3.2 Hydrological and Water Use

There are costs associated with providing water for various needs during construction and operation of the new units. As described in Sections 4.2 and 4.4, construction of Units 6 & 7 is estimated to require a maximum of 565 gpm of potable water, used for such activities as dust abatement, mixing concrete, hydrotesting and flushing, and potable water used by the construction workforce. Miami-Dade County would be the source for construction water requirements.

As described in Section 3.3, water consumption during operations activities would total 2.95E10 gallons annually for both units. Cooling water makeup sources are reclaimed water and saltwater using radial collector wells. Potable water in the amount of 936 gpm (1.35 mgd) to 2553 gpm (3.68 mgd) would be supplied for non-cooling water use. Units 6 & 7 wastewater would be injected underground via permitted deep injection wells. Hydrological and water use impacts are anticipated to be SMALL.

10.4.2.3.3 Terrestrial and Aquatic Biology

Some costs associated with loss of terrestrial and aquatic populations and habitats during construction are anticipated. As described in Section 4.3, conversion of approximately 300 acres of primarily mudflat and wetland habitat would occur. However, these impacts would not significantly reduce the regional diversity of plants or plant communities due to the scarce natural conditions of the site. The potential losses from the project are not expected to be large enough to affect the long-term stability of terrestrial and aquatic resources in the area and the overall impact is anticipated to be SMALL.

10.4.2.3.4 Air Emissions

Relatively small amounts of air emissions from diesel generators and vehicles would be generated during construction and operation of the facilities. Cooling tower drift deposits salt on the plant property and adjacent areas, but the levels are not likely to result in any measurable impact on vegetation. Air emission impacts are anticipated to be SMALL.

10.4.2.3.5 Radioactive Emissions, Effluents, and Wastes

Minor radioactive air emissions are released into the atmosphere and discharged into deep injection wells. Low-level and high-level radioactive wastes are generated and need to be

disposed of according to local, state, and federal permitting regulations. Overall radioactive emissions, effluents, and waste impacts are anticipated to be SMALL.

10.4.2.3.6 Socioeconomic

It is anticipated that the region affords necessary infrastructure and services to meet the demands of the construction and operation workforce. If additional infrastructure and services are needed to meet the demands of the people moving into the area to support the construction and operation of the new units, these costs would be offset by the beneficial increased tax revenues to the local economy and the overall beneficial economic input to the region from those individuals and families.

10.4.2.4 Alternative Sites

In Subsection 9.3.3, the environmental impacts of construction and operation of the proposed project at four alternative sites (Glades, Martin, Okeechobee 2, and St. Lucie) were evaluated. Table 10.4-1 identifies the unavoidable adverse environmental impacts of construction and operation of the project as proposed at the four alternative sites.

10.4.3 SUMMARY

In accordance with guidance provided in NUREG-1555, Rev. 1, (ESRP 10.4), this section summarizes the benefits and costs of the proposed construction and operation of Units 6 & 7. This table also provides information regarding selected mitigation measures for potential impacts. Costs that are environmental impacts are those anticipated after proposed mitigation measures are implemented.

The costs of mitigation are not easily determined at this time. It is anticipated that mitigation would be built into the overall design (for example, scheduling to ensure construction is completed in the shortest possible time, using construction best management practices to limit erosion, fugitive dust, runoff, spills, and air emissions, and providing first-aid stations at the construction site). Relying on early and frequent communication between FPL and the affected communities could help to minimize cost and ensure effective management of the construction and operation of Units 6 & 7.

In summary, there is a resource need in the region of influence by 2022, with that need increasing every year thereafter. Following a comprehensive review and consideration of the factors discussed earlier, the FPSC determined that Turkey Point Units 6 & 7 will provide needed system reliability, fuel diversity, baseload capacity, reasonable affordable electricity, and the most cost-effective sources of power (FPSC 2008). It has been determined that the new nuclear facility should be located at the existing plant property in Miami-Dade County, Florida. Units 6 & 7 will

result in a reduction in emissions with respect to comparably sized coal- or gas-fired alternative power generating facilities.

While the additional direct and indirect creation of jobs for the construction and operation of the new facility may place a temporary burden on local services and infrastructures, the annual taxes and revenue generated by the new workers contribute to the local economy and the region's productivity.

In conclusion, the construction and operation of the proposed project is needed by the service area and the benefits outweigh the economic, environmental, and social costs.

