CHAPTER 1 LIST OF TABLES

Number	Title
1.2-1	Authorizations for Turkey Point Units 6 & 7

CHAPTER 1 INTRODUCTION

1.1 THE PROPOSED PROJECT

This section introduces the applicant and owner and provides a brief description of the proposed project, including descriptions of the site location, the selected reactor type and other plant design features, pre-application public participation activities, and major project activity dates.

Pursuant to the Atomic Energy Act of 1954, as amended, and Title 10 of the CFR, the NRC is responsible for licensing the construction and operation of domestic nuclear power plants. In accordance with the provisions of 10 CFR Part 52, Subparts B (Standard Design Certifications) and C (Combined Licenses), and supporting guidance, Florida Power & Light Company (FPL) has developed a COL Application for submittal to the NRC for construction and operation of two new nuclear generating units, Units 6 & 7, at the existing Turkey Point plant property in Miami-Dade County, Florida. The COL Application includes an Environmental Report (ER), in accordance with the provisions of 10 CFR Part 51 and the National Environmental Policy Act of 1969 (NEPA), as amended. The ER provides an analysis of the reasonably foreseeable impacts to the environment from site preparation, construction, operation, and decommissioning of Units 6 & 7.

This ER follows the content and organization of the NRC's *Standard Review Plans for Environmental Reviews for Nuclear Power Plants*, also known as NUREG-1555, Revision 0 (October 1999). Available draft revisions to this guidance have been considered, as practicable. Pursuant to 10 CFR Part 51, the NRC is required to perform a review of the environmental impacts of the construction and operation of Units 6 & 7; this ER supports that review. 10 CFR Part 51 requires that environmental impacts from the proposed project be evaluated and described in a concise, clear, and analytical manner. This report describes the project and potential alternatives and the methods and sources used in the environmental impact analysis.

Environmental issues identified in this ER are evaluated using a three-tier standard of significance as defined in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, Footnote 3, as follows:

SMALL — Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

MODERATE — Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE — Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

1.1.1 PURPOSE AND NEED

FPL's purpose is to provide additional baseload generation to maintain system reliability, increase fuel diversity, and allow progress toward meaningful CO_2 emissions reductions. The need for Units 6 & 7 has been determined by the state of Florida as described in Chapter 8. The proposed action is for the NRC to authorize FPL to construct and operate two PWRs at the Turkey Point plant property.

1.1.2 PROJECT DESCRIPTION

This subsection provides a brief summary of project information. Subsequent sections, particularly Chapter 3, give additional details of the proposed project.

1.1.2.1 The Applicant and Owners

FPL is the owner of the Turkey Point plant property and the existing power plants. FPL would own proposed Units 6 & 7. FPL is the operator of the existing power plants and would be the operator of Units 6 & 7. The new units would be operated as baseload plants to supply the needs of the FPL service territory. Additional information about FPL is provided in Part 1 of this COL Application.

1.1.2.2 Site Location

The Turkey Point plant property comprises approximately 9400 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead and bordered by Biscayne Bay to the east. Currently located on the Turkey Point plant property are five FPL power plants: two natural gas/oil steam electric generating units (Units 1 & 2), two pressurized water reactor nuclear units (Units 3 & 4), and one natural gas combined-cycle steam electric generating unit (Unit 5). Figure 2.1-4 shows the location of the Turkey Point plant property and regional features of the area. The new units would be constructed on an approximately 218-acre area (the Units 6 & 7 plant area) south of Units 3 & 4. Figure 2.1-3 shows the location of Units 6 & 7 on the Turkey Point plant property. Additional information regarding the Turkey Point plant property and the Units 6 & 7 plant area is provided in Section 2.1.

1.1.2.3 Reactor Information

FPL proposes to build and operate two AP1000 units, a nuclear plant design certified under 10 CFR 52, Subpart B. The total gross thermal MW output per unit is 3415 MWt with a nominal net electrical output of at least 1000 MWe. Additional details on the AP1000 design are provided in Section 3.2.

1.1.2.4 Cooling System Information

During normal operation of Units 6 & 7, waste heat would be dissipated by mechanical draft cooling towers. Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. The primary source would be water reclaimed for reuse after processing by the Miami-Dade Water and Sewer Department, conveyed via pipelines to the Turkey Point plant property. An onsite FPL reclaimed water treatment facility would further treat the reclaimed water for use in the cooling system. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting horizontally from the caisson. The well caissons would be located on the Turkey Point peninsula, east of the existing units.

Blowdown would control the accumulation of dissolved solids in the cooling system. Blowdown water would be discharged through the use of deep injection wells to the Boulder Zone, a cavernous, high-permeability South Florida geologic horizon located at depths of approximately 2800–3500 feet in the lower Floridan aquifer.

Descriptions of the cooling system, makeup water sources, and the anticipated modes of cooling system operation and discharge are provided in Sections 3.3 and 3.4.

1.1.2.5 Transmission System Information

Eight 230 kV transmission lines currently connect the existing Turkey Point units to the transmission system by way of two corridors, one proceeding to the north and one to the west. Two new 500 kV circuits and three new 230 kV circuits would be built to connect Units 6 & 7 to the electric grid. Plans are for the new transmission lines to proceed from the a new onsite substation (Clear Sky), with the 500 kV circuits connecting to the existing Levee substation and the 230 kV circuits connecting to the existing Turkey Point, Davis, Miami, and Pennsuco substations. Final transmission routes are selected through the state of Florida's Power Plant Siting Act (PPSA) process. To the extent practicable, new transmission lines would be routed in existing rights-of-way owned by FPL, in many places adjacent to existing transmission lines. Additional information on proposed transmission corridors serving Units 6 & 7 is provided in Sections 2.2 and 3.7. The proposed configuration of the transmission system for Units 6 & 7 is shown in Figure 2.2-5.

1.1.2.6 Public Involvement

FPL has an active community and public outreach program. The outreach principles include:

- Open, honest, and accessible communication with the general public and all key stakeholders

- Keeping state and local agencies and business organizations informed regarding the progression of the proposed project by meeting and briefing public officials from the affected area

- Using media opportunities to explain the project planning and licensing processes

- Actively soliciting input on proposed plans for the project, including any offsite facility and transmission and pipeline corridor location selection, and answering questions and inquiries that come to FPL. Special efforts are made in the ER preparation process to solicit and incorporate inputs on matters of environmental justice

These activities would continue as the regulatory review processes progress at the local, regional, state, and federal levels.

1.1.2.7 Schedule for Major Activities

No site preparation activities would occur until the site is certified under the PPSA and the required U.S. Army Corps of Engineers permits are obtained. The project schedule assumes a 69-month duration for preconstruction activities. Unit 6 construction would have an approximate 66-month duration for construction activities (48-month standard plant construction plus activities under NRC authority [e.g. slurry wall]) and an approximate 6-month duration for fuel load and startup. Unit 7 construction is planned to begin approximately 12 months after Unit 6 construction initiation and would follow an identical construction and fuel load/startup duration. Units 6 & 7 would initiate electric generation output in or about 2022 and 2023, respectively. A description of the construction schedule and milestone activities is included in Section 3.9.

1.2 STATUS OF REVIEWS, APPROVALS, AND CONSULTATIONS

In this section, the federal, state, regional, and local environmental protection licenses, permits, reviews, approvals, and consultations, collectively called authorizations, that are applicable to the proposed action to construct and operate Units 6 & 7 are identified. The information listed below is included in Table 1.2-1 for each authorization:

- Jurisdictional agency
- Authority, law, or regulation that dictates the requirement
- Description of the requirement
- License or permit number as applicable
- Date of application or date issued
- Description of the activities covered

FPL is in the process of initiating actions to obtain the necessary authorizations. Appendix A contains copies of consultation letters and responses received to date. The bulleted items below describe some of the principal required authorizations.

- *Endangered Species Act of 1973* (16 U.S.C. 1531-1544, as amended) — The *Endangered Species Act of 1973* requires federal agencies to ensure that agency action is not likely to jeopardize any species that is listed or proposed for listing as endangered or threatened. Depending on the action involved, the Act requires consultation with the U.S. Fish and Wildlife Service (USFWS) about effects on non-marine species, the National Marine Fisheries Service (NMFS) for marine species, or both. Because of the proximity of the Turkey Point site to the Atlantic Ocean, consultation with the USFWS and the NMFS is required.

- *National Historic Preservation Act of 1966* (16 U.S.C. 470) — The *National Historic Preservation Act of 1966* requires that federal agencies that have the authority to license an initiative consider (before the license is issued) the effects of the initiative on historic properties or properties eligible for protection under the National Historic Preservation Act.

- *Federal Coastal Zone Management Act of 1972* (16 U.S.C. 1451-1456) — The *Federal Coastal Zone Management Act* imposes requirements on applicants for a federal license to conduct an activity that could affect a coastal zone. The Act requires the applicant to certify to the licensing agency that the proposed activity would be consistent with the state's federally approved coastal zone management program. FPL would certify to the NRC that the

proposed project is consistent with the federally approved state of Florida Coastal Zone Management Plan.

- *Federal Water Pollution Control Act of 1972, as amended by the Clean Water Act of 1976* (33 U.S.C. 1251, et seq.)*, also known as the "Clean Water Act"* —The *Clean Water Act, Section 401*, requires any federal license applicant, who plans to conduct activities that might result in a discharge into navigable waters, to provide the licensing agency a certification from the state that the discharge would comply with applicable Clean Water Act requirements; the *Clean Water Act,Section 404*, requires applicants proposing the discharge of dredge or fill materials into "waters of the United States" to obtain a permit for this activity from the U.S. Army Corps of Engineers.

- *Rivers and Harbors Act of 1899* (33 U.S.C.401 et. seq.) The *Rivers and Harbors Act, Section 10,* prohibits the creation of any obstruction, and prohibits the excavation or filling, within navigable waters of the United States without prior authorization from the U.S. Army Corps of Engineers.

- The Florida Power Plant Siting Act, Sections 403.501-403.518, Florida Statutes, mandates a site certification process for obtaining a single site-related license that will include state, regional, and local requirements for construction and operation of a power plant and associated facilities of the type and magnitude being proposed by FPL.

Preconstruction activities, according to NRC requirements, are those that may be initiated before a COL or LWA is issued. Pursuant to 10 CFR 50.10(c), "No person may begin the construction of a production or utilization facility on a site on which the facility is to be operated until that person has been issued either a construction permit under this part, a combined license under part 52 of this chapter, an Early Site Permit authorizing the activities under paragraph (d) of this section, or a LWA under paragraph (d) of this section." NRC regulations at 10 CFR 50.10(a) define activities which are (and are not) considered to be construction. Activities not defined as construction may be initiated without prior NRC authorization. However, according to Florida PPSA requirements, no preconstruction or construction activity may occur before site certification is issued.

A COL applicant may begin certain preconstruction activities without prior NRC authorization before receipt of a COL or LWA, such as:

- Preconstruction plans and exploration activities such as soil boring/sampling, installation of monitoring wells, or installation of additional geophysical borings as defined in 10 CFR 50.10(a)(2) and the removal and/or relocation of existing facilities in the new plant footprint

- Site preparation activities such as installation of temporary facilities, construction support facilities, service facilities, utilities, docking and unloading facilities, excavations for facility

structures and foundations, and construction of structures, systems, or components (SSCs) that do not constitute construction as defined by 10 CFR 50.10(a)(1).

On December 24, 2007, the Miami-Dade County, Florida, Board of County Commissioners approved Resolution Z-56-07 (Miami 2007), approving, with conditions, FPL's request for unusual use of the proposed plant site to allow construction and operation of Units 6 & 7 and ancillary structures and equipment.

SUBJECT: Request for Information on Federal Listed Species in Miami-Dade County, Florida

Dear Mr. Wrublik:

Florida Power & Light Company (FPL) is preparing permit and license applications to the U.S. Nuclear Regulatory Commission (NRC), the Florida Department of Environmental Protection (FDEP) and the United States Army Corps of Engineers (USACE) to allow construction and operation of two new nuclear units and associated project features at our existing Turkey Point property in Miami-Dade County, Florida (the "proposed action"). As part of the permitting and licensing process, FPL is required to assess impacts of the proposed action, including those on Federal listed species in accordance with the Endangered Species Act . Consistent with 10 CFR Part 51, FPL requests that the U.S. Fish and Wildlife Service ("Service") provide it with information in your possession showing known occurrences of federal listed (or proposed for listing) species that could potentially be affected by the proposed action. FPL will include a copy of this request and your response in both the State of Florida Site Certification Application and the NRC Combined Operating License Application Environmental Report. Information about the property and the proposed action follows.

The Turkey Point property is located in Miami-Dade County Florida, adjacent to Biscayne Bay and Card Sound, about 25 miles south of Miami (Figure 1). The total, non-contiguous property area is approximately 11,000 acres. The developed portion of the property includes a natural gas fueled generating unit; two oil/gas-fired generating units, and two nuclear-powered generating units. The proposed action would further develop approximately 300 acres of the property west and south of these existing units, primarily within an existing cooling canal system. In addition, FPL will construct (1) pipelines to convey dual cooling water supplies (reclaimed and saline) to new cooling towers, (2) power transmission lines to connect the new units with the regional electric grid, and (3) a reclaimed water treatment facility to condition the reclaimed water for cooling water uses. In addition, because fill material is necessary for the unit foundations, FPL is proposing to place fill sourced from a commercial mine and/or from a nearby FPL-owned property approximately 4 miles northwest of the proposed site. These areas are shown in Figures 2 and 3. Figures 2A and 2B include the project features in the vicinity of the

proposed plant area. Figure 3 also provides an expanded view of the area showing the proposed transmission corridor.

Thank you for your attention to this request; I will follow-up with you to confirm receipt and to address any information needs or questions you may have. Should you need to talk to me earlier, please reach me by telephone at 561-691-7518.

Sincerely,

Barbara Linkiewicz

Service Federal Activity Code:	41420-2009-FA-0180
Service Consultation Code:	41420-2009-TA-0098
Date Received:	December 23, 2008
Project:	Two New Nuclear-Powered Generating Units at Turkey Point
County:	Miami-Dade

Dear Ms. Linkiewicz:

The Fish and Wildlife Service (Service) has received your letter dated December 23, 2008, for the project referenced above. We offer the following comments.

PROJECT DESCRIPTION

The proposed action would construct two new nuclear-powered electrical generating units at the Turkey Point Power Facility on 300 acres of undeveloped land located west and south of the existing units. The project will also include the construction of cooling pipes, cooling towers, and power transmission lines, and reclaimed water treatment facility. The project is located in Miami-Dade County, Florida.

THREATENED AND ENDANGERED SPECIES

American crocodile

The project is located within the geographic range of the threatened American crocodile (*Crocodylus acutus*). The American crocodile is known to occur and nest at the Turkey Point Power Plant within the cooling canal system.

No other records of federally listed species were not identified on your project site. The Service

has not conducted a site inspection to verify species occurrence or validate the GIS results. However, we assume listed species occur in suitable ecological communities and recommend site surveys to determine the presence or absence of listed species. Ecological communities suitable for listed species can be found in the species accounts in the *South Florida Multi-Species Recovery Plan*. This document is available on the web at: http://www.fws.gov/verobeach/index.cfm?Method=programs&NavProgramCategoryID=3&programID=107&ProgramCategoryID=3. We have also provided for your consideration two computer links: (1) http://www.fws.gov/verobeach/index.cfm?Method=programs&NavProgramCategoryID=3&programID=37&ProgramCategoryID=3, and (2) http://migratorybirds.fws.gov/. The first link provides links to lists of species protected under the Endangered Species Act of 1973 (as amended, 87 Stat. 884; 16 U.S.C. 1531 *et seq.*) for each county in south Florida. The County lists do not include State-listed species. Please contact the Florida Fish and Wildlife Conservation Commission to identify potential State-listed species occurring in the vicinity of your project. The second link provides information on species the Service is required to protect and conserve under other authorities, such as the Fish and Wildlife Coordination Act of 1958, as amended (48 Stat. 401; 16 U.S.C. 661 *et seq.*) and the Migratory Bird Treaty Act (40 Stat. 755; 16 U.S.C. 701 *et seq.*). A variety of habitats in south Florida occasionally provide resting, feeding, and nesting sites for a variety of migratory bird species. As a public trust resource, migratory birds must be taken into consideration during project planning and design.

Thank you for the opportunity to comment. If you have any questions, please contact me at 772-562-3909, extension 282.

Sincerely yours,

JAN 0 9 2009

Dear Colleague:

Pursuant to section 7(a)(2) of the Endangered Species Act (ESA), the Protected Resources Division of NOAA's National Marine Fisheries Service (NMFS) has reviewed your letter dated December 21, 2008, requesting information on federal listed species in Miami-Dade County, Florida.

____**There are no ESA-listed species** or designated critical habitat under our purview in the action area.

___**We cannot determine** impacts to threatened or endangered species, or designated critical habitat, under NOAA Fisheries purview because the letter lacks sufficient information to evaluate the project.
Enclosed are guidelines to conduct a proper biological evaluation.

___**Please provide a letter** from the lead federal action agency designating you to conduct ESA section 7 consultation with this office.

__X__**Enclosed is a list** of federally-protected species under the jurisdiction of NMFS for the state of Florida. Biological information on federally-protected species and candidate species can be found at the following website addresses: http://www.nmfs.noaa.gov/prot_res/prot_res.html; http://www.cccturtle.org; http://noflorida.fws.gov/SeaTurtles/seaturtle-info.htm); http://endangered.fws.gov/wildlife.html#Species; http://www.cmc-ocean.org/main.php3; http://floridaconservation.org/psm/turtles/turtle.htm; http://obis.env.duke.edu/data/sp_profiles.php; www.mote.org/~colins/Sawfish/SawfishHomePage.html; www.floridasawfish.com; www.flmnh.ufl.edu/fish/sharks/InNews/sawprop.htm;.Gulf sturgeon critical habitat rule and maps (http://alabama.fws.gov/gs/)

___**It is NMFS' opinion that the project will have no effect** on listed species or critical habitat protected by the ESA under NOAA Fisheries purview. No further consultation with NOAA Fisheries pursuant to section 7(a)(2) of the ESA is required unless the project description changes.

Consultation with NMFS' Habitat Conservation Division (HCD), pursuant to the Magnuson-Stevens Fishery Conservation and Management Acts requirements for essential fish habitat consultation, may be required. Please contact HCD at (727) 824-5317. If you have any ESA questions, please contact our ESA section 7 Coordinator, Eric Hawk, at (727) 824-5312 or by e-mail at eric.hawk@noaa.gov.

Sincerely,

2.1 STATION LOCATION

FPL proposes to construct and operate two Westinghouse AP1000 units at the existing approximately 9400-acre Turkey Point plant property in southeast Miami-Dade County, Florida. The two AP1000 reactors would be referred to as Units 6 & 7. This section describes the general location of the Turkey Point plant property and the Units 6 & 7 plant area.

Units 6 & 7 and supporting infrastructure would be located in the approximately 218-acre plant area delineated in Figure 2.1-1. The center point of the Unit 6 containment building would be approximately 215 feet west and 3625 feet south of the center point of the Unit 4 containment building. The center point of Unit 7 would be approximately 850 feet west of the center point of Unit 6. Unit 5 is located northwest of Units 1 through 4 and is independently cooled through the use of cooling towers. Units 1 through 4 use the cooling canals of the industrial wastewater facility for heat removal and are located at the northern boundary of the industrial wastewater facility. Units 6 & 7 would be located within the northeast corner of the industrial wastewater facility on an area surrounded by canals, referred to as the Units 6 & 7 plant area, just south of Units 1 through 5. The Units 6 & 7 containment buildings would be located at the following coordinates:

Coordinate System

Geographic, Decimal Degrees, North American Data 1983 (NAD83)		
Unit 6	25.424186 N	–80.331961 W
Unit 7	25.424186 N	–80.334536 W
Universal Transverse Mercator Zone 17, Meters, NAD83		
Unit 6	2812086.79 N	567179.31 E
Unit 7	2812086.79 N	566920.31 E
Florida State Plane East, U.S. Feet, NAD83		
Unit 6	396968 N	876646 E
Unit 7	396968 N	875796 E

The Turkey Point plant property is on the southeastern coast of Florida, bordering Biscayne Bay and Card Sound, in unincorporated southeast Miami-Dade County. It is located in all or portions of Sections 27, 28, 29, 30, 31, 32, 33, and 34 of Township 57S, Range 40E and Sections 4, 5, 7, 8, 9,16, 17, 18, 19, 20, 21, 28, 29, and 30 of Township 58S Range 40E. The Units 6 & 7 plant area would be located in portions of Sections 33 and 34 of Township 57S, Range 40E. The only existing access to the plant property is from SW 344th Street/Palm Drive as shown on Figure 2.1-1.

The Turkey Point plant property is approximately 25 miles south of Miami, 8 miles east of Florida City, and 4.5 miles east of the southeastern municipal limits of Homestead. The property is approximately 2 miles south of the Biscayne National Park Visitors Center and is within 3 miles of

the South Florida Water Management District conservation area (Model Lands Basin). A portion of the Biscayne Bay Aquatic Preserve runs along the coastal boundary of the Turkey Point plant property. The Homestead Bayfront Park lies approximately 1.5 miles north of Units 6 & 7, and 1.5 miles east of the L-31E canal. In addition, the plant property is adjacent to the 13,000-acre Everglades Mitigation Bank, owned by FPL. The exclusion area boundary for Units 3 & 4 is irregularly shaped, with a distance from the center of the existing Units 3 & 4 containment buildings of 4164 feet to the northern property line, 5582 feet to the southern property line, and a minimum distance of 1800 feet. The exclusion area boundary for Units 6 & 7 would be irregularly shaped, with a minimum distance from the center point of the Units 6 & 7 containment buildings of 1927 feet in the east to northeast direction.

Within Miami-Dade County, Homestead is the closest major population center to Units 6 & 7, with 55,036 residents during the 2005-2009 census range (USCB 2010). The distance to the center of the city of Miami (the nearest major city) is approximately 25 miles. The Homestead/Miami Speedway is located approximately 5 miles northwest of the Turkey Point plant property. Homestead Air Reserve Base, with both civilian and military operations, is approximately 4.5 miles northwest of the plant area. Miami International Airport is approximately 25 miles north of the plant property. There are no rail systems within 5 miles of the Turkey Point plant property (Figure 2.1-3). The Port of Miami is approximately 26 miles from the plant area. Key Largo is approximately 23 miles from the plant area. Figures 2.1-2, 2.1-3, and 2.1-4 provide, respectively, an oblique aerial photograph of the Turkey Point plant property, a map of the vicinity within 6 miles of Units 6 & 7, and a map of the region within 50 miles of Units 6 & 7.

2.2-6	50-Mile Land Use (Sheet 5 of 5)

2.2 LAND

This section describes the land characteristics of the Units 6 & 7 plant area, the Turkey Point plant property, and vicinity; transmission corridors and offsite areas; and the region. Land use impacts are presented in Sections 4.1 and 5.1.

2.2.1 THE SITE AND VICINITY

2.2.1.1 The Site

2.2.1.1.1 Turkey Point Plant Property

Units 6 & 7 would be collocated with two natural gas/oil steam electric generating units (Units 1 & 2), two pressurized water reactor nuclear units (Units 3 & 4), and one natural gas combined-cycle steam electric generating unit (Unit 5) on the approximately 9400-acre Turkey Point plant property located in unincorporated Miami-Dade County, Florida. The location of the Turkey Point plant property in relation to Biscayne Bay, Card Sound, and the Atlantic Ocean is shown in Figures 2.1-3 and 2.1-4. Figure 2.2-4 shows the 50-mile region. Figure 2.2-1 shows the location of the Turkey Point plant property boundary.

FPL is the owner of Units 1 through 5 and would be the owner of Units 6 & 7. All five existing units lie in the developed area of the Turkey Point plant property. Units 6 & 7 would be located in a previously undeveloped area of the plant property, south of Units 3 & 4. FPL directs land management activities for the Turkey Point plant property and is the NRC-licensed operator for Units 3 & 4. FPL would be the NRC-licensed operator for Units 6 & 7.

The Units 6 & 7 power blocks and associated infrastructure including mechanical draft cooling towers, makeup water reservoir, deep injection wells, substation, etc. would be located on an approximately 218-acre portion of the Turkey Point plant property, called the Units 6 & 7 plant area. The Units 6 & 7 plant area is south of Units 3 & 4 and is completely encircled by cooling canals of the industrial wastewater facility (Figure 2.2-1). Units 3 & 4 are south of Units 1 & 2. Unit 5 is located northwest of Units 1 & 2. The South Florida Water Management District Canal L-31E lies west of the Turkey Point plant property.

FPL owns all (Note: SFMWD L-31E Canal and certain roads within the property boundary are not owned by FPL) of the property within the Turkey Point plant property boundary, including the entire exclusion area, subject to certain encumbrances on portions of property within the exclusion area, specifically, certain canal, drainage, reclamation, oil, gas and mineral rights reservations held by the Trustees of the Internal Improvement Fund of the State of Florida and a canal reservation held by Miami-Dade County. Also, a small parcel of submerged land in the southeast and south-southeast portions of the exclusion area is located in the Biscayne Bay waterway. With the exception of the described submerged land, the site boundary entirely

encompasses the designated exclusion area for Units 6 & 7. Because of the location of the submerged land, this portion of the exclusion cannot be reasonably accessed except through FPL property.

Units 1–4 use the cooling canals of the industrial wastewater facility, located south and southwest of the existing units, to cool heated noncontact water (water used for cooling that does not come into direct contact with any raw material, product, by-product, or waste) and to recirculate water for reuse. Unit 5 uses cooling towers for system cooling and releases blowdown water to the industrial wastewater facility. The industrial wastewater facility is an integral part of the existing units design and is not a water of the United States or the state. The industrial wastewater facility occupies an area of approximately 5900 acres, and contains 39 canals (32 discharge and 7 return). The canals are shallow, generally 1 to 3 feet deep, with the exception of the grand canal (main return canal), north discharge canal, south collector canal, and the east return canal, all of which extend to a depth of elevation (North American Vertical Datum [NAVD] 88) –18 feet. The canals undergo routine maintenance including removal of aquatic vegetation to minimize flow restriction and maintenance of the berms.

The Turkey Point plant property is located on the shore of Biscayne Bay, in an unincorporated area of Miami-Dade County, Florida, approximately 8 miles east of Florida City, 4.5 miles southeast of the municipal limits of Homestead, and 25 miles south of Miami. Most of Miami-Dade County is within 50 miles of the Units 6 & 7 plant area, as well as portions of Monroe County, Broward County, and Collier County (Figure 2.1-4).

The plant property, including the approximately 2- by 5-mile closed loop industrial wastewater facility, is located in portions of Sections 27–34 of Township 57S, Range 40E, and all of Sections 4, 9, 16-17, 20-21 and portions of Sections 5, 7-8, 18-19, and 28–30 of Township 58S, Range 40E. Units 6 & 7 would be located in portions of Sections 33 and 34 of Township 57S, Range 40E. The centerpoint of the Unit 6 reactor would be located at 25.424186 N latitude and -80.331961 W longitude (see Figure 2.1-1), using a geographic reference system of decimal degrees, North American Datum 1983 (NAD83); the centerpoint of the Unit 7 reactor would be located at 25.424186 N latitude and -80.334536 W longitude (Figure 2.1-1).

The only existing public access to the plant property is via SW 344th Street/Palm Drive. Palm Drive is a two-lane road for approximately one-half of its length from the plant to Florida City. Palm Drive intersects U.S. Highway 1 in Florida City, approximately 9 miles from the plant. Both Palm Drive and U.S. Highway 1 are four-lane roads in the area of intersection. Palm Drive narrows to two lanes at SW 137th Avenue/Speedway Boulevard.

The plant property is on the shore of Biscayne Bay with several miles of the shoreline north and east of the property that includes the Biscayne Bay Aquatic Preserve and the Biscayne National Park. The Biscayne National Park headquarters is located approximately 2.3 miles north of

Units 6 & 7, adjacent to the Metropolitan Miami-Dade County Homestead Bayfront Park. The Everglades National Park is approximately 10 miles southwest of the plant property. Mangrove Point forms the dividing line between Biscayne Bay and Card Sound. The northern half of Mangrove Point is part of Biscayne National Park, and the southern half is state-owned. Land south and west of the Turkey Point plant property is the FPL-owned Everglades Mitigation Bank (EMB), comprised of approximately 13,000 acres of relatively undisturbed freshwater and estuarine wetlands. A mitigation bank is a wetland area that is created, restored, or enhanced for the purpose of providing compensatory mitigation of wetland losses elsewhere.

The plant property is located adjacent to Biscayne Bay and the Intracoastal Waterway, a 3000-mile waterway along the Atlantic and Gulf coasts of the United States. Some lengths of the coastline consist of natural inlets, saltwater rivers, bays, and sounds; others are man-made canals. Barge access is provided by an existing channel across Biscayne Bay for the delivery of heavy equipment and fuel oil.

A natural gas pipeline serving Units 1, 2, and 5, owned and operated by Florida Gas Transmission Company, LLC, terminates at Unit 5.

Figure 2.2-2 and Table 2.2-1 identify the current Florida Land Use, Cover, and Forms Classification System (FLUCCS) land use/land cover within the 9400-acre Turkey Point plant property. The classification data was generated as part of the Land Cover/Land Use 2004-05 Mapping Update Project by the South Florida Water Management District (SFWMD). Data used in this figure and table show the Level 3 FLUCCS classification coding.

2.2.1.1.2 Units 6 & 7 Plant Area

The Units 6 & 7 plant area is an approximately 218-acre island that is a sparsely vegetated, hypersaline mudflat, partially buffered from tidal influence by cooling canals that encircle the plant area (Figure 2.4-2). The industrial wastewater facility isolates the plant area from normal access. A bridge located southeast of the Land Utilization building provides access to the Units 6 & 7 plant area. The cooling canals encircling the plant area are deep, primary return, water canals leading to the Units 1-4 cooling water intakes.

The Units 6 & 7 plant area is located outside of the 100-year floodplain, with an existing elevation of -2.4 to 0.8 feet (NAVD 88) and is generally flat. The eastern margins of the plant area slope gently to the return canal on the east perimeter, which is separated from Biscayne Bay by a 15 foot-high berm. The perimeter berms, along the west and north margins of the plant area, range in height from approximately 3 to 15 feet above natural ground surface. A berm is not present between the plant area and the eastern return canal, permitting inundation and sheetflow across the plant area when water levels rise in the cooling canals of the industrial wastewater

facility. There are two remnant canals that cross the plant area from east to west; these remnant canals would be eliminated during construction of Units 6 & 7.

An ecological assessment of the Units 6 & 7 plant area and other areas on the Turkey Point plant property was conducted in 2008 to characterize the areas, including habitat description and surveys for threatened, endangered, and candidate species and species of special concern (state). The results of the characterization are described below in general terms, with a more complete ecological description provided in Section 2.4. Wetlands are the primary habitat types and non-wetland habitats make up the remainder.

Wetland habitats within the Units 6 & 7 plant area and adjacent laydown area include mudflats (188 acres), remnant and active canals (25 acres), dwarf mangrove (17 acres), open water (12 acres), mangrove heads (12 acres), and wetland spoil areas (10 acres) (Figure 2.4-2). Encircled by canals, the sparsely vegetated mudflats are inundated by water 3 to 4 months out of the year and a few hardy plant species, including saltwort, sea oxeye daisies, wood glasswort, and dwarf glasswort that can tolerate these conditions persist. Dwarf mangrove habitats contain the three locally abundant mangrove species, predominantly red mangrove with a few white and black mangrove, but the trees are stunted by high salinities and fluctuating water levels. The mangroves are located within the open water area on the western edge of the adjacent laydown area. The open water area joins the upper end of the cooling canals of the industrial wastewater facility. Harsh conditions in the open water area limit submerged aquatic vegetation to scattered patches of two seagrass species, widgeon grass and shoal grass. Mangrove heads, remnants of the original tidal creeks, contain primarily red mangrove, but white mangrove and black mangrove are also present. The connection between these creeks and Biscayne Bay were severed during construction of the cooling canals. Wetland spoil areas adjacent to the remnant canals are typically occupied by Australian pine, buttonwood, and mangrove.

Non-wetland areas within the Units 6 & 7 plant area and the adjacent laydown area to the west include approximately 20 acres of fill area/roadway habitat and approximately 8 acres of upland spoil piles (Figure 2.4-2). The former are limerock aggregate uplands filled for construction of access roads, parking areas, and research facilities. These areas are dominated by maintained grasses with wetland edges containing Brazilian pepper, buttonwood, and assorted herbaceous plants. Upland spoil piles were formed with spoil from the canal dredging operation. The vegetation in these areas is dominated by exotic species such as Brazilian pepper and Australian pine, as well as poisonwood, buttonwood, wild sage, ground orchid, and sea grape.

Figure 2.2-1 shows the location of the Turkey Point plant property boundary. Figure 2.2-3 shows the location of the exclusion area boundary (EAB) for Units 6 & 7 in relationship to the existing EAB for Units 3 & 4 (2009 acres) and the combined EAB (2070 acres) for all units. Table 2.7-12 identifies the distance to the EAB from the Units 6 & 7 power block area in each of the 16 major compass directions. These distances were calculated to model potential dispersion effects from

plant operations to offsite areas (Section 2.7). The minimum distance to the EAB is 1427 feet in the northeast direction.

There are no public roads, railroads or waterways within the EAB. There are no domestic residences within the plant property boundary, nor are there any residences within two miles of Units 6 & 7.

2.2.1.1.3 Other Areas

Additional facilities associated with Units 6 & 7 would be located outside of the Units 6 & 7 plant area but on the Turkey Point plant property including the FPL reclaimed water treatment facility and reclaimed water pipelines, radial collector wells and pipelines, nuclear administration and training buildings, parking areas, laydown areas, expanded equipment barge unloading area, security buildings, access and heavy haul roads, spoils areas, transmission infrastructure, and potable water supply pipelines. The locations of these facilities are presented in Figure 3.9-1.

- An FPL reclaimed water treatment facility would be constructed on approximately 44 acres of sawgrass marsh, dwarf mangroves, upland Australian pine, excavated canals, and exotic wetland hardwoods-Australian pine located at the northwest corner of the plant property between SW 344th Street/Palm Drive and the L-31E Canal.

- Four radial collector well caissons would be installed on the Turkey Point peninsula, east of the existing units, with laterals drilled horizontally in the subsurface beneath the floor of Biscayne Bay. The radial collector well water supply pipelines would be routed west from the caissons and south to the Units 6 & 7 cooling towers along the eastern side of the plant area.

- An approximate 32-acre area for location of a nuclear administration building, training building, and a parking area would be located on two adjacent parcels of land immediately north of the Units 6 & 7 plant area. These parcels of land are comprised of a variety of land cover types, the majority land cover being mangrove swamps. Two smaller laydown areas, totaling approximately one acre, would be located on paved areas within the existing facilities area of the plant property.

- The existing barge turning basin located at Turkey Point connects Biscayne Bay to the Turkey Point plant property and would be used for Units 6 & 7 plant module and component delivery, the transport of which is planned to be accomplished by barge. The barge turning basin is a dead-end canal approximately 300 feet wide, 1200 feet long, and 18 feet deep. The turning basin, constructed in 1979 for transport of major equipment to the existing units, was designed to allow for the maneuvering of major equipment barges within the basin and not in the bay or the bay channel. The turning basin is currently used for fuel deliveries for Units 1 & 2. Water depths in the entrance channel to the turning basin are between 8 and 12 feet. The

near shore shallow areas outside of the channel are generally less than 5 feet deep. The only flushing that occurs in the basin is from slight tidal action and rare westerly winds.

Fuel oil is delivered to the existing units by barge and tug from a fuel oil terminal at the Port of Miami on Dodge Island. The barge route is via the Intracoastal Waterway through Biscayne Bay using the existing barge channel. The barge channel is approximately 3.4 miles long and 90 feet wide with a depth of –11 feet NAVD (–9.37 feet mean low water) or more for the majority of its length. The fuel deliveries are currently made to the fuel oil unloading area near the head of the turning basin (southwest of the equipment barge unloading area; Figure 3.9-1) and would continue during the period of Units 6 & 7 module and component delivery; current fuel oil deliveries are typically 5–7 deliveries per week.

For each new unit, there would be approximately 80 round-trip barge deliveries of modules over an approximate six-year duration. The existing equipment barge unloading area, located on the north side of the turning basin (Figure 3.9-1 [Sheet 1]), would be extended landward to approximately 90 feet by 150 feet (0.31 acres) and 9 feet deep, with a total disturbed area, including concrete apron, of 130 feet by 250 feet (0.75 acres) to facilitate heavy equipment and component unloading for construction of Units 6 & 7.

- The existing heavy haul road, originating at the equipment barge unloading area, would be improved and terminate at three locations at the Units 6 & 7 plant area, to facilitate unloading plant modules and components. The road from the equipment barge unloading area to the Units 6 & 7 plant area would be approximately 2 miles long and 24 feet wide. The road would start at the equipment barge unloading area and extend generally west between and around Unit 5 and Units 1 & 2. The road would then extend generally south and cross over two new heavy haul bridges, one at the main cooling discharge canal and the other at the main cooling return canal. The heavy haul road would then terminate at three locations of the plant area.

- A new entrance to the Turkey Point plant property would be constructed for access to Units 6 & 7, beginning with onsite construction activities. The new entrance would be SW 359th Street. The existing SW 359th Street and the existing service road at the northern end of the cooling canals/industrial wastewater facility would be joined by a new road segment, and improved to four lanes, two eastbound and two westbound, and a bridge constructed over the L-31E canal to handle the traffic to and from Units 6 & 7. The SW 359th Street improvements would extend offsite from the Turkey Point plant property westward to connect to SW 117th Avenue and SW 137th Avenue/Tallahassee Road that would also be improved.

- Spoils areas would be established on the Turkey Point plant property south of the Units 6 & 7 plant area to allow dewatering of materials during construction of Units 6 & 7 from activities such as clearing, grubbing, and excavation. Three separate spoils areas, denoted as "A," "B,"

and "C" would be established at the southern end of the industrial wastewater facility. Spoils areas "A" and "C" would be located on the western and eastern side of the main return canal, respectively, and each pile would be 4.6 to 5 miles long. Spoils area "B" would be established at the southern end of the industrial wastewater facility and would be approximately 1.8 miles in length. The total area for spoils area "A," "B," and "C" would be approximately 77 acres, 18 acres, and 116 acres, respectively, resulting in a total spoils capacity of approximately 2 million cubic yards. The estimated height of the spoils pile will be determined after the spoils storage area has been surveyed and final dirt road width for the berms has been established. It is anticipated that the final spoils elevation will be approximately 16–20 feet NAVD 88.

- Existing transmission infrastructure on the Turkey Point plant property would be expanded to include: construction of the new 500/230 kV Clear Sky substation; construction of a single-circuit 230 kV transmission line between Clear Sky substation and the existing Turkey Point substation and six 230 kV underground connections with the new Units 6 & 7 transformers; and construction of the onsite portions of the new transmission lines from Clear Sky substation to the Levee and Pennsuco substations in the proposed West Corridor and from Clear Sky substation to the existing Davis substation, and then on to the Miami substation in the proposed East Corridor. Improvements at the Turkey Point substation would include a 0.9-acre expansion of the substation site to accommodate a new bay with two new 230 kV line terminals and enlargement of the existing relay vault building.

- Potable water pipelines, approximately 10 miles long, would be constructed to supply potable water for Units 6 & 7. The new water pipelines would deliver potable water from the Miami-Dade County Water and Sewer Department potable water source facility to the Units 6 & 7 plant area. Routing for the pipelines is identified in Figure 3.9-1. The pipelines would enter the Turkey Point plant property at the intersection of SW 117th Avenue and SW 359th Street, following the new four-lane SW 359th Street to a position on the plant property and then south to Units 6 & 7.

Other supporting infrastructure for Units 6 & 7, including an FPL-owned fill source, transmission lines and expanded substations, portions of the reclaimed water and potable water pipelines, and access roads, would be located offsite of the Turkey Point plant property and are discussed in Subsection 2.2.2.

2.2.1.1.4 Land Use

Laws adopted during 1984-1986 established Florida’s growth management system, including adoption of a state comprehensive plan. The laws also required regional planning councils to prepare and adopt comprehensive regional policy plans consistent with the state comprehensive plan. Miami-Dade, Broward, and Monroe Counties are included in the South Florida Regional Planning Council, which works with the regional community to identify issues and opportunities

that are regional in scope and create implementing strategies to achieve the desired future. The *Strategic Regional Policy Plan for South Florida (*SFRPC 2004) is the policy document that guides all of the Council's activities.

The Local Government Comprehensive Planning and Land Development Regulation Act (Chapter 163, Part II, Florida Statutes), also known as Florida's Growth Management Act, requires all of Florida's 67 counties and 410 municipalities to adopt local government comprehensive plans that guide future growth and development. The comprehensive plans contain chapters or "elements" that address future land use, housing, transportation, infrastructure, coastal management, conservation, recreation and open space, intergovernmental coordination, and capital improvements. A key component of the Act is its "concurrency" provision that requires facilities and services to be available concurrent with the impacts of development. The Act mandates that specific level of service standards for traffic, mass transit, parks, water, sewer, solid waste, and drainage be included in local comprehensive plans and that no development orders be issued when the adopted levels of service would not be met. The Act also requires consistency between the local plan, the applicable regional plan, and the state comprehensive plan, and all development regulations and orders must be consistent with the adopted local comprehensive plan.

Florida's Growth Management Act authorizes the Florida Department of Community Affairs, Division of Community Planning, to review comprehensive plans and plan amendments for compliance with the Act. Other review agencies, including the regional planning councils, water management districts, the Departments of State, Transportation, Environmental Protection, and Agriculture and Consumer Services, and the Florida Fish and Wildlife Conservation Commission, also review comprehensive plans and amendments and issue recommended objections. Local governments may amend their comprehensive plans twice per year.

Effective comprehensive planning has been a central focus of the Miami-Dade County government from its formation. The power to "prepare and enforce comprehensive plans for the development of the county" was one of 24 specified in the County Charter and a Department of Planning is one of the four departments required by it. Miami-Dade County developed its first land use plan in 1965 and has since enacted a series of increasingly more refined growth management plans and procedures.

The Miami-Dade County Comprehensive Development Master Plan (CDMP; MDC 2009) is adopted by ordinance by the Board of County Commissioners. This ordinance is codified at Chapter 12-114, Code of Miami-Dade County, Florida. The CDMP for Miami-Dade County, which is usually revised twice yearly, necessarily addresses both incorporated and unincorporated areas due to the many area-wide responsibilities of County government. Each of the 34 municipalities in Miami-Dade County is also required by Florida's Growth Management Act to adopt its own comprehensive plan for the area within its jurisdiction. The County CDMP

emphasizes the regulation of land development in the unincorporated areas and the County's jurisdictional responsibilities in municipal areas.

The Miami-Dade County CDMP is organized into eleven Plan Elements preceded by a statement of legislative intent: Land Use; Housing; Conservation; Aquifer Recharge and Drainage; Water, Sewer, and Solid Waste; Recreation and Open Space; Coastal Management; Intergovernmental Coordination; Capital Improvements; Educational; and Economic.

Miami-Dade County has more than 2000 square miles of land, of which almost 500 square miles have been developed for urban uses. The county-wide land use plan broadly defines land use categories, with the smallest distinguishable area of the land use map set at 5 acres. The land use portion of the CDMP includes a map for 2015-2025, which visually shows recommended future land uses by major categories, each of which is interpreted locally through zoning designations.

The Miami-Dade County CDMP has designated the location of Turkey Point, including the location of Units 6 & 7, as Environmental Protection Subarea F (Coastal Wetlands and Hammocks). These areas are low-lying, flood-prone, and characterized predominantly by coastal wetland communities. Accordingly, land use or site alteration proposals would be carefully evaluated case by case by federal, state, regional, and county agencies. In addition, necessary electrical generation and transmission facilities are permitted in this area. The approval of any new use, and the replacement or expansion of any existing use, would be conditioned upon its demonstrated consistency with the CDMP's adopted goals, objectives, and policies, and conformity with prevailing environmental regulations (MDC 2009).

All of Miami-Dade County is zoned, including the unincorporated portion of the county. According to the Miami-Dade County CDMP map, Units 1–5 have a future land use category which allows a full range of institutions, communications, and utilities. The Units 6 & 7 plant area is zoned as Interim District (GU). Nuclear reactors are a permitted use in this district with the approval of an Unusual Use by Miami-Dade County, as described below (MDC 2009).

After consultations with Miami-Dade County and its various agencies concerning application number Z07-207, the county's Developmental Impact Committee Executive Council issued its recommendation by concluding that the construction of two new nuclear reactors, with mitigation measures imposed through conditions of approval, would be consistent with the CDMP. The county issued its decision in 2007 to approve the Unusual Use to permit two new nuclear power stations and the associated facilities as well as the excavation and filling of the Units 6 & 7 plant area. The approval was issued by the Miami-Dade County Board of County Commissioners as Resolution Z-56-07, with identified conditions of approval.

The NRC Office of Nuclear Reactor Regulation has issued guidance to its staff regarding compliance with the federal Coastal Zone Management Act. This guidance acknowledges that Florida has an approved Coastal Zone Management Program. Units 6 & 7 would be located within the Florida coastal zone.