Table 10.4-1 (Sheet 1 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Project Description	Units 6 & 7 are at an existing fossil fuel and nuclear power generating facility, located in Miami-Dade County, Florida. The site is owned by FPL.	The Glades site is a greenfield site in Glades County, Florida.	The Martin site is an existing fossil fuel power generating facility in Martin County, Florida. The site is owned by FPL.	The Okeechobee 2 site is a greenfield site in Okeechobee County, Florida.	The St. Lucie site is an existing nuclear power generating facility in St. Lucie County, Florida. The site is owned by FPL.
Benefits					
Electricity Generated and Generating Capacity	Westinghouse AP1000 reactors for Units 6 & 7 have a rated total gross thermal megawatt output per unit of 3,415 MWt with a gross electrical output each of approximately 1,100 MWe.	The electricity generated and generating capacity would be similar to that of Units 6 & 7.	The electricity generated and generating capacity would be similar to that of Units 6 & 7.	The electricity generated and generating capacity would be similar to that of Units 6 & 7.	The electricity generated and generating capacity would be similar to that of Units 6 & 7.
Fuel Diversity	Nuclear generation provides an option to either a natural gas or coal baseload facility for electricity supply. Does not have price volatility of natural gas and reduces emissions. Unlike coal, fuel availability issues are limited.	Nuclear generation provides an option to either a natural gas or coal baseload facility for electricity supply. Does not have price volatility of natural gas and reduces emissions. Unlike coal, fuel availability issues are limited.	Nuclear generation provides an option to either a natural gas or coal baseload facility for electricity supply. Does not have price volatility of natural gas and reduces emissions. Unlike coal, fuel availability issues are limited.	Nuclear generation provides an option to either a natural gas or coal baseload facility for electricity supply. Does not have price volatility of natural gas and reduces emissions. Unlike coal, fuel availability issues are limited.	Nuclear generation provides an option to either a natural gas or coal baseload facility for electricity supply. Does not have price volatility of natural gas and reduces emissions. Unlike coal, fuel availability issues are limited.
Licensing Certainty	Resolution of design criteria through certification; resolution of site, construction and operational issues in COL Application; reliance on nuclear as generation.	Resolution of design criteria through certification; resolution of site, construction, and operational issues in COL Application; reliance on nuclear as generation.	Resolution of design criteria through certification; resolution of site, construction, and operational issues in COL Application; reliance on nuclear as generation.	Resolution of design criteria through certification; resolution of site, construction, and operational issues in COL Application; reliance on nuclear as generation.	Resolution of design criteria through certification; resolution of site, construction, and operational issues in COL Application; reliance on nuclear as generation.
Carbon Reduction	Nuclear power reduces carbon emissions by not producing 14 million tons per year CO_2 as coal or 6 million tons per year CO_2 as natural gas.	Carbon emissions reduction would be similar to Units 6 & 7.	Carbon emissions reduction would be similar to Units 6 & 7.	Carbon emissions reduction would be similar to Units 6 & 7.	Carbon emissions reduction would be similar to Units 6 & 7.
Increased Customer Choice	Retail choice of “clean” energy source in addition to menu of renewable sources.	Retail choice of “clean” energy source in addition to menu of renewable sources.	Retail choice of “clean” energy source in addition to menu of renewable sources.	Retail choice of “clean” energy source in addition to menu of renewable sources.	Retail choice of “clean” energy source in addition to menu of renewable sources.

Table 10.4-1 (Sheet 2 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Benefits (cont.)					
Local Economy	Addition of 3950 new employees to the workforce for construction of the new units. A workforce of approximately 806 employees would be needed for operation. Construction and operation workforce provide an economic benefit to the community.	A similar size workforce as Units 6 & 7 is anticipated.	A similar size workforce as Units 6 & 7 is anticipated.	A similar size workforce as Units 6 & 7 is anticipated.	A similar size workforce as Units 6 & 7 is anticipated.
Aesthetic Values	Selection of design and cooling tower technology allows for minimal aesthetic impacts. Site contains existing nuclear power facility structures.	Selection of design and cooling tower technology allows for minimal aesthetic impacts. No current facilities on site.	Selection of design and cooling tower technology allows for minimal aesthetic impacts. Site contains existing fossil fuel power facility structures.	Selection of design and cooling tower technology allows for minimal aesthetic impacts. No current facilities on site.	Selection of design and cooling tower technology allows for minimal aesthetic impacts. Site contains existing nuclear power facility structures.
Air Quality	Major beneficial impact in terms of avoidance of power plant emissions.	Major beneficial impact in terms of avoidance of power plant emissions.	Major beneficial impact in terms of avoidance of power plant emissions.	Major beneficial impact in terms of avoidance of power plant emissions.	Major beneficial impact in terms of avoidance of power plant emissions.
Land Use	Land to be used for Units 6 & 7 is owned by FPL and would be part of the existing power generating facility.	The Glades County site is on land that is currently a greenfield site. The land would need to be rezoned for development of the nuclear units.	Land to be used for the Martin site would be part of the existing power generating facility. Additional lands would need to be obtained for a cooling water storage reservoir.	The Okeechobee 2 site is on land that is currently a greenfield site. The land would need to be rezoned for development of the nuclear units.	Land to be used for the St. Lucie site is owned by FPL and would be part of the existing power generating facility.