2.2.1.2 The Vicinity

For the purposes of this environmental report, the vicinity is defined as the area within a 6-mile radius of the centerpoint between Units 6 & 7 (Figure 2.1-3).

The Turkey Point plant property and its immediate environs are located on the Floridan plateau, a partly submerged peninsula of the continental shelf. The topography of the area is flat and rises very gently from sea level to an approximate elevation of 10 feet (NAVD 88) at a point some 8 to 10 miles west of the plant property.

Biscayne Bay is immediately adjacent to the Turkey Point plant property (Figure 2.1-3) and the Units 6 & 7 plant area. To the east, 5 to 8 miles across Biscayne Bay, is a chain of offshore islands, comprising the northern part of the Florida Keys running in a northeast-southwest direction between the bay and the Atlantic Ocean, the largest of which, near the plant property, is Elliott Key. Figure 2.2-4 and Table 2.2-2 identify land use classifications in the vicinity of Turkey Point. The closest incorporated communities are Homestead and Florida City. Florida City is 8 miles west of the plant property and the municipal limits of Homestead are 4.5 miles west of the plant property. The nearest full-time residence is approximately 2.7 miles from the Units 6 & 7 plant area.

Land in the area surrounding the Turkey Point plant property is almost exclusively undeveloped. The FPL-owned EMB is adjacent to most of the western and southern boundaries of the plant property. The South Florida Water Management District Canal L-31E is also located to the west of the plant property. The eastern portions of the Turkey Point plant property are adjacent to the open waters of the Biscayne Bay Aquatic Preserve and Biscayne National Park. The southernmost eastern portion of the plant property is bounded by state-owned land located on Card Sound. Undeveloped land owned by Miami-Dade County is located to the north of the plant property and is part of Biscayne National Park.

There is one state-managed aquatic preserve, a wetlands habitat preserve, two national parks, and a national wildlife refuge in the vicinity of Units 6 & 7. Biscayne Bay Aquatic Preserve is a shallow, subtropical lagoon consisting of three separate areas of Biscayne Bay, located northeast, east, and southeast of the Turkey Point plant property (Figure 2.1-3). The northern part of the Preserve begins just south of Cape Florida on the east and south of Chicken Key on the west. The southern portion is in Card Sound. The Preserve is approximately 69,000 acres of submerged state land that has been designated as an Outstanding Florida Water, Class III. The

Florida Department of Environmental Protection (FDEP), Office of Coastal and Aquatic Managed Areas manages the Preserve. The Preserve offers recreational and commercial on- and in-water activities, such as boating, water sports, and fishing.

The Model Lands Basin was a Save Our Rivers (SOR) land acquired for conservation by the South Florida Water Management District. The Model Lands are fragmented, with state, local, and private ownership west of the Turkey Point plant property and east of U.S. Highway 1. With the exception of a small segment of Canal L-31E, the closest Model Lands properties are approximately 3 miles from the plant property. The Model Lands Basin is comprised largely of fresh and salt-water wetlands that form a contiguous habitat corridor with the Everglades National Park, the Southern Glades SOR project located further to the southwest, the Biscayne National Park, and other designated lands in Miami-Dade County.

Biscayne National Park is immediately north and east (Figure 2.1-3). The park headquarters building is approximately 2.3 miles north of the Units 6 & 7 plant area. The Biscayne National Park was first established in 1968 as a National Monument and was expanded in 1980 to approximately 173,000 acres of water, coastal lands, and 42 keys. The park fulfills a multi-purpose mission by managing natural and historic resources, advocating responsible stewardship, and enabling visitors to experience scenic vistas and compatible recreational activities. Boating is the most prevalent activity in the park, and recreational and commercial fishing are allowed. Other recreational activities include snorkeling, diving, camping, picnicking, and hiking.

Everglades National Park is approximately 10 miles southwest of the plant property. Everglades National Park consists of 1,509,000 acres, including most of Florida Bay. The Ernest Coe Visitors Center in the park is located approximately 16 miles southwest of Units 6 & 7. The Crocodile Lake National Wildlife Refuge is approximately 10 miles south of the plant property. The Big Cypress National Preserve is approximately 35 miles northwest of the plant property.

Homestead Bayfront Park is located adjacent to Biscayne National Park, within about 1.5 miles of the Units 6 & 7 plant area (Figure 2.1-3). Homestead Bayfront Park is a large recreational park south of the North Canal on Biscayne Bay which also includes a marina.

The Homestead Air Reserve Base is approximately 4.5 miles northwest of the Units 6 & 7 plant area (Figure 2.1-3). The base encompasses 2938 acres. The U.S. Air Force determined that it would make available 717 acres at the base to Miami-Dade County for future mixed economic uses that could include commercial development as well as residential or recreational uses. However, the U.S. Air Force rejected a proposal for a civilian commercial airport at the base.

The Homestead Miami Speedway is approximately 5 miles northwest of the Units 6 & 7 plant area. The speedway can seat 65,000 people in the grandstands, but has greater overall seating capacity and hosts various motor racing events throughout the year.

Land south and west of the plant property is the FPL-owned Everglades Mitigation Bank (EMB). The EMB comprises approximately 13,000 acres of relatively undisturbed freshwater and estuarine wetlands.

The predominant existing land uses in the immediate area surrounding the Turkey Point plant property are undeveloped land and protected areas (Figure 2.1-3). Land use adjacent to the Units 6 & 7 plant area comprises undeveloped land, Units 1 through 5, a gas pipeline, a potable water pipeline, and electric transmission infrastructure. The industrial wastewater facility is located to the immediate west and south of the Units 6 & 7 plant area.

Current land use within 6 miles of Units 6 & 7 is described in Table 2.2-2. Most of the area south and southwest consists primarily of marshland and glades and contains no resident human population (Figures 2.1-3 and 2.2-4). The area west to northwest within 6 miles of Units 6 & 7 consists primarily of agricultural land (Figure 2.2-4).

The agricultural lands are located to the west, northwest, and north of the plant property within Miami-Dade County. An assessment of soil types in the area of the plant property indicated that no prime farmland, as defined in the Farmland Protection Act (7 U.S.C. Section 4201(b)), occurs on the Turkey Point plant property in the vicinity. In addition, there is no indication of unique farmland in the 6-mile vicinity. Further discussion of agriculture in the four-county region surrounding the Turkey Point plant property is provided in Section 2.3.

The closest population center of 25,000 residents or more, as defined in 10 CFR 100.3, is Homestead (Figure 2.1-4). Homestead had a 2005-2009 census range population of 55,036 (USCB 2010). Homestead's political boundary is approximately 5 miles from Units 6 & 7 at its closest point. However, no resident population exists at this distance from Units 6 & 7. The nearest populated area of Homestead lies approximately 7 miles west of the Turkey Point plant property.

There are no hospitals located within 6 miles of Units 6 & 7. Homestead Hospital is the primary health care provider in the southeast portion of Miami-Dade County and is located approximately 9.6 miles northwest of Units 6 & 7. There are no existing public schools within 5 miles of Units 6 & 7. The closest public school is the Keys Gate Charter School, located approximately 6 miles west of the Units 6 & 7 plant area. There are no prisons within 6 miles of Units 6 & 7.

The Units 6 & 7 plant area is 10 miles east of the nearest rail line, which is owned by CSX (National Atlas 2008a), and is also located adjacent to a navigable waterway—Biscayne Bay. There is a U.S. Naval Reservation 7 miles southwest of the plant area (National Atlas 2008b).

There are two industrial facilities located within 6 miles of the Units 6 & 7 plant area, the RMC Florida Group Ltd. which mines limestone, and the Homestead Air Reserve Base.

Most of Miami-Dade County is underlain by Miami limestone. An area of past, present, or future mineral extraction is located within 4 miles of the Units 6 & 7 plant area (MDC 2009). There is an active limestone mine 6 miles west of the plant area (the RMC Florida Group Ltd. facility identified above) as well as an abandoned quarry 6 miles north of the plant area (MSHA 2008).

2.2.2 TRANSMISSION CORRIDORS AND OFFSITE AREAS

The existing transmission corridors are described in Subsection 2.2.2.1. Proposed transmission lines would be constructed in these corridors and are described in Subsection 2.2.2.2. Other offsite areas required to construct or operate the new units are identified in Subsections 2.2.2.3 through 2.2.2.6. Florida Land Use, Cover, and Forms Classification System (FLUCCS) land use/land cover data (level 3) was used to analyze potential impacts within the transmission corridors.

2.2.2.1 Existing Circuits

Existing transmission lines are identified in Figure 2.2-5. There are two 230 kV substations on the Turkey Point plant property—the 1-acre McGregor substation and the approximately 6-acre Turkey Point substation. The McGregor substation is approximately 0.25 miles west of the Turkey Point substation and is connected via one 230 kV circuit.

Seven 230 kV transmission circuits depart from Turkey Point substation and proceed northward to the Davis substation near the town of Three Lakes. These lines are within the Turkey Point-Davis transmission corridor. This corridor is typically 330 feet wide, 19 miles long, and typically contains four sets of transmission line structures. Three of the structure sets carry two outgoing 230 kV circuits each, and the fourth carries a single 230 kV circuit. The first 6 miles of the existing corridor pass through and alongside Biscayne National Park.

Currently, a single transmission circuit is located in the Turkey Point-Levee corridor. This corridor proceeds west, continues for approximately 7 miles, and turns north toward the Levee substation for approximately 16 miles. This corridor is nominally 330 feet wide.

In total, the corridors carrying the eight 230 kV transmission circuits from the Turkey Point plant property extend a distance of approximately 27 miles, and occupy approximately 1111 acres of land. They are contained in Miami-Dade County.

2.2.2.2 Proposed Circuits

Units 6 & 7 would require new transmission facilities to provide reliable interconnection and integration of approximately 2200 MW of new electricity generation into the FPL transmission system. Existing linear features would generally be followed where available, within two proposed corridors, a West Preferred or Secondary Corridor and an East Preferred Corridor, from the Units 6 & 7 plant area to existing substations (Figure 2.2-5). As depicted in Figure 2.2-5, the first leg of the Western Preferred or Secondary Corridor is the transmission corridor between Clear Sky substation and the initial junction at the Western Preferred or Secondary Corridor split. The second leg is defined as either the Western Preferred or Secondary Corridor option. The third leg is defined as the corridor between the Western Preferred or Secondary Corridor junction and the Levee substation.

Units 6 & 7 would be connected to a new 500/230kV substation known as Clear Sky substation, which would be constructed in the Units 6 & 7 plant area. The connection would be to the 230kV section of the substation via underground transmission facilities. The Clear Sky substation would have two 500 kV transmission lines, approximately 43 miles long, connecting it to the existing Levee 500kV substation in a proposed transmission West Preferred Corridor. A second new 230kV line, approximately 52 miles long, would be constructed in the same West Preferred Corridor between Clear Sky substation and a new 230kV bay position at the existing Pennsuco substation; the line would share the same right-of-way with the two new 500kV lines between Clear Sky and Levee substations.

In addition to the proposed new transmission lines in the West Preferred Corridor, a new 230 kV line, approximately 19 miles long, would be constructed to connect the Clear Sky substation to a new 230 kV bay position at the existing Davis substation in a proposed transmission East Preferred Corridor. In addition, a new 230 kV line, approximately 18 miles long, would be constructed (in a largely collocated existing right-of-way or other linear/transportation corridors) to connect the Davis substation to a new 230 kV bay position at Miami substation.

As described in Chapter 1, routing of the new 500 kV and 230 kV transmission lines requires certification through the Florida Power Plant Siting Act (PPSA) site certification application process. In addition, installation of these lines would require easement acquisition. Various approvals and agency notifications would be required for each of the required transmission lines and would be acquired as part of the PPSA process. Table 2.2-3 summarizes the major land uses along each corridor/option.

West Preferred or Secondary Transmission Corridor

The proposed transmission West Corridor includes two options, a West Preferred Corridor option and a West Secondary Corridor option. The proposed West Corridor, with either option, would

include two 500 kV single-circuit transmission lines connecting the new Clear Sky substation to the existing Levee substation and one 230 kV single-circuit transmission line connecting the Clear Sky substation to the existing Pennsuco substation.

From the Clear Sky substation, the two 500 kV and single 230 kV transmission lines would extend west and north to the Levee substation located in an area of unincorporated Miami-Dade County east of Krome Avenue (SR 997) and north of U.S. Highway 41 (Tamiami Trail). FPL currently has available right-of-way, either in fee or easement, for a significant portion of this distance. The total length of the line to Levee substation would be approximately 43 miles, of which approximately 13 miles would be a proposed relocation (preferred corridor option) of an existing right-of-way (secondary corridor option) partially located within Everglades National Park. The existing Levee substation would be expanded to accommodate the two new 500 kV lines.

The West Preferred corridor between Clear Sky and Levee substation (preferred option), which runs along the eastern boundary of Everglades National Park, has a current land use distribution described in Table 2.2-3. The West Secondary corridor between Clear Sky and Levee substation (secondary option), which runs through Everglades National Park, has a current land use distribution described in Table 2.2-3.

The single 230 kV transmission line (maximum current rating of 2990 amps) would extend from the Clear Sky substation to the Levee substation using the same transmission corridor, but would not connect to but bypass the Levee substation and follow largely an existing 230 kV transmission easement for approximately 8 miles to connect to the existing Pennsuco substation. The Pennsuco substation would be expanded to accommodate the single 230 kV line.

Current land use for the transmission corridor between Levee and Pennsuco substations is shown in Table 2.2-3.

All three transmission lines would be constructed within a single right-of-way of approximately 330 feet in width within either of the proposed West Corridors to the Levee substation. From Levee to Pennsuco, the single 230 kV line would be constructed largely in an existing right-of-way.

Two access-only corridors would be constructed as part of the West Preferred/Secondary Corridor alignments. These corridors would be used to access the transmission corridor and eventual right-of-way. No transmission structures would be built in these access corridors, although access roads or road improvements may be required. The two access corridors are:

- Tamiami Trail Corridor
- Krome Avenue Corridor

Current land use in the transmission line access corridors (Table 2.2-4) at Tamiami Trail is 2.74 acres of streams and waterways/canals, 3.06 acres of freshwater marshes, and 4.70 acres of roads and highways (Table 2.2-4).

Current land use for the transmission line access corridor at Krome Avenue is 85.33 acres of streams and waterways/canals, 56.81 acres of exotic wetland hardwoods, 143.40 acres of freshwater marshes, and 79.17 acres of roads and highways (Table 2.2-4).

East Preferred Transmission Corridor

The proposed East Preferred Corridor would include a single-circuit 230 kV transmission line. This line would provide connection from the Clear Sky substation to the existing Davis substation (maximum current rating of 2990 amps) and then connection from the Davis substation to the existing Miami substation (maximum current rating of 2300 amps), both substations located in Miami-Dade County. The Davis substation is located at the intersection of SW 136th Street and SW 127th Avenue. The Miami substation, located within the city limits of Miami, is at the intersection of SW 2nd Avenue and SW 3rd Street along the Miami River. There would be improvements made to both substations to accommodate the new 230 kV line.

The Clear Sky-Davis portion of the East Preferred Corridor would use an existing, 19-mile-long, multicircuit FPL transmission line right-of-way. This right-of-way has the ability to accommodate the proposed single-circuit 230 kV line without the need for additional right-of-way. However, for a portion of the Davis to Miami corridor, new rights-of-way would be required, but much of the proposed corridor includes existing transportation rights-of-way (e.g., U.S. Route 1, Metrorail). The Davis-Miami portion of the East Preferred Corridor is approximately 18 miles long.

Current land use for the transmission corridor between Clear Sky and Davis substations is shown in Table 2.2-3.

Current land use for the transmission corridor between the Davis and Miami substations is also shown in Table 2.2-3.

Also included as part of the East Preferred Corridor is another single-circuit 230 kV transmission line that would connect the Clear Sky substation to the Turkey Point substation on the plant property (maximum current rating of 2990 amps) that are approximately 0.4 miles apart. Improvements would be made to the Turkey Point substation to accommodate the new 230 kV line from Clear Sky substation.

In some portions of the proposed Davis-Miami transmission line section, it would be collocated with other transmission lines on the existing right-of-way. In some of the locations, to accommodate both power lines on one pole, teh transmission line would be constructed using double-circuit concrete poles directly embedded in the ground. An additional, short portion of the

Davis-Miami line section, located at the crossing of the Miami River adjacent to the existing Miami substation, would be constructed as an underground extruded dielectric cable system using cross-linked polyethylene (XLPE) insulating cables.

In some cases along the proposed transmission line routes, the new lines may also be designed to provide for other attachments such as electric distribution lines, communication facilities, or other utility equipment. The typical span lengths between structures along the three proposed transmission lines would range from approximately 200 to 750 feet, depending on site-specific right-of-way widths and other design considerations.

Transmission Substations

In addition to the new and modified transmission lines discussed above, the interconnection and integration of new Units 6 & 7 generating capacity would include one new substation and upgrades and expansions of the following existing substations (Figure 2.2-5): Turkey Point, Miami, Levee, Davis, and Pennsuco. Improvements at the Turkey Point, Levee, and Davis substations would require site expansions on existing FPL property in previously disturbed areas. Work at the Pennsuco substation would require acquisition of additional property for expansion on a previously disturbed area. Acreages and current land use for the areas of substation expansion are identified in Table 2.2-5.

The Clear Sky substation would be a new 500/230 kV switchyard constructed in the Units 6 & 7 plant area utilizing 230 kV underground facilities to connect Units 6 & 7 transformers for a total of six 230 kV underground connections. The two new 500 kV transmission lines to the Levee substation would be connected to the 500 kV section of the Clear Sky substation and three new 230 kV transmission lines, one each to the Davis, Pennsuco, and Turkey Point substations, would be connected to the 230 kV section of the Clear Sky substation.

The Turkey Point substation would be expanded by 0.9 acre to accommodate a new bay with two new 230 kV line terminals and enlargement of the existing relay vault building. The new bay would be rated at 3000 amps and include new pulloff towers, breakers, line switch, disconnect switches and all associated bus work, cable trench, foundations, conduits, and grounding. Current land use of the approximately 0.9 acre area of expansion for the Turkey Point substation is 100 percent electric power facilities.

The existing Levee substation, located at NW 41St Street and NW 147th Avenue, would be expanded by 2.3 acres to accommodate a new bay with two 500 kV line terminals. The interconnection work at the Levee substation would include filling, grading, and rocking an expansion area of approximately 130 x 850 feet to the north of the existing 500 kV yard for construction of a new bay and associated equipment. In addition, a new stormwater retention system would be constructed. Current land use of the 2.3 acres area of expansion for the Levee

substation is approximately 1.81 acres of exotic wetland hardwoods and 0.52 acres of electric power facilities.

The existing Pennsuco substation, located at 10800 NW 107th Avenue, would be expanded by 0.65 acres to accommodate addition of a stormwater retention system and installation of new equipment including a new 230 kV line terminal; new breakers and conversion/reconfiguration of existing buses, relocation of distribution transformers, and installation of a new pulloff structure and disconnect switches. Current land use of the 2.42 acres area of expansion for the Pennsuco substation is 100 percent rock quarries.

The existing Davis substation, located at 12701 SW 136th Street, would be expanded by 1.12 acres to accommodate addition of two new 230 kV line terminals and installation of a switchable inductor to control power flow for the line connecting to the Miami substation. Current land use of the approximately 1.12 acres area of expansion for the Davis substation is 100 percent tree nurseries.

The Miami substation, located at 122 SW 3rd Street, would be modified to expand the 230 kV section to a double bus configuration, add a new 230 kV line terminal for connection of the line from the Davis substation, and replace the autotransformer to match the long-term emergency rating of the Miami substation autotransformer all within the existing fence line.

2.2.2.3 Makeup and Potable Water Systems

Makeup water for the Units 6 & 7 cooling system would consist of both reclaimed water and saltwater. As described in Sections 3.4 and 3.9, reclaimed water pipelines would require approximately 9 miles of pipeline corridor between the FPL reclaimed water treatment facility on the plant property and the Miami-Dade Water and Sewer Department South District Wastewater Treatment Plant to the north (Figure 2.2-5). For about 6.5 miles of their length, the pipelines would be collocated with the existing Clear Sky-to-Davis transmission line right-of-way and adjacent road and canal rights-of-way, although most of the route is classified as wetland, agricultural, or electrical power transmission lines land use types. The remaining 2.5 miles would be located along new pipeline corridor. The reclaimed water pipelines from the FPL reclaimed water treatment facility would be routed south along the eastern side of the cooling canals to the makeup water reservoir, traversing the laydown area on the western side of the Units 6 & 7 plant area (Figure 3.9-1).

Current land use within the reclaimed water pipeline corridor is described in Table 2.2-6 and consists mainly of tree nurseries, solid waste disposal, sewage treatment, mangrove swamps, mixed wetland hardwoods, field crops, and streams and waterways/canals.

Saltwater would be supplied by four radial collector wells drawing water from below Biscayne Bay. The wells would be located on the Turkey Point peninsula, east of the existing units. Each

radial collector well would consist of a central reinforced concrete caisson extending below the ground level with horizontal laterals projecting up to a distance of 900 feet from the caisson in the subsurface beneath the floor of Biscayne Bay. The radial collector well locations are shown on Figure 3.1-3. The radial collector well pipelines would be routed west from the caissons and south to the Units 6 & 7 cooling towers along the eastern side of the plant area (Figure 3.9-1).

Potable water pipelines, approximately 10 miles long, would be constructed to supply potable water for Units 6 & 7. The new water pipelines would deliver potable water from the Miami-Dade County Water and Sewer Department potable water source facility to the Units 6 & 7 plant area. Routing for the pipelines is identified in Figure 3.9-1. Approximately 2.5 miles of the pipeline corridor (origination at SW 288th Street and SW 137th Avenue/Tallahassee Road to SW 328th Street/N. Canal Drive) would require new land disturbance. The major land categories disturbed would be mainly row crops, tree nurseries, streams and waterways/canals, mixed wetland hardwoods, exotic wetland hardwoods, freshwater marshes, and roads and highways. The remaining pipeline route would be along roadways that would be improved.

2.2.2.4 Fill Material

An estimated 10.7 million cubic yards of fill (Category I - safety-related; and Category II - general area) would be required to raise the elevation of the Units 6 & 7 plant area to a final elevation of 19 to 26 feet above sea level. As described in Section 3.9, fill material would be obtained from a combination of an FPL-owned fill source, other regional sources, or reused material.

The FPL-owned fill source is located approximately 4 miles northwest of the Turkey Point plant property (Figure 3.9-1). The fill source land, which is approximately 300 acres, is located northwest of the intersection of SW 107th Avenue and SW 312th Street. The land is predominantly tree nurseries and mixed wetland hardwood. The land surface elevation in this area is approximately 3-4 feet NGVD. The land is nearly flat, with a slope of 1-2 feet per mile to the east. Water levels in this area range from approximately 2 feet in the wet season to 1 foot in the dry season. The upper 4-5 feet of soil is a mixture of marl, peat, and fills. Rock (Miami oolite) is generally encountered 4-5 feet below land surface (bls). The Fort Thompson Formation and Key Largo Limestone (interbedded) are found between 9 and 74 feet bls. Surface drainage in the area is currently through swales and roadside ditches to Military or Mowry Canals and then east toward Biscayne Bay.

The aggregate mining operation at this location to obtain fill material for construction of Units 6 & 7 would create a lake in the deep cut areas. There would be a shallow (maximum 3-4 feet deep) littoral zone around the shoreline with 4:1 slopes. The final depth of the lake in the deep cut areas would be based on Miami-Dade County Department of Environmental Resources criteria for rock mining, which require a 10 foot vertical buffer between the bottom of the mine and the 250 mg/L chloride level in the aquifer.

2.2.2.5 Emergency Operations Facility

The existing emergency operations facility for Units 3 & 4 would also be used for Units 6 & 7. This facility is located offsite in Miami-Dade County at the intersection of West Flagler Street and SW 92nd Avenue. The facility is not further considered in this environmental report.

2.2.2.6 Roads and Highways

The roads and highways in the area surrounding the Turkey Point plant property and providing potential access to the property and the Units 6 & 7 plant area include U.S. and interstate highways, multilane divided state highways, and local streets. The major federal highways in Miami-Dade County are U.S. Highway 1, which bisects the county from north to south and continues south to the Florida Keys, and Interstates 75 and 95, which also have a north-south direction but terminate in Miami.

Two of the major state highways in Miami-Dade County are Florida's Turnpike and SR 997. Florida's Turnpike is a multilane, divided toll road that traverses much of Florida, linking Interstate 75 in the interior south of Ocala to Miami. The Homestead extension of Florida's Turnpike terminates at U.S. Highway 1 north of Florida City. SR 997 connects U.S. Highway 1 in Homestead with U.S. Highway 27, which fringes the western edge of metropolitan Miami and terminates in Homestead, becoming Krome Avenue. Krome Avenue continues south and terminates at U.S. Highway 1, south of Florida City.

The existing access road for the Turkey Point plant property is SW 344th Street/Palm Drive. SW 344th Street/Palm Drive intersects with U.S. Highway 1 and SR 997. It is a four-lane road that narrows at its intersection with SW 137th Avenue/Tallahassee Road to two lanes as it leads to the Turkey Point plant property. Access to the plant property and the Units 6 & 7 plant area from U.S. Highway 1 could also be made using SW 328th Street/N. Canal Drive, which parallels SW 344th Street/Palm Drive to the north. This road is linked to SW 344th Street/Palm Drive by cross streets such as the four-lane SW 137th Avenue/Tallahassee Road and the two-lane SW 117th Avenue. Access to the site from Florida's Turnpike could be made via the exit at SW 312th Street/Campbell Drive or via the Turnpike terminus at U.S. Highway 1. SW 312th Street/Campbell Drive is a four-lane road that parallels SW 344th Street/Palm Drive to the north. A connecting road is SW 137th Avenue/Tallahassee Road. The functional class for each of these roads is presented in Tables 2.5-14.

Road improvements are planned to allow access to the Turkey Point plant property for construction and operations. As described in Section 3.9, the improvements include the widening of three existing roadways and the development of existing unpaved roads to four paved roadways.

Acreages and current land use for the areas of road improvements are identified in Table 2.2-7.

2.2.3 THE REGION

The region is defined as the area within a 50-mile radius of the centerpoint between Units 6 & 7, but excluding the plant property and vicinity described in Subsection 2.2.1. All or parts of four counties are located within 50 miles: Broward, Collier, Miami-Dade, and Monroe. Figure 2.2-6 shows the 50-mile radius bounded by the four counties. Major land use classifications and waterways in the region are shown on Figure 2.2-6. Major highways and rail lines are shown on Figure 2.2-5.

In determining what regional land use information would be relevant to Subsection 2.2.3, the construction and operational impacts of the new units on regional land use were evaluated. Land use impacts identified were limited to the Turkey Point plant property, 6-mile vicinity, and those counties in the region that would receive the bulk of new residents and taxes. There are county land use plans for the four counties within the region (Broward 2009, Collier 2007, MDC 2009, and Monroe 2009). The plan that is most directly relevant to new Units 6 & 7 is the Miami-Dade CDMP, which is addressed in Subsection 2.2.1.1.

As summarized in Table 2.2-8, the regional land use area encompasses approximately 2,634,939 acres of FLUCCS land use data (FLUCCS data does not extend all the way out into the Atlantic Ocean, Gulf of Mexico, Biscayne Bay, Card Sound, or Florida Bay).

Within the region there are many federal, state, county, and city public lands that offer both recreational and educational services. Parks include Everglades National Park, Crocodile Lake National Wildlife Refuge, Biscayne National Park, Biscayne Bay Aquatic Preserve, and Homestead Bayfront Park among others.

There are two nearby major roadways. U.S. Highway 1, the closest major roadway to the plant property, intersects Palm Drive in Florida City. The southernmost access to Florida's Turnpike is from U.S. Highway 1, approximately 0.25 miles north of the U.S. Highway 1 intersection with Palm Drive. Other access/entrances to both U.S. Highway 1 and Florida's Turnpike are provided from various local roads that can be accessed from Palm Drive. Road access to the plant property is provided by SW 344th Street/Palm Drive, which extends from the Turkey Point plant entrance through the intersection with U.S. Highway 1.

Two Indian reservations are located within the region (Figure 2.5-25). The Miccosukee Indian Reservation is located 50 miles from the plant area. The Seminole Indians have a reservation north of Hollywood named Seminole Paradise.

In accordance with NUREG 1555, principal agricultural products, crop areas, and average annual yields are addressed below by county, along with other county-specific information. The most recent data available is from 2007. Table 2.2-9 presents information for farms and harvested lands in the region for the period 1997 to 2007.

2.2.3.1 Broward County

Broward County is bounded on the north by Palm Beach County, on the northwest by Hendry County, on the west by Collier County, on the east by the Atlantic Ocean, and on the south by Miami-Dade County. Primary access routes in Broward County include Interstates 95, 75, and 595, Florida's Turnpike, and SR 869 (Sawgrass Expressway).

Broward County consists of 1197 square miles, of which 787 square miles is conservation area and 410 square miles is developable area (Broward Aug 2003). Elevations range from sea level to 25 feet above sea level, with most of the county below 10 feet elevation.

As shown in Table 2.2-9, there were 547 farms totaling approximately 8737 acres in Broward County in 2007 (NASS 2007). The 2007 numbers reflect an increase from 347 farms in 1997 but a decrease in the total acreage of farms from 30,897 acres in 1997 (AgCensus 2004a).

In 2007, approximately 29 percent (2577 acres) of the 8737 acres of total farmland in Broward County was used as harvested cropland and 47 percent (4141 acres) as pastureland (NASS 2007). The chief agricultural products of Broward County are cattle, orchard crops, vegetables, poultry, hogs and pigs, and hay. In 2007, the yields of agricultural products for Broward County were:

- 1253 head of cattle and calves
- 347 acres of land in orchards
- 768 acres of vegetables for harvest
- 938 head of poultry (layers)
- 8 head of hogs and pigs
- 272 tons of hay

2.2.3.2 Collier County

Collier County is on the Gulf coast of Florida between the cities of Bonita Springs and the mainland component of Monroe County. Collier County is bordered on the north by Lee and Hendry counties, on the west by the Gulf of Mexico, on the south by Monroe County, and east by Miami-Dade and Broward Counties. The county seat of Collier County is located in East Naples, and is accessible by major roadways including Interstate 75 and U.S. Route 41.

The total area of Collier County is 2025 square miles (USCB 2009a). The elevation across the county ranges between sea level and 40 feet above sea level (Collier Apr 2005).

As shown in Table 2.2-9, the number of farms in Collier County increased from 235 in 1997 to 322 farms in 2007. However, farm acreage decreased from 277,279 acres in 1997 to 109,934 acres in 2007 (AgCensus 2004b, NASS 2007).

In 2007, 32 percent (35,288 acres) of the 109,934 acres of total farmland in the county were devoted to harvested cropland and 58 percent (63,612 acres) to pastureland (NASS 2007). Cattle and calves, poultry, orchards crops, vegetables, hogs and pigs, and hay are the chief agricultural products. In 2007, the yields of the primary agricultural products in Collier County were:

- 10,458 head of cattle and calves
- 21,622 acres of land in orchards
- 12,982 acres of vegetables for harvest
- 849 head of poultry (layers)
- 358 head of hogs and pigs
- 150 head of sheep and lambs
- 566 tons of hay

2.2.3.3 Miami-Dade County

Miami-Dade County is on the Atlantic Ocean coastline and is bounded on the north by Broward County, on the east and the south by Biscayne Bay, on the west by Collier County, and on the west and south by Monroe County. The county seat is the City of Miami, the county's largest municipality. Miami-Dade County is accessible by major roadways including Interstates 395, 75, 95 and 195, and U.S. Routes 1, 27, 41, and 441.

The total land area of Miami-Dade County is 1946 square miles (USCB 2009b). The elevation across the county ranges from 8 feet to 15 feet above sea level (MDC 2009).

In 2007, the county had 2498 farms covering 67,050 acres, representing an increase in the number of farms from 1576, but a decrease in total acreage from 85,093 in 1997 (AgCensus 2004c, NASS 2007).

Of the 67,050 acres of total farmland in the county in 2007, 73 percent (49,065 acres) were devoted to harvested cropland and 14 percent (9108 acres) to pastureland (NASS 2007). Cattle and calves, poultry, orchards crops, vegetables, hogs and pigs, sheep and lambs, sweet potatoes

(most of the reported Florida crop), and hay are the chief agricultural products. In 2007, the yields of the primary agricultural products in Miami-Dade County were:

- 3385 head of cattle and calves
- 11,365 acres of land in orchards
- 33,451 acres of vegetables for harvest
- 7755 head of poultry (layers)
- 135 head of hogs and pigs
- 972 head of sheep and lambs
- 541 tons of hay (for the year 2002; 2007 data not reported)
- 2825 acres of sweet potatoes

2.2.3.4 Monroe County

Monroe County is the southernmost county in Florida and consists of both mainland and island components. The county is located at the intersection of the Gulf of Mexico and the Atlantic Ocean and includes a large tract of land along the southwestern most part of mainland Florida, a small strip of land between Florida City and the U.S. Highway 1 causeway to Key Largo and all of the island chain known as the Florida Keys. Virtually all the Monroe County population (more than 99.9 percent) lives in the Florida Keys. Monroe County is bounded on the north by Collier County and Miami-Dade County, on the east by Miami-Dade County, on the east and south by the Atlantic Ocean, on the south and west by the Gulf of Mexico and on the north, south and west by the Florida bay. The county seat of Monroe County is in Key West, and is accessible by major roadway U.S. Highway 1.

Two-thirds of the large Monroe County mainland area south of Collier County (mainland Monroe) is protected by virtue of being part of the Everglades National Park, and the remainder by the Big Cypress National Preserve in the northeastern interior. The area is virtually uninhabited. The total land area of Monroe County is 997 square miles (USCB 2009c). Most of the Monroe County land area makes up the southwestern corner of the state of Florida. Two-thirds of Monroe County mainland is part of the Everglades National Park, while the remainder is part of the Big Cypress National Preserve and the islands of the Florida Keys.

In 2007, the county had 23 farms covering 187 acres, an increase from 18 farms in 2002, and an increase in acreage from 102 in 2002 (NASS 2007).

Cropland is the predominant use comprising 83 percent (156 acres) of the 187 acres of farmland in the county. Pastureland comprises 6 percent (12 acres) of farmland use in the county. In 2007, the yields of the primary agricultural products in Monroe County were not disclosed.

2.3 WATER

This section provides site-specific and regional descriptions of the hydrology, water use, and water quality conditions that could affect or be affected by the construction and operation of Units 6 & 7. The potential impacts of plant construction and operation on surface water and groundwater are described in Chapters 4 and 5, respectively.

Units 6 & 7 would be collocated with two natural gas/oil steam electric generating units (Units 1 & 2), two pressurized water reactor nuclear units (Units 3 & 4), and one natural gas combined-cycle steam electric generating unit (Unit 5) on the approximately 9400-acre Turkey Point property. The Turkey Point plant property is located in southeast Florida on the west bank of Biscayne Bay in Miami-Dade County, approximately 25 miles south of Miami, Florida, as shown on Figure 2.3-1. Major hydrologic features near the plant property are also identified in the figure. Areas surrounding the plant property are shown on Figure 2.3-2.

The 218-acre Units 6 & 7 plant area would be built up to higher elevations above the adjacent grade with finished grade elevations varying from 19 feet to 25.5 feet in North American Vertical Datum of 1988 (NAVD 88). The plant area would be surrounded by a retaining wall structure with the top of wall elevation varying from 20 feet to 21.5 feet NAVD 88. The Units 6 & 7 plant area is south of Units 3 & 4 and completely encircled by the cooling canals of the industrial wastewater facility (Figure 2.3-3, Figure 2.3-4) that are used by Units 1 through 4. Unit 5 uses mechanical draft cooling towers where the cooling tower makeup water is supplied from the Upper Floridan aquifer and the blowdown is routed to the industrial wastewater facility. The Units 6 & 7 plant area is sparsely vegetated consisting of mudflats, open water, dwarf mangroves, man-made remnant canals, wetland spoil areas, and mangrove heads and is isolated by the surrounding industrial wastewater facility. The existing grade elevation within the Units 6 & 7 plant area varies from approximately –2.4 feet to 0.8 feet NAVD 88.

2.3.1 HYDROLOGY

This subsection describes surface water and groundwater hydrology that could affect or be affected by the construction and operation of Units 6 & 7. The site-specific and regional data on the physical and hydrologic characteristics are also summarized to provide the basis for an evaluation of impacts on water bodies, aquifers, aquatic ecosystems, and social and economic structures of the area.

2.3.1.1 Surface Water Resources

The Units 6 & 7 plant area is located on the shore of Biscayne Bay within the Everglades drainage basin of the south Florida watershed subregion, as shown on Figure 2.3-5 (Marella 1999). As described in Section 2.6, the Turkey Point plant property is located in the Southern Slope subprovince of the Southern Zone subregion of the Florida Platform within the Atlantic

Coastal Plain physiographic province (Figure 2.6-1). The physiographic features in the Southern Zone subregion that govern surface water flows southward from Lake Okeechobee include the Immokalee Rise, Big Cypress Spur, Atlantic Coastal Ridge, and the Everglades physiographic sub-provinces (Figure 2.6-1). Higher topographic relief of the Immokalee Rise and Big Cypress Spur in the west and the Atlantic Coastal Ridge in the east of the Everglades historically guided the stormwater runoff and freshwater flows from Lake Okeechobee to drain south and southeast into the Everglades. However, flood control structures and an elaborate drainage canal system constructed in the past century has since modified the natural drainage basin, its freshwater discharge, and its interaction with the coastal bays of the Atlantic Ocean and Gulf of Mexico. The interaction of surface water and groundwater within the area further complicates the hydrology of the area (McPherson and Halley 1997, Godfrey 2006, Wolfert-Lohmann et al. 2007).

The Units 6 & 7 plant area is located in the low-lying areas of the Southern Slope physiographic subprovince on the western shore of Biscayne Bay (Figure 2.6-1). There are no lakes, major rivers, or dams located near the plant area, as shown on Figures 2.3-1 through 2.3-3. However, a network of drainage canals, which includes canals from the Everglades National Park-South Dade Conveyance System (ENP-SDCS) and local project (drainage) canals, provides freshwater supply to the Everglades National Park and controlled drainage from southeast Florida to the Biscayne Bay. Consequently, the hydrology near the Units 6 & 7 plant area is mainly governed by the dynamics of Biscayne Bay. In addition to Biscayne Bay, other major hydrologic features near the Units 6 & 7 plant area include the Everglades and the drainage canal system of southeast Florida, and the cooling canals of the industrial wastewater facility (see Figure 2.3-1 and Figure 2.3-3). Each of these hydrologic features is described below.

The Westinghouse AP1000 certified plant design has been selected for Units 6 & 7. The AP1000 design employs a passive containment that does not require offsite water sources to perform its safety-related functions. Units 6 & 7 would use mechanical draft towers for nonsafety-related circulating water system cooling. Makeup water for the circulating water system cooling towers would be from two independent water sources, each capable of supplying the required makeup water demand, as described in Section 3.4. The makeup water sources for the circulating water system would be reclaimed water from Miami-Dade Water and Sewer Department (MDWASD) water treatment facilities and saltwater from radial collector wells with horizontal laterals installed beneath the floor of Biscayne Bay. Therefore, there would be no direct withdrawals or discharges to surface waters associated with the operation of Units 6 & 7. It is noted however, that the majority of water recharging the radial collector wells would originate from Biscayne Bay. Cooling tower blowdown discharge and other applicable plant discharge effluents from Units 6 & 7 would be collected in a common blowdown sump and discharged into deep injection wells, as described in Section 3.4. None of the surface water bodies would be used as an effluent discharge point or heat sink for Units 6 & 7.

Units 6 & 7 transmission lines would use existing and new corridors. New corridors would be established to supplement existing corridors where necessary. The transmission corridors are described in Section 3.7.

2.3.1.1.1 The Everglades

The Everglades is the largest wetland in the continental United States and was part of the larger, natural Kissimmee-Okeechobee-Everglades watershed that once extended south from Lake Okeechobee to the southernmost extremity of peninsular Florida (McPherson and Halley 1997). Elevations within the Everglades, which was formed on limestone bedrock, are lower than the elevations in the Immokalee Rise or Atlantic Coastal Ridge physiographic subprovinces and slope towards the south with an average gradient less than 2 inches per mile (McPherson and Halley 1997, Galloway et al. 1999). The freshwater flow from Lake Okeechobee and the flat terrain of the basin supported the accumulation of layers of peat and mud that formed the historical Everglades wetlands over an area of approximately 4500 square miles (McPherson and Halley 1997, Galloway et al. 1999). Historically, overflows from Lake Okeechobee slowly moved through the Everglades as sheet flows. The overflow also provided the freshwater supply that sustained the ecosystem functions within the wetlands that were dominated by sawgrass and tree islands, the small, forested islands that are a prominent feature of the Everglades (McPherson and Halley 1997, Godfrey 2006). From the Everglades, water drained south to the Gulf of Mexico through a series of open-water sloughs. Hydrological features and direction of historical surface water flows are shown on Figure 2.3-6.

The Atlantic Coastal Ridge that separates the Everglades from the Atlantic coastline has a maximum elevation of approximately 20 feet above MSL datum (Galloway et al. 1999), which is equivalent to the National Geodetic Vertical Datum of 1929 (NGVD 29). At the National Oceanic and Atmospheric Administration (NOAA) tide gage station at Virginia Key, Florida, the NGVD 29 is located approximately 1.6 feet below the NAVD 88. This datum relationship is also considered applicable to the Units 6 & 7 plant area. Applying the datum conversion, the maximum elevation of the Atlantic Coastal Ridge is approximately 18.4 feet NAVD 88. The NAVD 88 is used as the reference vertical datum in this subsection. A conversion to NAVD 88 is provided when a reference to other vertical datums are made. Historically, nearly all of southeast Florida, except for the Atlantic Coastal Ridge, was flooded annually (Galloway et al. 1999). The floodwater discharged to Biscayne Bay through the undeveloped Miami, New, and Hillsborough Rivers and other sloughs that formed the transverse glades in the Atlantic Coastal Ridge.

Since the late nineteenth century, the south Florida watershed subregion has been affected by anthropogenic alterations (Ishman 1997, Godfrey 2006). Land reclamation for agriculture, construction of flood control levees and drainage canals, and urbanization has irreversibly modified the hydrology of the region. One of the major impacts of the hydrologic modification is the reduction of freshwater flow to the Everglades, which resulted in a degradation of the south

Florida ecosystem. Canals were first dug through the Everglades to drain water from the area south of Lake Okeechobee, thus enabling agriculture to develop during the late nineteenth century (McPherson and Halley 1997, Renken et al. 2005, Godfrey 2006). By the late 1920s, major canals were constructed and rivers in the transverse glades were modified to connect Lake Okeechobee with the Gulf of Mexico and Atlantic Ocean (Figure 2.3-7). In the west, the Caloosahatchee Canal connected Lake Okeechobee with the Gulf of Mexico. St. Lucie Canal in the east connected Lake Okeechobee with the St. Lucie River and estuary. In the southeast, the West Palm Beach, Hillsborough, North New River, South New River, and Miami (River) Canals connected Lake Okeechobee with the Biscayne Bay and the Atlantic Ocean (McPherson and Halley 1997, Renken et al. 2005, Godfrey 2006). Government-initiated flood control measures including levee construction and drainage channel modification began in the 1930s (Godfrey 2006).

The consequences of the Everglades watershed alterations were the destruction of plants and wildlife, soil subsidence, saltwater intrusion, and fires in the peat layers during periods of drought (Godfrey 2006). To counter the deteriorating environmental conditions, the U.S. Congress authorized the Central and Southern Florida Flood Control Project (C&SF project) in 1948 with a mandate to provide flood protection, water supply, prevention of saltwater intrusion, and protection of fish and wildlife resources (McPherson and Halley 1997, Godfrey 2006). The state of Florida formed the Central and Southern Florida Flood Control District in 1949, which later became the South Florida Water Management District (SFWMD), to work with the C&SF project. The C&SF project adopted a water-management plan for Lake Okeechobee and three water conservation areas (WCAs) to provide flood protection and water supply through a complex series of canals, levees, pumps, and control structures (McPherson and Halley 1997, Renken et al. 2005, Godfrey 2006). An area of approximately 800,000 acres was identified in the northern Everglades, on the basis of soil thickness and geologic formations, as potential agricultural land and referred to as the Everglades Agricultural Area (EAA), which was subsequently drained and farmed. The WCAs, which are approximately 900,000 acres of land enclosed by levees and canals, were constructed in the central Everglades (McPherson and Halley 1997). The locations of the EAA and the WCAs are shown on Figure 2.3-7.