Benefits (cont.)					
State/Local Tax Payments during Construction and Operations	Construction will generate tax revenues from sources including income tax, retail sales tax on materials, supplies, and selected construction services; retail sales tax on expenditures by workers; and corporate income taxes paid by contractors. During operation of the facility, local government tax revenues will accrue from property taxes and permitting and impact fees. Tax payments would occur annually over the life of the new reactor units. The impacts to the local tax base are considered SMALL and beneficial. Benefits (cont.)					
Effects on Regional Productivity	Anticipate an increase in regional productivity through the influx of construction and station operation workers. Workers will create additional new indirect (service-related) jobs in the region through the multiplier effect of direct employment. Construction workforce and their families will increase the population in the area. The expenditures of construction and facility operation workers for food, shelter, and services will create jobs, which will have a SMALL positive impact on the region's economy. Job creation will inject millions of dollars in the region's economy, reducing unemployment and creating business opportunities. Benefits (cont.)					
Technical and Other Non-monetary Improvements (for example, New Recreational Facilities and Improvements to Local Facilities)	Anticipate that existing local and county police, fire, and medical facilities and/or personnel would be able to accommodate the influx of construction and facility operation workers. Anticipate that the existing water supply and wastewater treatment facilities can accommodate the added increase in population. Anticipate that the existing education and social service facilities can accommodate the increase in population. Construction and operation activities should not have long-term, adverse impacts to recreational use of the surrounding area. Neither technical developments nor recreational enhancements are anticipated at this time from the construction and operation of the proposed nuclear facility. In addition, minor road improvements would occur near the proposed nuclear facility, on an as-needed basis, to support construction and operation activities. Table 10.4-1 (Sheet 6 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Benefits (cont.)					
Environmental Enhancement	Reduction in carbon emissions with the use of nuclear power. It is necessary to transport fill material to this site to increase the site elevation before construction for tidal purposes. Land acquisition would not be required at the Units 6 & 7 site because the site is already owned by FPL and is designated for power plant activities. Units 6 & 7 would use a combination of sources for cooling water makeup: reclaimed water obtained from treated wastewater and water obtained from the seawater aquifer under Biscayne Bay using radial collector wells. For heat rejection, a closed-loop system with mechanical draft cooling towers would be used.	Reduction in carbon emissions with the use of nuclear power. Because portions of the Glades site are within the 100-year floodplain, it is necessary to utilize fill material to increase the site elevation before construction. Fill material is assumed to be available from on-site excavations. Because this site is a greenfield site, it is estimated that 3,360 acres of land acquisition would be required. Freshwater sources (surface or groundwater) are available to supply the water needs for the Glades site, including the Caloosahatchee River/Canal, and the water would be transferred to the site via underground pipelines. For heat rejection, a closed-loop system with mechanical draft cooling towers would be used.	Reduction in carbon emissions with the use of nuclear power. The Martin site is outside of the 100-year floodplain and would, therefore, not require modification to site elevation. Land acquisition would be required at the Martin site for the cooling water storage reservoir. It is estimated that approximately 2,800 acres of land acquisition would be required. Freshwater sources (surface or groundwater) are available to supply the water needs for the Martin site, including the St. Lucie Canal, and the water would be transferred to the site via underground pipelines. For heat rejection, a closed-loop system with mechanical draft cooling towers would be used.	Reduction in carbon emissions with the use of nuclear power. Because portions of the Okeechobee site are within the 100-year floodplain, it may be necessary to utilize fill material to increase the site elevation before construction. Fill material is assumed to be available from on-site excavations. Because this site is a greenfield site, it is estimated that 3,360 acres of land acquisition would be required. Freshwater sources (surface or groundwater) are available to supply the water needs for the Okeechobee site, including the Kissimmee River, and the water would be transferred to the site via underground pipelines. For heat rejection, a closed-loop system with mechanical draft cooling towers would be used.	Reduction in carbon emissions with the use of nuclear power. Because the St. Lucie site is within the 100-year floodplain, it is necessary to transport fill material to this site to increase the site elevation before construction. Land acquisition would not be required at the St. Lucie site because the site is already owned by FPL and is designated for power plant activities. The St. Lucie site would employ the same type of ocean water intake and canal transfer system used for existing St. Lucie Units 1 & 2. For heat rejection, a closed-loop system with mechanical draft cooling towers would be used.