The construction of the flood control canals, levees, and structures by the C&SF project causes a large portion of runoff that originally flowed from the Kissimmee River and Lake Okeechobee into the Everglades to be diverted directly to the Gulf of Mexico by the Caloosahatchee Canal and to the Atlantic Ocean by the St. Lucie Canal. The remaining outflow from the lake discharges to the canals that pass through the EAA (McPherson and Halley 1997). Before flood control, agriculture, and urbanization development, which began in the late nineteenth century, the natural water level in the lake overflowed its southern bank at elevations 20 to 21 feet NGVD 29 (18.4 to 19.4 feet NAVD 88). Currently, the lake water level is artificially maintained at approximately 13 to 16 feet NGVD 29 (11.4 to 14.4 feet NAVD 88) (Galloway et al. 1999). Surface

water flows from the EAA into the WCAs are maintained by pumping, resulting in alterations in the timing and spatial distribution of flows, as well as a reduction in the volume of water discharged. As a result, water levels in the Everglades at present are generally shallower and have shorter hydroperiods than water levels prior to late nineteenth century development (McPherson and Halley 1997, Galloway et al. 1999). By 1930, the network of mostly uncontrolled canals drained large quantities of freshwater from the Everglades into the Atlantic Ocean, lowering the water levels in the Everglades as much as 6 feet compared to the predevelopment period (Renken et al. 2005). In the southern part of the Everglades, levees impede water flows and cause ponding, which became evident during the mid-1960s in WCA-3 with extensive flooding of tree islands. During periods of drought, water is released from Lake Okeechobee to the EAA and the WCAs. Most of the flows, however, never reach the interior marshes as the flows are confined to canals and nearby marshes (Wolfert-Lohmann et al. 2007). Post-development drainage patterns in the Everglades are shown on Figure 2.3-7.

By 2000, approximately 50 percent of the historic Everglades basin in Florida remained undeveloped (Renken et al. 2005). The rest of the area has been altered for agriculture or urban growth (Godfrey 2006). Most of the remaining portions of the Everglades at present are protected by public parks including Everglades National Park, Big Cypress National Preserve, Loxahatchee National Wildlife Refuge, the WCAs, the Fakahatchee Strand State Preserve, and other state lands (McPherson and Halley 1997). Everglades National Park was established in 1947 on marshland south of the WCAs and now covers approximately 1.4 million acres (McPherson and Halley 1997). Everglades National Park is approximately 15 miles west of the Units 6 & 7 plant area and is adjacent to the southeast Florida drainage canal system.

In 2000, the Federal Water Resources Development Act authorized a Comprehensive Everglades Restoration Plan (CERP) to guide the restoration, protection, and preservation of the water resources of central and southern Florida, including the Everglades (CERP 2008a). The plan covers 16 counties over an area of 18,000 square-miles and focuses on updating the C&SF project. The CERP includes more than 60 elements that would require more than 30 years to construct (CERP 2008a). The CERP projects would improve south Florida's ecosystem by restoring water flows that have changed over the past century. CERP projects would capture and store freshwater flows in surface and subsurface reservoirs, which are currently released to the Atlantic Ocean and Gulf of Mexico. The freshwater would be directed to the wetlands, lakes, rivers, and estuaries of south Florida while also ensuring future urban and agricultural water supplies (CERP 2008a). The reservoir storage areas would mainly be located within the EAA and WCAs.

2.3.1.1.2 Everglades National Park-South Dade Conveyance System

The development of reclaimed land from the Everglades for agriculture, urbanization, and flood control needs resulted in a gradual construction of canals and levees in the south Florida region

before the implementation of the C&SF project. The systematic and elaborate construction of drainage canals in southern Dade County was initiated in the 1960s. The federal Flood Control Act of 1962 authorized the C&SF project for southern Dade County. The C&SF project implemented a system of canals and structures to provide drainage for urban development, prevent over-drainage of agricultural lands, and prevent contamination of groundwater by saltwater intrusion (USACE 2007). The conveyance system relies on gravity drainage through a primary network of 12 canals with outlets to serve a system of secondary canals (USACE 2007). The stages of development of the canals during the 1950s and 1960s are shown on Figure 2.3-8.

The canal system was modified in the 1970s to meet the hydrologic needs of the Everglades National Park, as authorized by the updated Flood Control Act of 1968, by implementing the ENP-SDCS (USACE 2007). ENP-SDCS interconnected several drainage basins of the C&SF drainage project (Cooper and Lane 1987). Gated control structures were first installed at the eastern (coastal) end of the primary canals to release excess stormwater runoff to the coastal water bodies during the wet season and to manage saltwater intrusion during the dry seasons. Secondary controls on the inland reaches of canals were then installed to regulate flow eastward, control inland and agricultural flooding, and maintain higher water levels in the surficial aquifer system where appropriate (Renken et al. 2005). The surface water canal system was fully developed in the 1980s when the ENP-SDCS was completed. The progression of canal development during the 1970s through 1990 is shown on Figure 2.3-9. The conveyance system met its objectives by providing agricultural water supply, controlling inland flooding, and mitigating saltwater intrusion (Renken et al. 2005).

The ENP-SDCS was mandated to supply 55,000 acre-feet of water per year to the Everglades National Park. It made use of the existing canals from the C&SF project (Cooper and Lane 1987). The existing north-south directed borrow canals, L-30 and L-31N/L-31W, were enlarged to convey water from the Miami Canal (C-6) to the Everglades. The west-east running canals provide drainage from the South Dade development corridor to Biscayne Bay by control structures at the mouth of the canals (Renken et al. 2005). The locations of present day ENP-SDCS and C&SF project drainage canals are shown on Figure 2.3-10. The western borrow canal of the Levee L31-E (L-31E Canal) runs parallel to the Biscayne Bay coastline in southern Miami-Dade County, separating the coastal wetlands along the bay from the mainland. Starting north of Black Creek Canal (C-1) and extending to Card Sound Road in the south, the L-31E Canal has a levee crest elevation of approximately 7 feet NAVD 88 (SFWMD 2006a). Near the Turkey Point plant property, the levee and canal are located immediately west of the Turkey Point interceptor ditch and the industrial wastewater facility.

Based on the hydrology of the area, the U.S. Army Corps of Engineers (USACE) delineated water management subbasins in southern Dade County (Cooper and Lane 1987). At present, the water management area includes 17 subbasins that contribute flow to Biscayne Bay and the Everglades, as shown on Figure 2.3-10. Surface water flows from the drainage subbasins to

Biscayne Bay or the Everglades are controlled by numerous flow control structures. Flow control structures also control flow between the subbasin areas. The names of subbasins are based on the major canal in the subbasin. A summary of the subbasins (with names corresponding to the primary canal servicing each of the areas), drainage areas, and the control structures at basin outlets that regulate flow to Biscayne Bay is provided in Table 2.3-1 (Cooper and Lane 1987). The locations of the major control structures are shown on Figure 2.3-10.

Detailed flow and water level monitoring and measurements are performed as part of the operation of the structures in the ENP-SDCS. A search in the SFWMD database (DBHYDRO) for flow and water level monitoring data within the subbasins listed in Table 2.3-1 returned approximately 700 records (SFWMD 2009). The DBHYDRO database includes data from stations maintained by various agencies including USGS, SFWMD, and Everglades National Park. Monthly mean flow rates and water levels at four stations near the Units 6 & 7 plant area, S-197, S-20, S-21A, and S-21, were obtained from the SFWMD database. Details of the station locations and available data records are presented in Table 2.3-2. Monthly mean flow rates and water levels at the selected locations are presented in Tables 2.3-3 through 2.3-10. The location of these structures is shown on Figure 2.3-10.

2.3.1.1.3 Biscayne Bay

Biscayne Bay is a shallow coastal lagoon located on the lower southeast coast of Florida (Langevin 2001). The bay is approximately 38 miles long, approximately 11 miles wide on average, and has an area of approximately 428 square miles (USGS 2004 and Wingard 2004). Biscayne Bay began forming between 5000 and 3000 years ago as sea level rose and filled a limestone depression (Wolfert-Lohmann et al. 2007). The eastern boundary of Biscayne Bay is composed of barrier islands that also form part of the Florida Keys and separates the bay from the Atlantic Ocean (NOAA 2000). Coral reefs east of the barrier islands make up the northern extent of the Florida reef tract (USGS 2004). Several canals on the western shore discharge surface water into the bay, as described in Subsection 2.3.1.1.2. The Biscayne Bay subbasin is hydrologically connected with the Everglades, as shown in Figure 2.3-5. Biscayne Bay is connected to the Atlantic Ocean by a wide and shallow opening of coral shoal near the middle of the bay that is known as the safety valve, and by several channels and cuts (Cantillo et al. 2000). Because Biscayne Bay, unlike most estuaries, is not a drowned river valley, sediment inflow to the bay from rivers/canals is insignificant.

Part of Biscayne Bay is within the designated boundary of Biscayne National Park. With an area of 172,000 acres, Biscayne National Park is the largest marine park in the U.S. National Park system. More than 95 percent of Biscayne National Park is located in the marine environment (USGS 2006). The park contains a narrow fringe of mangrove forest along the mainland. Similar mangrove zones are present along the southern expanse of Biscayne Bay and in the northernmost islands of the Florida Keys including Elliott Key (BNP 2008b).

For basin-wide planning purposes, Biscayne Bay is divided into three subregions: North Bay, Central Bay, and South Bay (Cantillo et al. 2000). North Bay extends from approximately 5 miles north of the Miami-Dade/Broward County boundary to the highly urbanized shoreline near Miami, Florida; Central Bay extends from the shoreline near Miami, Florida to the Featherbed Banks east of Black Creek Canal; and South Bay extends from the Featherbed Banks east of Black Creek Canal to Barnes Sound (Figure 2.3-10). The Turkey Point plant property is located on South Bay, which is generally undeveloped and fringed by mangrove wetlands. The South Bay (also identified as the Lower Biscayne Bay) is approximately 100 square miles in area.

The average depth of Biscayne Bay is approximately 6 feet with a maximum depth of approximately 13 feet (Caccia and Boyer 2005). The volume of the bay at mean low water is approximately 1.5E10 cubic feet. The mean low water datum is located at approximately elevation -1.9 feet NAVD 88 at the NOAA Virginia Key, Florida station (NOAA 2008a).

Tides in Biscayne Bay are semidiurnal. NOAA maintains tidal stations in Biscayne Bay and surrounding areas (NOAA 2008b). A list of selected stations near Units 6 & 7 and their estimated tidal ranges are presented in Table 2.3-11. The stations with more than 10 years of record that remain in operation include Virginia Key, Florida (NOAA station 8723214), Vaca Key, Florida (8723970), and Key West, Florida (8724580) (NOAA 2008c, NOAA 2008d, and NOAA 2008e). The Virginia Key, Florida station is located approximately 25 miles north-northeast of the Units 6 & 7 plant area. The Vaca Key, Florida and Key West, Florida stations are located approximately 70 miles and 110 miles southwest of the plant area, respectively. Historical high and low water levels at these stations are presented in Table 2.3-12. Other stations, as listed in Table 2.3-11, are located within Biscayne Bay and Card Sound with only short periods of tidal data and are no longer active. The locations of the tidal stations are shown on Figure 2.3-12.

In Biscayne Bay, the great diurnal tide range, which is the difference between the mean higher high and mean lower low tide levels, is higher near the entrance of the bay, as shown in Table 2.3-11 and Figure 2.3-12. At the Cutler, Biscayne Bay, Florida station, the great diurnal range is 2.13 feet. Near the Units 6 & 7 plant area, the range is 1.78 feet, and in southern Biscayne Bay at Card Sound Bridge station, the range is reduced to 0.63 feet. The 100-year return period low water level in Biscayne Bay near the Units 6 & 7 plant area is estimated to be approximately –3.8 feet NAVD 88.

Monthly mean salinities vary widely over Biscayne Bay, ranging from a low of approximately 6 parts per thousand (ppt) to a high of 42 ppt, depending on the amount of rainfall and surface drainage reaching the coastal zone (Caccia and Boyer 2005). The bay is shallow and well mixed with only a weak salinity-based density gradient generated by the freshwater discharge from the canals on the western side. Salinity in the bay is affected by the pronounced wet-dry seasonal dynamics and is highest in June when rainfall is low and evaporation is high (BNP 2008b, Caccia

and Boyer 2005). Natural water temperatures range from 59°F to 92°F at the surface, with little or no thermal stratification.

Studies of Biscayne Bay show the principal circulation forces to be tidal. Hurricane storm events with persistent wind for long periods may also cause relatively large water movements. Measurements of tidal flow past discrete points such as Cutter Bank (east of the industrial wastewater facility) average approximately 50,000 acre-feet per day, or a continuous flow of 60,000 acre-feet per half tidal cycle. Tidal exchange between Biscayne Bay and the Atlantic Ocean is estimated to be less than 10,000 acre-feet per day. Apart from the wide and shallow opening of coral shoal near the middle of the bay, the major creeks and sloughs that control the tidal circulation within Biscayne Bay and interact with the Atlantic Ocean flows include Angelfish Creek, Broad Creek, and Caesar Creek in the South Bay and Virginia Key Channel in the North Bay. Measured data indicate a net southward tidal current magnitude of approximately 0.018 meter per second (0.06 foot per second) (Wang et al. 2003). The 10-year annual mean and seasonal freshwater inflow to the bay from major canals over a period from 1994 to 2003 are presented in Table 2.3-13 (Caccia and Boyer 2005).

Bathymetry variation within Biscayne Bay is shown on Figure 2.3-13. Long- and short-term shoreline change rates for the bay are not available. The average long-term rate of shoreline change for east Florida along the Atlantic coast shoreline is 0.2 ± 0.6 meter per year (0.66 ± 2.0 feet per year) (Morton and Miller 2005). This long-term shoreline rate of change is relatively small compared to shoreline changes for the other parts of the southeast Atlantic coast (Morton and Miller 2005). Shoreline changes within Biscayne Bay would be smaller than the rates for the Atlantic coast shoreline because the bay is protected from tide and wave actions by the barrier islands. The long-term trends in sea level rise at Miami Beach, Vaca Key, and Key West, Florida are approximately 2.39 ± 0.43 millimeters/year (0.09 ± 0.017 inch per year), 2.78 ± 0.6 millimeters/year (0.11 ± 0.024 inch per year), and 2.24 ± 0.16 millimeters per year (0.09 ± 0.006 inch per year), respectively (NOAA 2008f). Because Units 6 & 7 would not use surface water from or discharge process water into Biscayne Bay, detailed sediment transport properties for the bay are not provided.

The South Bay also includes Card Sound and Barnes Sound south of Biscayne Bay. Card Sound is part of the Biscayne Bay Aquatic Preserve of the Upper Florida Keys. Freshwater input to Card Sound is primarily surficial sheet flow with additional flow from groundwater upwelling (Ishman 1997). Circulation within Card Sound and Barnes Sound is restricted because of the enclosed configuration of the sounds by barrier islands that increases residence times of its waters (Ishman 1997).

The waters of Biscayne Bay support a rich and diverse ecosystem of marine fauna and flora, and the bay serves the coral reef and marine ecosystems of Biscayne National Park. As Biscayne Bay evolved and formed, a natural cyclical change occurred as a result of the large-scale

physical variation, such as sea level and climate change. Analysis of sediment core data from Biscayne Bay and Card Sound indicates that the Biscayne Bay ecosystem underwent many substantial changes between the last 100 and 500 years (Ishman 1997). Southern Biscayne Bay, including Card Sound and Barnes Sound, has been relatively isolated from direct marine influence for at least the last two centuries, and this area is less affected by the urbanization that has occurred to the north. Despite its relative isolation, however, the area has changed substantially during the last century (Ishman 1997). At Card Bank, salinity has varied substantially on multidecadal and centennial time scales relative to the variation observed at central Biscayne Bay sites. Marine influence at Card Bank has increased over the last century. The mud banks of central Biscayne Bay have become increasingly marine and increasingly stable (showing less fluctuation in salinity) during the last 100 years (Ishman 1997). The statutory and legal restrictions of surface water use and the list of impaired waters near the Units 6 & 7 plant area are described in Subsections 2.3.2.1.3 and 2.3.3.1.3, respectively.

2.3.1.1.4 Industrial Wastewater Facility

Units 1 through 4 use the cooling canals of the industrial wastewater facility for condenser and auxiliary system cooling (Figure 2.3-3). The industrial wastewater facility also receives cooling tower blowdown from Unit 5 and existing facilities drainage. The industrial wastewater facility is a closed-loop system of canals for cooling water recirculation with no surface water discharge or surface water interaction with surrounding hydrology. The unlined cooling canals act as a cooling basin that covers an area of approximately 5900 acres spread over a length of approximately 5 miles and a width of approximately 2 miles. Plant cooling water discharged to the canals on the northwestern side is distributed into 32 feeder canals flowing south. The feeder canals flow to a single collector canal in the south, which then distributes water to seven return canals flowing north to the intakes, as shown on Figure 2.3-14. The canals are approximately 200 feet wide with a centerline distance of approximately 290 feet (see Figure 2.3-14). The top elevation of the berms is approximately 7.8 feet above mean low water (5.9 feet NAVD 88). The feeder and return canals are shallow, generally 1 to 3 feet deep, with the exception of the westernmost return canal (formerly Card Sound Canal), which extends to a depth of –18 feet NGVD 29 (–19.6 feet NAVD 88). Routine maintenance of the canals is performed for the removal of aquatic vegetation to minimize flow restriction.

Plant circulating water for Units 1 through 4, and cooling tower blowdown from Unit 5 pumped at the northern end of the feeder canals provide the maximum hydraulic head at the northern end of the canals. The total circulating water flow in the industrial wastewater facility for Units 1 through 4 is 4250 cubic-feet per second. The cooling tower blowdown from Unit 5 is approximately 737 acre-feet per month (12.4 cubic feet per second). The hydraulic head is lowest at the north end of the return canals providing required water flow to the intake pumps. The difference in hydraulic head between the westernmost feeder canals and the easternmost return canals is approximately 3 feet that drives the circulating flow in the industrial wastewater facility. Water

level measurements and analysis suggest that the industrial wastewater facility acts to attenuate semi-diurnal and diurnal tidal influences from Biscayne Bay. Because the canals are not lined, groundwater flow interacts with water in the cooling canals. The cooling canals also experience losses as a result of evaporation and seepage. Makeup water for the industrial wastewater facility comes from treated process wastewater, rainfall, stormwater runoff, and groundwater infiltration. The water in the industrial wastewater facility is hypersaline with salinity concentrations approximately twice that of Biscayne Bay.

The initial design of the collector canal considered a connection of the canal with Card Sound (extending the westernmost return canal). However, the wastewater permit conditions required the canal to be cut off from Card Sound at the southern end of the industrial wastewater facility. At present, the remnant canal (south of the westernmost return canal) does not receive any surface water flow from the industrial wastewater facility and is only connected to Card Sound.

Along the northwest and west sides of the industrial wastewater facility, an interceptor ditch was constructed that has no surface water connection to the industrial wastewater facility or other surface waters. The interceptor ditch with a bottom elevation of –18 feet mean low water (or –19.9 feet NAVD 88) is located just west of and adjacent to the industrial wastewater facility, and east of the L-31E levee. The purpose of the ditch is to restrict inland movement of water from the industrial wastewater facility by pumping water from the interceptor ditch back into the industrial wastewater facility, thereby maintaining the water level in the ditch lower than the water level in L-31E Canal. Pumping from the interceptor ditch to the industrial wastewater facility is performed based on water level monitoring in the interceptor ditch and L-31E Canal at locations and frequencies agreed upon by FPL and SFWMD. This pumping prevents seepage from the industrial wastewater facility from moving landward toward the L-31E Canal and maintains freshwater west of the interceptor ditch.

2.3.1.1.5 Local Site Drainage

The Units 6 & 7 plant area is separated from the low-lying mangrove flatlands of the Biscayne Bay Coastal Wetlands. The Turkey Point units including the industrial wastewater facility is bordered by Biscayne Bay and the L-31E Canal to the east and west, respectively, by the Florida City Canal to the north, and by Card Sound Road and Card Sound to the south. Because the L-31E levee intercepted freshwater flows that historically discharged as sheet flow to the coastal wetlands and the bay east of the canal, the salinity of the wetlands has increased over time. Outflows from the canals near Units 6 & 7 are controlled by two flow control structures, S-20 and S-20F. Public works projects in the early 1900s in this area for mosquito control and land reclamation included shallow ditches approximately 6 to 10 feet wide. The shallow mosquito ditches run north-south, and the drainage ditches run east-west that provided quick drainage of the wetlands. Remnants of the ditches can still be identified in the area (Ruiz and Ross 2004).

The SFWMD has undertaken a plan (Biscayne Bay Coastal Wetlands Project) to restore the Biscayne Bay ecosystem that would include areas surrounding the Turkey Point units. At present, FPL maintains wetland areas north and west of Unit 5 (TP 5 Mitigation Area). FPL is also implementing a wetland mitigation project west and southwest of the Units 6 & 7 plant area (Everglades Mitigation Bank). These wetland areas are shown on Figure 2.3-2 and Figure 2.3-3. Locations of wetlands near the Units 6 & 7 plant area, as designated by the U.S. Fish and Wildlife Services, are shown on Figure 2.3-15.

The Biscayne Bay Coastal Wetlands Project would provide overland sheet flow in a 13,600-acre area through the construction of spreader canals and other structures (CERP 2008b). The increased natural water flow is designed to improve the ecology of Biscayne Bay including its freshwater and tidal wetlands, nearshore bay habitat, marine nursery habitat, oysters, and the oyster reef community. Any future hydrologic changes brought about by the project would not have any adverse flooding and water use impacts on Units 6 & 7.

The design basis flood elevation for Units 6 & 7 was predicted from a probable maximum surge event combined with the effects of wind-driven wave activity. The design basis flood elevation thus obtained is at 24.8 feet NAVD 88. The corresponding hurricane surge stillwater level is 21.1 feet NAVD 88. The Federal Emergency Management Agency (FEMA) Flood Insurance Study for Dade County indicates that the most severe flooding of the county would be as a result of hurricane storm surge events (FEMA 1994). The Flood Insurance Study estimated the surge elevations (stillwater level) at selected transect locations along the Biscayne Bay shoreline. The Units 6 & 7 plant area lies between Transect 30 in the north to Transect 31 in the south. The maximum stillwater levels in the transects vary between 12.0 feet and 12.4 feet NGVD 29 for a 500-year return period, which are approximately 10.4 feet and 10.8 feet NAVD 88.

2.3.1.2 Groundwater

The regional, local, and site-specific data on the physical and hydrologic characteristics of the groundwater resources are summarized in this subsection to provide the basic data for an evaluation of impacts on the aquifers in the area.

2.3.1.2.1 Description and Onsite Use

This subsection contains a description of the regional and local physiography and geomorphology, groundwater aquifers, geologic formations, and groundwater sources and sinks. Regional and onsite uses of groundwater are presented in Subsection 2.3.2, including groundwater production and groundwater flow requirements of Units 6 & 7.

2.3.1.2.1.1 Site and Regional Physiography and Geomorphology

Units 6 & 7 are located in Miami-Dade County, Florida, approximately 25 miles south of Miami, 8 miles east of Florida City, and 9 miles southeast of Homestead. The Turkey Point plant property is located within the Southern Slopes subprovince of the Southern Zone of the Florida Platform (a partly submerged peninsula of the Continental Shelf) within the Atlantic Coastal Plain physiographic province (Figure 2.3-16). It is bordered on the east by Biscayne Bay, on the west by the Everglades Mitigation Bank, and on the northeast by Biscayne National Park. The Florida Platform is underlain by approximately 4000 to 15,000 feet of clastic deposits (quartz sands, silt, marl, and clay) and nonclastic deposits of carbonate rocks (shell beds, calcareous sandstone, limestone, dolostone, dolomite, and anhydrite). The sediments range in age from Paleozoic to Recent and overlay the basement complex of Jurassic and Paleozoic age. A description of the regional and site-specific geology, physiography, and geomorphology is provided in Section 2.6.

The physiographic features surrounding Units 6 & 7 are the Atlantic Coastal ridge, the Everglades, and the Florida Keys. The geomorphology of Florida has been described in the literature (White 1970 and Randazzo and Jones 1997) as having three zones: Northern, Central, and Southern. The plant property is in the Southern Zone (Figure 2.3-16). The property spans former coastal mangrove swamps and tidal flats along the west margin of Biscayne Bay that were altered to create the existing and industrial wastewater facility/cooling canals.

The existing ground surface in the Units 6 & 7 plant area is generally flat, with elevations ranging from –2.4 to 0.8 feet NAVD 88. Vegetated depressions resulting from surficial erosion or solutioning are observed on the plant area. Two remnant canals cross the Units 6 & 7 plant area and are connected to the industrial wastewater facility on the eastern side. The 5900-acre industrial wastewater facility, of which 4370 acres is water surface, is the predominant surface water feature on the plant property. A detailed description is provided in Subsection 2.3.1.2.2.5.

The surficial geology within the Units 6 & 7 plant area consists primarily of organic muck. The organic muck is described as either light gray–dark gray to pale brown with trace amounts of shell fragments and little to no reaction to hydrochloric acid, or black to brown with organic fibers and strong reaction to hydrochloric acid. The thickness of the muck across the Units 6 & 7 plant area typically varies from 2 to 7 feet with an average thickness of 3.4 feet (MACTEC 2008). The Miami Limestone underlies the muck and is a marine carbonate consisting predominately of white to gray oolitic limestone with varying abundances of fossils such as mollusks, bryozoans, and corals.

2.3.1.2.1.2 Regional Groundwater Aquifers

The regional hydrostratigraphic framework of Florida consists of a thick sequence of Cenozoic sediments which comprise three major aquifers: (1) the surficial aquifer system, (2) intermediate

aquifer system/confining unit, and (3) the Floridan aquifer system (SEGS 1986). The hydrologic parameters and lithologies of each aquifer system vary widely across the state. A generalized hydrostratigraphic column is presented in Figure 2.3-17.

Surficial Aquifer System

The surficial aquifer system is defined by the Southeastern Geological Society (SEGS) Ad Hoc Committee (SEGS 1986) as "the permeable hydrologic unit contiguous with the land surface that is comprised principally of unconsolidated to poorly indurated, siliciclastic deposits.” Rocks making up the surficial aquifer system belong to all or part of the Upper Miocene to Holocene Series, consisting primarily of quartz sands, shell beds, and carbonates. In southern Florida, the surficial aquifer system consists of the Tamiami, Caloosahatchee, Fort Thompson, and Anastasia Formations; the Key Largo and Miami Limestones; and undifferentiated sediments (SEGS 1986).

The surficial aquifer system is under mainly unconfined conditions; however, beds of low permeability may cause semi-confined or locally confined conditions in its deeper parts. The base of the surficial aquifer system coincides with the top of laterally extensive and vertically persistent beds of low permeability belonging to the intermediate aquifer system/confining unit. Regionally, the thickness of the surficial aquifer system ranges from approximately 20 to 400 feet.

The main aquifer in the surficial aquifer system in southeastern Florida is the Biscayne aquifer, which is used for primary water supply. The Biscayne aquifer has been declared a sole-source aquifer (SSA) by the U.S. Environmental Protection Agency (EPA). An SSA is defined as “an underground water source that supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer. These areas have no alternative drinking water source(s) that could physically, legally, and economically supply all those who depend upon the aquifer for drinking water” (U.S. EPA 2011). Figure 2.3-18 shows the locations of SSAs in EPA Region 4. The figure also contains a description of the limits of the Biscayne SSA. Although the Biscayne aquifer underlies the Units 6 & 7 plant area, it contains saline to saltwater in this area and is not usable as a potable water supply.

Intermediate Aquifer System/Confining Unit

Regionally, a sequence of relatively low-permeability, largely clayey deposits approximately 900 feet thick forms a confining unit that separates the Biscayne aquifer from the underlying, fresh-to-saltwater Floridan aquifer system. The confining unit also contains transmissive units that can locally act as an aquifer system.

The SEGS (1986) defines the intermediate aquifer system/confining unit as "all rocks that lie between and collectively retard the exchange of water between the overlying surficial aquifer system and the underlying Floridan aquifer system.” In general, the rocks of this system consist of fine-grained siliciclastic deposits interlayered with carbonate strata of Miocene or younger age.

In areas where poorly yielding to nonwater-yielding units occur, the term "intermediate confining unit" is used. In areas where low- to moderate-yielding units are interlayered with relatively impermeable confining beds, the term "intermediate aquifer system" applies. The aquifer's units within this system contain water under confined conditions. The top of the intermediate aquifer system/confining unit coincides with the base of the surficial aquifer system. The base of the intermediate aquifer, or confining unit, is at the top of the vertically persistent, permeable, carbonate section that comprises the Floridan aquifer system. The sediments comprising the intermediate aquifer system/confining unit are widely variable across the state. In the southern part of the state, the Hawthorn Group, consisting of the Peace River Formation and the Arcadia Formation, forms both an intermediate confining unit and an intermediate aquifer system. The Hawthorn Group sediments are up to approximately 900 feet thick in southern Florida (Figure 2.3-17). In many areas of the state, permeable carbonates occurring at the base of the Hawthorn Group may be hydraulically connected to the Floridan aquifer system and locally form the top of the Upper Floridan aquifer. The intermediate confining unit provides an effective aquiclude for the Floridan aquifer system throughout the state.

Floridan Aquifer System

The Floridan aquifer system underlies approximately 100,000 square miles in southern Alabama, southeastern Georgia, southern South Carolina, and all of Florida. Potable water is present in some parts of the aquifer. As defined by Miller (1986), the Floridan aquifer system is a vertically continuous sequence of interbedded carbonate rocks of Tertiary age that are hydraulically interconnected by varying degrees and with permeabilities several orders of magnitude greater than the hydrogeologic systems above and below. The system may occur as a continuous series of vertically connected carbonate sediments or may be separated by sub-regional to regional confining beds (Miller 1986). The Floridan aquifer formally consists of three main hydrogeologic units: the Upper Floridan aquifer, the middle confining unit, and the Lower Floridan aquifer (Figure 2.3-17). Porosity and permeability in the aquifer units vary widely depending on location and formation.

In southern Florida, the Floridan aquifer system is composed of all or parts of the Cedar Keys Formation, Oldsmar Formation, Avon Park Formation, Ocala Limestone, Suwannee Limestone, and, possibly, the basal carbonates of the Hawthorn Group in limited areas.

In southern Florida, the top of the Floridan aquifer system ranges in elevation from approximately –1000 feet National Geodetic Vertical Datum of 1929 (NGVD 29) to more than –1100 feet NGVD 29 with thicknesses ranging from approximately 2300 feet to more than 3400 feet (Miller 1986). Throughout most of southern Florida, the Floridan aquifer system occurs under confined conditions.

2.3.1.2.1.3 Local Hydrogeology

Two major aquifers underlie the local area including all of Miami-Dade County and the Units 6 & 7 plant area:

- The surficial aquifer system, comprised of the Biscayne aquifer
- The Floridan aquifer system consisting of the Upper Floridan aquifer, the middle confining unit, and the Lower Floridan aquifer

A site-specific hydrostratigraphic column developed from borings drilled up to maximum depths of approximately 615 feet below ground surface (bgs) is presented in Figure 2.3-19.

The Biscayne aquifer extends from near surface to a depth of approximately 240 feet near Fort Lauderdale and approximately 80 to 115 feet locally.

The Upper Floridan aquifer extends from approximately 1000 to 1200 feet bgs. The middle confining unit extends from approximately 1200 to 2400 feet bgs. The Lower Floridan aquifer extends from approximately 2400 feet bgs to an undetermined depth thought to be greater than 4000 feet bgs in the Miami-Dade County area. The Boulder Zone in the Lower Floridan aquifer extends from approximately 2800 to at least 3000 feet bgs at the MDWASD South District Wastewater Treatment Plant (SDWTP)(Starr et al. 2001), which is located approximately 9 miles north of the Units 6 & 7 plant area.

Surficial (Biscayne) Aquifer

The surficial aquifer system comprises all the rocks and sediments from the land surface downward to the top of the intermediate confining unit. These lithologic materials consist primarily of limestones and sandstones with sands, shells, and clayey sand with minor clays and silts. The base of the system is defined by a significant change in hydraulic conductivity. Sedimentary bedrock and unconsolidated sediments in the surficial aquifer system have a wide range of hydraulic properties and locally may be divided into one or more aquifers separated by less-permeable or semi-confining units. Within the surficial aquifer system, the major water-producing unit is the unconfined Biscayne aquifer, which underlies the Units 6 & 7 plant area and all of Miami-Dade County and parts of Broward, Monroe, and Palm Beach counties, as shown in Figure 2.3-21. The aquifer contains carbonate rocks, sandstones, and sand extending from land surface to an elevation of approximately –10 feet NGVD 29 in southern Miami-Dade County and deepening northward to more than elevation –240 feet NGVD 29 in southeastern Palm Beach County and eastern Broward County (Figure 2.3-22). These formations include, from oldest to youngest (bottom to top): the upper portion of the Tamiami Formation, Caloosahatchee Formation, Fort Thompson Formation, Anastasia Formation, Key Largo Limestone, Miami Limestone, and Pamlico Sand (Fish and Stewart 1991). However, the entire

sequence of units is not present in any one place. In the vicinity of the plant area, the formations within the Biscayne aquifer include the Miami Limestone, Key Largo Limestone, and the Fort Thompson Formation (Figure 2.3-19). The Fort Thompson Formation and Key Largo Limestone are the major water producing formations within the aquifer (Miller 1990). Site-specific boring data (Subsection 2.3.1.2.1.4) indicates that the maximum thickness of the Biscayne aquifer is approximately 115 feet at the Units 6 & 7 plant area.

The water table occurs primarily within the organic soils (muck) or the Miami Limestone and fluctuates in response to variations in tide levels, recharge, natural discharge, water levels in adjacent canals, and well withdrawal/injection. The aquifer extends beneath Biscayne Bay and the Atlantic Ocean. Because of the aquifer's high permeability, and in response to the lowering of inland groundwater levels due to pumpage, saltwater has migrated inland along the base of the aquifer and affects the entire coastal zone. Saltwater moves inland and upward in response to low inland groundwater levels and moves seaward and downward in response to high inland groundwater levels (Klein and Hull 1978).

Biscayne aquifer groundwater use in the immediate vicinity of the plant area has been limited due to saline to saltwater composition. Figure 2.3-23 (Langevin 2001) shows the approximate location of the freshwater-saltwater interface in the area. The figure indicates that the saltwater interface at the base of the aquifer is approximately 6 to 8 miles inland of the Units 6 & 7 plant area.

Intermediate Confining Unit

The intermediate confining unit (upper confining unit for the Upper Floridan aquifer) extends from the base of the surficial aquifer system to the top of the Floridan aquifer system and is characterized by complex interbedded lithologies of the Hawthorn Group. These lithologies consist primarily of silty clay, calcareous sands, silts, calcareous wackestones, limestones, sandstones and sands, and obtain a thickness of approximately 600 to 1050 feet at Turkey Point (Reese 1994). Site information suggests a thickness of approximately 700 feet just to the north of Units 6 & 7 site (Unit 5 Upper Floridan aquifer production wells PW-3 [JLA Geosciences 2006]) to approximately 1000 feet southwest of the site (Dames & Moore 1975).

The top of the Hawthorn Group occurs at approximately –100 feet MSL southwest of the site (Dames & Moore 1975) to approximately –215 feet MSL at Units 6 & 7 and production well PW-3 (JLA Geosciences 2006) in the vicinity of the site. The unit is not exposed at the land surface. Sand beds and limestone lenses comprise the permeable parts of the system, however, the overall hydraulic conductivity of the group is very low and provides good confinement for the underlying Floridan aquifer system.

Floridan Aquifer System

The Floridan aquifer system underlies the Units 6 & 7 plant area and all of Florida. The system formally consists of three main hydrogeologic units: the Upper Floridan aquifer, the middle confining unit, and the Lower Floridan aquifer (Figure 2.3-17). In the Miami-Dade County area, the top of the Floridan aquifer system is found at a depth of approximately 1000 feet bgs, is approximately 3000 feet thick, and is directly overlain by the intermediate confining unit. The Floridan aquifer system forms the deepest part of the active groundwater flow system in southeastern Florida (Reese 1994 and SEGS 1986).

Floridan Aquifer System: Upper Floridan Aquifer

The top most hydrogeologic unit of the Floridan aquifer system is the Upper Floridan aquifer. This unit is overlain by the intermediate confining layer that acts as a confining unit to the Upper Floridan aquifer (Stewart 1980). The Upper Floridan aquifer consists of several thin water-bearing zones of high permeability interlayered with thick zones of low permeability. The hydrogeology of the Upper Floridan aquifer varies throughout Florida. In southeastern Florida, the aquifer has been interpreted to include a thinner Suwannee Limestone and extends down into the Avon Park Formation (Figure 2.3-17). Confinement is typically better between flow zones in southwestern Florida than in southeastern Florida (Reese and Richardson 2008). In southeastern Florida, the Upper Floridan aquifer ranges from 100 feet to greater than 400 feet in thickness as shown on Figure 2.3-24. In the vicinity of the Turkey Point plant property, the Upper Floridan aquifer is approximately 200 feet thick.

Although the Upper Floridan aquifer is a major source of potable groundwater in much of Florida, water withdrawn from the unit in southeastern Florida, including Miami-Dade County, is brackish and variable in quality (Reese and Richardson 2008).

Floridan Aquifer System: Middle Confining Unit

The middle confining unit of the Floridan aquifer system underlies the Upper Floridan aquifer, separating it from the Lower Floridan aquifer. In many places, the middle confining unit is divided into upper and lower units separated by the Avon Park permeable zone (Figure 2.3-17). The middle confining unit contains beds of micritic limestone (wackestone to mudstone), dolomitic limestone, and dolomite (dolostone) that are distinctly less permeable that the strata of the Upper Floridan aquifer and Lower Floridan aquifer. The elevation of the top of the middle confining unit is approximately –1200 feet NGVD 29 and the thickness is approximately 1000 feet in the vicinity of the Turkey Point plant property (Reese and Richardson 2008).

Floridan Aquifer System: Lower Floridan Aquifer

The Lower Floridan aquifer in southern Florida consists of a thick sequence of low permeability rocks separated by relatively thin permeable zones (Miller 1986). The aquifer underlies the middle confining unit and extends from a depth of approximately 2400 feet bgs to a depth that is undetermined, but thought to be greater than 4000 feet bgs in the Miami-Dade County area. The Lower Floridan aquifer includes the lower part of the Avon Park Formation, the Oldsmar Limestone, and the upper part of the Cedar Keys Formation (Figure 2.3-17). The base of the Lower Floridan aquifer (or the base of the Floridan aquifer system) is marked by impermeable, massive anhydrite beds of the Cedar Keys Formation (Miller 1986).

A highly permeable zone in the Lower Floridan aquifer known as the Boulder Zone occurs in southern Florida. The Boulder Zone contains saltwater and has been permitted by the Florida Department of Environmental Protection as a zone to discharge treated sewage and other wastes disposed of through injection wells operated in South Florida.

In southern Florida, the Lower Floridan aquifer contains thick confining units above the Boulder Zone. These confining units are similar in lithology to the middle confining unit of the Floridan aquifer system (Reese 1994). The base of the Lower Floridan aquifer is below the base of the Boulder Zone, with the lower section consisting of permeable dolomites or dolomitic limestones of the Cedar Keys Formation (Meyer 1989 and Reese 1994).

2.3.1.2.1.4 Site-Specific Hydrogeology

A subsurface investigation was conducted for Units 6 & 7 between February and June 2008 to evaluate soil, bedrock, and groundwater conditions at depths of up to a maximum of approximately 615 feet bgs. Subsurface information was collected from 94 geotechnical borings, 4 cone penetrometer tests (CPTs), 2 test pits, 22 groundwater observation wells, and 2 surface water stations. Data on the borings, test pits, and cone penetrometer tests in the form of boring logs, laboratory test results, etc., are provided in MACTEC 2008.

The surficial aquifer system within the Turkey Point plant property does not contain all of the regionally identified units. Those units identified within the plant property as a result of subsurface investigations are summarized in descending order as:

- Muck — The surface of the site consists of approximately 2 to 6 feet of organic soils called muck. The muck is composed of recent light gray calcareous silts with varying amounts of organic matter. This unit is not considered to extend into Biscayne Bay, where exposed rock and sandy material is present.

- Miami Limestone — The Pleistocene Miami Limestone is a white, porous sometimes sandy, fossiliferous, oolitic limestone.

- Upper Higher Flow Zone — At the boundary between the Miami Limestone and Key Largo Limestone is a laterally continuous, relatively thin layer of high secondary porosity. The Upper Higher Flow Zone was defined based on a review of geophysical logs and drilling records. The primary identifier was the loss drilling fluid identified at the boundary of the Key Largo Limestone and Miami Limestone. This observation was also coincident with an increase in the boring diameter as identified by caliper logging.

- Key Largo Limestone (interpreted as the Fort Thompson Formation elsewhere) — This is a coralline limestone (fossil coral reef) believed to have formed in a complex of shallow-water, shelf-margin reefs and associated deposits along a topgraphic break during the last interglacial period.

- Freshwater Limestone — At the base of the Key Largo Limestone is a layer of dark-gray fine-grained limestone, referred to as the Freshwater Limestone. Where present, the limestone is generally 2 feet or more thick and often possesses a sharp color change from light to dark gray at its base marking the transition from the Key Largo Limestone to the Fort Thompson Formation. It is not considered to be laterally continuous across the Turkey Point plant property.

- Fort Thompson Formation — The Pleistocene Fort Thompson Formation directly underlies the Key Largo Limestone. The Fort Thompson Formation is generally a sandy limestone with zones of uncemented sand interbeds, some vugs, and zones of moldic porosity after gastropod and/or bivalve shell molds and casts.

- Lower Higher Flow Zone — The Lower Higher Flow Zone lies within the Fort Thompson Formation. At the location of Units 6 & 7, a zone of secondary porosity was evident from the drilling and geophysical logs. This occurred at a depth of approximately 15 feet below the top of the Fort Thompson Formation and was assumed to extend across the model domain. Recent regional drilling conducted by the USGS (JLA 2010) did not identify a laterally persistent layer but rather more isolated zones at varying depths below the Upper Higher Flow Zone. In the groundwater flow model (Subsection 2.3.1.2.3), the Lower Higher Flow Zone represents an aggregation of these observations and is conservative due to the fact that it is modeled as laterally extensive.

- Tamiami Formation — The Pliocene Tamiami Formation directly underlies the Fort Thompson Formation. The Tamiami Formation generally consists of well-sorted, silty sand, but is locally interlayered with clayey sand, silt, and clean clay. The contact between the Tamiami Formation and the Fort Thompson Formation is an inferred contact picked as the bottom of the last lens of competent limestone encountered. The Tamiami Formation represents a semi-confining unit.

The most permeable portions of the Miami Limestone and Key Largo Limestone are considered to be acting as one hydrogeological unit and designated the “upper monitoring zone.” The underlying Fort Thompson is designated the “lower monitoring zone.” The maximum thickness of the Biscayne Aquifer is approximately 115 feet at the Units 6 & 7 plant area.

Twenty groundwater observation wells, two deep geotechnical piezometers, and the two surface water monitoring stations were installed in the Units 6 & 7 plant area as follows:

- Ten observation well pairs used for measuring groundwater levels (or 20 individual observation wells) were installed across the plant area. These wells were completed to depths ranging from 24 to 110 feet bgs and were installed in the Miami Limestone/Key Largo Limestone and the Fort Thompson Formation.

- Two deep geotechnical piezometers, one at each reactor site, were installed to a depth of approximately 135 feet bgs. These two piezometers were installed to measure pore pressure in the Tamiami Formation and are not part of the groundwater level monitoring network.

- Two surface water monitoring stations (SW-1 and SW-2) were installed in the canals surrounding the Units 6 & 7 plant area. The pressure transducers were set several feet below the water level in the canals to allow monitoring of the surface water level variations.

Groundwater level and surface water level measurements commenced in the 20 observation wells and 2 surface water stations in June 2008 and continued through June 2010. Observation wells OW-606D and OW-706D, installed as piezometers for geotechnical purposes, are not part of the groundwater level monitoring network. Groundwater level measurements are made using electronic recording pressure transducers.

Figure 2.3-25 shows the locations of the 20 observation wells, 2 piezometers, and 2 surface water stations in the plant area. Table 2.3-14 presents the construction information for the wells. The observation wells are named in three series that represent the location and screened intervals of the wells:

- OW-600 series wells and geotechnical piezometer are located in the Unit 6 power block area and include "U," "L," and "D" suffix wells monitoring the Key Largo Limestone, the Fort Thompson Formation, and the upper Tamiami Formation, respectively.

- OW-700 series wells and geotechnical piezometer are located in the Unit 7 power block area and include "U," "L," and "D" suffix wells monitoring the Key Largo Limestone, the Fort Thompson Formation, and the upper Tamiami Formation, respectively.

- OW-800 series wells are located outside of the power block areas and include "U" and "L" suffix wells that monitor the Key Largo Limestone and the Fort Thompson Formation, respectively.

A supplemental groundwater investigation was conducted between January and March 2009 at the Units 6 & 7 plant area. Four test wells and fifty observation wells were installed for the purpose of conducting aquifer pumping tests. Two pumping wells were located at each unit, with one well completed as an open-hole to test the upper Biscayne aquifer (Key Largo Limestone) and one well completed as an open-hole to test the lower Biscayne aquifer (Fort Thompson Formation). The constant rate pumping tests were conducted in February and March 2009. The observation wells at each unit consisted of five well clusters containing five wells each, installed in the following test zones:

- Upper aquitard (Miami Limestone)
- Upper Biscayne aquifer test zone (Key Largo Limestone)
- Middle aquitard (freshwater limestone unit)
- Lower Biscayne aquifer test zone (Fort Thompson Formation)
- Lower aquitard (Upper Tamiami Formation)

An additional aquifer pumping test was performed on the Turkey Point peninsula (the landmass extending out into Biscayne Bay) to evaluate the hydrogeologic suitability of that area for the installation and operation of radial collector wells. Seven observation wells and one pumping well were installed on the Turkey Point peninsula in February 2009 to support the investigation.

The pumping test interval corresponds to the lower Miami Limestone, a cemented sand and the upper portion of the Key Largo Limestone. The test zone encompassed the likely depth intervals of the radial collector laterals. The pumping and observation wells were completed as open holes. The observation well open hole intervals were located above, at, and below the depth of the test interval. Step drawdown and constant rate tests were performed in April and May 2009 (HDR 2009).

Descriptions and locations of the aquifer pumping test wells and observation wells are presented in Subsection 2.3.1.2.2.3.

2.3.1.2.2 Groundwater Sources and Sinks

This subsection contains a description of the historic groundwater levels, groundwater flow direction(s) and gradients, seasonal and long-term variations of groundwater levels, horizontal

and vertical permeability and total and effective porosity of the geologic formations beneath the plant area, reversibility of groundwater flow, the effects of water use on hydraulic gradients and groundwater levels beneath the plant area, and groundwater recharge areas. This information has been organized into five subcategories as follows: (1) groundwater horizontal and vertical flow directions, (2) temporal groundwater trends, (3) aquifer properties, (4) hydrogeochemical characteristics, and (5) groundwater recharge and discharge.

2.3.1.2.2.1 Groundwater Flow Directions

Groundwater flow directions are provided in the following sections by aquifer.

Biscayne Aquifer

Regional groundwater flow in the Biscayne aquifer is generally toward the east-southeast. Figures 2.3-26 and 2.3-27 (Langevin 2001) show potentiometric surface maps of the Biscayne aquifer for May and November of 1993. The potentiometric maps show localized effects from surface water canals and cones of depression associated with groundwater well fields. Based on the regional data, the hydraulic gradient in the vicinity of the Turkey Point plant property is approximately 0.00002 foot per foot. The elevations in NGVD 29 used by the U.S. Geological Survey (USGS) are approximately 1.53 feet higher than the NAVD 88 elevations used for the plant area data (NOAA 2008g).

Potentiometric surface maps for the upper and lower monitoring zones of the Biscayne aquifer in the immediate vicinity of the Units 6 & 7 plant area are shown on Figures 2.3-28 through 2.3-35 and Figures 2.3-69 through 2.3-74). A separate map was prepared for each high and low tide time sequence for the upper (Miami and Key Largo Limestones) and lower (Fort Thompson Formation) monitoring zones. For the purposes of this analysis, high and low tides refer to the approximate local highs and lows obtained from the observation well hydrographs. The water levels were corrected to equivalent reference heads. FSAR Subsection 2.4.12, Appendix 2AA describes the data evaluation process for the transducer generated water level data and the calculation of reference heads from observed head data.

These maps indicate that the highest portion of the potentiometric surface in the lower monitoring zone generally runs from the southwestern portion of the Units 6 & 7 plant area near OW-735L to the central portion of the Units 6 & 7 plant area near OW-706L. Flow patterns extend radially in multiple directions from this high spot, but flow patterns are not symmetrically arrayed. The June 2010 data for the lower zone indicate a general southwest to northeast flow pattern. The lower monitoring zone potentiometric surfaces and resulting flow patterns are similar for all high and low tide conditions examined.

In the upper monitoring zone, a relative high spot in the potentiometric surface runs from the northwest near OW-812U to the center of the Units 6 & 7 plant area near OW-706U. A second

high spot in the potentiometric surface is evident in the southeast corner of the Units 6 & 7 plant area near OW-636U. A relatively low region in the potentiometric surface extends from the southwest near OW-735U to the east-central portion of the Units 6 & 7 plant area near OW-805U and OW-606U. The June 2010 data for the upper zone indicate a general east to west flow pattern.

Because of the complexity of the observed flow patterns in the upper and lower monitoring zones, one to three flow path lines were used to calculate horizontal gradients for each potentiometric surface shown in Figures 2.3-28 through 2.3-35 and Figures 2.3-69 through 2.3-74. The average horizontal gradient in the upper monitoring zone across all examined tidal conditions is 0.0003 ft/ft, and the average horizontal gradient in the lower monitoring zone is 0.001 ft/ft.

Vertical hydraulic gradients were computed for selected observation well pairs on the site. Table 2.3-15 presents the vertical hydraulic gradients determined from these well pairs. The overall vertical hydraulic gradient is generally upward across the plant area. The vertical hydraulic gradients do not vary significantly between high and low tidal cycles.

In general the groundwater flow conditions in the Biscayne aquifer at the Units 6 & 7 plant area can be summarized as follows:

- The upper and lower monitoring zones exhibit complex horizontal flow patterns.
- Vertical hydraulic gradients indicate upward flow potential.
- The vertical (upward) gradient is approximately an order of magnitude larger than the horizontal gradient in the lower monitoring zone. The average horizontal gradient in the lower monitoring zone is, in turn, approximately a factor of three larger than the average horizontal gradient in the upper monitoring zone.

Floridan Aquifer

Regional groundwater flow in the Upper Floridan aquifer is generally toward the east. Figure 2.3-36 shows a potentiometric surface map of the Upper Floridan aquifer for May 1980 (Meyer 1989). The apparent hydraulic gradient in the vicinity of the Turkey Point plant property is approximately 0.00006 foot per foot. South Florida is in the brackish to saline portion of the aquifer, and groundwater development has generally been restricted to industrial water supplies.

Determination of groundwater flow directions and hydraulic heads in the Boulder Zone have been unreliable due to the lack of head data and the transitory effects of ocean tides, earth tides, and atmospheric tides (Meyer 1989). Regional groundwater movement in the Lower Floridan aquifer in southern Florida is estimated to follow the circulation pattern described as follows: 1) cold

seawater moves inland through the Lower Floridan aquifer, 2) heating of the seawater in the Lower Floridan aquifer during inland movement results in lower fluid density, 3) upwelling of this seawater from the Lower Floridan aquifer occurs through the middle confining unit, and 4) dilution of the seawater (further reducing fluid density) results in its transport back to the ocean by seaward flowing groundwater in the Upper Floridan aquifer. Figure 2.3-48 illustrates this circulation pattern (Meyer 1989). This circulation is generally very slow due to the low permeability of the middle confining unit.

There are no Floridan aquifer monitoring wells installed at the Units 6 & 7 plant area. Dual-zone monitoring wells would be installed as part of the deep injection wells.

2.3.1.2.2.2 Temporal Groundwater Trends

Regional temporal trends in the Biscayne aquifer groundwater levels are monitored by the USGS (USGS 2010) and the SFWMD (SFWMD 2010). Figure 2.3-37 presents a map of wells and surface water control structures in the vicinity of the Turkey Point plant property used for long-term monitoring of groundwater and surface water levels. Figures 2.3-38 and 2.3-39 show the hydrographs for these locations. The locations show varying degrees of short-term tidal influence and fluctuations associated with precipitation events. The long-term trends in the wells and surface water indicate a generally steady water level over the period examined. Well G-1183 shows the largest magnitude of fluctuation with water level elevations ranging from 6.38 to –0.59 feet NGVD 29. The remaining wells show a range of fluctuation of less than 3.5 feet.

Figure 2.3-40 shows hydrographs of the Biscayne aquifer monitoring wells for Units 6 & 7. The hydrographs contain data gaps, which were a result of the data being rejected, a loss of transducer data due to storm preparation activities or equipment failure. A partial listing of water level data from the transducers is presented in FSAR Subsection 2.4.12, Appendix 2AA. Appendix 2AA also describes the data evaluation process for the transducer generated level data. The results of this evaluation indicate that the present data is sufficient for use.

Regional temporal trends in the Floridan aquifer have been monitored by the USGS (2008). A hydrograph of a well completed in the Upper Floridan aquifer is shown on Figure 2.3-41. The wellhead elevation is 4.50 feet NGVD 29 and the hydraulic head inside the well ranges from 30 to 42.6 feet NGVD 29, indicating that the potentiometric surface in this area is above ground surface.

2.3.1.2.2.3 Aquifer Properties

This subsection provides a summary of the regional, local, and site-specific hydrogeologic parameters of the different aquifer units. These parameters include transmissivity, storativity (storage coefficient), specific yield, hydraulic conductivity (permeability), and leakage coefficient (leakance). The following are definitions of these properties:

- Transmissivity — The rate at which a fluid of a specified density and viscosity is transmitted through a unit width of an aquifer or confining bed under a unit hydraulic gradient and is a function of the properties of the fluid, the porous medium, and the thickness of the porous medium (Fetter 1988).

- Storativity (Storage Coefficient) — The volume of water released from or taken into storage per unit surface area of the aquifer per unit change in head (Fetter 1988).

- Specific Yield — The ratio of the volume of water a rock or soil will yield by gravity drainage to the volume of the rock or soil (Fetter 1988).

- Hydraulic Conductivity (Permeability) — A coefficient of proportionality describing flow per unit time under a unit hydraulic gradient through a unit area of a porous medium and is a function of the properties of the fluid and the porous medium (Fetter 1988).

- Leakage Coefficient (Leakance) — The quantity of water that flows across a unit area of the boundary between the main aquifer and its semi-confining bed, typically expressed as seconds^{-1}or days^{-1} derived from the relationship K'/b' where K' is the hydraulic conductivity of the semi-confining unit and b' is its thickness (Davis and DeWeist 1966).

Typical values of hydraulic conductivity, porosity, and thickness for different formations in Miami-Dade County are shown on Table 2.3-16 (U.S. EPA 2003). The values are based on weighted averages for management of treated wastewater. The weighted average values presented in Table 2.3-16 were developed by the EPA to support a risk assessment of wastewater disposal. The data were based on a literature review of published values of the hydrogeologic parameters used to characterize the hydrologic units in Miami-Dade County. The weighted means of the data were calculated to determine representative values to be used in the risk assessment. The weighted mean method essentially reduces the effect of extreme data outliers and may not be representative of actual conditions. These values were not used in the hydrogeologic analysis of site conditions.

Table 2.3-17 presents aquifer test results for tests performed within 15 miles of Units 6 & 7. Figure 2.3-42 shows the locations of these tests. The data were obtained from the SFWMD DBHYDRO database and the Dames & Moore site investigation report (SFWMD 2009 and Dames & Moore 1971). The tests were performed in the Biscayne aquifer, the Floridan aquifer, and confining layers. The tests include standard aquifer performance tests and packer tests used for assessment of the injection and confining layers for deep injection well permitting. The Boulder Zone packer tests listed in Table 2.3-17 show transmissivities lower than those reported for other regional testing of the Boulder Zone. The depths given on the table suggest that the tests were performed in the interval between the top of the Lower Floridan aquifer and the top of the Boulder Zone as determined from cross section Y-Y in Reese and Richardson (2008).

Surficial/Biscayne Aquifer

Hydrogeologic properties of the Biscayne aquifer vary based on lithology. Along the coast, where the Biscayne aquifer is the thickest, transmissivities are lower due to the amounts of sandy material. In central and south Miami-Dade County, the aquifer is thinner with higher hydraulic conductivity due to the occurrence of cavernous limestone (Klein and Hull 1978). The permeable limestone content in the aquifer decreases northward and the overall transmissivity of the aquifer decreases with increased sand content. Transmissivities for the highly permeable limestones and less permeable sandstones and sands of the aquifer in the vicinity of Units 6 & 7 have been estimated to range from less than 1.0E06 gallons per day per foot to 3.0E06 gallons per day per foot (Dames & Moore 1971).

According to Parker et al. (1955), the Biscayne aquifer is the most productive of the shallow non-artesian aquifers in the area. The Biscayne aquifer is one of the most permeable in the world with transmissivity values (hydraulic conductivity x saturated thickness) for the highly permeable limestones ranging from 4.0E06 to 15.0E06 gallons per day per foot (5.4E05 to 2.0E06 square feet per day) with a median value of 5.0E06 gallons per day per foot (6.7E05 square feet per day) and storage coefficients ranging from 0.047 to 0.247. In Broward County, transmissivities are reported to range from about 4.0E05 gallons per day per foot (5.4E04 square feet per day) to 4.0E06 gallons per day per foot (5.4E05 square feet per day) with storage coefficients as high as 0.34 (Sherwood et al. 1973). A generalized distribution of the transmissivities in the Biscayne aquifer is presented in Figure 2.3-43 (Merritt 1996).

Large-capacity municipal wells are commonly completed as open holes and yield from approximately 500 to more than 7000 gallons per minute with only small drawdowns. Specific capacities obtained from pumping tests are on the order of 1000 gallons per minute per foot of drawdown in Miami-Dade County (Klein and Hull 1978).

Two studies performed to the northwest of the plant property by the USGS (Cunningham et al. 2004 and Cunningham et al. 2006) examined the vertical variations in aquifer properties of the Biscayne aquifer. Table 2.3-18 presents the results of testing core samples. The locations of the core samples are shown on Figure 2.3-42. Figure 2.3-44 is a plot of core properties versus elevation.The core samples were tested for horizontal air permeability, vertical air permeability, porosity, and grain density. The horizontal air permeability test included a maximum permeability at 90 degrees to the maximum permeability direction to assess horizontal anisotropy. The studies included a detailed examination of the core samples to determine lithology and fossil assemblages. As a result of this examination, the authors were able to subdivide the Biscayne aquifer into a series of high-frequency depositional cycles that ranged from a freshwater to a marine depositional environment. These depositional cycles control the permeability and porosity of the aquifer. The freshwater and transitional portions of the depositional cycles are characterized by lower permeability (<1000 milliDarcies) and porosity (<20 percent), while the

marine portions of depositional cycles exhibit higher permeability (>1000 milliDarcies) and porosity (20–40 percent). This general observation appears to support the site-specific findings regarding the fresh water limestone layer and the other marine and transitional units identified at the Units 6 & 7 plant area. The vertical changes in properties as a result of these depositional cycles can be seen on the figure. Figure 2.3-45 presents a plot of the vertical anisotropy ratio ($K_{vertical}$:$K_{horizontal}$) versus elevation using the vertical permeability and maximum horizontal permeability determined from the USGS laboratory core testing. The graph indicates that the central tendency of the anisotropy measurements is approximately one. This value was used as a starting point for groundwater model calibration.

As part of the Units 6 & 7 investigation, a total of 10 observation wells were installed in the upper part of the Biscayne aquifer in the Miami Limestone/Key Largo Limestone (“U” suffix wells) and 10 observation wells were installed in the Fort Thompson Formation (“L” suffix wells). The screen depths for the upper (“U”) wells range from 14 to 28 feet bgs and for the lower (“L”) wells they range from 85 to 110 feet bgs. The locations and installation details of the wells are provided in Figure 2.3-25 and Table 2.3-14, respectively.

Thirty-one in situ hydraulic conductivity tests (slug tests) were conducted in these wells. These data were imported into AQTESOLV™ for Windows version 4.5 (Duffield 2007) and evaluated using either the Butler, KGS (Kansas Geological Survey), McElwee-Zenner, or Springer-Gelhar solution methods (MACTEC 2008). Hydraulic conductivity values obtained for wells screened in the upper part ("U" wells) of the Biscayne aquifer range from 3 to 319 feet per day with a geometric mean of 61.3 feet per day. For the wells screened in the lower part ("L" wells) of the aquifer, values range from 1.0 to 120 feet per day with a geometric mean of 20.1 feet per day. The results of the tests are summarized in Table 2.3-19. The results suggest that the rate-limiting recharge of the well filter pack may be influencing the results of the tests. The rate-limiting recharge effects are caused by the formation having a higher hydraulic conductivity than the filter pack material; this results in the filter pack controlling the slug test response rather than the formation. This interpretation is supported by site vicinity aquifer tests (Dames & Moore 1971) and other regional studies (Table 2.3-17) that suggest much higher hydraulic conductivity values for the aquifer. In addition, aquifer pumping tests are, in general, found to yield higher hydraulic conductivity values than slug tests.

Four aquifer pumping tests were conducted in the Units 6 & 7 power block area, in order to determine hydrogeologic properties of the Biscayne aquifer. These tests were performed to measure the hydrogeologic properties of the aquifer units and the overlying or underlying aquitards for use in the design and implementation of the construction dewatering system, development of the site groundwater flow model, and simulation of the radial collector wells in the groundwater model. Two test zones were identified within the Biscayne aquifer: the upper zone, which is located in the Key Largo Limestone, and the lower zone, which is located in the Fort Thompson Formation. The muck and Miami Limestone units are interpreted to have a lower

hydraulic conductivity than the underlying Key Largo Limestone. The freshwater limestone layer is interpreted to have a lower hydraulic conductivity than either the overlying Key Largo Limestone or the underlying Fort Thompson Formation. The Tamiami Formation is also interpreted to have a lower hydraulic conductivity than the overlying Fort Thompson Formation. Thus, the Miami Limestone, the freshwater limestone unit, and the Tamiami Formation were treated as aquitards in the subsurface profile. For the conditions at the plant area, the term aquitard is amended from its usual definition as a low permeability unit to a unit that has a much lower permeability than the aquifer units.

A total of four pumping wells and fifty observation wells were installed for aquifer characterization. Two pumping wells and twenty-five observation wells were installed at each unit location. The pumping wells at Unit 6 were designated PW-6U and PW-6L and at Unit 7 were designated PW-7U and PW-7L, with the U/L suffix indicating completion in either the upper (U) or lower (L) Biscayne aquifer test zone. The pumping wells were nominally 30-inches in diameter and were completed as open holes in the test intervals. The upper test zone wells (PW-6U and PW-7U) were both completed at a total depth of 45 feet bgs. The lower test zone wells (PW-6L and PW-7L) were completed at a total depth of 105 feet and 87 feet bgs, respectively. Each aquifer test location had two observation well clusters of five wells each installed at right angles to and approximately 10 feet from the pumping well. Additionally, a shared well cluster of five wells was installed between the two pumping wells at each unit location at a distance of approximately 25 feet. The observation well clusters at Unit 6 (C6-1 through C6-5) and Unit 7 (C7-1 through C7-5) each included wells designated as A through E completed in the following zones:

- Miami Limestone/Upper Aquitard (A)
- Key Largo Limestone/Upper Test Zone (D)
- Freshwater Limestone/Middle Aquitard (B)
- Fort Thompson Formation/Lower Test Zone (E)
- Tamiami Formation/Lower Aquitard (C)

Figure 2.3-46 presents the configuration of the pumping and observation wells for Units 6 & 7.

Each pumping test was conducted at a constant discharge rate and drawdown data was collected for a period of 8 hours, followed immediately by the recovery period during which water level data were collected for an additional 8 hours. The discharge rate for each test was selected based on data collected during a step-drawdown test conducted on each pumping well prior to initiation of the 8 hour drawdown test. Discharge rates for the tests ranged from approximately 3300 gpm to 5100 gpm.

The pumping test results were interpreted using the AQTESOLV™ (Duffield 2007) computer program. This program contains solution options for different hydrogeologic conditions such as unconfined, confined, and leaky conditions. Two interpretation methods were used: the Theis method and the Hantush leaky aquifer with aquitard storage method. The Theis method was applied to the time-drawdown data, to provide an upper bound on transmissivity, because the Theis method assumes no leakage. The Hantush leaky method with aquitard storage was used to evaluate the distance-drawdown and time-drawdown relationships in the pumping zone observation wells ("D" or "E" series wells). Table 2.3-20 presents a summary of the averages of the aquifer testing results. Based on these analyses, the average transmissivity for the upper Biscayne aquifer is approximately 2.3E06 gallons per day per foot and for the lower Biscayne aquifer it is approximately 1.3E05 gallons per day per foot. Details of the pumping tests and the analytical methods are provided in FSAR Subsection 2.4.12, Appendix 2BB.

An additional aquifer pumping test was performed on the Turkey Point peninsula to evaluate the hydrogeologic suitability of that area for the installation and operation of radial collector wells. A single test zone in the upper portion of the Biscayne aquifer was targeted as the production interval. The test zone was completed as a 26-inch diameter open hole in pumping well PW-1 and extended from 22 feet bgs to 46 feet bgs. This interval corresponds to the lower Miami Limestone, a cemented sand and the upper portion of the Key Largo Limestone and encompasses the likely depth intervals of the radial collector well laterals. A plan and geologic cross section at the Turkey Point peninsula from the exploratory drilling and aquifer testing program is presented as Figure 2.3-75 (HDR 2009). Note that the cemented sand indicated in Figure 2.3-75 was not observed in the borings located within the Units 6 & 7 plant area.

Seven observation wells were installed at the site. Four observation wells (MW-2 through MW-5) were installed at distances ranging from 925 feet to 2704 feet from pumping well PW-1. These wells were completed as open holes in the production zone interval. Observation well location MW-1 consisted of three wells. MW-1 DZ was a dual zone observation well constructed to monitor the production zone interval and a zone below the production zone interval in the Fort Thompson Formation (65 ft bgs to 75 ft bgs). Observation well MW-1 IS monitored the upper portion of the production zone interval (24 ft bgs to 35 ft bgs), while observation well MW-1 SS monitored a zone in the Miami Limestone above the production zone interval (12.7 ft bgs to 17.7 ft bgs). The configuration of the pumping and observation wells is shown on Figure 2.3-76.

The pumping test was conducted at a constant discharge rate. Drawdown data was collected for a period of 7 days, followed immediately by the recovery period during which water level data were collected for an additional 7 days. The discharge rate for the test was selected based on data collected during a step-drawdown test conducted in the pumping well prior to initiation of the 7-day constant rate test. The discharge rate for the constant rate test averaged 7100 gpm, and drawdown stabilized in the pumped well at approximately 11 feet bgs (HDR 2009).

The analyses of the drawdown and recovery data were performed with the AquiferWin32® software (Rumbaugh and Rumbaugh 2003) and AQTESOLV® (Duffield 2007). Well hydraulic equations for unconfined aquifers, confined aquifer with leaky conditions and partial penetration, and recovery data were applied. The analytical models that appeared to best fit the observed time drawdown data were the Hantush (1964) and Walton (1962) solutions, indicating a leaky aquifer. Results from the Turkey Point peninsula pumping test indicate a leaky aquifer system with a mean transmissivity value ranging from 700,000 to 1,200,000 ft^2/day (5.2 E06 to 8.9 E06 gallons per day per foot) (HDR 2009).

Intermediate Aquifer System/Confining Unit

The overall hydraulic conductivity of the intermediate aquifer system/confining unit is very low and provides good confinement for the underlying Floridan aquifer system (Bush and Johnston 1988). The leakage coefficient of this confining unit is highly variable, especially in the semi-confined areas where the confining beds may be either sandy or clayey. Leakage coefficient values of the upper confining unit, derived from computer model simulations, range from less than 0.01 inches per year per foot in tightly confined areas to more than 1.00 inches per year per foot in semi-confined areas (Bush and Johnston 1988). According to Bush and Johnston (1988), leakage coefficients calculated from aquifer test data, in general, are much larger than those obtained from simulation, ranging from 0.44 to 88 inches per year per foot. Their analyses indicate that in the majority of locations, leakage coefficients from aquifer test data are too large to realistically represent the exchange of water between the surficial aquifer and the Upper Floridan aquifer. The values obtained from aquifer test data can reflect not only downward leakage from the surficial aquifer, but upward leakage from permeable rocks beneath the pumped interval, as well as leakage from beds of relatively low permeability that might exist within the pumped interval. Upper confining unit leakage coefficients derived from Floridan aquifer test data are composite or lumped properties that include leakage from all available sources.

Floridan Aquifer System

The Floridan aquifer system is a confined series of aquifer zones, separated by aquicludes, that is approximately 3000 feet thick in southeastern Florida. Porosity and permeability in the aquifer vary widely depending on location and formation. High permeability values are the result of both fractured limestone and extensive secondary porosity derived from dissolution of carbonates. In the central part of the Lower Floridan aquifer within the Floridan aquifer system is the Boulder Zone. The Boulder Zone consists mainly of fractured dolostones, in which large cavities develop during drilling as the result of borehole collapse (Safko and Hickey 1992, Duerr 1995, and Maliva and Walker 1998). The Boulder Zone is used for underground injection of industrial and domestic wastes in South Florida.

Floridan Aquifer System: Upper Floridan Aquifer

Hydraulic parameters of the Upper Floridan aquifer vary considerably as a result of the wide variation in hydrogeologic conditions encountered at different locations. According to Johnston and Bush (1988), conditions that most affect transmissivity are the degree of solution development in the aquifer and, to a lesser extent, aquifer thickness. High transmissivities are usually found in the areas having less confinement because circulation of flow helps to develop solution openings in the aquifer. Transmissivities are lowest (less than 50,000 square feet per day) in the Florida panhandle and southernmost Florida (where the aquifer is confined by thick clay sections and contains thick sections of low-permeability limestone) and are highest (greater than 1,000,000 square feet per day) in the karst areas of central and northern Florida where the aquifer is generally unconfined or semi-confined (Johnston and Bush 1988).

Regionally, storage coefficients calculated from aquifer tests conducted in the Upper Floridan aquifer range from a low of 1.0E-05 to a high of 2.0E-2 with most values in the 1.0E-03 to 1.0E-04 range (Johnston and Bush 1988).

Dames & Moore (1975) installed a test production well, designated W-12295 as shown on Figure 2.3-42, and four observation wells southwest of the Units 6 & 7 plant area. They conducted a 90-day continuous pumping test of the principal artesian water-bearing zone (Upper Floridan aquifer). The test production well was completed as an open hole between approximately 1130 feet and 1400 feet bgs. Calculated average values for transmissivity, storage coefficient, and leakance obtained from graphical solutions of the test data were 400,000 gallons per day per foot (53,600 square feet per day), 6.0E-04, and 0.002 gallons per day per cubic foot, respectively. Bush and Johnston (1988) report a transmissivity of approximately 232,000 gallons per day per foot (31,000 square feet per day) for the Upper Floridan aquifer.

The most transmissive zone is generally found at the top of the unit and is estimated to range between 10,000 to 60,000 square feet per day. According to Bush and Johnston (1988), at wells S-1532 and S-1533 on the Turkey Point plant property the transmissivity is 31,000 square feet per day (Reese 1994). Transmissivity of the Upper Floridan aquifer is highest in west central Florida (greater than 100,000 square feet per day) with lower transmissivities (less than 10,000 square feet per day) in central Florida (Reese and Richardson 2008).

The Upper Floridan aquifer water supply wells used for Unit 5 cooling water and Units 1 & 2 process water included the performance of an aquifer pumping test as part of the well installation process. The results of this test indicate a transmissivity of 244,000 gallons per day per foot, a storage coefficient of 2.0E-04, and a leakance of 5.0E-03 gallons per day per cubic foot (6.7E-04 day^{-1}). These values are consistent with the values reported from other nearby tests in the Upper Floridan aquifer.

Floridan Aquifer System: Middle Confining Unit

The middle confining unit of the Floridan aquifer system includes most of the Avon Park Formation (Reese and Richardson 2008) (Figure 2.3-17). Reese (1994) places the base of the middle confining unit at the top of the first permeable zone, which in general is in the Oldsmar Formation. However, this permeable zone has been identified in places to be within the lower Avon Park Formation, above the top of the Oldsmar Formation. The base of the middle confining unit is encountered at a depth of about 2460 feet in a well (MDS-I12) drilled in southeastern Miami-Dade County, 230 feet below the top of the Oldsmar Formation (Reese 1994). Based on core sample analysis, packer tests, and aquifer tests conducted at the MDWASD South District Wastewater Treatment Plant site, the hydraulic conductivity of the middle to lower part of the confining unit ranges from 3.0E-03 to 3.0 feet per day (Reese 1994). Vertical hydraulic conductivity measured in eight core samples from a well drilled in eastern Broward County, reported by Reese (1994), ranged from 1.3E-04 to 0.24 feet per day. Core analyses of the low porosity (<15%) dolostones from the Floridan aquifer middle confining unit in Palm Beach County gave vertical hydraulic conductivities of less than or equal to 1.7E-08 centimeters per second. The lowest recorded value was 2.7E-09 centimeters per second (Maliva et al. 2007).

Floridan Aquifer System: Lower Floridan Aquifer

The Lower Floridan aquifer underlies the middle confining unit and extends from a depth of approximately 2400 feet bgs to a depth that is undetermined, but thought to be greater than 4000 feet bgs in the Miami-Dade County area. This thick sequence of carbonate rocks contains several permeable zones separated by thick confining units (Miller 1986). These confining units are similar in lithology to the middle confining unit of the Floridan aquifer system (Reese 1994). Underlying the confining beds in the lower part of the Lower Floridan aquifer is the highly transmissive Boulder Zone, which is of varying thickness. The base of the Lower Floridan aquifer extends below the base of the Boulder Zone with the lower section consisting of permeable dolomites or dolomitic limestones of the Cedar Keys Formation (Miller 1986, Meyer 1989, and Reese 1994). Because the Lower Floridan aquifer is deeply buried in southern Florida and contains saltwater, the unit has not been intensively drilled or tested; therefore, the hydraulic characteristics are not well known (Miller 1986).

Boulder Zone

The Boulder Zone is a highly transmissive zone of cavernous limestones and dolomites found in the lower Oldsmar Limestone in the Lower Floridan aquifer in southeastern Florida. However, locally the Boulder Zone may range upward to the middle of the Oldsmar Limestone or downward to the top of the Cedar Keys Formation (Miller 1986). It consists mostly of massively bedded dolostones within which secondary permeability has been extensively developed. The term "Boulder Zone" is a misnomer because no boulders are present other than large chunks

occasionally broken off during drilling. The difficult slow drilling and rough bit behavior, similar to that observed drilling in boulders, encountered while drilling dolostone, gave rise to the term "Boulder Zone" (Miller 1986). The Boulder Zone can be up to 700 feet in thickness (Reese and Richardson 2008). Based on previous studies in the region (Reese and Richardson 2008, Starr et al. 2001, Dames & Moore, 1975, and Miller 1986), the Boulder Zone underlies a 13-county area in southern Florida with the elevation of the top of the zone ranging from about –2000 feet NGVD 29 to about –3400 feet NGVD 29, Figure 2.3-47 (Miller 1986). The Boulder Zone is found at a depth of approximately 2800 feet at the Turkey Point plant property.

Transmissivities ranging from 3.2E06 to 24.6E06 square feet per day have been reported for the Boulder Zone (Meyer 1989). A measured hydraulic conductivity value of approximately 4250 feet per day was obtained from an injection well at the SDWTP, operated by the MDWASD in Miami-Dade County. This value is approximately two orders of magnitude larger than measured values in the overlying portion of the Lower Floridan aquifer and the middle confining unit (Fish and Stewart 1991).

2.3.1.2.2.4 Hydrogeochemical Characteristics

The state of Florida has conducted an extensive characterization of the background water quality in the major aquifer systems (FGS 1992). The data have been subdivided into properties for each of the water management districts. Tables 2.3-21 and 2.3-22 present typical site-specific geochemical parameters for the Biscayne aquifer, the Floridan aquifer, and precipitation at Everglades National Park.

The state of Florida has classified the groundwater in the vicinity of Turkey Point as Class G-III waters to identify groundwater that has no reasonable potential as a future source of drinking water due to high total dissolved solids content (Merritt 1996). Field-measured groundwater quality indicator parameters (temperature, pH, dissolved oxygen, specific conductivity, turbidity, and oxidation-reduction potential) obtained during the collection of samples from observation wells (installed in the Biscayne aquifer as part of the Units 6 & 7 characterization investigation) are summarized in Table 2.3-21. The results of the laboratory analyses of the water samples are presented in Table 2.3-22.

Water quality data were collected as part of the Turkey Point peninsula pumping test activities. Grab samples, collected at various time intervals, were taken from the test well, monitoring wells, Biscayne Bay, and the Industrial Wastewater Facility. The analytes include cations, anions, and stable isotopes. A summary of the water quality data collected as part of the Turkey Point pumping test is presented in Table 2.3-32. Additional data and information regarding these water quality analyses can be found in HDR 2009.

Although the Upper Floridan aquifer is a major source of potable groundwater in much of Florida, water withdrawn from the unit in southeastern Florida, including Miami-Dade County, is brackish and variable with chloride and dissolved solid concentrations greater than 1000 mg/L. Groundwater samples from the Upper Floridan aquifer production wells at Unit 5 (Table 2.3-22) show an average chloride concentration of 2900 mg/L.

Average dissolved solids concentration of Boulder Zone groundwater is approximately 37,000 mg/L total dissolved solids (Meyer 1989). There is also a pronounced temperature anomaly present in the Boulder Zone with the lowest observed temperatures (approximately 50°F) occurring along the southeastern coast. The temperature increases from the Straits of Florida toward the center of the Florida Plateau, suggesting recharge from cold seawater through the lower part of the Floridan aquifer system. The groundwater circulation pattern is shown on Figure 2.3-48 (Meyer 1989).

Figure 2.3-49 presents a Piper trilinear diagram of the plant property and regional geochemical data. Examination of the diamond field on the diagram indicates that the plant property groundwater, Biscayne Bay, and the industrial wastewater facility data all plot together on the diagram, indicating similar geochemical compositions. These waters are classified as a sodium-chloride water type.

2.3.1.2.2.5 Aquifer Recharge and Discharge

Groundwater Discharge

Natural discharge of groundwater in the Biscayne aquifer is by seepage into streams, canals, or the ocean; by evaporation; and by transpiration by plants. Induced discharge is through wells pumped for municipal, industrial, domestic, and agricultural supplies. Evapotranspiration, transpiration, and groundwater discharge are greatest during the wet season when water levels, temperature, and plant growth rates are high. Pumpage of groundwater constitutes a part of the total discharge from the aquifer. The effect of pumpage is amplified because it is greatest during the dry season when recharge and aquifer storage are least. Most of the water that circulates in the surficial aquifer system is discharged by canals (Fish and Stewart 1991). There is very little direct runoff of precipitation; however, regional discharge of the surficial aquifer into drainage canals and directly into Biscayne Bay is estimated to be approximately 15 to 25 inches per year (Parker et al. 1955). It is estimated that 20 inches of the approximately 60 inches of annual rainfall in Miami-Dade County is lost directly by evaporation, approximately 20 inches is lost by evapotranspiration after infiltration, 16 to 18 inches is discharged by canals and by coastal seepage, and the remainder is used by man (Meyer 1989 and Parker et al. 1955). Nearly 50 percent of the rainfall that infiltrates the Biscayne aquifer is discharged to the ocean (Klein and Hull 1978).

Groundwater Recharge

There are several mechanisms affecting recharge of the surficial/Biscayne aquifer in Miami-Dade County including (Fish and Stewart 1991):

- Infiltration of rainfall or irrigation water through surface materials to the water table
- Infiltration of surface water imported by runoff from the north in the water-conservation areas or by canals
- Infiltration of urban runoff by way of drains, wells, or ponds
- Groundwater inflow from southwestern Broward County

Recharge by rainfall is greatest during the wet season, from June to November, and recharge by canal seepage is greatest during the dry season, from December to May. The average annual rainfall in Miami-Dade County is approximately 60 inches, of which approximately 38 inches is recharge to the aquifer (Parker et al. 1955). Recharge occurs over most of Miami-Dade County during rainstorms. The low coastal groundwater levels and the low, but continuous, seaward gradient indicate the very high transmissivity of the aquifer, the high degree of interconnection between the aquifer and the canals, and the effectiveness of the canals in rapidly draining floodwaters (Fish and Stewart 1991).

Recharge to the Floridan aquifer system is directly related to the confinement of the system. The highest recharge rates occur where the Floridan aquifer is unconfined or poorly confined as in those areas where the system is at or near land surface or where the confining layers are breached by karst or other structural features. The Floridan aquifer system is confined, with upward vertical gradients, and is approximately 1000 feet bgs in the vicinity of the Turkey Point plant property.

Groundwater–Industrial Wastewater Facility Interaction

Units 1–4 use the 5900-acre closed-loop industrial wastewater facility for condenser cooling (Figure 2.3-61). The canals comprising this facility are shallow, approximately 3 feet deep with the exception of the grand canal (main return canal), north discharge canal, south collector canal, and the east return canal, all of which are approximately 18 feet deep. The canals convey warm water south from the existing units and return cooled water for use by Units 1 through 4. The industrial wastewater facility does not directly discharge to fresh or marine surface waters; however, because the canals are not lined, water in the canals interacts with groundwater in the unconfined Biscayne aquifer, which immediately underlies the bottom of the industrial wastewater facility. Makeup water for the industrial wastewater facility comes from treated process water, rainfall, stormwater runoff, and groundwater infiltration. There is a net inflow to the industrial

wastewater facility from the Biscayne aquifer beneath the canals. The water in the canals has a salinity greater than that of seawater due to the effects of evaporation, with salinity concentrations approximately twice that of Biscayne Bay.

An interceptor ditch adjacent to the west side of the industrial wastewater facility and east of the L-31E Canal and levee was constructed at the same time as the industrial wastewater facility (Figure 2.3-61). The purpose of the interceptor ditch is to keep water from the industrial wastewater facility from influencing groundwater quality to the west in the upper portion of the aquifer. This is accomplished by the existence of a natural freshwater hydraulic gradient during the wet season and by pumping water as necessary from the interceptor ditch into the westernmost canal (Canal 32) of the industrial wastewater facility during the dry season when natural freshwater hydraulic gradients are low. Operation of the interceptor ditch prevents seepage from the industrial wastewater facility from moving landward toward the L-31E Canal in the upper portion of the aquifer and thereby helps to maintain existing groundwater quality in the Biscayne aquifer west of the interceptor ditch. Table 2.3-23 presents the manual staff gage readings along various transects between the L-31E Canal and the westernmost canal in the industrial wastewater facility from 2008 through February 18, 2011. The table also indicates pumping activities to maintain seaward flow. Figure 2.3-50 presents hydrographs of canal, interceptor ditch, and industrial wastewater facility Canal 32 water elevations for the year 2008.

2.3.1.2.3 Groundwater Flow Model

In order to better characterize the groundwater flow system, a three-dimensional numerical groundwater flow model was used. The model code used was MODFLOW-2000 (Harbaugh et al. 2000) as implemented in the Visual MODFLOW software. The MODFLOW model is a constant-density, three-dimensional finite-difference model, with modular capability to add various equation solvers and boundary conditions to the basic model. The model developed for Units 6 & 7 used a geometric multigrid (GMG) solver.

The groundwater model layers were created based on the local and regional geology conditions at the site, as well as observations made during several field investigations. A general description of the groundwater model setup, including model layers, surface water features incorporated into the model, boundary conditions, and calibration/verification approach is provided in the following paragraphs.

Model Layer 1 — This layer consists of muck onshore and rock and sandy material on the floor of Biscayne Bay. The location of these layers is based on the results of investigations performed in 1971 (Dames & Moore 1971) and 2008 (MACTEC 2008). Specifically, muck is known to be present on land; however, this unit does not extend into Biscayne Bay, where exposed rock and sandy material are present in its place. The Model Layer 1 hydrostratigraphic units in Biscayne Bay were assigned using the Marine Resources Geographic Information System (MRGIS)

"Benthic Habitats — South Florida" file (FWRI 2010). Benthic zones designated as "Continuous Seagrass" were designated as sandy material in Layer 1, as loose material is necessary to support seagrass. "Patchy (Discontinuous) Seagrass" and "Hardbottom with Seagrass" benthic zones were designated as rock in Model Layer 1.

Model Layers 2/3 — This layer consists of marine limestone, referred to as the Miami Limestone. The Miami Limestone is a white, porous sometimes sandy, fossiliferous, oolitic limestone.

Model Layer 4 — This layer consists of marine limestone and is referred to as the Upper Higher Flow Zone. This layer is at the boundary between the Miami Limestone and Key Largo Limestone and can be described as a laterally continuous, relatively thin layer of high secondary porosity.

Model Layer 5/6 — This layer consists of marine limestone and is referred to as the Key Largo Limestone. This is a coralline limestone (fossil coral reef) believed to have formed in a complex of shallow-water, shelf-margin reefs and associated deposits along a topographic break during the last interglacial period.

Model Layer 7 — This layer consists of freshwater limestone and is referred to as the Freshwater Limestone, and where this is absent, the Key Largo Limestone. The limestone is generally two feet or more thick and often possesses a sharp color change from light to dark gray at its base, marking the transition from the Key Largo Limestone to the Fort Thompson Formation.

Model Layer 8/9 and 11/12/13 — This layer consists of marine limestone and is referred to as the Fort Thompson Formation. The Pleistocene Fort Thompson Formation directly underlies the Key Largo Limestone. The Fort Thompson Formation is generally a sandy limestone with zones of uncemented sand interbeds, some vugs, and zones of moldic porosity after gastropod and/or bivalve shell molds and casts.

Model Layer 10 — This layer consists of marine limestone and is referred to as the Lower Higher Flow Zone. At the location of Units 6 & 7, another zone of high secondary porosity was identified within the Fort Thompson Formation from drillers and caliper logs. This layer is approximately 15 feet beneath the top of the Fort Thompson Formation at the location of the proposed power blocks.

Model Layer 14 — This layer consists of well sorted silty sand, but is locally interlayered with clayey sand, silt, and clean clay and is referred to as the Tamiami Formation. The Pliocene Tamiami Formation directly underlies the Fort Thompson Formation. The contact between the Tamiami Formation and the Fort Thompson Formation is an inferred contact picked as the bottom of the last lens of competent limestone encountered. The Tamiami Formation represents a semi-confining unit.

The Upper and Lower Higher Flow Zones are relatively thin zones of high secondary porosity. These zones were defined based on a review of geophysical logs and drilling records and are assumed to be continuous across the model domain. The Upper Higher Flow Zone was primarily identified from the loss of drilling fluid at the boundary of the Key Largo Limestone and Miami Limestone. This observation was also coincident with an increase in the boring diameter as identified by the caliper logging. The Lower Higher Flow Zone was identified at a depth of approximately 15 feet below the top of the Fort Thompson Formation from the 2008 subsurface investigation borings within the Units 6 & 7 plant area. In 2010, 14 borings were drilled in and around the Turkey Point plant area as part of the FPL Units 3 & 4 Uprate Conditions of Certification (JLA Geosciences 2010). These borings did not identify a laterally persistent layer corresponding to the Lower Higher Flow Zone identified within the Units 6 & 7 plant area, but rather more isolated zones at varying depths. As represented in the model, the Lower Higher Flow Zone represents an aggregation of these observations and is conservative due to the fact it is modeled as laterally extensive. The location and lateral persistence of the Upper Higher Flow Zone is generally confirmed by the 2010 borings (JLA Geosciences 2010). Cunningham et al. 2009 discuss the presence and origin of high flow zones in the Biscayne aquifer.

The groundwater model incorporated the local and regional surface water features as different types of boundary conditions, based on the feature and its conceptual contribution to groundwater flow. These boundary conditions include the following:

Biscayne Bay — This feature is located east of Units 6 & 7 and is a shallow, subtropical lagoon along the southeastern coast of Florida. The bay is conceptualized as a general-head boundary at the top of Model Layer 1 to represent the exchange of water between the bay and the underlying aquifer.

The head is specified at -1.05 ft NAVD 88 for the calibration phase of model development, based on the average of the monthly surface elevation between February 2009 and May 2009. The use of this type of boundary condition allows for limiting the exchange of water between Biscayne Bay and the underlying aquifer based on the sea floor sediments.

Cooling Canal System, Card Sound Canal, and other offsite canals — The cooling canals of the industrial wastewater facility are a closed system and do not discharge directly to adjacent surface water; however, the canals are unlined and, therefore, interact with groundwater. The other canals (e.g., Card Sound Canal, L-31E Canal, C-107 Canal, and Florida City Canal) are open systems that also interact with groundwater. The canals are specified as river boundaries to account for surface water-groundwater interaction based on surface water level elevation and conductance of the sides and bottom of the canals.

Finally, other model boundaries were conceptualized and included in the groundwater model as follows:

Recharge/Evaportranspiration Boundary — These boundaries are applied to the top of Model Layer 1. These conditions are applied to land surfaces only, including wetlands. No recharge/evapotranspiration is applied to surface water bodies, buildings, or paved areas.

Horizontal Flow Barrier Boundary — Mechanically Stabilized Earth (MSE) Retaining Wall and Cut-Off Walls for Units 6 & 7. The horizontal flow barrier boundary was used to simulate the effects of the excavation cut-off walls surrounding the power blocks for Units 6 & 7 for construction dewatering and the MSE retaining wall surrounding the plant area.

Model Domain Perimeter — General-head boundary conditions are assigned to the perimeter of all model layers. The general-head boundary represents the influence of conditions beyond the model area.

No-Flow Boundary — Bottom of the model — The bottom of the model is designated a no-flow boundary because water levels in the Biscayne aquifer are expected to be negligibly affected by upward leakage through the Lower Tamiami Formation and Hawthorne Group, which is several hundred feet thick and acts as a confining layer.

No-Flow Boundary — Units 6 & 7 Excavations — The excavations are designated as inactive to flow. Minor seepage will occur through the cut-off walls into the excavations but the quantities will be insignificant.