Table 10.4-1 (Sheet 7 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Benefits (cont.)					
Construction Cost Note: Cost value is a roll-up of the internal cost values for constructing the facility, which include land, labor, materials, and equipment.	The proposed reactors at Units 6 & 7 will each be rated with a net electrical output of greater than or equal to 1,000 MWe. In accordance with Subsection 4.4.2, FPL estimates a total escalated construction cost of $18.7 billion, which includes the cost of constructing Units 6 & 7.	The proposed reactors will be similar to the proposed reactors at the Units 6 & 7 site (net electrical output of greater than or equal to 1,000 MWe). Construction costs will be similar to the Units 6 & 7 site.	The proposed reactors will be similar to the proposed reactors at the Units 6 & 7 site (net electrical output of greater than or equal to 1,000 MWe). Construction costs will be similar to the Units 6 & 7 site.	The proposed reactors will be similar to the proposed reactors at the Units 6 & 7 site (net electrical output of greater than or equal to 1,000 MWe). Construction costs will be similar to the Units 6 & 7 site.	The proposed reactors will be similar to the proposed reactors at the Units 6 & 7 site (net electrical output of greater than or equal to 1,000 MWe). Construction costs will be similar to the Units 6 & 7 site.
Transmission System	The Units 6 & 7 site would require a transmission system, consisting of three additional 230 kV transmission lines and two additional 500 kV lines to connect the new nuclear units to the existing FPL transmission system. The lines would be routed approximately 89 miles along two separate transmission corridors.	It was assumed that the Glades site would require approximately 121 miles of new transmission corridor to connect the new nuclear units to the existing FPL transmission system at the Andytown Substation in Broward County.	It was assumed that the Martin site would require approximately 31 miles of new transmission corridor to connect the new nuclear units to the existing FPL transmission system at the Corbett substation in Palm Beach County.	It was assumed that the Okeechobee 2 site would require approximately 38 miles of new transmission corridor to connect the new nuclear units to the existing FPL transmission system at the Corbett substation in Palm Beach County.	It was assumed that the St. Lucie site would require approximately 63 miles of new transmission corridor to connect the new nuclear units to the existing FPL transmission system at the Corbett substation in Palm Beach County.
Operating Cost Note: Cost value is a roll-up of the Internal cost values for operating the facility which include labor, materials, and services.	The nuclear industry's average production cost in 2007 was 1.68 cents per kWh.	Costs would be similar to the Units 6 & 7 site.	Costs would be similar to the Units 6 & 7 site.	Costs would be similar to the Units 6 & 7 site.	Costs would be similar to the Units 6 & 7 site.

Table 10.4-1 (Sheet 8 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Benefits (cont.)					
Land Use	The Units 6 & 7 plant area is a 220-acre area located on the existing FPL-owned 9400-acre plant property, on which five electric generating units are currently operational. The site is currently zoned for permitted use for nuclear reactors through an unusual use approval by Miami-Dade County (Section 4.1). The site consists of hypersaline mudflats; open water, dwarf mangroves, upland and wetlands spoils areas, man-made remnant canals, mangrove heads, and fill areas/roadways (Section 2.2). Most of the site (61 percent) is comprised of mudflats surrounded by man-made cooling canals. Based on land disturbance totals and the change of land use from agricultural to industrial, land use impacts from the project are anticipated to be SMALL.	The Glades site is approximately 3,360 acres (excluding offsite project components) and is developed for agricultural and farm use. The topography of the site is generally flat with a mean elevation of 15 feet. Approximately 306 acres of wetlands are within the project area, excluding the conceptual transmission corridor. The site is surrounded by sugarcane fields. Based on a potentially affected area of approximately 9,287 acres (including the conceptual transmission corridor) and the permanent change of land use from agricultural to industrial, land use impacts at the Glades site and the transmission corridor would be LARGE.	The Martin site is an existing 11,300-acre area that includes five fossil-fired power units and a solar unit. The plant site is owned by FPL although additional land would need to be acquired given that a new 3,000-acre cooling water storage reservoir would be required. The site includes an area of mixed pine flat wood and scattered small wetlands, a 1,200-acre area that has been set aside as a mitigation area, and a 400-acre peninsula of wetland forest, the Barley Barber Swamp, that is preserved as a natural area. Approximately 163 acres of wetlands are within the project area, excluding the conceptual transmission corridor. Because the site already hosts multiple power generation units, construction of additional power units would not alter site land use. Based on a potentially affected area of approximately 4,674 acres, most of which would occur off the existing Martin plant site	The Okeechobee 2 site is a 3,360-acre undeveloped site (excluding offsite project components). The site is not owned by FPL but is considered potentially available. The site is used primarily for farmland and agriculture. The county has substantial cattle, dairy, and citrus operations. The site is generally flat with a mean elevation of 28 feet. Approximately 1,500 acres of wetlands are within the project area, excluding the conceptual transmission corridor. Based on a potentially affected area of approximately 6,567 acres (including the conceptual transmission corridor) and the permanent change of land use from agricultural to industrial, land use impacts at the Okeechobee 2 site and the transmission corridor would be LARGE.	The St. Lucie site is an FPL-owned nuclear power generation station located on the 1,130-acre site on Hutchinson Island. The site is bordered by the Atlantic Ocean and the Indian River Lagoon. The nominal site elevation is 0 to 5 feet above sea level, which falls within the 100-year floodplain. West of the facility, the land gradually slopes downward to a mangrove fringe bordering the intertidal shoreline of the Indian River Lagoon. East of the facility, land rises from the ocean shore to form dunes and ridges approximately 15 feet above mean low water. Two county parks with beach access lie within the property boundary. Because the site already hosts nuclear power generation units, construction of additional power units would not alter area land use. Based on a potentially affected area of approximately 2,828 acres (including the conceptual transmission corridor and

Table 10.4-1 (Sheet 10 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
Benefits (cont.)					
Water Use	Construction for Units 6 & 7 is estimated to require a maximum of 565 gpm of water, used for such activities as dust abatement, mixing concrete, hydrotesting and flushing, and potable water use by the construction force. Miami-Dade County would be the source for construction water requirements (Section 4.2). As described in Section 3.3, water consumption during fuel cycle activities would total 2.95E10 gallons annually for both units. Cooling water makeup sources are reclaimed water from county-treated wastewater and water drawn from the seawater aquifer underlying Biscayne Bay using radial collector wells. Public water in the amount of 936 gpm (1.35 mgd) to 2,553 gpm (3.68 mgd) would be supplied for non-cooling water use. Units 6 & 7 wastewater will be injected underground via permitted deep injection wells. Hydrological and water use impacts are anticipated to be SMALL.	Consumptive water use for a nuclear facility at the Glades site would be similar to that which is proposed for Units 6 & 7 at the Turkey Point site. Major freshwater surface water sources exist that could meet the water use needs of the facility. Lake Okeechobee offers a potential water supply of more than 360 cfs, and the annual average flow of the Caloosahatchee River/Canal near the site is approximately 592 cfs. The estimated groundwater potential at the Glades site is approximately 155 cfs. These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Glades site. Water use impacts are anticipated to be SMALL.	Consumptive water use for a nuclear facility at the Martin County site would be similar to that which is proposed for Units 6 & 7 at the Turkey Point site. Major freshwater surface water sources exist that could meet the water use needs of the facility. Lake Okeechobee offers a potential water supply of more than 360 cfs, and the annual average flow of the St. Lucie Canal near the site is approximately 842 cfs. The estimated groundwater potential at the Martin site is approximately 155 cfs. These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Martin site. Water use impacts are anticipated to be SMALL.	Consumptive water use for a nuclear facility at the Okeechobee 2 site would be similar to that which is proposed for Units 6 & 7 at the Turkey Point site. Major freshwater surface water sources exist that could meet the water use needs of the facility. Lake Okeechobee offers a potential water supply of more than 360 cfs, and the annual average flow of the Kissimmee River near the site is approximately 919 cfs. The estimated groundwater potential at the Okeechobee 2 site is approximately 155 cfs. These water sources are suitable to satisfy potable and process water demands associated with construction and operation at the Okeechobee 2 site. Water use impacts are anticipated to be SMALL.	Consumptive water use for a nuclear facility at the St. Lucie site would be similar to that which is proposed for Units 6 & 7 at the Turkey Point site. Existing St. Lucie Units 1 & 2 receive water from the city of Ft. Pierce and the Ft. Pierce Utilities Authority for potable and service uses at the plant. The freshwater is derived from groundwater sources on the mainland, and plant operations do not involve any additional groundwater withdrawal. Average potable water usage at the plant is approximately 131,500 gpd with no restrictions on supply. The addition of two more power units would nominally double this daily potable water requirement. Water is withdrawn from the Atlantic Ocean in a once-through arrangement to cool St. Lucie Units 1 & 2. A closed loop, tower-cooled system would be developed for the new power units, whereby consumptive losses are replaced from the Atlantic Ocean and blowdown water is routed to the Atlantic Ocean. Water use impacts are anticipated to be SMALL.

Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs					
Air Quality	The construction and operation of the power facility would meet applicable federal, state, and local air quality permitting regulations.	The construction and operation of the power facility would meet applicable federal, state, and local air quality permitting regulations.	The construction and operation of the power facility would meet applicable federal, state, and local air quality permitting regulations.	The construction and operation of the power facility would meet applicable federal, state, and local air quality permitting regulations.	The construction and operation of the power facility would meet applicable federal, state, and local air quality permitting regulations.
Terrestrial Biology	Terrestrial species that are listed as threatened or endangered by the U.S. Fish and Wildlife Service (USFWS) and the state of Florida and have the potential to occur within the Units 6 & 7 site and vicinity are described in Subsection 2.4.1. Conversion of approximately 300 acres of primarily mudflat habitat would not significantly reduce the regional diversity of plants and plant communities (Section 4.3). Some potential impacts to wetlands and sensitive species may occur, but mitigation is available to offset any affects. Impacts from the project to terrestrial ecological resources are anticipated to be SMALL (Sections 4.3, 5.3, and 5.6).	Terrestrial species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur within Glades County are presented in Table 9.3-8. Glades County has a low number of sensitive species, there are no known sensitive species onsite, and the transmission corridor is relatively short; however, up to 1,873 acres of wetlands (approximately 650 acres of high quality wetlands) could be affected by project construction and operation (including those found in the conceptual transmission corridor). Impacts to terrestrial resources, including threatened and endangered species from construction and operation of the nuclear plant and transmission corridor at the Glades site, would be MODERATE.	Terrestrial species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur within Martin County are presented in Table 9.3-10. There are no known sensitive species onsite, and the transmission corridors would be relatively short. Impacts to terrestrial resources, including threatened and endangered species from construction and operation of the nuclear plant and transmission corridor at the Martin site, would be SMALL.	Terrestrial species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur within Okeechobee County are presented in Table 9.3-12. Okeechobee County has a low number of sensitive species; there are no known sensitive species onsite. The site area includes a relatively small area of undisturbed woodlands that could be potentially affected by project construction and operation. However, it also includes over 2,000 acres of wetlands, including approximately 1,300 acres of wet prairies and 300 acres of high quality wetlands that could be potentially affected. Impacts to terrestrial resources, including threatened and endangered species from construction and operation of the nuclear plant and transmission corridor at the Okeechobee 2 site, would be MODERATE.	Terrestrial species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur within St. Lucie County are presented in Table 9.3-14. There are no designated critical terrestrial habitats for endangered species in the vicinity of St. Lucie Units 1 & 2. Important wetland habitat (mangrove) would be permanently lost from plant construction and the widening of SR A1A. There are beach and dunes, mangrove, and tropical hammock habitats that are important, as they represent important coastal ecosystems that have been reduced by development. Also, these habitats support a variety of animal species. Impacts to terrestrial resources, including threatened and endangered species from construction and operation of the nuclear plant and transmission corridor at the St. Lucie site, would be MODERATE.

Table 10.4-1 (Sheet 12 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs (cont.)					
Terrestrial Biology (cont.)		Most of the site is an active sugarcane field that is unsuitable habitat for most wildlife species because of the lack of native vegetation and the amount and frequency of human disturbance. The site has been modified to allow for irrigation using an irrigation/ drainage ditch network throughout the site. Any wetland functions that are impacted during construction would be replaced or restored.			St. Lucie County has a low number of sensitive species, but endangered species are present at the site and important coastal habitat is found nearby. The project would impact nearly 1,000 acres of wetlands from onsite and offsite construction activities, including over 400 acres of mangrove habitat. Construction of the transmission corridor would also potentially affect over 2,000 acres. Impacts from construction would be MODERATE. Impacts from operation include drift from vapor plumes that would be high in salt and minerals. However, surrounding ecosystem is adapted to higher salinity and use of drift eliminators would help reduce impacts to SMALL.