The numerical groundwater model was then calibrated and validated as follows:

- Three pumping tests were used in the model calibration phase; two of these tests were conducted in the Key Largo Limestone and one in the Fort Thompson Formation.
- The model included a validation step, whereby an additional pumping test was simulated following the calibration phase.
- A range for the hydraulic conductivity anisotropy value of between 8:1 and 15:1 was used for the various hydrogeologic units. These values were determined during calibration and constrained by literature and field observations.

Qualitative comparisons of model results were made to regional potentiometric surface maps (Langevin 2001) and the interaction of groundwater with the cooling canal system. The interaction of groundwater with the cooling canal system was assessed by comparing model results against estimates obtained from an independent steady-state water balance model.

The calibrated and validated groundwater model was then utilized to simulate construction dewatering and steady-state radial collector well operation. The modeling approach and impacts of these predictive runs are further discussed in Sections 4.2 (dewatering) and 5.2 (radial collector well operation). Additionally, Section 5.3 provides a discussion of the ecological impacts of radial collector well operations. A detailed discussion of the groundwater model development, conceptual design, and calibration is presented in FSAR Appendix 2CC.

2.3.2 WATER USE

This section describes surface water and groundwater uses that could affect or be affected by the construction or operation of Units 6 & 7 and associated transmission corridor and offsite facilities. Consumptive and nonconsumptive water uses are identified, and water diversions, withdrawals, consumption, and returns are quantified. In addition, this section describes statutory and legal restrictions on water use and provides the projected water use for Units 6 & 7.

2.3.2.1 Surface Water Use

Surface water bodies around the Turkey Point plant property include Biscayne Bay, Card Sound, the industrial wastewater facility, numerous named and unnamed canals, and various wetlands. Figures 2.3-1 through 2.3-3 show the relationship of the Turkey Point plant property to these major hydrologic features. The locations of designated wetlands near the Turkey Point plant property are shown on Figure 2.3-15.

The natural drainage of the area is to the east and south towards Biscayne Bay. The shallow tidal creeks and swales in the area are submerged, and therefore any flow they may have is sluggish. This, together with the permeable limestone bedrock of the area, results in approximately two-thirds of the rainfall percolating directly to the water table aquifer. In the absence of well-defined stream channels, heavy precipitation runs off in a slow, sheet flow towards the Biscayne Bay.

A complex network of levees, canals, and control structures was constructed to manage the water resources in the lower east coast region of Florida. The major canals, operated and maintained by the SFWMD, are used to prevent low-lying coastal areas from flooding and to prevent saltwater intrusion into coastal aquifers (Wolfert-Lohmann et al. 2007).

The surface water body that is within the hydrologic system where the Units 6 & 7 plant area is located and that could potentially affect or be affected by the construction and operation of the new units is Biscayne Bay. For construction or operation of Units 6 & 7, there would be no surface water withdrawal directly from or discharging to Biscayne Bay. It is noted, however, that one of the two primary sources of makeup water would be saltwater obtained from radial collector wells located on the Turkey Point peninsula, east of the existing units. As described in Subsection 2.3.2.2.2.2, each radial collector well would consist of a central reinforced concrete

caisson extending below the ground level with horizontal laterals projecting up to a distance of 900 feet from the caisson in the subsurface beneath the floor of Biscayne Bay. The water recharging the radial collector wells would originate from Biscayne Bay.

2.3.2.1.1 Consumptive Surface Water Use

2.3.2.1.1.1 Present Consumptive Surface Water Use

In South Florida, most (approximately 90 percent) of the water used in homes and businesses comes from groundwater sources, with the remainder coming from surface water sources (SFWMD 2008b).

The consumptive use of water in the state of Florida is regulated by the water management districts, as prescribed in Part II of Chapter 373 of Florida Statute (F.S.). According to the consumptive water-use permit files of SFWMD (2008c), 139 projects in Miami-Dade County were permitted for surface water withdrawals as of October 2008 and are summarized in Table 2.3-24. Eighty-three percent of the permitted projects are for landscape irrigation, and the remaining are for irrigation of golf courses and agriculture, industrial and dewatering uses, and other minor uses. All consumptive surface water uses are self-supplied, and there are no surface water withdrawals for potable water. A total of 9410 million gallons per year are allocated annually for six industrial uses, most of which are used for quarry sites and rock washing facilities. Seven golf course irrigation projects are permitted to withdraw 1360 million gallons per year, and 115 landscape irrigation projects are permitted to withdraw approximately 1123 million gallons of surface water per year.

Figure 2.3-51 shows the location of permitted users within 10 miles of Units 6 & 7, and Table 2.3-25 presents the details of their permits. Onsite ponds/lakes and canals are the major sources of surface water for these users. There are no permitted surface water users in the immediate vicinity of Units 6 & 7. The nearest surface water user is located approximately 6 miles west-northwest of Units 6 & 7.

Because all the surface water uses are self-supplied and have limited metered data, it is difficult to estimate the actual monthly withdrawal rates of surface water. In cases of agricultural and landscape irrigation, however, monthly withdrawal rates can be estimated from the monthly supplemental crop requirement data shown in the water use permit applications (SFWMD 2008c). The monthly supplemental crop requirements are calculated according to the SFWMD's Supplemental Crop Requirement and Withdrawal Calculation (SFWMD 2008d), which varies by crop, soil type, and local climatology. Figure 2.3-52 shows monthly supplemental crop requirement applied for some typical crops in the Homestead area in 2008. As seen in this figure, the monthly supplemental crop requirement has a large seasonal variation—it is high in the spring and summer seasons, and low in the fall and winter seasons.

Most of the freshwater withdrawn from surface water sources is not returned to its surface source. Irrigation water applied for agricultural and landscape uses is consumed by the processes of evapotranspiration and infiltration into the subsurface. As indicated in the SFWMD permit files (SFWMD 2008c), most of the surface water withdrawn for industrial and dewatering uses is drained to sedimentation basins where the water percolates back into an aquifer or is returned to onsite borrow pits/lakes and recycled.

Surface waters of Miami-Dade County serve as receiving water bodies for both domestic and industrial discharges. Table 2.3-26 lists the major facilities that discharge treated wastewater or cooling water into canals, bays, or the open ocean. As seen in this table, the sources of the surface discharge water originate primarily as groundwater. Two MDWASD Wastewater Treatment Plants discharge treated wastewater into the ocean.

According to Ecology & Environment, Inc. (2007), approximately 16.2 million gallons per day of wastewater, which represents approximately 5 percent of the total volume of public water supplied by the MDWASD, is currently reused in the MDWASD system. Most of the reuse is for process water and irrigation at the regional wastewater treatment plants.

2.3.2.1.1.2 Future Consumptive Surface Water Use

The SFWMD prepares water supply plans for each of its four planning areas to support planning initiatives and address local issues. The regional water supply plans encompass a minimum 20-year future planning horizon and are updated every 5 years. Each regional water supply plan update provides revised water demand estimates and projections.

According to the SFWMD's *Water Supply Plan Update 2005–2006* (SFWMD 2006b), the total water demand of the lower east coast region which includes Miami-Dade, Monroe, Broward, and Palm Beach counties will increase by 27 percent between 2005 and 2025, as shown in Table 2.3-27.

Agricultural water withdrawal demands are projected to decline by 9 percent by 2025 due to a decrease in agricultural acreage. However, withdrawal demands for public supply, domestic self-supply, and recreational (landscape and golf course) irrigation are projected to increase by more than 30 percent by 2025.

Power generation water use and withdrawal demand are both expected to increase significantly during the planning period, reflecting the development of new power generation facilities in the lower east coast planning area. Industrial demands, which include construction and mining dewatering, are relatively small and historical data do not indicate any trends in use. Therefore, the industrial water use levels are expected to remain constant through the projection period.

In Miami-Dade County, surface water is rarely used as a source for public or domestic water supply, as already indicated in Table 2.3-24. Moreover, there is no surface water use and withdrawal permit for Units 6 & 7 anticipated in the future. Although the withdrawal demand for recreational water use could be increased in the future, the total consumptive surface water use is not expected to significantly increase in Miami-Dade County.

2.3.2.1.2 Nonconsumptive Surface Water Use

The Turkey Point plant property is adjacent to a large area of protected marine environments: Biscayne National Park is located to the east, and Biscayne Bay Aquatic Preserve (Card Sound portion) and John Pennekamp Coral Reef State Park are located to the southeast as shown in Figure 2.3-53.

As described in NPCA (2006), Biscayne National Park encompasses much of Biscayne Bay, making it one of the largest marine parks in the National Park system. The park protects part of the third-largest coral reef system in the world and the longest stretch of mangrove forest remaining on Florida's east coast, providing habitat and nursery grounds for most of the region's important commercial and recreational fish, shellfish, and crustaceans. It is also a source of environmental education and recreation.

According to Biscayne National Park (BNP 2008a), the park encompasses approximately 181,500 acres, 95 percent of which is under water. Therefore, most of the activities in this national park are water-related activities such as boating, canoeing, diving, fishing, sailing, snorkeling, swimming, and waterskiing.

Commercial fishing has been allowed within the boundaries of Biscayne National Park since the park became a National Monument in 1968. According to the landings data presented by the Fish and Wildlife Research Institute (FWRI 2008), the average annual landing amounts and trips in the entire Miami-Dade County region was 1.7 million pounds and 8186 trips for the period of 2003 through 2007. Four major species represented more than 60 percent of the total amounts: pink shrimp (20 percent), spiny lobster (15.6 percent), bait shrimp (14.1 percent), and ballyhoo (10.8 percent). Major species that commercial harvesters target include pink shrimp, spiny lobster, blue crab, stone crab, and finfish.

Recreational fishing is among the most popular activities undertaken in Biscayne National Park. According to the park's internal annual fisheries report (NPS 2006), the park hosts thousands of recreational fishing vessels annually; the 1997 total was estimated to be approximately 33,000 fishing vessels. Most fishermen tend to be recreational anglers, with approximately 20 percent engaging spearfishing and 30 percent fishing further offshore (east of the park's islands). The areas that most fishermen use are along the reef tract (hard bottom substrate) and the area

inside the bay near Adams Key (mixed substrate). The composition of the catch covers common reef species, such as snappers, grunts, and lobster (NPS 2006).

Pleasure boating, or cruising, remains a popular water-based activity in South Florida and in Biscayne National Park. The number of registered vessels has increased steadily, reaching a total of 62,324 registered vessels in Miami-Dade County in 2007. Of this total, 59,651 are pleasure craft, and approximately half of these are between 16 to 26 feet long (Florida Department of Highway Safety and Motor Vehicles 2007).

Diving is also an important recreational activity in and around Biscayne National Park. Survey results estimate that there were 3.25 million person-days spent snorkeling and diving in natural and artificial reefs in Miami-Dade County from June 2000 to May 2001 (Johns et al. 2001). During that period, the estimated total use was 9.17 million person-days, including activities such as fishing and glass-bottom boating.

Biscayne National Park hosts over 500,000 visitors annually (NPS 2009). Biscayne National Park is open year-round, but the majority of park visits occur from April to July and in October. Table 2.3-28 presents the monthly variation of number of visitors for the period of 2005 through 2007. Visitors spent approximately 152,000 person-days per year in the park during the period.

There are several public beaches in Miami-Dade County. Homestead Bayfront Park, which accommodates a natural atoll pool and beach (Miami-Dade County 2008a), is located within 6 miles of the plant area, as shown in Figure 2.3-53. Homestead Bayfront Park also accommodates fishing in designated areas and along the canal and bay for barracuda, snapper, mullet and sea bass (Miami-Dade County 2008b). Five boat ramps and a yachting marina known as Herbert Hoover Marina are located in the park (Miami-Dade County 2008c).

The Atlantic Intracoastal Waterway runs through Biscayne Bay, and Hawk Channel is a shipping lane that transverses Biscayne National Park on the outside of the Keys (NPS 2006). Commercial and noncommercial vessels pass through the waterway along the eastern side of the bay. Traffic includes cargo vessels, transportation vessels, and cruise ships. The navigational usage of the Atlantic Intracoastal Waterway in the Miami-Dade county district is difficult to quantify, but it is expected to be significant based on the large number of registered vessels within the county.

Barges delivering fossil fuel to Units 1 & 2 use Biscayne Bay. The fossil fuels are delivered from the port of Miami through Biscayne Bay to the units typically hauling between 11,500 and 14,000 barrels of bunker “C” fuel oil per trip. The number of barge trips from 2004 to 2008 varied between 95 and 277 per year.

Other than the navigational use of Biscayne Bay for shipping fossil fuel for Units 1 & 2, there are no nonconsumptive surface water uses by the existing units.

As described in Section 3.9, barges delivering components and modules for the construction of Units 6 & 7 would also use Biscayne Bay. There would be approximately 80 round-trip barge deliveries for modules and components for each unit over an approximately six-year duration.

2.3.2.1.3 Statutory and Legal Restrictions on Surface Water Use

The consumptive use of water in the state of Florida is regulated by the water management districts, as prescribed in Part II of Chapter 373 of Florida Statute (F.S.). This regulation applies to public water supplies, agricultural and landscape irrigation, contamination cleanup, commercial/industrial uses, and dewatering/mining activities. Water uses that are exempt from the permitting process include domestic uses for single-family homes, water used for fire fighting, saltwater and reclaimed water uses (SFWMD 2008f).

Specific water body restrictions on water use imposed by federal, state, or local regulations that are relevant to Units 6 & 7 are summarized below:

- Biscayne National Park is designated as an Outstanding Florida Water and an Outstanding National Resource Water pursuant to Rule 62-302.700 of Florida Administrative Code (F.A.C.). Any discharges or activities that may cause degradation of water quality and natural resources, other than that allowed in Rule 62-4.242(2) and (3) of F.A.C., are prohibited.

- The Biscayne Bay Aquatic Preserve is managed by the FDEP in accordance with F.S. 258.397 and F.A.C. 18-18. Activities such as dredging, filling, drilling of wells, and erection of structures are regulated to preserve the water quality and aquatic resources.

- Pursuant to the Resolution (No. Z-56-07, conditions 4 & 5) of the Board of County Commissioners of Miami-Dade County, FPL shall not apply for any water withdrawals from the Biscayne aquifer as a source of cooling water for the proposed facilities, and shall use reclaimed or reuse water to the maximum extent possible.

2.3.2.1.4 Plant Water Use

2.3.2.1.4.1 Existing Units Water Use

Units 1-4 use the 5900-acre closed-loop industrial wastewater facility for condenser and auxiliary system cooling. Condenser cooling water is pumped from the intake portion of the industrial wastewater facility and through the plant's condensers where it gains heat. The heated water is discharged to the discharge portion of the industrial wastewater facility. The head difference between the discharge and intake in this closed-loop system causes the heated water to flow through the industrial wastewater facility, dissipating heat along the way, and eventually returning the cooled water to the plant intake. The required condenser cooling water is 574,300 gallons per minute (gpm) for Units 1 & 2, and 1.25 million gpm for Units 3 & 4. Incidental rainfall, some

stormwater runoff, treated process wastewater, and groundwater inflows, compensate for evaporative cooling losses from this system.

Unit 5 uses a closed-cycle cooling system with mechanical draft cooling towers. The required cooling tower makeup water is supplied by groundwater from the upper production zone of the Floridan aquifer. A 90-day average withdrawal of 14.06 million gallons per day and an average annual withdrawal of 4599 million gallons per year are permitted to be used for cooling water for Unit 5 and process water for Units 1, 2, and 5 (FDEP 2007). The cooling tower makeup water for Unit 5, which is currently withdrawn from the Floridan aquifer, may switch to reclaimed water if a reliable source of reclaimed water becomes available (FDEP 2007).

Units 3 & 4 use approximately 690 gpm of water from the Miami-Dade public water supply system. Plant water use includes process (primary demineralizer water makeup), potable, and fire protection water. The Newton water treatment plant, which is part of Miami-Dade's public water supply system, supplies the existing units.

The process wastewater from the existing units is released into the industrial wastewater facility, and the sanitary wastewater is sent to an onsite treatment plant and disposed of through an underground injection well.

The State Industrial Wastewater Facility Permit No. FL0001562, issued by the FDEP, authorizes releases of industrial wastewater to the closed-loop cooling system and subsequently to groundwater. The permit does not authorize the existing units to discharge to surface waters of the state. The industrial wastewater facility is an integral part of the existing units design and is not waters of the state.

2.3.2.1.4.2 Units 6 & 7 Water Use

Units 6 & 7 would use closed-cycle, mechanical draft cooling towers for both circulating water system cooling and service water system cooling.

The primary source of makeup water for the circulating water cooling towers would be reclaimed water supplied by the MDWASD South District Wastewater Treatment Plant, which is located approximately 9 miles north of the Turkey Point plant property (Figure 2.3-51). When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, radial collector wells supplying saltwater would be used to supplement the supply. The raw water system would be designed to supply 100 percent of the makeup water from either reclaimed water or saltwater, or any combination of both. The ratio of water supplied by the two makeup water sources would vary depending on the availability of reclaimed water from the MDWASD South District Wastewater Treatment Plant. The circulating water system would be designed to accommodate the differing water quality of the two sources.

Municipal water from the Miami-Dade County public water supply system would serve as the source for potable water, makeup water to the service water system, demineralized water, fire protection, and miscellaneous water uses.

The cooling tower blowdown and wastewater from Units 6 & 7 would be discharged to the Boulder Zone of the Lower Floridan aquifer via deep injection wells, as described in Subsection 3.3.1.2.

The water use quantities and diagrams for the plant during operation are presented in Section 3.3, and water use during construction is discussed in Section 4.2.

Details on the transmission lines are provided in Section 3.7. As presented in Subsection 4.2.1.1.10, the impacts of the transmission line on the surface water use are expected to be small.

2.3.2.2 Groundwater Use

This section contains a description of the historical, current, and projected groundwater use at and in the vicinity of the Turkey Point plant property. SSAs within the region are also identified and described.

The hydrostratigraphic framework of Florida, including Miami-Dade County and the vicinity of the Turkey Point plant property, consists of a thick sequence of Cenozoic sediments that comprise two major aquifers. The two major aquifers are (SEGS 1986):

- The surficial aquifer system, including the Biscayne aquifer.
- The Floridan aquifer system consisting of the Upper Floridan aquifer, the middle confining unit, and the Lower Floridan aquifer. The Floridan aquifer is separated from the Biscayne aquifer by the intermediate confining unit.

The Biscayne aquifer is the most productive of the shallow aquifers in southeastern Florida, and it is the prime source of drinking water for the municipal water systems south of Palm Beach County, including Miami-Dade County. However, saltwater intrusion affects the entire coastal zone of the aquifer, thereby limiting use of the aquifer for drinking water in the vicinity of the Turkey Point plant property as a result of the saline to saltwater composition of the groundwater. Figure 2.3-23 shows the approximate location of the freshwater-saltwater interface in the area. The figure indicates that the saltwater interface at the base of the aquifer is approximately 6 to 8 miles inland of the Turkey Point plant property. Provisional data from the USGS (2009b) showing the 2008 freshwater-saltwater interface in Southeast Florida indicates a similar pattern to that shown on Figure 2.3-23.

The Floridan aquifer system consists of three units in southeastern Florida: the Upper Floridan aquifer, the middle confining unit, and the Lower Floridan aquifer. In southeastern Florida, groundwater in the Upper Floridan aquifer is brackish and variable in quality. The aquifer typically contains saline water, which is defined as greater than 250 mg/L of chloride, or saltwater, which is greater than 19,000 mg/L of chloride as defined (by the SFWMD) (SFWMD 2008g). The Upper Floridan aquifer, however, is the primary aquifer used for seasonal storage of both raw and treated freshwater within the aquifer storage and recovery (ASR) systems in southern Florida. Approximately 30 aquifer storage and recovery sites in southern Florida have their storage zone completed within or planned for the Upper Floridan aquifer (Reese and Richardson 2008).

The Boulder Zone of the Lower Floridan aquifer contains saltwater which is used for deep well injection of treated municipal wastewater and reverse osmosis concentrate in Miami-Dade County. Injection occurs below the middle confining layer at depths of approximately 2800 feet or greater, approximately 900 feet below the base of the lowest underground source of drinking water (USDW) (defined as an aquifer that contains water with a total dissolved solids concentration of less than 10,000 mg/L (U.S. EPA 2003 and Reese and Richardson 2008).

2.3.2.2.1 Regional Groundwater Use

Historical, current, and projected groundwater use in the vicinity of the Turkey Point plant property was evaluated using information from the U. S. Geological Survey (USGS) and the SFWMD.

2.3.2.2.1.1 Historical Groundwater Use

Freshwater withdrawal of groundwater has been monitored for Miami-Dade County by the USGS (Marella 2005 and Marella 2008). In the Miami-Dade County area, freshwater is restricted to the Biscayne aquifer. However, the Turkey Point plant property is in an area of the Biscayne aquifer with Class G-III groundwater (non-potable water use). Groundwater use has shown a steady increase between the 1960s and the present as shown on Figure 2.3-55. The primary groundwater use in Miami-Dade County is for public water supply, followed by agricultural irrigation. Beginning in approximately 1985, a new category of use was introduced—recreational irrigation. This category includes golf course irrigation and other types of turf grass irrigation. Table 2.3-29 presents the groundwater use for each category.

The underlying Upper Floridan aquifer typically contains saline water to saltwater. In 1990 and 1995, no groundwater use was reported from the Floridan aquifer for Miami-Dade County (Marella 1992 and Marella 1999). In 2000, water use of 3.68 million gallons per day from the Upper Floridan aquifer was reported for the county with a use category of industrial (Marella and Berndt 2005).

2.3.2.2.1.2 Current Use

Figure 2.3-56 shows the current groundwater users in Miami-Dade County based on water use permits filed with the SFWMD (SFWMD 2011). The figure does not show wells that do not require a water use permit, such as domestic wells, wells used exclusively for fire fighting, or those wells withdrawing saline or saltwater. Table 2.3-30 lists the public water supply systems in Miami-Dade County along with the population served (FDEP 2008a). Figure 2.3-57 (FDEP 2008d) presents the major well fields in Miami-Dade County and their associated groundwater protection zones.

In addition to the traditional uses of the groundwater aquifer, other uses of the groundwater aquifer are present in south Florida. These include disposal of municipal and industrial wastewater in Class I injection wells and the use of ASR wells. The ASR wells are used to inject raw or partially treated water into the aquifer for later extraction and use. Figure 2.3-58 shows the typical configuration of Class I injection wells and ASR wells in south Florida. ASR wells are typically completed as open-hole wells in the Upper Floridan aquifer. Class I injection wells are typically completed as open-hole wells in the Boulder Zone portion of the Lower Floridan aquifer which is below the lowermost USDW. Figures 2.3-59 and 2.3-60 show the locations of these wells in Florida (FDEP 2008b).

2.3.2.2.1.3 Projected Use

Projected groundwater use in Miami-Dade County was obtained from the *Lower East Coast Water Supply Plan*, 2005–2006 update (SFWMD 2006b). Figure 2.3-55 includes projections of groundwater use through 2025. The projections combine domestic and public water supply categories into one total value.

2.3.2.2.2 Local Groundwater Use

This section provides a description of the current and projected groundwater use in the vicinity of the Turkey Point plant property.

2.3.2.2.2.1 Current Use

Units 1 through 4 use the cooling canals of the industrial wastewater facility for condenser and auxiliary system cooling (Figure 2.3-3). The canals also receive cooling tower blowdown from Unit 5 and existing facilities drainage. The industrial wastewater facility is a closed-loop system (Figure 2.3-61) that includes the canal network adjacent to Units 6 & 7. There are no discharges to surface water from the industrial wastewater facility. Cooling water for Unit 5 and process water for Units 1, 2, and 5 are obtained from Upper Floridan aquifer saline production wells (PW-1, PW-3, and PW-4). The locations of these production wells, which were commissioned in February 2007, are shown in Figure 2.3-62. Monthly production from each of the wells is shown in Figure 2.3-63. The average combined production from the three wells is approximately 170

million gallons per month. Water supply for other water uses at Turkey Point comes from the potable water system of the MDWASD.

A single Class V, Group 3 gravity injection well is used to dispose of up to 35,000 gallons per day of domestic reclaimed water at the Units 3 & 4 wastewater treatment plant. The well, designated IW-1, is open from 42 to 62 feet below ground surface and is 8 inches in diameter.

2.3.2.2.2.2 Projected Use

Reclaimed water from the MDWASD or saltwater from radial collector wells would be the two sources of cooling water for Units 6 & 7. The total makeup flow required from the radial collector wells is estimated to be 86,400 gpm; however, the actual amount of saltwater used would depend on the quality and quantity of reclaimed water available from the MDWASD. Water supply for potable water, service water system makeup, fire protection, and miscellaneous raw water use would be from the MDWASD.

Radial collector wells would consist of a central concrete caisson excavated to an optimal target depth. The caisson diameter is based on the size of pumps and number of laterals required. The optimal target depth of the caisson will be based on the available drawdown and the desired elevation of the laterals. Screened sections will be incorporated along the lateral based on site conditions. Once the caisson and laterals are installed, groundwater will infiltrate into the laterals and flow back to the caisson. The water then will be pumped from the caisson.

Four radial collector wells, each capable of producing approximately 45 million gallons per day, would be installed. Figure 2.3-64 shows the location of the radial collector wells. At any time, one collector well will operate in standby mode as a reserve well in the event of an unplanned well outage or scheduled maintenance event. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground surface with laterals projecting horizontally from the caisson. The laterals would be advanced horizontally a distance of up to 900 feet from the caisson and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The wells would be designed and located to induce infiltration from Biscayne Bay.

Disposal of wastewater from Units 6 & 7 is planned to occur in Class I deep injection wells drilled at the site. The wells would inject the wastewater into the Boulder Zone of the Lower Floridan aquifer at depths of approximately 2900 to 3500 feet below ground surface. This injection zone has been used for the underground disposal of liquid wastes since 1943 (Maliva et al. 2007). The Boulder Zone is located beneath groundwater supplies that are currently or may be used in the future as a source of drinking water. Drinking water supply sources are typically not more than a few hundred feet deep and, therefore, far above the Boulder Zone (U.S. EPA 2000).

The Boulder Zone is permitted by the FDEP as a zone for the discharge of treated sewage and other wastes disposed of through injection wells. The Boulder Zone meets the Florida Department of Environmental Regulations criteria for Class I injection. The Boulder Zone has the following characteristics throughout its extent:

- Deep. The top of the Boulder Zone is 2000 to 3400 feet in depth.
- Confined. There is approximately 800 to 1000 feet of confining limestone and dolomite beds between the Boulder Zone and the base of the Underground Source of Drinking Water.
- Thick. The Boulder Zone is up to 700 feet in thickness.
- Porous. The Boulder Zone has well developed secondary permeability.
- Highly Transmissive. The transmissivity of the Boulder Zone is up to 24.6E06 square feet per day.
- Contains groundwater with total dissolved solids concentration >10,000 mg/L. The average dissolved solids concentration of Boulder Zone groundwater is approximately 37,000 mg/L.

Over 90 Class I injection wells are used to dispose of over 200 million gallons per day of secondary treated wastewater in southeast Florida (Bloetscher and Muniz 2006).

Deep injection wells would be used for the disposal of non-hazardous industrial wastewater consisting of cooling tower blowdown, sanitary wastewater, and miscellaneous plant wastewater from Units 6 & 7. The wastewater disposal requirements for Units 6 & 7 are estimated to be a combined total of approximately 20 million gallons per day when using only reclaimed water from the MDWASD as a cooling water source, and as high as 90 million gallons per day when using only saltwater as a cooling water source. Therefore, the combined disposal volumes are estimated to be between 20 million and 90 million gallons per day when using a combination of reclaimed water and saltwater for cooling. The wells would be Class I industrial injection wells with a total capacity of 90 million gallons per day. The deep injection wells would consist of 10 primary wells and 2 backup wells. The injection zone would be in the Boulder Zone of the Lower Floridan aquifer, which is at a depth of approximately 2900 feet bgs in the plant area. Approximately 800 to 1000 feet of confining limestone and dolomite beds would be present between the injection zone and the base of the USDW.

Deep injection well design includes determining the allowable injection rate and the area of review. Section 62-528.415 (1)(f)2 FAC (FDEP 2008b) states that the hourly peak injection rate should not exceed a velocity of 10 feet per second. Based on a review of data from other deep injection wells in southeast Florida, it is estimated that each deep injection well would have a maximum allowed injection capacity of 18.6 million gallons per day at a peak hourly flow.

However, it is estimated that each well would be operated at an injection rate of approximately 10 million gallons per day.

The casing in the deep injection wells for Units 6 & 7 would be seated at a depth of approximately 2800 feet bgs to maximize the thickness of the confining strata between the injection zone and base of the USDW. Grouting the pilot holes drilled for core and data collection, prior to reaming the holes for casing placement, would be employed to prevent the possible development of double borehole conditions. Additionally, all Class I injection wells are required to have a dual-zone monitoring system that consists of a zone open below the deepest USDW and a zone located in the USDW for geochemical and pressure monitoring.

The temperature and total dissolved solids concentration of the injected effluent will be variable. The injected effluent temperature would vary seasonally. The maximum and minimum expected temperatures would be 91°F and 65°F, respectively. The expected wastewater TDS when using reclaimed water would be 2721 mg/L; when using saltwater from the radial collector wells, the expected wastewater TDS would be 57,030 mg/L. Based on the temperature and TDS values, the density of the injected fluid is estimated to range from 996.8 kilograms per cubic meter (100-percent reclaimed water in the summer) to 1042.2 kilograms per cubic meter (100-percent saltwater in the winter).

2.3.2.2.3 Sole Source Aquifers

EPA has designated two SSAs that are located entirely within the state of Florida, the Volusia-Floridan aquifer and the Biscayne Aquifer, as shown on Figure 2.3-18 (U.S. EPA 2011). The Volusia-Floridan aquifer is located in east-central Florida, well beyond the boundaries of the local hydrogeologic system underlying the plant area; however, the Biscayne aquifer underlies the site and Miami-Dade County. An SSA is defined as “an underground water source that supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer. These areas have no alternative drinking water source(s) that could physically, legally, and economically supply all those who depend upon the aquifer for drinking water” (U.S. EPA 2011). Saltwater intrusion affects the entire coastal zone of the Biscayne aquifer including the Turkey Point plant property. As a result, groundwater beneath the Turkey Point plant property is not used as a drinking water source because of its salinity.

2.3.3 WATER QUALITY

This subsection describes the water quality characteristics of surface water bodies and groundwater aquifers that could affect plant water use, wastewater injection, and stormwater runoff or be impacted by preconstruction/construction and operation of Units 6 & 7.

2.3.3.1 Surface Water

Surface water bodies of primary interest near the Units 6 & 7 plant area include Biscayne Bay, Card Sound/Card Sound Canal, and the cooling canals of the industrial wastewater facility. These water bodies have the potential to be affected as a result of the construction (e.g., surface water runoff), and operation (e.g., radial collector well operation) of Units 6 & 7. They are addressed in the following paragraphs.

2.3.3.1.1 Biscayne Bay and Card Sound/Card Sound Canal

The Units 6 & 7 plant area is located adjacent to Lower Biscayne Bay. Card Sound is south of Biscayne Bay. Card Sound Canal starts at the southern end of the industrial wastewater facility and terminates at Card Sound. Card Sound Canal is not hydraulically connected to the industrial wastewater facility; however, it is connected to Card Sound. Therefore, Card Sound Canal would be expected to have similar water quality to Card Sound. The locations of Biscayne Bay, Card Sound, and the Card Sound Canal relative to Units 6 & 7 are shown in Figures 2.3-1 and 2.3-3.

Biscayne Bay's beauty and utility invites a diversity of recreational and commercial water activities, including powerboating, sailboating, catamaraning, canoeing, sculling, waterskiing, other motorized watercraft, parasailing, swimming, windsurfing, snorkeling, diving, and fishing.

Biscayne Bay is also important navigationally as part of the Intracoastal Waterway and home to the Port of Miami, one of the busiest cargo and passenger ports in the world. Biscayne Bay provides for a variety of educational and research activities. Several marine science and education facilities use Biscayne Bay and include the University of Miami School of Rosenstiel School of Marine and Atmospheric Sciences, Florida International University, Barry University, the National Oceanic & Atmospheric Administration, the Southeast Fisheries Laboratory, and the Miami Seaquarium. The MAST (Maritime and Science Technology) Academy is a local magnet school located on Virginia Key and is dedicated to students interested in marine science. In addition to these institutions, several governmental agencies as well as scientists from remote locations conduct research and education programs pertaining to Biscayne Bay (FDEP 2008f).

To meet the requirements of Section 303(d) of the federal Clean Water Act, the 1999 Florida Watershed Restoration Act was created directing the Florida Department of Environmental Protection (FDEP) to implement a comprehensive, integrated watershed approach to evaluating and managing impacts to Florida's waters (FDEP 2006b). Units 6 & 7 would be located in the Everglades (HUC 090202)/Florida Bay (HUC 090203) watersheds as shown in Figure 2.3-5. This watershed is currently managed by the SFWMD, a regional Florida state-run agency responsible for water quality, flood control, water supply, and environmental restoration in 16 counties from Orlando to the Florida Keys (SFWMD 2008i). South Florida's coastal systems support spiny lobster, penaeid shrimp, blue crab, oyster, spotted sea trout, stone crab, and many other marine

and freshwater species of commercial and recreational interest. Coastal ecosystems are especially vulnerable because they attract intense human development, making these areas especially prone to habitat loss and alteration. (SFWMD 2008h) One of the SFWMD's goals is to manage freshwater discharge to south Florida's estuaries in a way that preserves, protects, and, where possible, restores essential estuarine resources. The SFWMD seeks to ensure that estuaries receive not only the right amount of water at the right time but also clean, high-quality water. (SFWMD 2008h)

Biscayne Bay water quality is monitored by the SFWMD through a project with the four-letter code name BISC (renamed BBWQ). Project BISC (Project BBWQ) is monitored by two entities: the Miami-Dade County Department of Environmental Resources Management and the Florida International University. The entities monitor different parts of Biscayne Bay with the same goals, which are to determine water quality and provide data to SFWMD staff and outside agencies. (SFWMD 2011)

Miami-Dade County Department of Environmental Resources Management's monitoring program consists of monthly surface water monitoring in Biscayne Bay and its tributaries. Routine monitoring was initiated to detect spatial and seasonal water quality trends, determine impacts on the health of the bay ecosystem, and identify areas of degradation. (SFWMD 2011)

The program with Florida International University is part of an integrated monitoring network known as the South Florida Coastal Water Quality Monitoring Network. The network monitors water quality on the coastal regions of south Florida. The data generated from the South Florida Coastal Water Quality Monitoring Network is used to examine water quality trends along the Florida coast as well as address issues concerning freshwater inflow, water clarity, salinity, and nutrient availability patterns. (SFWMD 2011)

Project BISC (Project BBWQ) monitors the following parameters: temperature, dissolved oxygen, pH, turbidity, nitrogen oxides, nitrate, ammonia, total Kjeldahl nitrogen, orthophosphate, total phosphate, silica, chlorophyll A, nitrite, total nitrogen, salinity, total organic carbon, and alkaline phosphate. Figure 2.3-66 depicts the monitoring stations that are potentially affected as a result of the construction and operation of Units 6 & 7. Table 2.3-31 presents the monthly average, maximum and minimum water qualities for Project BISC (Project BBWQ) samples collected between 1993 and 2010 at varied depths of sampling local to the Turkey Point plant property. To analyze horizontal variations in Biscayne Bay, the data is presented at two depth ranges: less than 1 meter and greater than or equal to 1 meter. To analyze temporal variations, the data is presented monthly.

Analysis of the data from Project BISC (Project BBWQ) for horizontal spatial variation reveals that alkaline phosphate, silica, and nitrogen oxides are slightly elevated in samples closest to the shore (BISC 101, 110, and 122). Nitrogen oxide is shown to be the highest among the samples

taken from the canals (MW01, MW04 and FC03). Total Kjeldahl nitrogen and nitrate are slightly elevated at sampling location BISC 101. Water quality data from samples taken in Card Sound (locations BB47, BB48, BISC 121 and 135) shows no meaningful water quality differences when compared to data from Biscayne Bay. In summary, Biscayne Bay, including Card Sound, is relatively consistent in regard to horizontal spatial variations.

As shown in Table 2.3-31, temperature, dissolved oxygen, and salinity were sampled at two depths and there was no meaningful variation in the data. The water quality data shown in Table 2.3-31 is consistent with the data analyzed for other sample locations in Biscayne Bay at varying depths and, as a result, it can be concluded that Biscayne Bay is relatively consistent in regard to vertical spatial variations in water quality.

Seasonal analysis of the data collected through Project BISC (Project BBWQ) shows higher concentrations of total nitrogen during the summer months for all sampling locations. In addition, the temperature of Biscayne Bay varies from an average monthly maximum of 31.1°C in July at BISC 101 to an average monthly minimum of 17.5°C in January at BB44 (average of samples taken at greater than 1 foot deep). Otherwise, most likely because of the limited atmospheric temperature variation seasonally (Florida's proximity to the equator), there is minimal seasonal variation in Biscayne Bay.

2.3.3.1.2 Industrial Wastewater Facility

Stormwater runoff from the construction and operation of Units 6 & 7 would be routed to the industrial wastewater facility which is described in Subsection 2.3.1.1.4. Water quality sampling and analyses were performed in the industrial wastewater facility in 2003. The results are summarized in Table 2.3-32.

The industrial wastewater facility receives tidal inflow and outflow from the saline aquifer beneath Biscayne Bay because of the exceptional porosity of the underlying rock. The industrial wastewater facility does not directly discharge to fresh or marine surface waters; however, because the canals are not lined, groundwater does interact with water in the industrial wastewater facility. Makeup water for the industrial wastewater facility comes from treated process water, rainfall, stormwater runoff, and groundwater infiltration to replace evaporative and seepage losses. Consequently, the water in the canals is hypersaline because of the effects of evaporation, with salinity concentrations approximately twice that of Biscayne Bay.

Analysis of the industrial wastewater facility temperatures has been performed using a steady-state energy balance model developed for Unit 5 in 2003. This analysis used 5 years of data to predict temperatures in the industrial wastewater facility. Depending on the time of year and plant capacity factors, the temperature of heated water from Units 1 through 4 entering the industrial wastewater facility ranges from approximately 85ºF to 105°F, while cooled water

returning to the units ranges from approximately 70ºF to 90°F. The predicted average monthly temperatures in the industrial wastewater facility range from 95.9°F for water entering to 82.6°F for water leaving (i.e., cooling water intakes). The associated predicted annual average temperature difference (ΔT) across the industrial wastewater facility is 13.4°F over the 5-year period analyzed. To predict the maximum temperatures in the industrial wastewater facility, data from June 1998 was used. The highest monthly temperatures were predicted for this period, with the highest temperature reported at 106.1°F, that had cooled down to approximately 94.8°F at the south end of the industrial wastewater facility, and then further cooled to approximately 91.9°F when returning to the units. Because continuous flow through the canals occurs, spatial variations in water quality and seasonal variation, other than temperature, are not expected.

Liquid radioactive waste effluent from Units 3 & 4 is also discharged to the industrial wastewater facility. The tritium level in the cooling canals is monitored and averaged 5250 picocuries per liter during 2000-2007.

2.3.3.1.3 Section 303(d) List of Impaired Waters

Section 303(d) of the Clean Water Act requires states to develop a list of waters not meeting water quality standards or waters not supporting their designated uses. Chapter 99-223, *Laws of Florida*, sets forth the process by which the list is refined through more detailed water quality assessments. Total maximum daily loads are required for the waters determined to be impaired based on these detailed assessments because technology-based effluent limitations, current effluent limitations required by state or local authority, or other pollution-control requirements are not stringent enough to meet current water quality standards. (FDEP 2008e)

To protect present and future most beneficial uses of the waters, water quality criteria have been established for each designated use classification. While some criteria are intended to protect aquatic life, others are designed to protect human health (FDEP 2008f). The Southeast Coast/Biscayne Bay is given surface water Class III-recreation, propagation, and maintenance of a healthy, well-balanced population of fish and wildlife classification.

Biscayne Bay, Card Sound, and Card Sound Canal do not appear on the 2006 Florida 305(b) Report of impaired waters, and are not listed in Section 303(d) impaired waters. Biscayne Bay is described as having "fairly good water quality" (FDEP 2006b).

As shown in Figure 2.3-67, there are only three Section 303(d)-listed waters in the Southeast Florida Coast Water Basin and located within 15 miles of Units 6 & 7. These waters are FL-3303 or C-111 Canal (Aerojet Canal), FL-3033A (a stream in South Dade County), and FL-3304 Canal (Military Canal located at Homestead Air Reserve Base). The closest Section 303(d)-listed water to Units 3 & 4 is the Military Canal at Homestead Air Reserve Base, which is approximately 5 miles from the Units 6 & 7 plant area. The Florida Keys, located just south of Biscayne Bay, are

Section 303(d)-listed waters impaired for nutrients. The Homestead Air Reserve Base is impaired for cadmium, copper, and lead. The Aerojet Canal is impaired for dissolved oxygen and mercury and the FL-3033A stream is impaired for dissolved oxygen and nutrients. Because the Units 6 & 7 plant area is not located close to surface waters on the Section 303(d) list and does not have an intake from or discharge to these water bodies, there would be no interaction between Units 6 & 7 and these Section 303(d)-listed water bodies.

2.3.3.1.4 Surface Water Pollutant Sources

Figure 2.3-68 shows the National Pollutant Discharge Elimination System (NPDES) discharges within 15 miles of Units 6 & 7. The closest industrial NPDES discharger to Units 6 & 7, located adjacent to the plant area, but not permitted to discharge to waters of the state of Florida or waters of the United States, is Units 1 through 5 (Permit Number: FL0001562). All the other permitted NPDES discharges shown on Figure 2.3-68 are remotely located in relation to the plant and, therefore, would not interact with Units 6 & 7.

2.3.3.2 Groundwater

Groundwater in the vicinity of the Turkey Point plant property is not used as a water source because of its salinity. The state of Florida has classified these as Class G-III waters to identify groundwater that has no reasonable potential as a future source of drinking water due to high total dissolved solids content (Merritt 1996). Field-measured groundwater quality indicator parameters (temperature, pH, dissolved oxygen, specific conductivity, turbidity, and oxidation-reduction potential) obtained during the collection of samples from 12 observation wells (installed in the Biscayne aquifer as part of the site characterization investigation) for field-measured parameters are summarized in Table 2.3-22. The results of the laboratory analyses are presented in Table 2.3-23. Table 2.3-32 presents a summary of water quality data collected as part of the Turkey Point peninsula pumping test. Additional data and information regarding these water quality analyses can be found in HDR 2009. The state of Florida has conducted an extensive characterization of the background water quality in the major aquifer systems (FGS 1992). Tables 2.3-22 and 2.3-23 also present typical geochemical parameters for the Biscayne aquifer, the Floridan aquifer, and precipitation at Everglades National Park.

This data was taken from the surficial aquifer at depths of approximately 20 or 100 feet below local ground surface. The location of these wells is shown in Figure 2.3-25.

Chemically, the water in the middle confining unit is similar to seawater, but salinity varies greatly at the top of the unit as the upward moving saline water from the Lower Floridan is blended with the seaward flowing freshwater in the Upper Floridan aquifer (Meyer 1989).

Although the Upper Floridan aquifer is a major source of potable groundwater in much of Florida, water withdrawn from the unit in southeastern Florida, including Miami-Dade County, is brackish

and variable with chloride and dissolved solid concentrations greater than 1000 mg/L. Groundwater samples from the Upper Floridan aquifer production wells at Unit 5 show an average chloride concentration of 2900 mg/L.

Treated wastewater, sanitary waste, blowdown, and treated liquid radioactive waste effluent would be injected into the Boulder Zone of the Lower Floridan aquifer via deep injection wells that would terminate approximately 2900-3000 feet below grade. Subsurface injection, the practice of emplacing fluids in a permeable underground aquifer by gravity flow or under pressure through an injection well, is one of a variety of wastewater disposal or reuse methods applied in Florida. Permits for underground injection wells are issued by the FDEP Underground Injection Control Program. The injection wells permitted by the FDEP Underground Injection Control Program are divided into the EPA's five classes (Class I through Class V) based on the similarity in the fluids injected, activities, construction, injection depth, design, and operating techniques (FDEP 2008b, U.S. EPA 2008b). Class I wells are used for discharging wastewater to the Boulder Zone of the Lower Floridan aquifer, where the wastewater from Units 6 & 7 would be injected. The closest facility to Units 6 & 7 currently permitted for subsurface injection is the MDWASD, approximately 9 miles north, which injects secondary treated municipal wastewater. This facility has 13 active Florida Class I wells (wells used to inject nonhazardous waste or municipal waste below the lowermost underground sources of drinking water). The next closest facility to Units 6 & 7 that is permitted for Class I deep well injection is more than 30 miles north with two active wells. Miami-Dade County injects 91.31 million gpd (average annual) to injection wells. Florida has more than 125 active Class I wells, with the majority of these wells being used to dispose nonhazardous, secondary treated effluent from domestic wastewater treatment plants, like the MDWASD (FDEP 2008c).

Additionally, the EPA's *Relative Risk Assessment of Management Options for Treated Wastewater in South Florida* evaluated the potential stressors to human health or ecology (U.S. EPA Apr 2003). These potential stressors include any dissolved or entrained wastewater constituents that may reach receptors in sufficient concentrations to cause adverse human health or ecological effects. In this evaluation, water quality data was obtained from the MDWASD South District Wastewater Treatment Plant, which receives secondary treatment (secondary treatment is the standard practice for municipal wastewater treatment facilities in South Florida). This data was compared to the EPA's maximum contaminant levels for drinking water. Drinking water standards are a good indicator of the health of the groundwater in the Boulder Zone because aquifers above the Boulder Zone are used for drinking water in Florida. It was concluded that South Florida's municipal wastewater (Dade County, Miami-Dade North District) that has received secondary treatment does not exceed the EPA's primary drinking water standard maximum contaminant levels for any constituents at the point of injection to the Boulder Zone. Although FDEP §62-520-410 does not require non-potable water use groundwater aquifers Class G-IV to meet primary drinking water standards, the fact that the Boulder Zone does meet the

EPA's primary drinking water standard maximum contaminant levels is indicative of the health of the groundwater.

Δh = Lower Reference Head — Upper Reference Head
ΔL = Lower Screened Interval Midpoint — Upper Screened Interval Midpoint
i = Δh/ΔL (negative value indicates downward flow potential and positive value indicates upward flow potential)
Reference Head values are estimated using the density of water in the well and correcting the water level to the average density of seawater in Biscayne Bay.

Table 2.3-16
Representative Hydrogeologic Properties in Miami-Dade County[a]

Hydrogeologic Unit or Subunit	Hydraulic Conductivity (feet per day)		Porosity	Approximate Depth (feet bgs)	Unit Thickness (feet)
	Horizontal	Vertical			
Biscayne aquifer	1524	15	0.31	0–230	230
Intermediate confining unit	90	0.1–2.38	0.1–0.31	230–840	610
Upper Floridan aquifer	42	0.42–2.38	0.1–0.32	840–2060	1220
Middle confining unit	4.7	0.04–1.50[b]	0.1–0.43	2060–2550	490
Lower Floridan aquifer	0.01	0.1	0.1–0.4	2550–2750	200[c]
Boulder Zone	6540	65	0.2	2750–3250	500

(a) Values in this table represent weight and averages for risk assessment for measurement of treated wastewater and thus may not be representative of actual conditions.
(b) The vertical hydraulic conductivity included here may be two to three orders of magnitude higher than other measurements in South Florida. Maliva et. al. 2007 indicates a vertical hydraulic conductivity range of 3E-04 to 3E-05 feet per day based on core measurements.
(c) The Lower Floridan aquifer extends below the Boulder Zone; the thickness presented is only for the portion above the Boulder Zone.

Adapted from U.S. EPA 2003

Geometric Mean: Upper: 61.3 feet per day
Lower: 20.1 feet per day

Source: Appendix G Groundwater Data, MACTEC 2008
N/A = Not Applicable
NC = Not Conducted
KGS = Kansas Geological Survey
For wells with multiple tests, test results were averaged and used to calculate the geometric mean.
Data from these tests are considered not valid due to rate-limiting recharge effects from the filter pack.

Not analyzed

SFWMD = South Florida Water Management District
(a) MACTEC 2008.
(b) Spiked analyte recovery is outside stated control limits. Method performance confirmed using Laboratory Control Spike sample results.
(c) Analyte not detected at or above the method detection limit.
(d) Method blank contamination. The associated method blank contains the target analyte at a reportable level. These data should be used with caution.
(e) Estimated result. Result is less than the reporting limit.
(f) Everglades National Park.
(g) FGS 1992.
(h) Test conducted on Nitrogen, as Ammonia.
(i) TDS is estimated as specific conductance in milliSiemens per centimeter x 1000 x 0.65, specific conductance values are listed in Table 2.3-21.
(j) Based on specific conductance measurements collected February 3-5, 2009.
(k) Assumes specific conductance equals 99 milliSiemens per centimeter.
(l) Samples collected and analyzed during routine groundwater level monitoring.

Pumping Required

ND = No data; NR = Data not readable

Table 2.3-24
Surface Water Uses in Miami-Dade County Permitted by SFWMD

Use Category	Number of Permits	Annual Allocation[a] (Million Gallon)
Public supply	1	0.04[b]
Industrial	6	9,411
Agricultural	3	57
Nursery	2	23
Aquaculture	1	27
Golf Course	7	1,360
Landscape	115	1,123
Dewatering	4	N.S.[c]

(a) For some permits that have no annual allocation data, the average daily allocations multiplied by 365 are assumed.
(b) This use is for a temporary construction trailer bathroom purposes.
(c) Not Specified.

1 Concentrations for certain years appear as outliers with other sample data collected for the month. The outliers were removed to calculate the average concentrations but are still shown as maximums or minimums so that all sample data collected is captured.

2 ND = No data; TEMP. = Temperature; D.O. = Dissolved Oxygen; TURB. = Turbidity; NOX = Nitrate + Nitrite; NO2 = Nitrite; NO3 = Nitrate; NH4 = Ammonia; TOT N = Total Nitrogen; TKN = Total Kjeldahl Nitrogen; OPO4 = Orthophosphate; TPO4 = Total Phosphate; AlkPO4 = Alkaline Phosphate; SIO2 = Silica (Silicon Dioxide); CHLOR A = Chlorophyll A; SAL. = Salinity; TOC = Total Organic Carbon

Table 2.3-32
Water Quality Summary from Turkey Point Pumping Test

Locations	Total Dissolved Solids	Chloride	Sulfate	Bromide	Bicarbonate Alkalinity	Boric Acid	Calcium	Magnesium	Potassium	Sodium	Strontium

2.4 ECOLOGY

This section describes the terrestrial and aquatic resources found within the planned construction areas, the Turkey Point plant property, and the southeastern region of Florida. It provides the baseline from which to assess potential impacts of construction activities and facility operations associated with Units 6 & 7.

Regional Landscape

The approximately 9400-acre Turkey Point plant property is located in Miami-Dade County, Florida, approximately 25 miles south of Miami on the coast adjacent to Biscayne Bay and Card Sound (Figure 2.4-1). The plant property is located within the subtropical coastal ecosystem of southeastern Florida. Much of the original coastal zone in the region has been converted to agriculture or residential/developed land. However, the Turkey Point plant property lies in a largely rural area dominated by swamp/marsh areas, even though the property is relatively close (25 miles) to the metropolis of Miami. The predominant land uses within 6 miles of the center point of Units 6 & 7 are listed in Table 2.2-2. This area is typified by low elevation, generally less than elevation 10 feet (NAVD 88) (up to 10 miles west of Biscayne Bay), with open marsh and mangrove swamp habitats interspersed with tidal creek drainages flowing east and south toward Biscayne Bay and Card Sound. Many of the wetlands have become degraded by invasive exotic species such as Brazilian pepper (*Schinus terebinthifolius*), Australian pine (*Casuarina equisetifolia*), melaleuca (*Melaleuca quinquenervia*), and old world climbing fern (*Lygodium* species).

The hydrology of southern Florida is influenced by an extensive system of canals and levees created to buffer climatic extremes (flooding and drought). These water management structures were built in the 1950s and 1960s by the federal government and are managed by the South Florida Water Management District (SFWMD), a state agency. Approximately 1800 miles of canals and levees currently exist in southern Florida including Miami-Dade County, the location of the Turkey Point plant property. The corridors containing the proposed transmission lines and reclaimed water pipelines cross several of these canals.

General Site Description

The Turkey Point plant property contains two natural gas/oil steam electric generating units (Units 1 & 2), two pressurized water reactor nuclear units (Units 3 & 4), and one natural gas combined-cycle steam electric generating unit (Unit 5). Approximately 340 acres of the Turkey Point plant property consist of generating facilities, buildings, and parking areas, switchyard, and transmission line corridors associated with Units 1 through 5 (Subsection 2.2.1.1). In addition to the existing generating facilities and supporting infrastructure, a major landscape feature of the site is the approximately 5900-acre (2 miles by 5 miles) industrial wastewater facility. Current land use at the Turkey Point property is described in Section 2.2 and shown in Figure 2.2-3. The

existing Turkey Point facilities were established on mangrove-covered tidal flats, on land elevated by fill material. Although numerous drainage ditches and the industrial wastewater facility are located throughout the plant property, it contains no lakes or perennial streams. The Turkey Point plant property lies immediately adjacent to Biscayne Bay and Card Sound. The interface between the plant property and the bay/sound is primarily red mangrove (*Rhizophora mangle*) swamp. Seagrass beds containing shoal grass (*Halodule wrightii*), turtle grass (*Thalassia testudinum*), and manatee grass (*Syringodium filiforme*) are found throughout Biscayne Bay (NPS 1999).

Units 1-4 use the cooling canals of the industrial wastewater facility for condenser and auxiliary system cooling. The industrial wastewater facility also receives cooling tower blowdown from Unit 5. It is a closed-loop system that includes the canals adjacent to the Units 6 & 7 plant area (Figure 2.4-1). The industrial wastewater facility consists of 32 canals that carry warm water south away from the units and 7 canals that return cooled water to the units. Approximately 4400 acres of the industrial wastewater facility are open water. The canals are 200 feet wide and 1 to 3 feet deep. The berms are approximately 90 feet wide. Activities within the industrial wastewater facility include aquatic plant removal (3-year cycle), terrestrial vegetation removal from the berms (10-year cycle), and monitoring of the American crocodile (*Crocodylus acutus*) (see Subsection 2.4.1.2). The shallow canals are hypersaline (typically 40–50 parts per thousand [ppt] salinity), with water temperatures as high as 100.4^{o}F (38^{o}C). Because of these environmental conditions, the resident fish assemblage is dominated by species adapted to living in harsh conditions (e.g., sheepshead minnow and several *Fundulus* species). The approximately 167 miles of the industrial wastewater facility are not waters of the United States or the state.

Units 6 & 7 Plant Area

The power blocks, makeup water reservoir, switchyard, and other infrastructure would be located on the Units 6 & 7 plant area, immediately south of Units 3 & 4 within the industrial wastewater facility. The plant area is approximately 218 acres that is a sparsely vegetated hypersaline mudflat, buffered from tidal influence by the industrial wastewater facility (see Figure 2.4-2). Two remnant canals cross the plant area. An ecological assessment of the Units 6 & 7 plant area and the adjacent laydown area was conducted in 2008, including habitat characterization and surveys for federal and state listed species. Wetlands were the primary habitat types occurring on this site, with non-wetland habitats making up the remainder.

Wetland habitats within the Units 6 & 7 plant area and the adjacent laydown area include mudflats (187.5 acres), remnant and active canals (25 acres), dwarf mangrove (17 acres), open water (16 acres), mangrove heads (12 acres), and wetland spoil areas (10 acres). Encircled by canals, the sparsely vegetated mudflats are typically inundated by water 7 to 8 months out of the year and a few hardy plant species that can tolerate these conditions persist, including saltwort (*Batis maritima*), sea oxeye daisies (*Borrichia* spp.), woody glasswort (*Salicornia virginica*), and dwarf glasswort (*Salicornia bigelovii*). Dwarf mangrove habitats contain red mangrove as well as

a few white mangrove (*Laguncularia racemosa*) and black mangrove (*Avicennia germinans*) stunted by high salinities and fluctuating water levels. The mangroves are located within the open water area on the western edge of the laydown area. The open water area joins the upper end of the industrial wastewater facility. Harsh conditions in the open water area limit submerged aquatic vegetation to scattered patches of widgeon grass (*Ruppia maritima*) and shoal grass. Mangrove heads, remnants of the original tidal creeks, contain primarily red mangrove, but white mangrove and black mangrove are also present. The connection between these creeks and Biscayne Bay were severed during construction of the industrial wastewater facility. Wetland spoil areas adjacent to remnant canals are typically occupied by Australian pine, buttonwood (*Conocarpus erectus*), and mangrove.

Non-wetland areas within the Units 6 & 7 plant area and adjacent laydown area include approximately 20 acres of fill area/roadway habitat and approximately 8 acres of upland spoil piles (Figure 2.4-2). The former are limerock aggregate uplands filled for construction of access roads, parking areas, and the land utilization facility. These areas are dominated by maintained grasses with wetland edges containing Brazilian pepper, buttonwood, and assorted herbaceous plants. Upland spoil piles were formed with spoil from the canal dredging operation. The vegetation in these areas is dominated by exotics such as Brazilian pepper and Australian pine, as well as poisonwood (*Metopium toxiferum*), buttonwood, wild sage (*Lantana involucrata*), ground orchid (*Bletia* spp.), and sea grape (*Cocoloba uvifera*).

The surface grade of the plant area varies from approximately elevation –2.4 to 0.8 feet (NAVD 88). The eastern margins of the plant area slope gently to the east perimeter canal, which is separated from Biscayne Bay by a 15 foot-high berm. There is no berm between the Units 6 & 7 plant area and the canal; however, when water levels rise in the canal, there is sheet flow to the west and the mudflats are inundated. The remnant canals would be eliminated during filling of the Units 6 & 7 plant area.

Laydown Areas

Two laydown areas would be created, 46 acres and 6 acres in extent. These areas consist largely of habitats including reservoirs larger than 500 acres, dwarf mangroves, and fill areas.

Nuclear Administration and Training Buildings and Parking Area

Nuclear administration and training buildings and a parking area would be located on two adjacent parcels (32 total acres) immediately north of the Units 6 & 7 plant area. These parcels consist largely of mangrove swamps and fill areas.

Reclaimed Water Pipelines and FPL Reclaimed Water Treatment Facility

Underground pipelines would bring reclaimed water from the Miami-Dade Water and Sewer Department (MDWASD) South District Wastewater Treatment Plant (SDWWTP) to the FPL reclaimed water treatment facility for eventual use as makeup water. The pipelines would extend approximately 9 miles between the SDWWTP and the FPL reclaimed water treatment facility. For about 6.5 miles of their length, the pipelines would be collocated with the existing Clear Sky-to-Davis transmission line right-of-way and adjacent road and canal rights-of-way. Primary land covers are summarized in Table 2.2-6. The FPL reclaimed water treatment facility would be established on approximately 44 total acres of sawgrass marsh, dwarf mangroves, upland Australian pine, excavated canals, and exotic wetland hardwoods-Australian pine located at the northwest corner of the plant property between SW 344th Street/Palm Drive and the L-31E Canal. The portion of the reclaimed water pipelines on the Turkey Point plant property (from the FPL reclaimed water treatment facility to the makeup water reservoir) would traverse roads and highways which are accounted for within the heavy haul road disturbed area.

Potable Water Pipelines

Potable water pipelines, approximately 10 miles in length, would bring potable water from the Miami-Dade County Water and Sewer Department to the Units 6 & 7 plant area. The pipelines would generally follow existing roadways/corridors. Much of the pipelines would be adjacent to or within the corridors containing the access road improvements and construction along SW 328th Street/N. Canal Drive to SW 117th Avenue to SW 359th Street to the plant area. The habitats/land covers associated with this corridor include a variety of land cover types, with the majority land type consisting of farms, wetlands, and roads.

Radial Collector Wells and Pipelines

Radial collector wells would provide a backup source of makeup water for Units 6 & 7. Four radial collector wells would be located on a 3-acre area on the northeastern tip of Turkey Point. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The well location area is primarily industrial habitat, with a thin strip of mangroves on the Biscayne Bay shore. Water supply pipelines from the radial collector wells to the cooling towers on the plant area would occupy approximately 13 acres and would be trenched under an existing perimeter access road, potentially impacting land types including stream and waterways/canals, mangrove swamps, and fill areas.

An additional 3-acre laydown area for the radial collector well construction would be built along the northwest-facing shore of barge turning basin, on previously disturbed industrial habitat.

Spoil Areas

Spoils from the Units 6 & 7 plant area, FPL reclaimed water treatment facility, and other construction locations would be deposited on three areas (total approximately 211 acres) within the industrial wastewater facility. Two of these areas would be located on wide berms on either side of Grand Canal, the primary north-south canal in the center of the facility. The third would be along a strip of land below the southern end of the industrial wastewater facility. All three areas have been used historically for spoil deposition and contain scattered patches of early succession vegetation (grasses, low shrubs, etc.).

Equipment Barge Unloading Area and Heavy Haul Road

The existing barge turning basin would be expanded, with a 0.31-acre equipment barge unloading area to be excavated, as part of a total disturbed area of 0.75 acres, on previously disturbed industrial lands, classified as electric power facilities, on a shore of the barge turning area. A heavy haul road would be built over existing roads between the equipment barge unloading area and the Units 6 & 7 plant area.

Transmission Laydown Areas

In support of transmission expansion, an approximately 3-acre laydown area would be established on previously disturbed lands (concrete pads currently functioning as parking areas), made up of ditches, dwarf mangroves and electric power facilities, on the north side of SW 360th Street.

Previously Disturbed Areas on the Turkey Point Plant Property

Several previously disturbed areas on the Turkey Point plant property would be impacted including: security buildings and associated pull-off and parking areas, transmission infrastructure improvements (e.g., towers and bridges), sanitary waste pipeline from the existing units to the Units 6 & 7 plant area. These areas are typically previously filled areas or existing concrete pads.

Access Roads

A total of 10.8 miles of roadway expansions and improvements would be needed for construction-related travel (workers, fill material deliveries, equipment, etc.) for Units 6 & 7. These improvements would be located adjacent to and along existing roads, transmission rights-of-ways, and canals. The access roads would traverse a variety of land cover types, the majority of which includes wetlands, farms, and disturbed areas.

FPL-Owned Fill Source

Offsite borrow material would be supplied from an approximately 300 acre site about 4.8 miles northwest of Units 6 & 7, other regional sources, or reused material. Most of the 300-acre site is comprised of tree nurseries, Brazilian pepper, ditches, exotic wetland hardwoods, wetland scrub, freshwater marshes and roads and highways.

Transmission Corridors

Transmission lines would extend, primarily along existing transmission corridors, from the Turkey Point plant property to the Levee, Pennsuco, Davis, and Miami substations (Figure 2.2-5). Existing transmission lines generally pass through typical habitats associated with the coastal region of southeast Florida. For the Clear Sky to Levee lines, land use classes are outlined in Table 2.2-3. Some remnant pine rockland habitat is found along this line. This line would extend approximately 43 miles. The initial segment of this corridor would be new construction, crossing the northern end of the industrial wastewater facility and requiring new towers/poles and several bridges across the canals to access the tower sites on the berms. The line continues west for approximately 12 miles and turns north toward Levee. The northern section of this line crosses the eastern portion of the ENP (Figure 2.2-5). A likely alternative to impacting the ENP (West Option) follows the same corridor from Turkey Point, but shifts east to border the ENP (East Option) rather than cross it (Figure 2.2-5). A land exchange has been proposed to relocate the approximately 8-mile-long segment of this corridor within the ENP to the periphery of the park.

The route of the Clear Sky to Pennsuco line would use the Clear Sky to Levee corridor, then bypass the Levee substation and follow an existing 230 kV transmission easement for approximately 8 miles to connect to the existing Pennsuco substation. Land types traversed are described in Table 2.2-3.

The Clear Sky to Davis corridor would extend approximately 19 miles north from the Turkey Point plant property through land use classes described in Table 2.2-3, using existing transmission rights-of-way.

The Davis to Miami corridor extends east for approximately 4 miles from the substation through land use classes outlined in Table 2.2-3, although it borders two protected pine rockland areas. This segment of the corridor is typically mowed to a low level. The corridor would then extend to the north for approximately 13 miles along a Miami Metro bus and rail corridor adjacent to U.S. Highway 1 through areas shown in Table 2.2-3.

2.4.1 TERRESTRIAL ECOLOGY

2.4.1.1 Terrestrial Wildlife

Wildlife species found in and around the Turkey Point plant property are typical of those in southeastern Florida coastal areas. Approximately 90 species of birds have been observed on or

near the Turkey Point plant property and associated transmission corridors during surveys from 1972 and more recent surveys (2005–2009) (Table 2.4-1). These observed species reflect the predominance of aquatic habitats within and adjacent to the property. They include 19 shorebird species, 11 wading bird species, 6 seabird species, and 5 other waterbird species (pelicans, cormorants, mergansers). Several of these avian species are listed as endangered or designated as species of special concern and are described in Subsection 2.4.1.1. A late winter survey for birds around the construction areas resulted in 36 avian species observed (see Table 2.4-1). Nine avian species (25%) were considered wintering birds, including most of the shorebirds. Most wading birds were relatively common, and the double-crested cormorant (*Phalacrocorax minor*) and white ibis (*Eudocimous albus*) were considered abundant. The predominance of observed water birds (wading birds, shorebirds, pelicans, etc.) was indicative of the primary habitats available: the industrial wastewater facility and the adjacent mangrove wetlands. A late summer survey in June 2009 occurred to document wet/breeding season avian species. The late summer survey for birds around the construction areas resulted in 39 avian species observed. Wading birds, shorebirds and other water birds made up over half (54 percent) of the species observed. Such species as white ibis, least tern, white-crowned pigeon, common ground-dove, prairie warbler, red-winged blackbird and common nighthawk were the most abundant species observed on site. The breeding season was evident by the presence of juvenile (young-of-the-year) birds, including juveniles of most species of wading birds and shorebirds. The species composition is consistent with the predominance of aquatic/wetland habitats available at the site.

The diversity of mammalian fauna observed in surveys from the 1970s to the present is limited, also due to the predominance of aquatic habitats. Mammals observed on the property include white-tailed deer (*Odocoileus virginianus*), raccoon (*Procyon lotor*), opossum (*Didelphis virginiana*), eastern cottontail (*Silvilagus floridanus*), and various species of small rodents (Table 2.4-2). A small mammal trapping effort in April 2009 indicated that cotton rats (*Sigmodon hispidus*) and black rats (*Rattus rattus*) were the dominant small mammals in the construction activity areas (Figure 2.4-3a). They were the only mammal species captured during 345 trap-nights (Sherman live traps). Cotton rats were found essentially site-wide and were relatively abundant whereas black rats were primarily found within the Units 6 & 7 plant area and adjacent mangrove areas. Based on pedestrian surveys, raccoons were also wide-spread and relatively abundant. Marsh rabbits (*Silvilagus palustris*) and/or their sign were relatively common within the vegetated portions of the spoil deposition areas. White-tailed deer and Virginia opossum sign were seen in the mangrove areas west of the industrial wastewater facility and along SW 344th Street/Palm Drive, respectively. No bats were observed during one hour of surveys between the existing facilities and a mangrove area.

Other fauna observed on the Turkey Point plant property since the 1970s include reptiles and amphibians (Table 2.4-2). The American crocodile is the most conspicuous reptile on site, breeding in the industrial wastewater facility and using all canals as travel corridors (see details in

Subsection 2.4.1.1). Surveys for reptiles, excluding American crocodiles, and amphibians occurred from April 13–16, 2009 and employed coverboards, minnow traps, dip nets, and pedestrian searches. Twenty coverboards were installed in late March of 2009 (Figure 2.4-2) within several areas that would be disturbed during Units 6 & 7 plant construction and checked daily during the week of April 13–16. Four minnow traps were set adjacent to Palm Drive and seven were set in the standing water within the administrative building/parking area site (two mangrove areas immediately north of the Units 6 & 7 plant area). The minnow traps were checked each day for two days. Dip nets were dragged through aquatic vegetation within the two mangrove areas. Planned construction areas were searched during approximately 1000 minutes of pedestrian surveys (all areas combined). The April 2009 survey efforts documented four species of snakes, three species of lizards, three species of amphibians, and one species of turtle (Table 2.4-2). Based on these surveying efforts, only the Cuban brown anole (*Anolis sangrei*) was considered relatively abundant. Four of the 12 herpetological species observed were exotic species: Cuban brown anole, green iguana (*Iguana iguana*), Mediterranean gecko (*Hemidactylus turcicus*), and greenhouse frog (*Eleutherodactylus planirostris*).

Several of the animal species observed within the Turkey Point plant property are considered an invasive or exotic species and several exotic plant species (see the preceding section) exist on the property. Many other exotic animal species exist within the region, some as close as the adjacent Everglades Mitigation Bank (EMB) (see Subsection 2.4.1.3) (FPL 2008a), and, therefore, could exist on the Turkey Point plant property. These exotic species include marine toad (*Bufo marinus*), Cuban tree frog (*Osteopilus septentrionalis*), rock dove (*Columba livia*), scarlet ibis (*Eudocimus rubber*), spectacled caiman (*Caiman crocodylus*), and Indo-pacific gecko (*Hemidactylus garnoti*).

Wildlife species found within the Turkey Point plant property are common to the region and would be expected to be found in off-site project areas associated with Units 6 & 7: access roads, reclaimed water pipelines, transmission corridors and FPL owned fill source.

Although the Turkey Point plant property hosts such potential disease vectors as ticks and mosquitoes, no vector-borne diseases resulting from them are known.

2.4.1.2 Threatened and Endangered Species

The U.S. Fish and Wildlife Service (USFWS) is responsible for designating areas as “critical habitat” for federally listed endangered and threatened species. Such areas are protected to aid the recovery of the species and may require special management activities. Critical habitats associated with two species found in the Turkey Point plant property are addressed below within the descriptions of the individual species.

Endangered and threatened species listed for Miami-Dade County, the location of the Turkey Point plant property and the existing and proposed transmission corridors, are identified in Table 2.4-3 although only a few species exist on Turkey Point plant property. The list is based on classifications of the USFWS (USFWS Feb 2008a) and Florida Natural Areas Inventory (FNAI 2008). Four federally-listed species have been observed within the Turkey Point plant property: American crocodile, Eastern indigo snake, Florida manatee, and wood stork. As described below, several state-listed species have also been observed. Approximately 170 animal and plant species are either federal- or state-listed as endangered, threatened, or candidates, or designated (not listed) species of special concern for Miami-Dade County, with the vast majority being plant species (Table 2.4-3). It should be noted that records of federally-listed species on the state and federal Web sites occasionally differ, with the state including all counties within the historical range of these species and the federal listing including only counties with sightings. As a conservative approach, species in counties from both sources have been included. Also, it is acknowledged that these listings reflect only recorded or historical occurrences and the possibility exists that other (unrecorded) rare species might exist in this county. Contacts have been initiated with the appropriate federal and state agencies regarding the existence of endangered and threatened species.

American crocodiles inhabit coastal estuarine marshes, tidal swamps, and creeks/canals of southern Florida, the Caribbean, and Central America. They were down-listed from federally endangered to threatened in 2007 because populations were expanding (USFWS Mar 2007a). Their recovery was linked to the conservation efforts at Turkey Point. Construction of the industrial wastewater facility eliminated several thousand acres of relatively natural potential habitat (tidal mangrove) for this species in the 1970s. However, crocodiles discovered and colonized the industrial wastewater facility, which now hosts approximately one-third to one-half of the breeding population of crocodiles in the United States. From 2005 to 2008, FPL biologists have reported 21 to 26 crocodile nests in the industrial wastewater facility, making it the second largest breeding aggregation in the state of Florida. A crocodile management plan prescribes maintenance procedures for the industrial wastewater facility (timing and method of vegetation clearing in canals and on berms) least likely to disturb nests, hatchlings, and adults. Additional management activities have included excavating small ponds on and around the berms as sanctuaries and/or freshwater catchments, clearing berms of exotic vegetation and providing shade by planting native tree species. FPL has also established a crocodile monitoring program to document breeding success and survival within the industrial wastewater facility. This monitoring includes hatchling studies involving weighing, measuring, and permanently marking (clipping scutes and embedding microchips with unique identification numbers) individual hatchlings. Much of the Turkey Point plant property and adjacent lands to the east, south, and west, including the Units 6 & 7 plant area, have been designated critical habitat for the American crocodile (Figure 2.4-4; USFWS Sep 1977). Most crocodile nesting occurs in the southwestern corner of the industrial wastewater facility; however, a limited number of nests have been

observed on berms within the northern portion of the return canals (Figure 2.4-5). Nesting crocodiles have never been documented within the Units 6 & 7 plant area. The plant area consists primarily of low areas that are not typically used by crocodiles because of lack of suitable nesting substrate and limiting foraging opportunities. A limited number of crocodiles have been observed basking on the perimeter shore of the plant area.

Crocodiles are unlikely to be found within aquatic habitats west of the L-31E Canal associated with the access roads, reclaimed water pipelines, FPL-owned fill source, and transmission corridors.

Wood storks (*Mycteria americana*) are large wading birds that nest in trees and shrubs over water and forage on fish in shallow wetlands in the southeastern United States. They are federal- and state-listed as endangered. They feed by touch, literally bumping into their prey, and thus require shallow wetlands relatively clear of vegetation in order to forage efficiently. They are seen in low numbers in the shallow portions of the industrial wastewater facility during the winter months. Three wood storks were observed foraging/roosting in shallow wetlands in the laydown area immediately west of the Units 6 & 7 plant area. They do not nest on or near the Turkey Point plant property but have historically nested in three colonies south of Tamiami Trail and one colony north of Tamiami Trail. Portions of both corridors fall within the core foraging areas of a total of nine colonies (radius of 18.4 miles around each colony). Wood storks could also be found within aquatic habitats associated with the access roads, reclaimed water pipelines, and FPL-owned fill source. Critical habitat has not been defined for this species.

The Eastern indigo snake (*Drymarchon corais couperi*) is a federally threatened species that inhabits a variety of habitats in the southeastern United States from scrub and sandhill to wet prairies and mangrove swamps. Their existence is frequently linked to gopher tortoise populations and use of their subterranean burrows. Indigo snakes have been observed south of the industrial wastewater facility in the Everglades Mitigation Bank (in 2004) and within an area south of SW 344th Street/Palm Drive, adjacent to the FPL child daycare facility (in 1981) and at two locations in the Eastern Preferred transmission line corridor (in 2011). Eastern indigo snakes could also be found within appropriate habitats found near the access roads, reclaimed water pipelines, FPL-owned fill source, and transmission corridors. Critical habitat has not been defined for the indigo snake.

Manatees (*Trichechus manatus*) are large marine mammals that frequent warm water estuarine habitats including rivers, marshes, bays, and sounds in Florida and other southeastern coastal states. They use warm water refuges in the cooler months, including freshwater springs and heated effluent from power plants. Manatees are federal- and state-listed as endangered, and their critical habitat includes Biscayne Bay and Card Sound adjacent to the Turkey Point plant property and the streams, rivers, and canals entering these water bodies (Figure 2.4-3a; USFWS Sep 1977). Manatees have been observed in the barge turning basin and nearby state canals.

Four endangered and one threatened species of sea turtle inhabit Biscayne Bay and Card Sound at varying times of the year. These include the endangered green sea turtle (*Chelonia mydas*), leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtles (*Erytmochelys imbricata*), Kemp's ridley sea turtle (*Lepidochelys kempii*), and threatened loggerhead sea turtle (*Caretta caretta*). Of these, the loggerhead turtle is the most common in the vicinity of the Turkey Point plant property. These turtles typically forage within the bay and sound, but beach habitats that they need for their nesting do not exist on the mainland shoreline near Turkey Point. It should be noted that the Kemp's ridley sea turtle is not listed for Miami-Dade County, but is listed for the adjacent Monroe County.

The Florida panther (*Felis concolor coryi*) is a large, federally endangered cat that inhabits the Everglades region. Their population size within the region is estimated at fewer than 60 animals. They use a combination of upland hammocks and dense saw palmetto thickets and prey on deer and feral hogs. State-maintained databases of (1) movement patterns of radio-collared panthers (approximately 30 years of data), (2) panther mortalities (typically collisions with motor vehicles; approximately 40 years of data), and (3) panther den locations (approximately 16 years of data) were examined relative to the various construction areas, some of which are within or adjacent to the primary and secondary zones of the Panther Focus Area (PFA). There have been no confirmed panther movements/occurrences, mortalities, or dens found on the main plant site, within the corridors of the proposed reclaimed or potable water pipelines, or within the FPL-owned fill source area. There have been no movements/occurrences of radio-collared panthers and no known dens within 5 miles of the proposed access road modifications since 1988. There have been no known mortalities of panthers within 2 miles of the proposed access road modifications since 1988, but one mortality occurred in 2007 within 5 miles of the proposed access road. Multiple movements/occurrences and one den are known near the two Clear Sky to Levee transmission line options and five mortalities have occurred within 5 miles of these corridors.

The Everglades snail kite (*Rostrhamus sociabilis plumbeus*) is a federally endangered species that inhabits tropical, open freshwater marshes and shallow lakes in southern Florida. They depend on apple snails (*Pomacea paludosa*) as prey, caught at the surface of freshwater marshes. Critical habitat exists west and north of the proposed Clear Sky to Levee transmission corridors (Figure 2.4-4; USFWS Sep 1977), but a single Everglades snail kite was observed in the area of the proposed transmission corridors bordering the ENP during recent reconnaissance. The species has been documented using the wetlands of the EMB adjacent to the Turkey Point plant property as recently as 2003.

The Cape Sable seaside sparrow (*Ammodramus maritimus mirabilis*) is a federally endangered species that inhabits seasonally inundated freshwater interior marshes. There may be scattered populations of these sparrows in Miami-Dade County, primarily in prairies to the east of Shark Slough in the ENP. These prairies do not occur on the Turkey Point plant property and the

species has not been observed on the property. Critical habitat exists within the ENP; smaller critical habitat areas occur northwest of nearby Florida City (Figure 2.4-4; USFWS Nov 2007b).

The bald eagle (*Haliaeetus leucocephalus*) was de-listed in 2007, but remains protected under the Bald and Golden Eagle Protection Act. Eagles do not nest on or near the Turkey Point plant property, but some have been observed flying near the existing units and along the transmission corridors and a single adult eagle was observed perched near the northwest corner of the industrial wastewater facility. Eagle nesting has historically occurred within one mile of the West Preferred corridor in the Doral area.

Several state-listed species have been observed on or adjacent to the Units 6 & 7 plant area. These include two threatened species: the least tern (*Sterna antillarum*) and the white-crowned pigeon (*Columba leuccephala*). A Florida burrowing owl (*Athene cunicularia floridana*), designated as "species of special concern," was observed on one occasion in 2010 along the main north-south access road in the southern portion of the industrial wastewater facility. Florida burrowing owls typically inhabit open, well-drained landscapes such as pastures and mowed areas. Six wading birds designated as “species of special concern” have been observed on or adjacent to the 6 & 7 plant area: little blue heron (*Egretta caerulea*), roseate spoonbill (*Ajaia ajaja*), snowy egret (*Egretta thula*), tricolored heron (*Egretta tricolor*), reddish egret (*Egretta rufescens*), and white ibis (*Eudocimus albus*). Many of these wading bird species were observed during 2008–2009 reconnaissance along the transmission corridors and all wading bird species could possibly use appropriate wetland habitats associated with the access roads, reclaimed water pipelines, FPL-owned fill source, and transmission corridors.

No federal- or state-listed plants (see Table 2.4-3) have been observed on the Units 6 & 7 plant area. Multiple surveys of the transmission corridors for federal and state-listed plants in 2008 and 2009 documented 36 listed species (Table 2.4-4). Three were federally-listed candidate species: Florida brickell-bush (*Brickellia mosieri*), pineland deltoid spurge (*Chamaesyce deltoidea ssp. pinetorum*), and sand flax (*Linum arenicola*). All three, as well as several state-listed species, are endemic pine rockland habitats. A 9-acre pine rockland area (maintained by fire, not mowing) contained 23 listed plant species. Pine rocklands are savanna-like forests on limestone outcrops. They have a single canopy species, South Florida slash pine (*Pinus elliottii var. densa*), and a dense understory of shrubs and herbs. Pine rocklands are typically fire-maintained communities, fire serving to eliminate many invading hardwoods and exotic plant species and reduce duff layers (USFWS 1999).

Several listed plant species were found on disturbed habitats (e.g., spoil piles). Spoil piles/ disturbed areas adjacent to the existing corridor within the Turkey Point plant property (exiting west from the facility) contained three species of state listed species: locustberry (*Byrsonima lucida*), Mullein nightshade (*Solanum donianum*), and West Indian trema (*Trema lamarckianum*). These same plant species could possibly occur in similar habitat along the access road and reclaimed water pipeline corridor.

2.4.1.3 Other Important Species and Habitats

"Important species" are defined in the *Standard Review Plans for Environmental Reviews for Nuclear Power Plants* (NUREG-1555) as those that are federally or state-listed as threatened or endangered, proposed for listing as threatened or endangered, commercially or recreationally valuable, essential to the maintenance or survival of species that are rare or commercially or recreationally valuable, critical to the structure and function of the local terrestrial ecosystem, or serve as biological indicators. Game species fall within the "commercially or recreationally valuable" species category. The primary game species on the Turkey Point plant property are white tailed deer, rabbits, and mourning doves. Hunting and/or trapping of game animals is not allowed on Turkey Point property. No "travel corridors" for terrestrial game species cross the property; however, waterfowl likely use the industrial wastewater facility and other wetlands on the property during migration. American crocodiles use the canals as travel corridors to move throughout the plant property and possibly into the nearby mangrove swamps and marshes.

Important habitats, as defined under NUREG-1555, include wildlife refuges, sanctuaries, or preserves, habitats identified by federal or state agencies as rare or to be protected, wetlands, floodplains, other resources specifically protected by federal or state regulation, or land areas identified as critical habitat for threatened or endangered species. Much of the Turkey Point plant property, particularly the industrial wastewater facility, is classified as critical habitat for the crocodile (Figure 2.4-4) and segments of the access roads and transmission corridors could also have this classification. Locations of other critical habitats were discussed within their species descriptions in Subsection 2.4.1.2.

The mangrove forests of South Florida are a vital component of the estuarine and marine environment in this region and thus mangrove areas, especially red mangrove (*Rhizophora mangle*), should be considered important as an indicator habitat of the south Florida region. Mangroves are plants that are highly adaptive to the extreme conditions associated with shorelines habitats, including soft sediments (prop roots), high salinities (adaptive root membranes), and oxygen-poor soils (prop roots). These forests provide a detrital base for organic food webs and significant habitat for arboreal, intertidal and subtidal organisms, including shellfish, crustaceans, fish, and birds. Some of the species that are highly dependent on mangrove systems are mangrove rivulus (*Rivulus marmoratus*), reddish egrets, mangrove cuckoos (*Coccoyzus minor*) and white-crowned pigeons. The majority of mangroves within the project construction areas are on lands disturbed and previously impacted by the construction and operation of the Turkey Point complex and isolated from Biscayne Bay; however, they likely still provide structural habitat for mangrove community wildlife.

The Everglades Mitigation Bank (EMB) contains approximately 13,000 acres of relatively undisturbed freshwater and estuarine wetlands west and south of the industrial wastewater facility (Figure 2.4-1). This land is also owned and managed by FPL and it operates as a

commercial mitigation bank with wetland habitat credits that can be purchased to offset regional wetland impacts. The EMB contains the following vegetative habitats: sawgrass marsh, wet prairie, hypersaline mangrove, tidal mangrove, coastal band mangrove, and coastal ridge mangrove. Many of these habitats contain distinctive “tree island” habitats embedded within them. The EMB is home to 14 species of amphibians, 39 species of reptiles, 14 species of terrestrial mammals, and approximately 150 species of birds (FPL 2008a).

The 181,500-acre Biscayne National Park lies east and north of the Turkey Point plant property. The park preserves mangrove wetlands, extensive open water habitats (Biscayne Bay), the northernmost of the Florida Keys, and coral reef habitat (NPS 2006).

The Crocodile Lake National Wildlife Refuge is a 6600-acre facility located 10 miles south of the Turkey Point plant property on Key Largo in Monroe County. Its primary function is to create refuges for crocodiles and other wildlife associated with mangrove/keys habitats (USFWS 2008b).

The ENP occupies over 1.5 million acres in Miami-Dade and Monroe Counties and its eastern boundary is located approximately 10 miles southwest of the Turkey Point plant property. The park includes most of Florida Bay and is undergoing extensive restoration efforts to repair historical impacts to the system’s hydrology.

2.4.2 AQUATIC ECOLOGY

The primary aquatic habitat found on the Turkey Point plant property is the 5900-acre industrial wastewater facility. The industrial wastewater facility encompasses the Units 6 & 7 plant area. There is also an interceptor ditch along the northwest and west sides of the industrial wastewater facility. To restrict the inland movement of groundwater, water from the interceptor ditch is pumped back into the industrial wastewater facility.

Other aquatic habitats adjacent to the Turkey Point plant property include Lower Biscayne Bay, Card Sound, and the ENP. The proposed transmission lines, reclaimed water pipelines, and road upgrades may affect aquatic species in wetlands, drainage canals, and other man-made channels. Subsection 2.4.2.1 describes the aquatic communities of each of these aquatic habitats.

2.4.2.1 Aquatic Communities

The following subsections include descriptions of important aquatic resources at the Units 6 & 7 plant area, the Turkey Point plant property, and surrounding areas. These descriptions include information related to the abundance of important species found and the value of the habitats present.

2.4.2.1.1 Turkey Point Plant Property

The surface water habitats on the Units 6 & 7 plant area include hypersaline mudflats, remnant canals, channels, dwarf mangrove wetlands, and open water. The Units 6 & 7 plant area and the adjacent laydown area are largely wetland habitats (approximately 272 acres) (Figure 2.4-2). All of these habitats support only a limited number of aquatic species because of the harsh conditions of water level fluctuations, high water temperatures, and high salinities. Specific FLUCCS land use classes are outlined in Table 2.2-1.

Wetlands within the Units 6 & 7 plant area are reduced in functional value because of their use as part of the industrial wastewater facility. The altered hydrology, soils, salinity, and temperature reduce the functional value of mangrove systems when compared to undisturbed tidal mangroves of Biscayne Bay. Wetland functional value is influenced by the surrounding landscape characteristics, specifically the existing units, the extensive cooling canals, and the lack of natural tidal inundation.

The industrial wastewater facility supports a variety of aquatic species typical of a shallow, subtropical, hypersaline environment, including phytoplankton, zooplankton, marine algae, rooted plants, crabs, and estuarine fish (Table 2.4-5). The most abundant fish in the industrial wastewater facility are killifish (Family Cyprinodontidae) and live-bearers. FPL employees have also reported seeing game species, such as the common snook (*Centropomus undecimalis*) and tarpon (*Megalops atlanticus*), in the industrial wastewater facility. Sampling of large fish in the cooling canals is not feasible because sampling gear could easily trap young crocodiles. The larger game fish species, such as tarpon, can be long-lived (up to 78 years); individuals in the cooling canals are likely older individuals that occurred there in 1973 when the canals were isolated from Biscayne Bay. They may persist in the cooling canals until the end of their natural life spans without reproducing. It is plausible, though undocumented, that small numbers of other gamefish species occasionally enter the cooling canals of the industrial wastewater facility as larvae carried by hurricane storm surge. For example, Hurricane Andrew carried a storm surge between 8 and 9 feet at Turkey Point. (Andrews et al. 2001). Although recreationally important in other areas, none of the fish or other marine life in the industrial wastewater facility is available for recreational or commercial fishing. However, fish and crabs life in the industrial wastewater facility support a variety of wading birds and a resident population of the American crocodile.

Within southern Biscayne Bay and Card Sound, there are 11 aquatic species that are protected under the Endangered Species Act or are candidates for listing. Of these, 10 are found in Biscayne Bay and Card Sound, but are not known or expected to be in the industrial wastewater facility. These are Johnson's seagrass *(Halophila johnsonii),* the mangrove rivulus *(Rivulus marmoratus)*, the small-toothed sawfish *(Pristis pectinata),* five species of sea turtle, described in Subsection 2.4.1.1, the American alligator *(Alligator mississippiensis),* and the Florida manatee (Table 2.4-6). Johnson's seagrass occurs along the Florida coast from Sebastian Inlet to central

Biscayne Bay at Virginia Key, Key Biscayne. This seagrass is not known to occur as far south as the Turkey Point plant property. The mangrove rivulus is a fish that inhabits crab burrows in mangrove areas, and it could be present in mangrove areas fringing the plant site, but is unlikely to be present in the industrial wastewater facility due to lack of habitat. The small-toothed sawfish inhabits inshore bars, seagrass beds, and mangrove areas, and is unlikely to exist in the industrial wastewater facility due to lack of habitat. The sea turtles are found in marine habitats that open to the sea, such as Biscayne Bay and Card Sound. The industrial wastewater facility is not a suitable habitat and is not connected to Biscayne Bay.

The approximately 44-acre area proposed for the FPL reclaimed water treatment facility contains approximately 39.5 acres of wetlands in the form of sawgrass, dwarf mangroves, excavated canals, and exotic wetland hardwoods - Australian pine. This area is assumed to contain aquatic species typical of disturbed dwarf mangrove, sawgrass, and excavated canal habitats. Historical tidal connection to this area has been interrupted by construction and operation of the existing units, Palm Drive, and the industrial wastewater facility. Aquatic organisms existing in the area in November 2007 are presented in Table 2.4-5.

Radial collector wells would be constructed on approximately 3 acres of land classified as fill area. As described in Section 2.2, the radial collector wells would include laterals extending underground offsite from an onsite caisson at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. Wildlife species existing near the radial collector wells and associated pipeline corridor would be similar to those observed on the Turkey Point plant property.