Table 10.4-1 (Sheet 13 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs (cont.)					
Aquatic Biology	Aquatic species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur within the Units 6 & 7 site and vicinity are described in Subsection 2.4.2. Units 6 & 7 wastewater, including cooling water tower blowdown discharge, will be injected underground via permitted deep injection wells, so there will be no discharge impacts to aquatic resources. Cooling water makeup sources are reclaimed water from county-treated wastewater and water drawn from the seawater aquifer underlying Biscayne Bay using radial collector wells, so there will be no entrainment or impingement of aquatic organisms and no resultant disruption of existing populations. Impacts from project to aquatic ecological resources are anticipated to be SMALL (Sections 4.3 and 5.3).	Aquatic species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur in Glades County are presented in Table 9.3-8. Wastewater, including cooling water tower blowdown discharge, will be injected underground via permitted deep injection wells, so there will be no discharge impacts to aquatic resources. Proposed facilities at the site will include cooling towers that would reduce the amount of cooling water withdrawal required for plant operation. Through the use of cooling towers with an appropriate intake design, potential adverse impacts from entrainment or impingement of aquatic organism would be SMALL and would not significantly disrupt existing populations.	Aquatic species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur in Martin County are presented in Table 9.3-10. Wastewater, including cooling water tower blowdown discharge, will be injected underground via permitted deep injection wells, so there will be no discharge impacts to aquatic resources. Proposed facilities at the site will include cooling towers that would reduce the amount of cooling water withdrawal required for plant operation. Through the use of cooling towers with an appropriate intake design, potential adverse impacts from entrainment or impingement of aquatic organism would be SMALL and would not significantly disrupt existing populations.	Aquatic species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur in Okeechobee County are presented in Table 9.3-14. Wastewater, including cooling water tower blowdown discharge, will be injected underground via permitted deep injection wells, so there will be no discharge impacts to aquatic resources. Proposed facilities at the site will include cooling towers that would reduce the amount of cooling water withdrawal required for plant operation. Through the use of cooling towers with an appropriate intake design, potential adverse impacts from entrainment or impingement of aquatic organism would be SMALL and would not significantly disrupt existing populations.	Aquatic species that are listed as threatened or endangered by the USFWS and the state of Florida and have the potential to occur in St. Lucie County are presented in Table 9.3-14. Operation under the NPDES permit should result in the maintenance of a balanced, indigenous population of fish, shellfish, and other aquatic organisms in the vicinity of the discharge structure. Proposed facilities at the site will include cooling towers that would reduce the amount of cooling water withdrawal required for plant operation. Through the use of cooling towers with an appropriate intake design, potential adverse impacts from entrainment or impingement of aquatic organism would be minor and would not significantly disrupt existing populations. However, because of the known presence of endangered species at the site, the impact from plant construction would be considered MODERATE.

Table 10.4-1 (Sheet 14 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs (cont.)					
Aquatic Biology (cont.)					Plant operation is not expected to entrain more turtles, fish or cause more takes, and impacts from operations would be considered SMALL.
Socioeconomic	Socioeconomic impacts associated with the construction and operation of Units 6 & 7 is described in Sections 4.4 and 5.8. The overall population level is anticipated to be sufficiently large that the impact on area employment from construction and operation of Units 6 & 7 would be low. It is expected that the impact on housing and community services would be negligible. The site area appears to have sufficient population centers within commuting distance such that its public services sector would be able to absorb the population in-migration associated with plant construction and operation with minimal impact.	The region of influence that includes Glades, Hendry, Lee, and Okeechobee Counties has a 2006 population estimate of 663,439, which is a 26.7 percent increase from the 2000 population. The economies of the four counties in the region of influence are dominated primarily by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force resides in Lee County.	The region of influence that includes Martin, Okeechobee, Palm Beach, and St. Lucie Counties has a 2006 population estimate of 1,706,536, which is a 14.8 percent increase from the 2000 population. The economies of the four counties in the region of influence are dominated primarily by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force resides in Palm Beach County.	The region of influence that includes Martin, Okeechobee, Palm Beach, and St. Lucie Counties has a 2006 population estimate of 402,347, which is a 23.2 percent increase from the 2000 population. The economies of the four counties in the region of influence are dominated primarily by educational, health, and social services; retail trade; and agriculture, forestry, fishing and hunting, and mining. Most of the labor force resides in St. Lucie County.	The region of influence that includes St. Lucie, Martin, Indian River, and Palm Beach Counties has a 2006 population estimate of 1,796,230, which is a 14.9 percent increase from the 2000 population. The economies of the four counties in the region of influence are dominated primarily by educational, health, and social services; agriculture, forestry, fishing and hunting, and mining; and retail trade. Most of the labor force resides in St. Lucie County.

Table 10.4-1 (Sheet 15 of 18)
Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs (cont.)					
Socioeconomic (cont.)	The region affords necessary infrastructure and services to meet the demands of the construction and operation workforce. If additional infrastructure and services are needed to meet the demands of the people moving into the area to support the construction and operation of the new facility, these costs should be offset by the beneficial increased tax revenues to the local economy and the overall beneficial economic input to the region from those individuals and families. Socioeconomic impacts from construction and operational activities of the project are anticipated to be SMALL and beneficial for all aspects but transportation. A negative MODERATE impact of the project to the local area could occur from increased traffic.	70 percent of the construction workers and 85 percent of the operation workers would relocate from outside the region of influence. The total projected increase in population attributable to the peak total construction workforce at the Glades site would be 6,669 people, a 1.3 percent increase in the region of influence population. This would pose a SMALL impact on the population for the region of influence. The total population increase attributable to project operations is 2,901 people, posing a SMALL impact on population for the region of influence.	Because of the location of the Martin site to population centers, 50 percent of the construction workers and operation workers would relocate from outside the region of influence. The total projected increase in population attributable to the peak total construction workforce at the Martin site would be 4,729 people, a 0.3 percent increase in the region of influence population. This would pose a SMALL impact on the population for the region of influence. The total population increase attributable to project operations is 1,706 people, posing a SMALL impact on population for the region of influence.	70 percent of the construction workers and 85 percent of the operation workers would relocate from outside the region of influence. The total projected increase in population attributable to the peak total construction workforce at the Okeechobee 2 site would be 6,669 people, a 2.0 percent increase in the region of influence population. This would pose a SMALL impact on the population for the region of influence. The total population increase attributable to project operations is 2,901 people, posing a SMALL impact on population for the region of influence.	50 percent of the construction workers and operation workers would relocate from outside the region of influence. The total projected increase in population attributable to the peak total construction workforce at the St. Lucie site would be 4,729 people, a 0.3 percent increase in the region of influence population. This would pose a SMALL impact on the population for the region of influence. The total population increase attributable to project operations is 1,310 people, posing a SMALL impact on population for the region of influence.