The roadway improvements would involve widening of existing paved roads and paving existing unpaved roads. In addition, intersection improvements at six locations would be made to accommodate peak construction traffic. The roadway improvements are about 10.75 miles in length, of which about 5.5 miles would be on FPL property. Aquatic habitats potentially affected by roadway improvements include canals, freshwater marshes, and mangroves. Other land use types are illustrated in Table 2.2-7. The new 4-lane roadway planned for SW 359th Street would run along the northern edge of the industrial wastewater facility. Construction of this road would be separated from the cooling canals of the industrial wastewater facility by the existing berms as well as construction buffers. Canals occur adjacent to the roadway rights-of-way associated with SW 344th Street/Palm Drive and SW 328th Street/N. Canal Drive. In-stream vegetation is minimal within the man-made canals adjacent to existing roadways, due to the steep slopes and minimal littoral zone. These canals provide habitat for common freshwater forage fishes native to south Florida, as well as for nonindigenous fishes commonly inhabiting canals of Miami-Dade County. Areas of mangroves occur adjacent to SW 359th Street near the L-31 Canal.

Fish were surveyed during Summer 2009 in seven areas that would be potentially impacted by construction of Units 6 & 7. These sample areas included the two remnant canals on the plant area, the dead-end canal (laydown area), pools within the mangrove areas (nuclear

administration building, training building, and parking area), wetlands adjacent to SW 344th Street/Palm Drive (in the area of the FPL reclaimed water treatment facility), a portion of the return canal, shallow flats in the east-central part of the nuclear island, and two locations along the cooling canals of the industrial wastewater facility (see Figure 2.4-3b).

Fish were collected using (8-foot diameter) cast nets, a 20-foot-long minnow seine, and standard "Gee" type minnow traps. All fish collected were hardy species common in estuarine habitats in south Florida. No rare, unusual, sensitive, or protected species were collected. One additional species, the Atlantic needlefish (Strongylura marina), was observed in the return canal but not captured. The Atlantic needlefish is a common inhabitant of coastal waters from New England to the Florida Keys and west to Mexico.

2.4.2.1.2 Offsite Areas

The Turkey Point plant property is adjacent to mangroves that are tidally inundated with waters from Biscayne Bay, a shallow, subtropical bay supporting seagrasses, sponges, coral reefs, and a variety of marine life. Outside of the plant property, dominant aquatic surface water bodies include Biscayne Bay, Card Sound, and the approximately 13,000-acre EMB.

Much of the land surrounding the Turkey Point plant property is managed for environmental conservation purposes by government agencies. Biscayne National Park and the Biscayne Bay Aquatic Preserve are located northeast, east, and southeast of the plant property. The ENP is located approximately 10 miles southwest of the Turkey Point plant property. The FPL-owned EMB is situated to the southwest of the Turkey Point plant property adjacent to the ENP to the west and Biscayne Bay and Card Sound to the east.

2.4.2.1.2.1 Offsite Mangrove Tidal Flats

Mangrove tidal flats are generally described as a coastal community composed of red mangrove and/or black mangrove, which are present in pure or predominant stands. Most of the area within the undeveloped areas and surrounding the existing units is classified as dwarf red mangrove flats, established within the shallow, tidally flushed area adjacent to Biscayne Bay and Card Sound. The dwarf mangrove tidal flat community contains mangroves less than 24 inches high, stunted in response to decreased nutrient availability and increased salinity. Most of the mangrove community north of the existing units experiences sheet flow-type flushing of tidal waters, and exhibits more saline conditions with decreased nitrogen and phosphorus available for plant uptake. Where tidal creeks cut through the dwarf mangrove flat, the adjacent mangroves are up to 20 feet high as a result of exposure to the nutrient-rich tidal creek water with lower salinities.

The mangrove tidal flats are inundated with approximately 1 to 6 inches of hypersaline water in the form of sheet flow. The Southeast Fisheries Science Center of the National Marine Fisheries

Service (NMFS) in Miami is conducting baseline surveys in the area to provide a context in which to study the effects of the Comprehensive Everglades Restoration Plan. The study area includes the western margins of central and southern Biscayne Bay, Card Sound, and Barnes Sound, which form a semi-continuous, 30-mile stretch of mangrove-lined shoreline that is interspersed with natural creeks, artificial channels, and freshwater canal mouths. Mangroves immediately adjacent to the site were included in a study of the abundance and size distribution of three species of fish: gray snapper (*Lutjanus griseus*), great barracuda (*Sphyraena barracuda*), and goldspotted killifish (*Floridichthys carpio*) (Serafy et al. 2007).

Serafy et al. (2007) showed that fish occurrence in this 30-mile stretch of red mangrove varies according to the latitude, season, species, and abundance metric being evaluated. The shoreline serves to varying degrees as habitat for mature and immature gray snapper, and mostly immature great barracuda. Conversely, the goldspotted killifish observed in the coastal mangrove habitat were almost exclusively adults (Serafy et al. 2007).

2.4.2.1.2.2 Biscayne Bay/Card Sound

Biscayne Bay is a shallow subtropical saline lagoon located on the southeast coast of Florida. The eastern boundary of Biscayne Bay is composed of barrier islands that eventually become part of the Florida Keys. The western shore is the Florida mainland. Biscayne Bay is connected to the Atlantic Ocean by several channels and cuts, some natural and some man-made. Major tributaries are (north to south) Arch Creek, Biscayne Canal, Little River, Miami River, Coral Gables Waterway, Snapper Creek Canal, Black Creek, Goulds Canal, North Canal, Florida City Canal, and Model Land Canal.

Biscayne Bay was formed during the Holocene Period (approximately 12,000 years ago) as rising sea level filled a limestone depression. It is not a drowned river valley like most estuaries. Unlike most other estuaries, Biscayne Bay does not receive a sediment load from tributary rivers. Biscayne Bay can be divided into three areas: North Bay, Central Bay, and South Bay. The Atlantic Intracoastal Waterway traverses the western portion of Biscayne Bay and Card Sound, and a barge trench is maintained from the Intracoastal Waterway to the existing units.

The Turkey Point plant property is located on South Bay (also identified as Lower Biscayne Bay), which is generally undeveloped and fringed by mangrove wetlands. The main canals draining into this portion of Biscayne Bay are Black Creek, Princeton Canal, Military Canal, Mowery Canal, and Model Land Canal. Ocean exchange is restricted to the tidal creeks between the islands of the northern portion of the Florida Keys.

South Bay is approximately 100 square miles (64,000 acres) in area. The average depth is on the order of 5 feet at mean low water, with a maximum depth of 13 feet. The volume at mean low water is on the order of 1.5E10 cubic feet. Mean tide is 1.65 feet on the mainland shore and 1.55

feet on Elliott Key (eastern side). Salinities vary widely, ranging from 24 to 44 ppt, depending on the amount of rainfall and surface drainage reaching the coastal zone. The vertical salinity gradient in Biscayne Bay is relatively low, and the water can be considered vertically homogeneous. Natural water temperatures range from 59°F to 92°F at the surface, with little or no stratification.

Biscayne National Park was first established in 1968 as a national monument and was expanded in 1980 to approximately 173,000 acres of water, coastal lands, and 42 islands. Boating is the most popular activity in the park, and recreational and commercial fishing are allowed. Other recreational activities include snorkeling, diving, camping, picnicking, and hiking.

A portion of Biscayne Bay Aquatic Preserve is located approximately one-half mile to the east of the Units 6 & 7 plant area (Figure 2.4-1). The preserve is a shallow, subtropical lagoon consisting of three separate areas of Biscayne Bay. The northern part of the preserve is just south of Cape Florida on the east, and south of Chicken Key on the west. The southern portion of the preserve is in Card Sound. These areas of the preserve are separated by Biscayne National Park. The preserve is approximately 69,000 acres of submerged state land that has been designated as an Outstanding Florida Water, defined as waters worthy of special protection because of their natural attributes. The Florida Department of Environmental Protection, Office of Coastal and Aquatic Managed Areas, manages the preserve. The preserve offers recreational and commercial in-water activities, including power boating, sailboating, canoeing, sculling, waterskiing, jet skiing, hang gliding, swimming, windsurfing, snorkeling, diving, and fishing.

Aquatic Communities of Biscayne Bay/Card Sound

Important communities in Biscayne Bay and Card Sound include the mangrove forest on its eastern edge, and seagrasses, which are found primarily in Central and South Bays. The mangrove forest is one of the longest continuous stretches of mangroves remaining on the east coast of Florida. The lush seagrass beds provide food and refuge for approximately 70 percent of the area's recreationally and commercially important marine species. Seagrass beds are also a food resource for sea turtles and the Florida manatee. Important seagrass species are shoal grass, turtle grass, and manatee grass. Biscayne Bay and Card Sound are nursery areas for the spiny lobster *(Panulirus argus),* and the area from Cape Florida south through Card Sound is designated a Lobster Sanctuary by the State of Florida. Highly desired game fish in Biscayne Bay and Card Sound include tarpon *(Megalops atlanticus),* snook, red drum *(Sciaenops ocellatus),* permit (Trachinotus falcatus), and sea trout (Cynoscion spp.).

Studies were conducted in Biscayne Bay and Card Sound adjacent to area for Units 3 & 4 in the early 1970s (AEC 1972). Fish and invertebrate sampling conducted in the red mangrove community along the shoreline of Biscayne Bay resulted in over 50 species of fish, dominated by

gray snapper, mullet (*Mugil* spp.), and yellowfin mojarra (*Gerres cinereus*). Five species of invertebrates were collected, with 90 percent represented by the blue crab (*Callinectes sapidus*).

Baseline Aquatic Biological Characterization Study

In March 2008, a one-year Baseline Aquatic Biological Characterization Study in Card Sound Canal was initiated adjacent to the Units 6 & 7 plant area and in nearshore waters of Card Sound. The sampling program includes bi-weekly trawling for juvenile and adult fish and shellfish and netting for fish and shellfish eggs and larvae at five stations (two within Card Sound Canal and three in the nearshore area of Card Sound near the mouth of the canal). Results are summarized below for the first three quarters of sampling and for the 12-month period overall.

Trawl Samples

In Spring 2008, species richness was twice as high at Card Sound stations as at the two Card Sound Canal stations. Mojarra (*Eustinostomus* spp.) and pink shrimp (*Farfantepenaeus* duorarum) comprised over 90% of the total catch at Card Sound Canal stations. A greater variety of fish and invertebrates were caught at Card Sound stations. Common fish included mojarra, grunts (*Haemulon* spp.), and pinfish (*Lagodon rhomboides*). Numerically abundant invertebrates in Card Sound trawls included penaeid shrimp (*Farfantepenaeus* and *Litopenaeus* spp.), green sea urchin (*Lytechnius variegates*), and mud crabs (*Xanthoidea*).

In Summer 2008 trawl samples, species richness was more than twice as high at the Card Sound stations than at the two Card Sound Canal stations. Three taxa (mojarra, pink shrimp, and bivalves) comprised 80% of the total catch at the Card Sound Canal stations, whereas 15 taxa accounted for 77% of the catch in Card Sound. Common fish included mojarra, pinfish, bluestriped grunts (*Haemulon sciurus*), and fringed pipefish (*Anarchopterus criniger*). Numerically abundant invertebrates in Card Sound trawls included sea urchins, pink shrimp, bivalves, mud crabs, gastropods, hermit crabs (*Paguroidea*), brittle stars (*Ophiuroidea*), and caridean shrimp.

In Fall 2008, trawl samples, species richness was more than twenty times higher at the Card Sound stations than at the two Card Sound Canal stations. Bivalves comprised 98% of the total catch at the Card Sound Canal stations, whereas 13 taxa accounted for 76% of the catch in Card Sound. Common fishes included pinfish, fringed pipefish, bluestriped grunt, white grunt (*Haemulon plumierii*), and silver jenny (*Eucinostomus gula*). Numerically abundant invertebrates included mud crabs, pink shrimp, hermit crabs, sea urchins, gastropods, bivalves, brittle stars, and caridean shrimp.

A total of 125 taxa of fish and invertebrates were collected during trawl sampling. Fourteen taxa accounted for more than 75 percent of all specimens collected. Commercially-important penaeid shrimp, primarily pink shrimp, accounted for the largest percentage (16.7 percent) of all

specimens captured by trawl over the 12-month monitoring period. The most abundant fish species included pinfish, mojarras, and grunts. On average, more than twice as many specimens were collected at each station at night than during the day; nearly all of the penaeid shrimp were captured at night. More than twice as many taxa were collected, and catch per unit effort was four times higher, at Card Sound Stations than at Card Sound Canal Stations. No clear-cut seasonal trends in distribution or dominant fish and shellfish taxa were apparent.

Plankton Samples

Plankton samples were sorted and specimens assigned to one of four categories: fish eggs, fish larvae (ichthyoplankton), commercially important (CI) meroplankton, and non-commercially important (NCI) meroplankton). The CI meroplankton are represented primarily by decapod crustaceans with commercial value, such as edible shrimps (penaeid species), lobster, blue crabs, and stone crabs, but also include some mollusks (e.g., clams, oysters, squid, etc.) and several other organisms used as bait or in medical research (e.g., mole crabs, horseshoe crabs, and mantis shrimps). The NCI taxa represent a variety of other decapod crustaceans, such as grass shrimp, hermit crabs, and mud crabs (*Xanthidae*).

In Spring 2008, eggs were 3.5 times more abundant in Card Sound Canal samples than in Card Sound samples. Both areas were dominated by unidentified eggs and clupeid (herrings and sardines) eggs. Unidentified eggs were those that contained no embryo, were damaged, or could not be assigned to an egg complex based on observed characteristics. Nearly six times as many fish larvae were collected at the Card Sound Canal stations as at the Card Sound stations (per unit volume of water filtered). Both the Card Sound Canal and Card Sound samples were dominated by a few groups of ichthyoplankton (gobies, sleepers, herring, shad, sardines, and menhaden). In addition, Card Sound stations contained labrisomid blennies and flag and tube blennies. CI meroplankton were not abundant in spring samples (on average, fewer 3000 individuals per million gallons of water filtered for all stations and photoperiods combined). Samples from Card Sound Canal Stations contained almost exclusively stone crab and blue crab larvae (98% combined). Card Sound stations were dominated by blue crabs and mantis shrimp, with several other taxa also contributing substantially to the catch. NCI meroplankton were more abundant than CI meroplankton at all stations; overall abundances were four times greater in Card Sound Canal than in Card Sound. Brachyuran crabs and caridean shrimp dominated the NCI catch at all stations.

In Summer 2008, egg samples were again predominately unidentified or clupeid eggs. Fish larvae were 3.7 times more abundant in Card Sound Canal samples than in Card Sound samples. Card Sound Canal stations were dominated by larvae of herring, shad, sardines, menhaden, gobies, and sleepers, while Card Sound Stations were dominated by gobies, silverside (*Atherinomorus stipes*), labrisomid blennies, herring, shad, sardines, and menhaden. CI meroplankton were not abundant in general. Samples from Card Sound Canal Stations

contained almost exclusively stone crab and blue crab larvae (99% combined). Card Sound stations were dominated by blue crabs, stone crabs, and mantis shrimp, with several other taxa also contributing substantially to the catch. The abundance of CI meroplankton for all taxa combined was almost three times higher at the Card Sound Canal stations than the Card Sound stations. As in the Spring 2008 samples, NCI meroplankton were more abundant than CI meroplankton at all stations; overall abundances were nine times greater in Card Sound Canal than in Card Sound. Brachyuran crabs and caridean shrimp dominated the NCI catch at all stations.

In Fall 2008, samples of eggs and ichthyoplankton showed a reversal of abundances compared to previous seasons. Eggs were 40% more abundant in Card Sound than in the Card Sound Canal. As in previous seasons, however, unidentified eggs dominated all samples. Fish larvae were 1.2 times more abundant in Card Sound samples than in Card Sound Canal samples. Card Sound stations were dominated by larvae of chaenopsid blennies, gobies, labrisomid blennies, and dragonets (*Diplogrammus pauciradiatus*). Card Sound Canal stations were dominated by larvae of anchovies, gobies, sleepers, and porgies (*Sparidae*). Relatively few CI meroplankton were collected in Fall 2008. The abundance of CI meroplankton for all taxa combined was about 40% higher at the Card Sound Canal stations than the Card Sound stations. Stone crab and blue crab larvae made up 95% of the CI catch in the Card Sound Canal. Card Sound stations were dominated by stone crabs, blue crabs, mantis shrimp, and brown shrimp. As in the Spring and Summer 2008, samples, NCI meroplankton were more abundant than CI meroplankton at all stations; overall abundances were twice as high in Card Sound Canal than in Card Sound. Brachyuran crabs and caridean shrimp dominated the NCI catch at all stations.

The majority of fish eggs (57 percent) could not be assigned to a particular family or group of families because they contained no discernable embryo or were damaged. The vast majority of those that could be identified were in the herring family. More eggs were collected during the night than during the day, and more than twice as many eggs per cubic meter were collected in the Card Sound Canal than in Card Sound. Egg densities were greatest in the spring and summer.

Of the 51 taxa of ichthyoplankton identified during the 12-month monitoring period, herrings, gobies, sleepers, and blennies were dominant. More ichthyoplankton were collected during the night than during the day, and more than four times as many ichthyoplankton were collected per cubic meter in the Card Sound Canal than in Card Sound. Ichthyoplankton densities peaked in April, May, and June, then declined through the late summer and into fall. Abundance trends were similar at Card Sound Canal and Card Sound stations.

During the baseline sampling year, 23 taxa of meroplankton were collected. Nighttime samples had an average of about 25 percent more meroplankton than day samples. Densities in Card Sound Canal samples were more than four times greater than in Card Sound samples. Nine

commercially important shellfish taxa were identified; most were blue crab and stone crab larvae. Commercially important meroplankton made up only 2 percent of the combined samples. Densities of commercially important taxa were low (0.442 per cubic meter) compared with overall meroplankton catches (19.899 per cubic meter). Commercially important meroplankton were equally abundant in daytime and nighttime samples, but were 45 percent more abundant in the Card Sound Canal than in Card Sound. Commercially important meroplankton were most abundant in the spring and summer. Abundance declined rapidly in September and remained low through the following March.

2.4.2.1.2.3 Everglades Mitigation Bank

The EMB contains 13,000 acres of relatively undisturbed freshwater and estuarine wetlands, including sawgrass marsh, wet prairie, herbaceous flats, dwarf mangrove, scrub mangrove, coastal band mangroves, coastal ridge mangroves, and disturbed areas that support the exotic species Australian pine and Brazilian pepper. FPL manages the EMB to maintain functioning wetland habitat that may be purchased as mitigation credits to offset wetland impacts within the bank's service area.

2.4.2.2 Important Species of Biscayne Bay and Card Sound

NOAA’s (National Oceanographic and Atmospheric Administration) Estuarine Living Marine Resources program was developed to provide a consistent database of the distribution, abundance, and life history characteristics of important fishes and invertebrates in U.S. estuaries. Four criteria were used to select the 44 species included in the database: (1) commercial value, (2) recreational value, (3) indicator of environmental stress, and (4) ecological value (Nelson et al. Oct 1991). These criteria are similar to those used to identify important species in NUREG-1555.

Because the Estuarine Living Marine Resources program covered 20 estuaries throughout the southeastern United States, the selected species list may not adequately represent the south Florida estuarine fauna, which includes species from the tropical Caribbean biogeographic province (Nelson et al. Oct 1991). However, of the 30 fish species and 10 invertebrate species that were evaluated by NOAA, 12 fish and 6 invertebrates were common, abundant, or highly abundant in Biscayne Bay, as shown in Table 2.4-7.

2.4.2.3 Other Important Species

Rare species include species listed by the USFWS or the NMFS as threatened or endangered species proposed for listing by these agencies, species that are candidates for listing by these agencies, and species that are listed as threatened or endangered by the state in which the proposed facilities are located. Although diadromous (migratory) fish are not one of the groups

designated by the NRC as “important,” they are considered in the impacts assessment to the extent warranted by their presence in the vicinity (See Subsection 2.4.2.3.1.1).

2.4.2.3.1 Rare/Sensitive Species

Construction and operation of Units 6 & 7 could potentially impact populations of important aquatic species in habitats adjacent to the Turkey Point plant property, including lower Biscayne Bay/Card Sound. Plant and animal species designated by the USFWS, the Florida Fish and Wildlife Conservation Commission or the Florida Department of Agriculture and Consumer Services as endangered, threatened, species of special concern, commercially exploited, or under review, are included in this category. Construction and operation of Units 6 & 7 would result in no impacts to rare or sensitive aquatic species.

Other than the American crocodile, described in Subsection 2.4.1, no listed aquatic or semi-aquatic species occur within the plant property. A number of federal- and state-listed plants and animals are associated or potentially associated with the area surrounding the developed portions of the Turkey Point plant property, including two fish: the mangrove rivulus and the smalltooth sawfish (NMFS 2008d) (Table 2.4-6).

Mangrove Rivulus

The mangrove rivulus is a state and federal species of special concern. It was not reported to occur on the Turkey Point plant property, but is known to occur in the vicinity where suitable habitat exists. Its range closely parallels that of the range of the red mangrove, the preferred habitat of the mangrove rivulus. The rivulus is found in the Caribbean and Central America, and ranges as far north as Florida, where it is locally rare (FMNH 2008a). The mangrove rivulus is primarily a saltwater or brackish water species, with limited occurrence in freshwater. It can tolerate salinities from 0–68 ppt. Within the Everglades and along Florida's west coast, this fish occurs in stagnant, seasonal ponds and sloughs as well as in mosquito ditches within mangrove habitats. Along the east coast of Florida, it occurs in elevated marsh habitats above the intertidal zone, often within the burrows of the great land crab (*Cardisoma guanhumi*). This preferred microhabitat may provide shelter from cool winter temperatures, allowing for a more northerly distribution than would otherwise be possible. Great land crab burrows also provide areas of refuge during the dry season, when seasonal pools of water dry up. The mangrove rivulus is able to survive in moist detritus without water for up to 60 days. This fish has been observed slithering and flipping across land during the rainy season to reach pools of water or crab burrows containing water (FMNH 2008a).

This carnivorous fish feeds heavily on terrestrial and aquatic invertebrates when its habitat becomes flooded. The mangrove rivulus eats ants and flying insects as well as aquatic invertebrates such as polychaete worms, gastropods, mollusks, and mosquito larvae. The

mangrove rivulus has been observed jumping out of the water to capture termites, returning to the water to swallow its prey. It may also be cannibalistic, feeding on other mangrove rivulus, while living in crab burrows containing very limited food resources (FMNH 2008a).

Predators include other fish and wood storks, as well as possibly the Atlantic saltmarsh snake which is often found in crab burrows containing mangrove rivulus (FMNH 2008a).

The mangrove rivulus was designated a species of concern in Florida by NOAA in 1997. The species is extremely vulnerable to habitat modification and fragmentation, environmental alteration, and human development/encroachment (NMFS Nov 2007).

Smalltooth Sawfish

The federally endangered smalltooth sawfish has been observed in Biscayne Bay and the Biscayne Bay Aquatic Preserve (NMFS 2006). Although habitat destruction and overfishing have succeeded in eradicating the smalltooth sawfish from most of its former range, it survives in small pockets, notably in south Florida (FMNH 2008b). Loss of the mangrove habitat that juveniles rely on is cited as one of the primary reasons for listing the species as endangered (NMFS 2006). The U.S. distinct population segment of the smalltooth sawfish was listed as endangered by the NMFS in 2003 (FR Apr 2003), and is currently undergoing a 5-year review by the NMFS to ensure that the listing classification is accurate (FR May 2008).

This sawfish primarily occurs in estuarine and coastal habitats such as bays, lagoons, and rivers. It does at times occur in deeper waters, however, and may make crossings to offshore islands. It can tolerate freshwater. When foraging, the smalltooth sawfish swings its saw from side to side, impaling prey fishes on the rostral teeth. The sawfish then scrapes the captured prey off against the substrate and consumes it. The saw is also used to disturb muddy bottoms in search of small prey items, including benthic invertebrates such as crustaceans. Sawfishes are ovoviviparous, producing embryos that mature internally and are nourished by a yolk sac. Gestation is believed to last a year, with 15–20 pups born per litter (FMNH 2008b).

2.4.2.3.1.1 Diadromous Species

No anadromous fish exist in surface water on the Turkey Point plant property, and no major rivers flow into Biscayne Bay or Card Sound. True anadromous species in the south Atlantic Ocean (e.g., blueback herring, American shad, and striped bass) tend to spawn in major rivers flowing into the Atlantic Ocean further north; none of these rivers occurs much south of the St. Johns River in northern Florida (Nelson et al. Oct 1991). One migratory diadromous fish species, the American eel, is reported to occur in Biscayne Bay (Nelson et al. Oct 1991). Adults, juveniles and larvae are common in both low and high salinity portions of the bay (see Table 2.4-7). Because Biscayne Bay is not fed by any river, the eel does not use the bay to access inland waters, as is its habit in other estuaries.

The American eel occurs in rivers and streams along the east coast of the U.S. from Maine to Florida. It occurs throughout most of Florida in both fresh and brackish waters and in Atlantic and Gulf of Mexico drainages. The American eel is primarily riverine but does occur in ponds and lakes, especially oriented to structure and flow. Recent reports have raised concerns over the status of the American eel stock and have urged increased protection (FWC 2008a). In 1999, the South Atlantic Fisheries Management Council (SAFMC) developed a Fishery Management Plan for the American eel, which is an interstate cooperative effort to protect and enhance the Atlantic stock of American eel in the United States while providing for a sustainable harvest of the species. The Florida Fish and Wildlife Conservation Commission monitored young-of-year and adult yellow eels in northeast Florida waterways.

In response to a petition received in November 2004, the USFWS, on July 6, 2005, announced in a 90-day finding that it was initiating a status review to determine if listing the American eel was warranted (FR Jul 2005). The description of population status indicated that population declines have been most dramatic in Canada and New England and populations may be stable in the southeastern United States. On February 2, 2007, USFWS published its findings on a Petition to List the American Eel (FR Feb 2007). After a thorough review of all available scientific information, the USFWS found that listing the American eel as either threatened or endangered was not warranted.

2.4.2.3.2 Nuisance Species

Literature was surveyed for information on the presence of nuisance species on the Turkey Point plant property or in the vicinity of the property that could create biofouling problems in cooling water systems or cause “other significant problems.”

South Florida is host to a large variety of nonindigenous freshwater aquatic species, more than any other drainage in the state; fish, amphibians, reptiles, crustaceans, mollusks, and plants have been introduced, although not all have established reproducing populations (USGS 2008). The effects of many of the nonindigenous species have not been well documented (Courtenay 1997). However, some nonindigenous species are clearly known to cause economic or ecological harm. Among the known nuisance species in the vicinity of the Turkey Point plant property is the Asiatic clam (*Corbicula fluminea*) (USGS 2008).

The Asiatic clam is a problematic invasive mollusk from southeastern Asia. It is a small bivalve that is typically found at high densities and has a relatively high growth rate. Because of its tolerance of a wide variety of aquatic conditions and its high reproductive rate, it has developed into a pest that clogs ditches and interferes with pipes and heat exchangers of power plants. The Asiatic clam is primarily a freshwater species that tolerates, but does not thrive in, brackish water (Warren 1997). The Asiatic clam is well established in south Florida (USGS 2008). The Asiatic clam has not been recognized as a nuisance for the existing units.

2.4.2.4 Habitat Importance

Many marine fish and estuarine fishes that are federally managed by the SAFMC and NMFS rely on coastal bays during part of their lives. The Sustainable Fisheries Act of 1996, identifying the contribution of habitat loss and degradation on fishery declines, amended the Magnuson-Stevens Act to create a program to protect essential fish habitat. The statute defined essential fish habitat as “those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity” (Connolly 2002). A description of essential fish habitat is in 50 CFR 600.10 of the regulations implementing the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act; P.L. 104–297). The SAFMC and NMFS are responsible for designating essential fish habitat for each life stage of federally managed marine fish species.

In addition, the NMFS developed regulations (50 CFR Part 600 Subpart J; 62 FR 665531) to guide Fisheries Management Councils in the implementation of the essential fish habitat provisions. The essential fish habitat regulations encourage councils to identify habitat areas of particular concern within areas designated as essential fish habitat to focus conservation priorities on specific habitat areas that play a particularly important role in the life cycles of federally managed fish species. The intent of the NMFS in encouraging the designation of habitat areas of particular concern is to help focus conservation efforts on localized areas that are vulnerable to degradation or especially important ecologically. Habitat areas of particular concern should be subsets of the total area necessary to support healthy stocks of fish throughout all of their life stages. Healthy populations of fish require not only the relatively small habitats identified as habitat areas of particular concern, but also other suitable areas that provide habitat functions that support larger numbers of fish needed to support sustainable fisheries and a healthy ecosystem (NMFS 2001).

The SAFMC has designated portions of Biscayne Bay and Card Sound essential fish habitat for several groups of managed species, including snapper-grouper, coastal migratory pelagics, highly migratory species, penaeid shrimp, red drum, and spiny lobster. Each of these is addressed below.

2.4.2.4.1 Snapper-Grouper Fishery Management Plan

Ten families of fishes containing 73 species are managed under the snapper grouper plan (NMFS 2008a). As coastal inlets, all of Biscayne Bay and Card Sound meet the criteria for essential fish habitat and habitat areas of particular concern. Areas within the coastal inlets that are designated habitat areas of particular concern for species in the snapper-grouper management unit include near shore hard bottom areas, mangrove habitat, oyster/shell habitat, and seagrass habitat along the western edges of these water bodies (NMFS 2008b). During a 2-year study of recreational fishing in Biscayne Bay in the early 1980s, the gray or mangrove

snapper was the most important finfish species, by weight, harvested recreationally (Berkeley 1983).

As part of designating habitat areas of particular concern for the snapper-grouper management unit, NMFS provided a generalized profile of the gray snapper, which is presented below (NMFS 2008c). One of the most commonly caught marine fishes in Florida, the gray snapper exists in marine and estuarine waters from North Carolina and Bermuda through Brazil. Spawning activity occurs offshore and peaks during the summer and early fall. Eggs and larvae are planktonic and occur offshore. Flexion of the caudal fin occurs at 4.2 millimeters. Planktonic larval duration is estimated to range from at least 25 to 40 days, with a mean of 33 days post-fertilization based on otolith microstructure. Settlement sizes range from approximately 10 to 20 millimeters. Larvae appear competent to settle at ages from approximately 3 to 5 weeks. Maturity is reached at approximately 200 millimeters total length, probably during the third year. Gray snappers reach a maximum length of 720 millimeters and a maximum age of 10 years (NMFS 2008c).

In contrast to most snapper species, there is substantial literature on habitat use in juvenile stages of gray snapper, mostly from south or central Florida. Settlement stages and early juveniles primarily use grass beds before migrating to hard structures in deeper waters with growth.

Based on reviews of 40 years of surveys, and new sampling in the Biscayne Bay area, newly settled stages of gray snapper commonly existed in grass beds, were consistently absent from mangrove and hard bottom habitats, and were uncommon or rare from all habitats exceeding 5 meters deep. Early juvenile stages (2.5 to 7.0 centimeters) were more widely distributed, particularly on the habitat scale, existing among a variety of hard structures as well as mangroves and grass beds. The absence of newly settled life stages of gray snapper from hard bottom and mangrove habitats may result from the older resident fauna and more concentrated predation pressures in these habitats (NMFS 2008c).

In summary, early stages of gray snapper exist in estuaries and shallow marine areas. Bottom types of high value include seagrass flats (*Thalassia, Syringodium,* and *Halodule*); soft marl bottoms, fine marl mud with shell and rock outcrops; mangrove roots; hard bottom structures; and shallow basins with seagrasses adjacent to mud banks (NMFS 2008c).

2.4.2.4.2 Coastal Migratory Pelagic Fishery Management Plan

Areas designated as essential fish habitat for coastal migratory pelagic fishes in the vicinity of the Turkey Point plant property include nearshore hard bottom south of Cape Canaveral and Atlantic coast estuaries with high numbers of Spanish mackerel and cobia based on the Estuarine Living Marine Resources program abundance data (NMFS 2008d). According to the Fish and Wildlife Research Institute and SAFMC internet map service for displaying essential fish

habitat, only a small area of Biscayne Bay is considered essential fish habitat. No habitat areas of particular concern have been designated for this management group. The Estuarine Living Marine Resources data show that Spanish mackerel do exist in Biscayne Bay, but are not considered abundant (Table 2.4-7). During a 2-year study of fishing in Biscayne Bay in the early 1980s, low catches of Spanish mackerel were reported in Biscayne Bay (Berkeley 1983). Biscayne Bay is not included on the list of estuaries considered as essential fish habitat. A limited amount of habitat exists, but due to the pelagic nature of these species, their presence near Turkey Point is unlikely.

2.4.2.4.3 Penaeid Shrimp Fishery Management Plan

For penaeid (brown, white, and pink) shrimp, essential fish habitat in the vicinity of the Turkey Point plant property includes inshore estuarine nursery areas such as tidal freshwater, estuarine, and marine emergent wetlands; tidal palustrine forested areas; mangroves; tidal freshwater, estuarine, and marine submerged aquatic vegetation (e.g., seagrass); and subtidal and intertidal nonvegetated flats. This applies from North Carolina through the Florida Keys (NMFS 2008e). All of Biscayne Bay and Card Sound meet the criteria for essential fish habitat and habitat areas of particular concern for penaeid shrimp. The western vegetated edges of Lower Biscayne Bay and Card Sound are of particular importance.

Of the three species, only the pink shrimp is highly abundant in Biscayne Bay. The other two species are considered rare (Nelson et al. Oct 1991). In a 2-year survey of recreational fishing in Biscayne Bay conducted in the early 1980s, pink shrimp was the single most important species harvested (by weight) accounting for 29 percent of the total recreational harvest from Biscayne Bay (Berkeley 1983). Shrimp were most abundant at seagrass stations along the western side of the bay. In South Bay, they were most abundant during fall and winter, but in North Bay they were most abundant in summer (Berkeley 1983).

Offshore water also serves as habitat for larval and postlarval shrimp. These shrimp are planktonic and feed on zooplankton in the water column. Shrimp enter the inshore habitat as postlarvae and maintain a benthic existence (NMFS 2008e).

2.4.2.4.4 Red Drum Fishery Management Plan

For red drum, essential fish habitat includes all the following habitats to a depth of 50 meters offshore (FWC 2008b):

- Tidal freshwater
- Estuarine emergent vegetated wetlands (flooded salt marshes, brackish marsh, and tidal creeks)

- Estuarine scrub/shrub (mangrove fringe)
- Submerged rooted vascular plants (sea grasses)
- Oyster reefs and shell banks
- Unconsolidated bottom (soft sediments)
- Ocean high salinity surf zones
- Artificial reefs

The area covered includes Virginia through the Florida Keys.

The red drum is distributed along the Atlantic coast, in the ocean and estuarine areas in relation to their stage of maturity. Juvenile red drum use the shallow backwaters of estuaries as nursery areas and remain there until they move to deeper water portions of the estuary associated with river mouths, oyster bars, and front beaches. Estuarine wetlands are especially important to larval red drum. The types of estuarine systems vary along the Atlantic and subsequently, the preferred juvenile habitat also varies with distribution. Young red drum are found in quiet, shallow, protected waters with grassy or slightly muddy bottoms. Shallow bay bottoms or oyster reef substrates are preferred by subadult and adult red drum. Adult red drum use the oceanic system, which is the area of the Atlantic ocean from the beachfront seaward. Large red drum are thought to migrate along the Atlantic coast and are subjected to man's alterations of the natural system. Nearshore artificial reefs along the Atlantic are also known to attract red drum as they make their spring and fall migrations. In the fall and spring, red drum concentrate around inlets, shoals, capes, and from the surf zone to several miles offshore (FWC 2008b).

Areas that meet the criteria for essential fish habitat-habitat areas of particular concern for red drum include all coastal inlets, all state-designated nursery habitats of particular importance to red drum; documented sites of spawning aggregations described in the habitat plan; other spawning areas identified in the future; and habitats identified for submerged aquatic vegetation (FWC 2008b).

2.4.2.4.5 Spiny Lobster Fishery Management Plan

Essential fish habitat for spiny lobster includes (SAFMC 1998):

- Nearshore shelf/oceanic waters
- Shallow subtidal bottom
- Seagrass habitat

- Unconsolidated bottom (soft sediments)
- Coral and live/hard bottom habitat
- Sponges
- Algal communities (*Laurencia*)
- Mangrove habitat (prop roots)

Essential fish habitat-habitat areas of particular concern for spiny lobster include Florida Bay, Biscayne Bay, and Card Sound (SAFMC 1998).

Spiny lobster begin their existence in the Florida Keys as larvae that arrive on oceanic currents. As planktonic larvae, they pass through 11 life stages in more than 6 months. They then metamorphose into a transitional swimming stage that is found along Florida's southeast coast year-round. They travel through channels between the Keys and enter nursery areas in Florida Bay and the Gulf, where they preferentially settle into clumps of red alga. In 7 to 9 days, they metamorphose into juveniles and take a solitary residence in the algal clumps for 2 to 3 months. When juvenile spiny lobster reach a carapace length of 15 to 16 millimeters, they leave the algal clumps and reside individually within rocky holes, crevices, coral, and sponges. They remain solitary until carapace length reaches approximately 25 to 35 millimeters, when they begin congregating in rocky dens. They remain in these nurseries for 15 months to 3 years (NMFS 2008f).

Adult lobsters move to deeper waters in the coral reef environment, where they occupy dens or holes during daylight hours. They are nocturnal feeders and predominantly prey on mollusks and crustacea, including hermit crabs and conch. Adults move to the offshore reef to spawn, and larvae are swept up the east coast by the Florida current (NMFS 2008f).

In addition to providing essential fish habitat and habitat areas of particular concern for the federally managed species listed above, Biscayne Bay and Card Sound provide nursery and rearing habitat for other important estuarine species (listed in Table 2.4-7), as well as for non-harvested forage species that support the harvested species.

2.4.2.4.6 Highly Migratory Species (Sharks and Skates) Fishery Management Plan

In addition, NMFS is in the process of reviewing and updating essential fish habitat for highly migratory species, including sharks (NMFS 2008g). Essential fish habitat regulations call for a comprehensive review of all essential fish habitat information, and this amendment constitutes the comprehensive review and proposed update of essential fish habitat for all highly migratory species (HMS). New information on the biology, distribution, habitat requirements, life history

characteristics, migratory patterns, spawning, pupping, and nursery areas of Atlantic HMS were taken into consideration when updating essential fish habitat in this amendment. The proposed updated Fishery Management Plan designates coastal areas of Biscayne Bay and Card Sound as essential fish habitat for various life stages of sharks, including several large coastal sharks (three species of hammerhead shark (*Sphyrna zygaena, S. lewini, and S. mokarran*), nurse shark (*Ginglymostoma cirratum*), bull shark (*Carcharhinus leucas*), Caribbean reef shark (*C. perezi*), dusky shark (*C. obscurus*), lemon shark (*Negaprion brevirostris*), sandbar shark (*C. plumbeus*), silky shark (*C. falciformis*), spinner shark (*C. brevipinna*), and tiger shark (*Galeocerdo cuvier*) and one small coastal shark, the bonnethead (*Sphyrna tiburo*).

2.4.2.5 Preexisting Environmental Stresses

Much of the preexisting stress to habitats on the Turkey Point plant property and in the area immediately surrounding the property is the result of past development activity. The natural topography, soils, and hydrology of areas adjacent to the property have been altered as a result of the construction of existing units, the support facilities, and the industrial wastewater facility. Units 3 & 4 were constructed on mangrove-covered tidal flats. Natural surface water drainage features have been modified through road building and the industrial wastewater facility.

Mangrove heads along historical tidal creek channels within the surrounding mudflats have also been stressed by development as well as by natural causes. The historical tidal connections to Biscayne Bay were severed during construction of the industrial wastewater facility, which has resulted in hypersaline conditions, altered hydrology, and elevated temperatures. Whereas undisturbed tidal creeks of Biscayne Bay typically contain dense mangrove growth along the entire creek channel, the channels within the Units 6 & 7 plant area contain sparse pockets of mangroves, likely a result of stress caused by the hypersaline conditions and drastic fluctuations in water levels. Mangroves in the vicinity have not fully recovered in health or extent from a severe freeze in 1989 and Hurricane Andrew in 1992.

The industrial wastewater facility is not considered a natural habitat, and, therefore, some environmental stress is to be expected. The cooling canals of the industrial wastewater facility contain hypersaline water (approximately 40 to 50 ppt), shallow depths (approximately 3 feet), and maximum temperatures between 95°F to 100°F. The biotic community is restricted to those species that can survive under the limiting conditions of salinity, temperature, and depth. The predominant aquatic vegetation is widgeon grass and the dominant fish are forage fish. Predatory fish, including snook and tarpon, have been observed in the industrial wastewater facility, although the environmental conditions are not conducive to successful reproduction for these fish.

Within Biscayne Bay and Card Sound, preexisting stresses are more difficult to evaluate. Nearly all the nearshore habitat in these coastal waters is protected; however, anthropogenic effects are

still evident. Basins in southern Biscayne Bay, including Card Sound, have been the focus of much attention in recent times because of the persistent algal bloom that developed in this region during autumn 2005. An increase in green macro-algae in this region during the late 1990s and early part of this decade is notable, because it could indicate chronic nutrient enrichment that could have played some role in the current phytoplankton bloom (SFWMD & FDEP Mar 2008).

2.4.2.6 Reclaimed Water Pipelines Aquatic Resources

The reclaimed water pipeline corridor would extend approximately 9 miles between the SDWWTP and the FPL reclaimed water treatment facility. For about 6.5 miles of their length, the pipelines would be collocated with the existing Clear Sky-to-Davis transmission line right-of-way and adjacent road and canal rights-of-way. Land use includes wetland, marsh, and swamp habitats (Table 2.2-6) (Section 2.2). The pipelines would be generally underground. Aquatic invertebrates and fishes typical of the area exist in canals and wetlands crossed by this pipeline corridor; however, no areas designated by the USFWS as critical habitat for endangered or threatened aquatic invertebrate or fish species occur in Miami-Dade County**.**

2.4.2.7 Radial Collector Wells and Pipelines Aquatic Resources

Radial collector wells installed beneath Biscayne Bay would also provide an alternate source of makeup water for the new units. The four wells would be located within three acres of fill area on the northern edge of Turkey Point. Habitats adjacent to the filled lands include coastal mangroves and Biscayne Bay. The radial collector well laterals would be installed horizontally at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. Water would flow into the laterals and flow by head force to the collection caisson located onshore where the water would be pumped via one or more pipelines to Units 6 & 7. Pipelines would occupy land classified as streams and waterways/canals, mangrove swamps and fill area. Construction laydown areas would potentially impact approximately 3 acres of fill areas.

Construction of the radial collector wells would not affect aquatic resources in the vicinity. The only important aquatic species is the mangrove rivulus, a state and federal species of special concern (described in Subsection 2.4.2.3.1) that is associated with red mangrove communities. Red mangroves exist in the general vicinity of the construction area. Because this species is closely tied to the distribution of red mangrove, any activity that removes red mangrove could have a potential impact on this fish. However, construction of the radial collector wells would not impact red mangroves because the wells would be located within three acres of previously filled lands on the northern edge of Turkey Point. No presently undisturbed mangrove habitat would be affected by well construction. Areas of temporary mangrove impacts resulting from radial collector well delivery pipeline installation would be restored through replacement of excavated wetland soils to original grade, facilitating natural reestablishment of the vegetative community. Environmental best management practices would reduce the amount of erosion and

sedimentation associated with construction, and would limit impacts to aquatic communities in down-gradient water bodies. Because the well laterals would be drilled beneath Biscayne Bay, and surface water and sediment would not be disturbed, no increases in turbidity or sedimentation would result.

Benthic macroinvertebrates were sampled and seagrasses were surveyed from Biscayne Bay near the Turkey Point peninsula in March 2009. Sediment samples collected from 250 to 750 feet offshore in 3 feet of water were passed through a 0.5 mm sieve to collect macroinvertebrates. The majority of the 123 taxa identified from the Biscayne Bay samples were polychaetes and crustaceans. Abundance, species richness, and diversity were greatest at the station nearest to the shore.

Seagrasses were surveyed in approximately 49-hectares around the Turkey Point peninsula. Essentially the entire survey area was found to contain turtle grass or shoal grass. Turtle grass coverage was densest immediately surrounding the peninsula, but densities were variable. Shoal grass was less widespread, occurring most often in shallow waters along or near the peninsula shoreline. The two species often co-occurred, but shoal grass was absent at many sampling locations.

2.4.2.8 Aquatic Resources Along Transmission Corridors

Existing transmission lines generally pass through typical habitats associated with the coastal plain region of southeast Florida: wetlands, agricultural fields, pasture/rangeland, and residential/developed lands. A full listing of land uses within the transmission corridors can be found in Table 2.2-3. The proposed transmission lines extend from Clear Sky to Levee, Clear Sky to Pennsuco, Clear Sky to Miami (via Davis substation) through a variety of urban, agricultural, range, and wetlands habitats (see Figure 2.2-5).

Wetland land cover percentages along the 43-mile-long Clear Sky-to-Levee line are listed in Table 2.2-3. This line would cross the eastern expansion of the ENP (Figure 2.2-5). An alternative route is relocated eastward to run along the border of the ENP rather than through the park.