Summary of the Benefits and Costs of the Construction and Operation of Units 6 & 7

Category	Turkey Point Units 6 & 7	Glades	Martin	Okeechobee 2	St. Lucie
External Costs (cont.)					
Socioeconomic (cont.)		The creation of direct and indirect jobs is projected at 4574 new jobs in the region of influence during the peak construction period, a 2 percent increase in the total labor force. This would potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic benefits attributable to project construction would be beneficial and SMALL within the region of influence. An estimated 1,050 workers would be required for the operation of the two nuclear power units. This is projected to result in a total of 2055 jobs in the region, a 0.9 percent increase in the total labor force in the region of influence. The socioeconomic impacts attributable to project operation would be beneficial and SMALL.	The creation of direct and indirect jobs is projected at 3208 new jobs in the region of influence during the peak construction period, a 0.5 percent increase in the total labor force. This would potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic benefits attributable to project construction would be beneficial and MODERATE in Okeechobee County and SMALL in the other counties within the region of influence. An estimated 1,050 workers would be required for the operation of the two nuclear power units. This is projected to result in a total of 1197 jobs in the region, a 0.2 percent increase in the total labor force in the region of influence.	The creation of direct and indirect jobs is projected at 4259 new jobs in the region of influence during the peak construction period, a 3.2 percent increase in the total labor force. This would potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic benefits attributable to project construction would by beneficial and SMALL within the region of influence. An estimated 1,050 workers would be required for the operation of the two nuclear power units. This is projected to result in a total of 2203 jobs in the region, a 1.7 percent increase in the total labor force in the region of influence. The socioeconomic impacts attributable to project operation would be beneficial and SMALL.	The creation of direct and indirect jobs is projected at 3178 new jobs in the region of influence during the peak construction period, a 0.5 percent increase in the total labor force. This would potentially reduce unemployment and would likely create business opportunities for goods and service-related industries and the housing industry. Overall, the economic benefits attributable to project construction would by beneficial and SMALL within the region of influence. An estimated 806 workers would be required for the operation of the two nuclear power units. This is projected to result in a total of 907 new jobs in the region, a 0.1 percent increase in the total labor force in the region of influence. The socioeconomic impacts attributable to project operation would be beneficial and SMALL.

Environmental Justice	No anticipated short-term impact on availability of housing units in the area during construction.	No anticipated short-term impact on availability of housing units in the area during construction.	No anticipated short-term impact on availability of housing units in the area during construction.	No anticipated short-term impact on availability of housing units in the area during construction.	No anticipated short-term impact on availability of housing units in the area during construction.
	Local infrastructure surrounding Units 6 & 7 site is described in Section 2.2. There are sufficient roads that provide access to plant property. However, some additional construction of local access roads to the Units 6 & 7 site would be required. The impact of the construction and operations workforces on transportation would be MODERATE (Sections 4.4 and 5.8).	There are sufficient roads that provide main access to the proposed Glades site. However, construction of local access roads would be required. Railroad spurs would also be required. The impact of the construction and operations workforces on transportation would be MODERATE.	There are sufficient roads that provide main access to the Martin site. However, construction of local access roads would be required. Railroad spurs would also be required. The impact of the construction and operations workforces on transportation would be LARGE.	There are sufficient roads that provide main access to the proposed Okeechobee 2 site. However, construction of local access roads would be required. The impact of the construction and operations workforces on transportation would be LARGE.	There are sufficient roads that provide main access to the St. Lucie site. However, improvement to local roads would be required. The impact of the construction and operations workforces on transportation would be MODERATE.
	Radiological exposure would be below limits to workers and public.	Radiological exposure would be below limits to workers and public.