The Levee-to-Pennsuco corridor would cross a variety of land cover types (Table 2.2-3).

The approximately 19-mile-long Clear Sky-to-Davis line would be built within an existing corridor (Figure 2.2-5), the percentages of and types of wetland land classes are shown in Table 2.2-3. No towers would be built within water bodies. The lines would span the water bodies.

The approximately 18-mile-long Davis-to-Miami line would largely be built within an existing corridor (Figure 2.2-5), of which there are no wetlands present (Table 2.2-3).

The only special-status fish species in Miami-Dade County that potentially could occur along the proposed transmission corridors is the mangrove rivulus, although the corridors would not include ideal habitat (mangrove) for the fish. Other special-status species might exist in the aquatic and wetland habitats crossed by the proposed corridors.

2.4.2.9 Roadway Improvements

Wetlands and terrestrial habitats affected by the roadway improvements are described in Subsection 2.4.1. Aquatic habitats potentially affected by roadway improvements are described below.

Canals occur adjacent to the roadway right-of-ways associated with SW 344th Street/Palm Drive and SW 328th Street/N. Canal Drive. In-stream vegetation is minimal within the man-made canals adjacent to existing roadways, due to the steep slopes and minimal littoral zone. These canals provide habitat for common freshwater forage fishes native to south Florida, such as mosquitofish (*Gambusia holbrooki*), sailfin molly (*Poecilia latipinna*), least killifish (*Heterandria formosa*), sunfish (*Lepomis spp.*), and gar (*Lepisosteus spp.*). Nonindigenous fishes commonly inhabiting canals of Miami-Dade County include peacock bass (*Cichla ocellaris*), spotted tilapia (*Tilapia mariae*), blue tilapia (*Oreochromis aureus*), Mayan cichlid (*Cichlasoma urophthalmus*), jaguar guapote (*Cichlasoma managuense*), and oscar (*Astronotus ocellatus*).

Areas of mangroves occur adjacent to SW 359th Street near the L-31 Canal. These areas are dominated by a mixture of red mangrove (*Rhizophora mangle*) and black mangrove (*Avicennia germinans*), along with several other plant species.

(a) Habitat categories include: C — cooling canal area, F — facilities area, M — mangrove area[8], T — transmission corridor.
(b) Avian surveys within the Turkey Point plant property prior to the seasonal surveys:
FES: surveys of the canal area, mangrove areas (E of canals) in 1972–1973.
DERM: surveys of the plant area on August 29, 2007, by Miami–Dade County Dept. Environmental Resources Mgmt.
Surv1: surveys of the Units 6&7 and construction staging areas in November, 2007, and June, 2008.
Surv2: reconnaissance of the general facility, cooling canals, and transmission corridors in May 2008, and during other wildlife surveys in April 2009 (does not including the seasonal avian surveys).
(c) During the late winter 2009 avian surveys, species were classified by their relative abundance: A = abundant (> 50 individuals observed), C = common (10 — 50 observed), U = uncommon (< 10 observed).
(d) Florida burrowing owls were not observed during the surveys described in footnotes b and c. A single Florida burrowing owl was observed on October 18, 2010, on a dirt road in the southern portion of the industrial wastewater facility.

Table 2.4-2
Wildlife Observed on/near the Turkey Point Plant Property and Along the Existing/ Proposed Transmission Corridors

Common Name	Scientific Name	General Habitat[a]	Early Surveys[b]	April 2009 Surveys
Mammals				
Virginia opossum	*Didelphus virginiana*	M, T	—	Y
White-tailed deer	*Odocoileus virginiana*	M, T	—	Y
Rice rat	*Oryzomys palustris*	C, M	Y	—

Amphibians				
Florida cricket frog	*Acris gryllus dorsalis*	C, M	Y	—
Southern toad	*Bufo terrestris*	C, T	—	Y
Greenhouse frog	*Eleutherodactylus planirostris*	M	—	Y
Green tree frog	*Hyla cinerea*	C, M, T	Y	—
Little grass frog	*Hlya ocularis*	C, M, T	Y	—
Squirrel tree frog	*Hyla squirella*	C, M, T	Y	—
Florida chorus frog	*Pseudacris nigrita verrucosa*	C, M	Y	—
Bullfrog	*Rana catesbeiana*	C, M, T	Y	—
Southern leopard frog	*Rana utricularia*	M, T	—	Y

(a) General habitat categories: C = industrial wastewater facility (including proposed construction site); F = existing facilities (Units 1–5); M = mangrove swamp; and T = transmission corridors; and S = south of the industrial wastewater facility.
(b) Observation recorded in AEC 1972, and reconnaissance in 2003 and 2008.
(c) Observations recorded south of industrial wastewater facility in 2004, 2008, 2009, 2010, 2011; observations recorded along transmission corridor in 2011. Indigo snakes were not observed during the surveys described in footnote b.

Notes:
Mixing Zone = Waters with intermediate salinity, from nearly fresh to almost seawater
Seawater Zone = Waters with at least 25 ppt salinity
Common = Frequently encountered but not in large numbers; does not imply a uniform distribution throughout the salinity zone
Highly Abundant = Often encountered in substantial numbers relative to other species
Abundant = Numerically dominant relative to other species
Blank cell = Absent

2.5 SOCIOECONOMICS

This section describes the socioeconomic resources that have the potential to be impacted by the construction and operation of Units 6 & 7. This section is divided into four subsections: demography, community characteristics, historic properties, and environmental justice. These subsections include descriptions of spatial and temporal considerations, where appropriate. For purposes of socioeconomic analysis, regional socioeconomic data has been collected and analyzed to determine the appropriate socioeconomic region of influence (ROI).

In order to determine the counties that could potentially be impacted by the construction and operation of new Units 6 & 7, several characteristics of each county whose boundaries are at least partially within a 50-mile radius were reviewed. Those counties are Broward, Collier, Miami-Dade and Monroe. All of Miami-Dade County is within the 50-mile radius and the majority (64 percent) of Monroe County is within the 50-mile radius. A smaller portion, 37 percent, of Broward County and a very small portion, less than 3 percent, of Collier County lie within the 50-mile radius. For each of the four counties, several characteristics were examined:

- Percentage of current Turkey Point workforce that reside in the county
- Population size and density of the county
- Number of residents of the population center within the county and the center's driving distance from the Turkey Point plant property
- Mean travel time to work (in minutes) for the county
- Total employment for the county
- Construction employment for the county
- Worker commuting patterns of residents in the county

The population data in this section was updated to reflect the American Community Survey Estimates for 2005-2009. The population projections in Table 2.5-1 and FSAR Subsection 2.1.3, however, used the 2010 Census dataset in order to be consistent with the base population utilized by the Florida Office of Economic Development and Research for the state projected population growth between 2010 and 2030. The 2010 Census dataset was also used in FSAR Subsection 2.1.3 to calculate the same base growth rate multiplier as the state, so that the population projections would be consistent with those projected by the state through 2030.

Miami-Dade County

Miami-Dade County is the host county for new Units 6 & 7. In 2005-2009, Miami-Dade County had an estimated population of approximately 2.5 million (USCB 2010c). The County's 2000 population density of 1158 persons per square mile was approximately 15 times the national average of 80 and 4 times the average of Florida of 296 persons per square mile (USCB 2009c). The county's largest population center is Miami which had an estimated population of 418,480 in 2005-2009 (USCB 2010c). The Turkey Point plant property is located approximately 25 miles south of Miami. The driving distance from many other residential clusters in the county to Turkey Point is shorter, when compared to the driving distance from populated areas in other counties within the 50-mile region. In 2005-2009, the county's mean travel time to work was 29.9 minutes (USCB 2010a). More than 90 percent of Miami-Dade County residents who travel to work are employed within the county. Of workers employed at a site within the Miami-Dade County, 86 percent were residents of the county (Table 2.5-6). The majority, 83.3 percent, of the current Turkey Point workforce resides in Miami-Dade County (Table 2.5-3).

Miami-Dade County has a large construction workforce. In 2009, Miami-Dade County's total employment was 1,369,128. Of that total, construction employment was 64,702 (Table 2.5-8).

Miami-Dade County would be the major recipient of property tax revenues from new Units 6 & 7.

It was determined that because of the large population base, the large construction work force, the reasonable commuting distance, the established residence-to-work site commuting patterns in south Florida, and the propensity of workers that live in the county, Miami-Dade County could potentially experience socioeconomic impacts.

Broward County

Broward County is where 6.4 percent of the current Turkey Point workers reside (Table 2.5-3). The county's population center, Fort Lauderdale is outside the 50-mile radius. The mean commute time to work in the county was 26.9 minutes in 2005-2009 (USCB 2010a). The majority, 76 percent, of the working residents of Broward County who commute to a work site, travel to a site within Broward County; approximately 15 percent of Broward County residents who commute to work travel to a work site in Miami-Dade County. If the percentage of the new construction workers that choose to live in Broward County were similar to the percentage of current workers that call the county home (Table 2.5-3), the large 2005-2009 population base of the county, 1,759,132 (USCB 2010c), then the new workers and family members would represent less than 0.02 percent of the population. Given the small number of current Turkey Point workers residing in Broward County, the resident workers commuting patterns, and short mean commute time, Broward County is not included in the socioeconomic ROI for Units 6 & 7.

Monroe County

Monroe County contains the islands of the Florida Keys, a portion of the Everglades National Park, and the Big Cypress National Preserve. In 2005-2009, Monroe County had a population of 74,024 (USCB 2010c), 7.0 percent fewer residents than in 2000 (USCB 2009b). The county's largest population center, Key West, with a 2005-2009 population of 22,914 (USCB 2010c), is an estimated 128 driving miles from Turkey Point. In 2000, 95.4 percent of Monroe County residents who traveled to a work place, commuted to a work site within Monroe County. Less than 3 percent of the resident workers traveled to Miami-Dade County for employment. Less than 5 percent of the current Turkey Point work force resides in Monroe County (Table 2.5-3). Thus, Monroe County is not included in the socioeconomic ROI for Units 6 & 7.

Collier County

Only a very small portion of Collier County is within a 50-mile radius of Turkey Point. The county population center, Naples, is more than 100 miles from the site. Of the current employees of Turkey Point, only 1 employee lives in Collier County (Table 2.5-3). Thus, Collier County is not included in the socioeconomic ROI for Units 6 & 7.

Region of Interest

Based on this analysis, the socioeconomic ROI for Units 6 & 7 was determined to be Miami-Dade County. Miami-Dade County would be the only county likely to potentially experience socioeconomic impacts. However, to comply with NUREG 1555 in the description of certain resources in the 50-mile radius, a description of those resources in counties partially contained within the 50-mile radius of the Units 6 & 7 plant area was included where appropriate. Those counties are Broward, Collier, and Monroe.

2.5.1 DEMOGRAPHY

This subsection describes the following demographic characteristics: population data by sector, population data by political jurisdiction, and transient populations. Information specific to low-income and minority populations along with migrant populations is characterized in Subsection 2.5.4.

2.5.1.1 Population Data by Sector

The population surrounding the Turkey Point plant property, within 50 miles, was based on 2010 United States Census Bureau (USCB) decennial census data. The population was shown in 10 concentric rings at 0 to 1 mile, 1 to 2 miles, 2 to 3 miles, 3 to 4 miles, 4 to 5 miles, 5 to 10 miles, 10 to 20 miles, 20 to 30 miles, 30 to 40 miles, and 40 to 50 miles from the new units, and 16 directional sectors, each sector consisting of 22.5 degrees (Figure 2.5-2). The populations for

years 2020 through 2090 have been projected by calculating a growth rate using state population projections (by county) as the base in 10-year increments (Table 2.5-1). The growth rate was calculated using this exponential growth rate formula $P_2 = P_1 \times e^{(rxn)}$, where P_2 is the projected population, P_1 is the initial population, r is the growth rate and n is the number of years. This period covers the construction and operation through the first 40 years plus 20 years of license renewal for both units.

The resident population distribution within 10 miles and up to 50 miles was computed by overlaying the 2010 census block group point data on the grids shown in Figures 2.5-1 and 2.5-2 and summing the populations of the census block points in each sector/radius. Population projections to year 2030 were obtained from the Office of Economic and Demographic Research of the Florida Legislature and used to calculate an exponential growth rate for each county within 50 miles (EDR 2011). The growth rate for each county was then used to project future populations (within each sector and radius, taking into account the percent of each sector in a particular county). The population distributions (including transient population to the 10-mile radius) and related information were tabulated for all radial distances within each of the 16 sectors. The current population within 50 miles is that shown for the year 2010.

2.5.1.2 Population Data by Political Jurisdiction

Population data by political jurisdiction to facilitate analyses has also been included. The area defined by a 50-mile radius from the midpoint between the new units (Figure 2.5-2) includes all or portions of four counties in south Florida (Table 2.5-2 and Figure 2.5-2): Miami-Dade, Monroe, Broward and Collier. Miami-Dade County is entirely in the 50-mile radius. Most of Monroe County also lies within the area, while only a small portion of Broward County and Collier County are within 50 miles (Table 2.5-2).

The Turkey Point plant property is approximately 25 miles south of Miami, Florida, and 8 miles east of Florida City, Florida, and 9 miles southeast of Homestead, Florida. The Turkey Point plant property is located in an unincorporated portion of Miami-Dade County. The closest population centers are the cities of Homestead and Florida City (Figure 2.5-1). Homestead had a 2000 population of 31,909 (USCB 2008) and a 2005-2009 population estimate of 55,036 (USCB 2010c). Florida City had a 2000 population of 7843 (USCB 2008) and a 2005-2009 population estimate of 9808 (USCB 2010c). The Homestead and Florida City area is also the residence of the largest concentration of current Turkey Point employees. Table 2.5-3 presents the residential distribution patterns of the current Turkey Point employees.

The 50-mile vicinity includes a major portion of the Miami-Fort Lauderdale-Pompano Beach, Florida Metropolitan Statistical Area; portions of the Naples-Marco Island, Florida Metropolitan Statistical Area; and portions of the Key West, Florida Micropolitan Statistical Area.

- The Miami-Fort Lauderdale-Pompano Beach, Florida, Metropolitan Statistical Area had a 2000 population of 5,007,992. From 2000 to 2005-2009, the population grew 9.5 percent. The 2005-2009 population estimate was 5,484,777.

- The Naples-Marco Island, Florida, Metropolitan Statistical Area had a 2000 population of 251,377. From 2000 to 2005-2009, the population grew 24.6 percent. The 2005-2009 population estimate was 313,165.

- The Key West, Florida, Micropolitan Statistical Area had a 2000 population of 79,589. From 2000 to 2005-2009, the population decreased 7.0 percent. The 2005-2009 population estimate was 74,024 (USCB 2010c).

The Naples-Marco Island, Florida, Metropolitan Statistical Area shares the same boundary as Collier County, Florida, and the Key West-Marathon, Florida, Micropolitan Statistical Area shares the same boundary as Monroe County, Florida.

Table 2.5-4 presents historical and projected population and growth rate data for the ROI (Miami-Dade County). For the purpose of comparison, population data for Florida is included in this table. From 1990 to 2000, the population of the ROI grew at an average annual rate of 1.53 percent. For the same period, Florida population grew at an average annual rate of 2.14 percent.

The population projections were completed using four extrapolation techniques and three different historical base periods. The four techniques were:

- Linear – the population changes by the same number of persons in each future year as the average annual change during the base period.

- Exponential – the population changes at the same percentage rate in each future year as the average annual rate during the base period.

- Share of growth – each county's share of state population growth in the future is the same as its share during the base period.

- Shift share – each county's share of the state population changes by the same annual amount in the future as the average annual change during the base period.

For the linear and share-of-growth techniques, base periods of five, ten, and fifteen years were used, yielding three sets of projections for each technique. For the exponential and shift-share techniques, a single base period of ten years was used, yielding one set of projections for each technique.

The starting point for each county's projection was the population estimate produced by the Bureau of Economic and Business Research for April 1, 2006. These estimates are based on 2000 Census counts and a variety of data and techniques showing population changes since 2000. The techniques described above provided eight projections for each county for each projection year (2010, 2015, 2020, 2025, and 2030). In order to moderate the effects of extreme projections, the highest and lowest projections for each county were excluded. The medium projection was then calculated by taking an average of the six remaining projections and adjusting the sum of the county projections to be consistent with the total population change implied by the state projections for each projection interval.

Between 2010 and 2030, the latest year for which data is provided, the average annual growth rates of the ROI and Florida are projected to slow. By 2030, the ROI is projected to slow to 0.81 percent annual growth rate (Table 2.5-4).

Florida has experienced a boom-bust economy over the last decade. From 2000 to 2006, a healthy national economy, strong state-wide real estate markets, and accelerating construction fueled Florida's population growth. Florida's population has increased at an average of about 340,000 people per year. (USCB 2009b)

In 2007, the national housing market and economy began to decline. In Florida, the phenomenon was magnified. As a result, there was a slowing in the population growth to about 149,800 persons per year from 2006 to 2009 (USCB 2009b). However, projections indicate that Florida's population is expected to return to more moderate growth levels of about 252,500 persons per year from 2010 to 2020 and about 255,100 persons per year from 2020 to 2030 (Table 2.5-4).

Table 2.5-5 lists the age distributions of the populations in the ROI, in 2005–2009, and compares them to the age distribution of the population in Florida.

2.5.1.3 Transient Populations

Regulatory Guide 4.7, Section C.4 defines transient populations as people (other than those just passing through the area) who work, reside part-time, or engage in recreational activities in a given area, but are not permanent residents of the area.[1] Under this definition, transients include people in:

- Workplaces
- Places where people reside part-time, such as hotels and motels and seasonal housing

1. People living in institutional settings such as correctional institutions and nursing homes, and noninstitutional settings such as college dormitories and military quarters are considered, by the USCB, as permanent residents and are included in the decennial census.

- Recreational areas or at special events

Transient information is presented in two formats: quantitatively within the 0- to 10-mile radius and qualitatively within the 10- to 50-mile radius. The transient population within 10 miles was estimated to be 40,521 based on major employers, overnight accommodations including hotels, motels, and seasonal housing, and major recreational areas and marinas.

These transient populations are included in Table 2.5-1 for values within the 0–10 mile radius. Transients within the 10- to 50-mile radius are not included in Table 2.5-1 because of a large amount of uncertainty associated with quantifying the transient population to 50 miles. This is because the 50-mile radius encompasses all or portions of four south Florida counties and all or portions of two major metropolitan areas that are popular vacation destinations for both U.S. and international tourists. Because of this uncertainty, the transient population was not keyed to sectors or projected for future years. However, a qualitative description is presented in this section and throughout Section 2.5.

A method for determining the number of transient workers entering an area is to analyze worker flows in and out of counties. The USCB tracks this data. Table 2.5-6 identifies the number of workers that traveled to a work site in Miami-Dade County for work in 2000. (More current inter-county work flows are not available from the USCB.) ROI transients include workers who reside outside the ROI, but traveled to a worksite in the ROI. According to the data in Table 2.5-6, 116,562 workers commuted from an area outside the ROI to a worksite in the ROI for work in 2000. Migrant populations are addressed in Subsection 2.5.4.2.

Within Miami-Dade County, in late 2011, there were approximately 361 hotels and motels with about 47,642 rooms (Table 2.5-35). Because of the seasonal variation in the number of visitors, the occupancy rates vary. In 2010, there were 38,302 vacant housing units in the ROI that were designated as seasonal, recreational, or occasional use (USCB 2010d). Housing in the ROI is reviewed in detail in Subsection 2.5.2.6.

Recreational facilities and special events in the 50-mile radius, which may affect the number of transients, are addressed in Subsection 2.5.2.5.

2.5.1.4 Turkey Point Units 3 & 4 Workforce

As reported in Section 5.11, currently there are 977 operation workers that support the operation of Units 1 through 5. Also, Units 3 & 4 are both on 18-month refueling cycles and, during each refueling event, an additional 600–1000 outage workers join the current operation workforce for a period of 25 to 35 days.

2.5.2 COMMUNITY CHARACTERISTICS

Units 6 & 7 would be located on the Turkey Point plant property, adjacent to Units 3 & 4. The Turkey Point plant property is located in Miami-Dade County, Florida, south of the city of Miami on the Atlantic coast. Based on an analysis of the residence location of current Turkey Point workers, regional demographics and labor markets, and intercounty worker commuting patterns, it has been determined that the construction and operation of the new units has the potential to impact socioeconomic variables (employment, population, income, housing, infrastructure, and community services) in only one county, Miami-Dade County. Therefore, that county is considered as the socioeconomic ROI. This section addresses the following community characteristics for the Miami-Dade County: economy, transportation taxes, land use, aesthetics and recreation, housing, public services, community infrastructure, and education. The aesthetics and recreation section contains data for the 50-mile radius because most of potential socioeconomic impacts to this resource may be experienced within that area.

2.5.2.1 Economy

Miami-Dade County is a consolidated government that includes the city of Miami. As noted in Subsection 2.5.1.2, Miami-Dade County is part of the Miami-Fort Lauderdale-Pompano Beach, Florida Metropolitan Statistical Area, which also includes Broward and Palm Beach Counties to the north. Miami-Dade County alone comprises of the Miami-Miami Beach-Kendall Metropolitan Division within the larger MSA (OMB Nov 2008). Principal cities in Miami-Dade County include Miami, Hialeah, Miami Beach, North Miami, Coral Gables, and Homestead. Another population center near Turkey Point is Florida City. Key Largo, located on the Florida Keys in Monroe County, is approximately 30 miles south of Florida City along U.S. Highway 1.

Miami-Dade County includes highly urbanized and suburban areas surrounding the city of Miami along the Atlantic Coast, rural agricultural areas further south, and the Everglades areas, including Everglades National Park, in the western half of the county. Near Turkey Point, the non-wetland area centered around the Homestead and Florida City area is primarily agricultural. The region's tropical climate allows the winter production of green beans, tomatoes, strawberries, and squash for distribution throughout the United States, as well as year-round production of tropical fruits and vegetables such as avocados, passion fruit, malanga, and boniato. Another sector of the industry is Asian specialties such as Thai guava, Thai basil, Thai eggplant, lemon grass, bitter melon and various herbs and spices (MDCAM 2008).

Table 2.5-7 details labor force, employment, and unemployment trends in Miami-Dade County from 2001 to 2011, as reported by the U.S. Bureau of Labor Statistics (BLS). In 2011, the Miami-Dade County labor force totaled 1.3 million people, representing 14.1 percent of the total Florida labor force. The Miami-Dade County labor force grew at an average annual rate of approximately 1.7 percent between 2001 and 2010. The population increased during that period

by an average annual rate of 1.0 percent, suggesting that a substantial portion of the population increase is from persons outside of the working age (i.e., children and the elderly or retired), and perhaps that there is a lower labor participation rate among those within the working age group (e.g., mothers staying at home rather than joining the work force). The size of the state's labor force was essentially flat over the same period, reflecting faster growth in other Florida counties than in Miami-Dade County. In 2011, 156,562 people in Miami-Dade County were unemployed. The 2011 average annual unemployment rate in the Miami-Dade County was 12.0 percent, compared to 10.6 percent for Florida and 8.9 percent for the United States (BLS 2012a). BLS data about the economy, including labor force information and unemployment rates, is not available for geographical areas smaller than the county level.

The U.S. Bureau of Economic Analysis (BEA) reports employment data broken out by industrial sector (as defined by the North American Industrial Classification System, or NAICS). The latest year for which BEA's data is published is 2009. As of 2009 in Miami-Dade County, in the nonfarm employment category, the services sector was the largest source of employment, accounting for 48.7 percent of jobs, slightly higher than Florida. The retail sector accounted for 9.9 percent of jobs, while the finance, insurance, and real estate sector provided 9.7 percent of the jobs, and local government provided 8.4 percent of jobs in Miami-Dade County. Construction provided 4.7 percent of the positions. These trends are fairly typical for a diversified urban economy. Table 2.5-8 summarizes employment by industry sectors for Miami-Dade County and Florida, while Figures 2.5-3 and 2.5-4 illustrate employment by industry sector in Miami-Dade County and in Florida, respectively.

Total employment in Miami-Dade County grew by an average of 0.5 percent annually between 2001 and 2009, with the highest absolute (number of new jobs) employment growth in health care and social assistance, 38,501 jobs; other services, except public administration, 22,557 jobs; and real estate and rental and leasing, 16,075 jobs. These trends reflect a period of higher-than-average home building and other growth in certain parts of Florida and in Miami-Dade County. This situation resulted in part from Florida's climate amenities and increased attraction for retirees, and in part from the increased availability of home mortgages to a wider segment of the population. These trends were prevalent over the past several years, and have only recently halted due to the recent economic downturn. Sectors experiencing declining employment were led by manufacturing with a loss of 22,465 jobs; positions in information services which declined by 13,709; and administrative and waste management services which lost 6962 jobs. During the same period, Florida's employment grew by an annual average rate of 1.0 percent, led by healthcare and social assistance, real estate and rental and leasing, and finance and insurance. Table 2.5-9 presents detailed employment trends by industry sector for Miami-Dade County and Florida.

Table 2.5-10 lists the Miami-Dade County major employers by the number of employees. The five largest public employers are Miami-Dade Schools, Miami-Dade County government, the federal

government, Florida state government, and Jackson Health System, while the five largest private employers are the University of Miami, Baptist Health South Florida, Publix Super Markets (a grocery chain), American Airlines, and Precision Response Corporation (marketing services).

In its Quarterly Census of Employment and Wages, the BLS collects employment and wage data by industrial sectors; the information is classified by the nature of a firm's business or an organization's activities. The year 2010 is the latest year for which final data is available. Table 2.5-11 presents employment trends for 2001 to 2010 for total workers in all nongovernment industry sectors, construction, heavy and civil engineering construction, utilities, and nuclear electric power generation. (Note that utilities data were not disclosed for 2001 for Miami-Dade County, and nuclear electric power generation data were not disclosed for any years for Florida or Miami-Dade County.[1])

Table 2.5-11 shows that construction employment dropped at similar rates nationally, in Florida, and in Miami-Dade County. This employment contraction also occurred, to a generally lesser degree, in the specialized heavy and civil engineering construction sector. Florida lost 3.0 percent of the jobs in the field, while Miami-Dade County fared better, losing only 0.3 percent of the positions. Employment in the utilities sector also declined during this period. Although employment data were not disclosed for either Florida or Miami-Dade County for the nuclear electrical power generation sector, national employment in the industry grew at a very modest 1.7 percent during the decade.

Table 2.5-12 shows average annual wage (not adjusted for inflation) trends from 2001 to 2010 for the same industrial sectors described above. Although employment dropped in all industrial sectors, in construction and in heavy and civil engineering construction nationally, in Florida and in Miami-Dade County, average annual wages rose about 3 percent in all industrial sectors, construction, heavy and civil engineering construction, and utilities in all three geographical areas. Average annual wages also rose in the study period at a faster rate in the nuclear electrical power generation field than the other analyzed sectors. Figure 2.5-5 compares wage trends in heavy and civil engineering construction for Miami-Dade County, the state of Florida, and the United States.

The Florida Agency for Workforce Innovation (FAWI) collects data by industrial sector and occupational category, and has projected employment levels for 2019 for each category. Table 2.5-13 shows 2011 employment totals for all industries in the construction sector, to include the heavy and civil engineering construction sectors and construction occupational categories. It

1. Area data may not be disclosed when data does not meet BLS or state agency disclosure standards regarding confidentiality or data quality (BLS 2012c). For example, if there are few firms in an area, data users could determine or approximate a firm's total payroll, hours worked, and other information that a firm may not want known to its competitors.

also reflects projected employment for 2019, the anticipated average annual change, and average hourly wages (for the occupational categories only). The table shows that the state has projected very slow growth in these sectors and occupations.

Per capita personal income provides a useful income comparison among regions. The BEA calculates per capita personal income by dividing the total personal income in an area by the area's population. In 2009 (the latest year for which the BEA provides data), the per capita personal income in Florida was $38,965, $670 less than the per capita personal income for the United States. The per capita personal income in Miami-Dade County in 2009 was $36,357, which represented 91.7 percent of the United States and 93.3 percent of Florida per capita personal income. As shown in Table 2.5-14, per capita personal income in Miami-Dade County grew by an average annual rate of 3.8 percent between 2001 and 2009 (not adjusted for inflation), showing stronger growth than Florida (3.4 percent) and the United States (3.1 percent) (BEA 2011b). Figure 2.5-6 illustrates income trends in Miami-Dade County, the state of Florida, and the United States.

2.5.2.2 Transportation

Miami-Dade County has an extensive roadway infrastructure including U.S. and interstate highways, multilane divided state highways, and local streets. The County operates public transportation services including rail, and express and local bus. Rail freight service in Miami-Dade County is provided by CSX. Rail passenger service is provided by Amtrak and TRI Rail. The County has public airports, heliports, and a seaplane base; a seaport for commercial freight and passenger service; and an intermodal transportation hub for air, rail, and ship. The County is also served by private airstrips, heliports (including the FPL corporate and Turkey Point heliports), and seaplane bases. The following subsections describe the transportation infrastructure.

2.5.2.2.1 Roads and Highways

The major federal highways in Miami-Dade County are U.S. Highway 1, which bisects the county from north to south and continues to the Florida Keys, and Interstates 75 and 95, which run north-south and terminate in Miami. These U.S. highways and interstates are shown on Figure 2.5-7.

Two major state highways in the County are Florida's Turnpike and SR 997. Florida's Turnpike is a multilane divided toll road that connects Interstate 75 in Central Florida to U.S. Highway 1 at Homestead/ Florida City. SR 997 (also known as Krome Avenue) runs from the Homestead area to its intersection with U.S. Highway 27 just south of the Broward County/ Miami-Dade County line, skirting the western Miami metropolitan area. These highways are shown on Figures 2.5-7 and 2.5-8a.

The existing access road for Turkey Point is SW 344th Street/Palm Drive, which runs east-west. Workers from the west, northwest, north and south can access the west end of Palm Drive from U.S. Highway 1, Krome Avenue or Florida's Turnpike. Workers from the north can also access Palm Drive by traveling south on SW 137th Avenue/Tallahassee Road or SW 117th Avenue, a street east of Tallahassee Road.

SW 328th Street/North Canal Drive runs east-west several blocks north of Palm Drive, and also can be accessed from Krome Avenue, U.S. Highway 1 or Florida's Turnpike. North Canal Drive intersects with Tallahassee Road, north of Tallahassee Road's intersection with Palm Drive, and therefore provides an alternative access to Turkey Point from the west for part of the commute. Tallahassee Road, North Canal Drive and Palm Drive are 4-lane roads for at least part of their distances and are classified as rural major collectors (Table 2.5-15), designed for travel at lower speeds and shorter distances than arterials which provide the highest level of speed and mobility. Florida considers rural major collectors to be any road that connects major or minor thoroughfares, or connects a major thoroughfare with a concentrated land use (FDOT 2003).

Both the Florida Department of Transportation and Miami-Dade County monitor traffic in the Homestead/ Florida City area, mostly at intersections of the major highways with major surface streets (Figure 2.5-8a and Tables 2.5-16 and 2.5-17). The major roads support much greater traffic volumes than local streets. Average traffic counts do not provide information on the range of traffic volumes. When analyzing traffic in Florida, consideration must be given to the seasonality of many residents. The Bureau of Economic and Business Research, Warrington College of Business Administration, University of Florida has compiled a series of research papers on the impact of seasonal residents to Florida (Galvez, 1997). Florida has approximately 1 million seasonal residents in January and approximately 170,000 in late summer (Nova Southeastern University 2009). Forty-one percent of the seasonal residents can be found in the southwest counties and 35 percent in the 10 southeastern counties, including Miami-Dade (Galvez, 1997).

Evacuation Routes

The severe weather evacuation routes in the Homestead and Florida City area are U.S. Highway 1, Florida's Turnpike, SR 997, and Card Sound Road (FDEM 2007). These routes are shown on Figure 2.5-8a.

Special Events Affecting Local Traffic

In addition to seasonal population fluxes, the level of traffic on the local roads described above would be impacted by events at the Homestead Miami Speedway. The Speedway operates 280 days a year, and hosts events sponsored by all six of America's premier motorsport championships. Many of its activities are not national events, such as Porsche/BMW Owners

Club meetings, SCCA Drivers School, VanEpps Teen Driving programs, and amateur formula, automobile and motorcycle races. The track has parking for 30,000 cars and 1300 RVs. The speedway lies at the intersection of SW 344th Street/Palm Drive and SW 137th Avenue/ Tallahassee Road. See Subsections 2.2.1.2 and 2.5.2.5 for additional details on this venue.

2.5.2.2.2 Public Transportation

Miami-Dade County operates public transportation services including rail, express bus, and local buses with multiple stops. The rail service has 22 stations and serves Miami. There are approximately 100 bus routes that serve a larger area. Bus routes that serve Homestead and Florida City are local with multiple stops, and express buses that link the area with Miami that have only a few stops. Buses use exclusive highway lanes called the busway, which ensures that they are not slowed by traffic congestion. The express route terminates at SW 344th Street/Palm Drive. The originating station (Dadeland South) has 1260 parking spaces (MDC 2009), and there are five “Park & Ride” parking lots located along the express route at SW 152th, SW 168th, SW 200th, SW 244th, and SW 296th Streets. Plans are being developed for a future Park & Ride lot at SW 344th Street/Palm Drive. (MDC 2008a)

In addition to this public bus transportation infrastructure, the TRI-Rail commuter train provides service to Miami International Airport and Fort Lauderdale/Hollywood International Airport. Connecting bus services to the portions of Miami-Dade County served by bus routes are available from TRI-Rail stations. (SFRTA 2008)

Miami-Dade County is constructing a ground transportation hub next to Miami International Airport—the Miami Intermodal Center. The anticipated opening date is 2011. Miami Central Station is to be one of the major facilities within the Miami Intermodal Center. Miami Central Station is to be situated between NW 25th Street on the north, NW 37th Avenue on the east, NW 21st Street on the south, and NW 38th Court on the west. The facility is designed to accommodate various transportation connections, thereby providing connectivity between various modes of transportation. The facility will feature grade level tracks for TRI-Rail, Metrorail, and Amtrak rail service. Bus depots will be provided for Greyhound, Miami-Dade Metrobus, and intra-city buses. Space will be provided for courtesy buses, shuttles, and taxis currently serving Miami International Airport. (FDOT 2008a)

2.5.2.2.3 Rail Service

Rail passenger service is provided to Miami by Amtrak and TRI-Rail; both have service to connecting rail lines across the United States (Amtrak 2008, SFRTA 2008). Neither rail service travels to locations south of Miami.

Rail freight service in Miami-Dade County is provided by CSX operating Class 1 rail lines (FDOT 2006). The CSX line services the Port of Miami and has an intermodal terminal in Miami

(CSX 2008). The rail line is shown in Figure 2.5-7. The rail line terminates in Homestead. The nearest rail crossing to Turkey Point is at SW 320th Street and is approximately 11 roadway miles to the plant entrance.

2.5.2.2.4 Air Transportation

Miami-Dade County has air transportation infrastructure including airports, airstrips, heliports, and a seaplane base.

The county operates five airports: Miami International, a major commercial airport in Miami, Kendall-Tamiami Executive Airport in Kendall, Dade-Collier Training and Transition Airport in Collier and Miami-Dade County. Also operated by the county are Opa-Locka Airport and Homestead General Aviation Airport (Miami-Dade Aviation Department 2008). Homestead is also host to the Homestead Air Reserve Base (U.S. Air Force 2008), which is the closest airport to Turkey Point. Another major commercial airport is located within 50 miles of Turkey Point in Broward County, the Fort Lauderdale/Hollywood International Airport. Also within 50 miles is Broward County's North Perry Airport. The location of these airports is shown in Figure 2.5-7. In addition, the county has several private airstrips including Burr's Airstrip 16 miles southwest of Miami and Lindbergh's Landing Airstrip 20 southwest of Miami (FDOT 2008b).

Miami-Dade has many privately owned heliports, including the FPL Helistop and the FPL Turkey Point Heliport (FDOT 2008b).

Rounding out the variety of air transportation infrastructure in Miami-Dade County is the Miami Seaplane Base. The facility lies on Watson Island near the southern tip of the Miami Beach peninsula (CFASPP 2007).

2.5.2.2.5 Deep Sea Ports

Deep sea ports are located in Miami-Dade County and the adjacent counties of Broward County to the north and Monroe County to the southwest. The Port of Miami is in Miami and is shown on Figure 2.5-7. The Port of Key West is in Key West in Monroe County and Port Everglades is in Fort Lauderdale in Broward County (FDOT 2008e). The Port of Miami offers passenger and freight services (MDC 2008b).

2.5.2.2.6 Atlantic Intracoastal Waterway

The Atlantic Intracoastal Waterway traverses the eastern coastline of Florida and intersects with the Port of Miami, as shown on Figure 2.5-7. The existing equipment barge unloading area at Turkey Point is accessed via the waterway to receive shipments of oil and equipment.

2.5.2.3 Taxes

Several tax revenue categories would be affected by the construction and operation of Units 6 & 7. These include corporate taxes on company profits, sales and use taxes on construction- and operations-related purchases and on the purchases made by project-related workers; property taxes related to the construction and operation of the units; and property taxes paid by incoming workers. The following subsections describe each type of tax and its application in the ROI (Miami-Dade County) and the state of Florida, and presents revenues and expenditures by category for local jurisdictions.

As shown in Table 2.5-18, the state of Florida's general revenues were $25.5 billion in 2011, while total tax revenues were $32.4 billion. Figure 2.5-9 illustrates Florida's revenues by source.

2.5.2.3.1 Personal and Corporate Income Taxes

Florida does not have a personal income tax (FDOR 2012d).

Corporations and artificial entities that conduct business, or earn or receive income in Florida, including out-of-state corporations, must file a Florida corporate income tax return unless specifically exempt. According to the Florida Department of Revenue web site, Florida's corporate income tax liability is computed using federal taxable income, modified by certain Florida adjustments, to determine adjusted federal income. A corporation doing business both within and outside of Florida may apportion its total income to Florida using a three-factor formula, which is a weighted average, designating 25 percent each to factors for property and payroll, and 50 percent to sales. Nonbusiness income allocated to Florida is added to the Florida portion of adjusted federal income. An exemption of $50,000, for tax years beginning on or after 1/1/2013, is subtracted to arrive at Florida net income, which is multiplied by 5.5 percent to compute the tax (FDOR 2012b).

Florida Statute §220.131 allows certain affiliated groups of corporations to elect to participate in the filing of a consolidated corporate income tax return. FPL is part of an affiliated group of corporations that has made this election. Under a consolidated Florida corporate income tax return the federal taxable income of the combined group is the same as the federal taxable income included in the affiliated groups consolidated federal tax return. The Florida adjustments, apportionment factor, and nonbusiness income allocations are all made on a consolidated basis and one exemption is available to the consolidated group. The resulting Florida net income is then multiplied by 5.5 percent to compute the tax.

In 2011[1], corporate income and excise tax accounted for 5.8 percent of the state's total tax revenues (Table 2.5-18).

2.5.2.3.2 Sales and Use Taxes

Florida imposes a state sales tax of 6 percent on the sale or rental of tangible personal property, certain services, admissions, and the rental or lease of real property and transient living accommodations. In addition, Florida law allows counties to levy discretionary sales surtaxes for various purposes, such as transit systems, infrastructure, indigent care, or health services. The eligibility for imposing a surtax differs by the type of tax. The authorized amounts also vary, but range from 0.5 to 1.5 percent. Generally, only the first $5000 of a single purchase is subject to the discretionary tax. Counties may also impose local option taxes on fuel, food and beverages, and tourism-related items (FDOR 2012d). Miami-Dade County imposes a 1 percent discretionary sales surtax in addition to the state sales tax (FDOR 2012a).

A dealer who sells and delivers taxable merchandise or taxable services is required to collect the surtax at the rate imposed in the county where the merchandise or service is delivered. For motor vehicle and mobile home sales, the applicable surtax rate is for the county where the vehicle or mobile home will be registered. Only the first $5000 of a single sale of tangible personal property is subject to discretionary sales surtax if the property is sold as a single item, in bulk, as a working unit, or as part of a working unit. The $5000 limit does not apply to commercial rentals, transient rentals, or services (FDOR 2012d).

Florida also imposes a 6 percent tax on out-of-state purchases imported into the state. The tax applies to all items purchased outside of Florida that would have been subject to tax if purchased in the state. Examples of such taxable purchases include purchases made by mail order, furniture delivered from dealers located in another state, and computer equipment delivered by common carrier. Items purchased and used in another state for at least 6 months before being brought into Florida are not subject to the tax. Additionally, Florida allows a credit for a lawfully imposed sales tax paid in another state (FDOR 2012d).

General grocery items are exempt from sales tax. This exemption does not apply to candies, soft drinks, alcoholic or malt beverages, food or drinks prepared on the sellers' premises and sold for immediate consumption, or food or drink sold by restaurants, hotels, amusement parks, racetracks, taverns, stadiums, theaters, or similar places of business. Prescription and common household medicines, prosthetic and orthopedic devices, hearing aids, eyeglasses, and dentures are examples of other items also exempt from sales tax (FDOR 2012f).

---

1. State and county fiscal years begin on July 1 and end on June 30. By convention, the fiscal year is referred to by the ending year, i.e., FY 2010-2011, or simply 2011.

In 2011, sales and use taxes accounted for 59.8 percent of Florida's tax revenues (Table 2.5-18).

2.5.2.3.3 Other Taxes on Sales and Services

Communications Services Tax

In 2001, Florida restructured taxes on telecommunications, cable, direct-to-home satellite, and related services. The law replaced and consolidated several different state and local taxes with a single tax comprised of two parts: the Florida communications services tax and the local communications services tax. Communications services include telecommunications, cable, direct-to-home satellite, and related services. This definition includes voice, data, audio, video, or any other information or signals, including cable services, transmitted by any medium. (FDOR 2012c)

The Florida Department of Revenue's web site provides some examples of services subject to the tax: local, long-distance, and toll telephone; cable television; direct-to-home satellite; mobile communications, including detailed billing charges, private line services, pager, and beeper services; telephone charges made by a hotel or motel; facsimiles, when not provided in the course of professional or advertising service; and telex, telegram, and teletype services. Governments, religious institutions, and certain nonprofit organizations are exempt from this tax. Residential telephone service is exempt from the state portion of the communications services tax. This service is subject to the state gross receipts and local portions of the tax. Mobile telephone, cable, and direct-to-home satellite services are fully taxable, even if provided to a residence (FDOR 2012c).

In 2011, communications services taxes accounted for 7.1 percent of the state's tax revenues (Table 2.5-18).

Documentary Stamp Tax

Florida levies a documentary stamp tax on deeds, bonds, notes, written obligations to pay money, mortgages, liens, and other evidences of indebtedness. According to the FDOR web site, the tax rate for documents that transfer an interest in real property is $0.70 per $100 (or portion thereof) of the total consideration paid, or to be paid, for the transfer. An exception is Miami-Dade County, where the rate is $0.60 per $100 (or portion thereof) when the property is a single-family residence. If the Miami-Dade property is anything other than a single-family residence, the tax rate is $0.60 plus $0.45 surtax per $100 (or portion thereof) (FDOR 2012e).

Examples of documents that may transfer interest in real property include:

- Warranty deeds

- Quit claim deeds
- Contracts for timber, gas, oil, or mineral rights
- Easements
- Contracts or agreements for deed
- Assignments of contract or agreement for deed
- Assignments of leasehold interest
- Assignments of beneficial interest in a trust
- Deeds in lieu of foreclosure

“Consideration” generally consists of:

- Money paid or to be paid
- Discharge of an obligation, mortgage or other lien encumbering the property
- Exchange of property
- Any other monetary consideration or consideration that has value.

In 2011, the documentary stamp tax accounted for 3.6 percent of the state’s tax revenues (Table 2.5-18).

2.5.2.3.4 Property Taxes — County, School District, and Special Districts

Under Florida law, both real property (land and permanent buildings) and tangible personal property (primarily business equipment) are subject to property tax. Property taxes are administered by local governments. Homeowners may be entitled to receive a homestead exemption on real property tax. The owner of taxable tangible personal property is required to file an annual tax return with the county property appraiser by April 1 of each year. Taxable tangible personal property includes machinery and equipment and other items that are used for business purposes.

FPL pays property taxes to Miami-Dade County and the Miami-Dade school district. Table 2.5-18 presents information from 2000 to 2011 on the total assessed value of the three fossil units and

the two nuclear units, and the total tax paid to the county and the school district. In 2011, taxes were $6.7 million on the nuclear units and $9.2 million on the fossil units, for a total of $15.9 million. The county received 55 percent of this tax, while the school district received 45 percent of the tax revenue.

FPL also pays personal property taxes for the existing units to Miami-Dade County, the Miami-Dade school district, and several special taxing districts. These include the Florida Inland Navigation District, the South Florida Water Management District, the Everglades Construction Project and the Children's Trust Authority. Table 2.5-20 provides the 2011 millage rate, taxable value, and taxes levied by each taxing entity. In 2011, FPL was levied $15.3 million in tangible personal property taxes on its properties at Turkey Point.

2.5.2.3.5 School Districts

In Florida, each of its 67 counties comprises a single school district (FDOE 2008). Therefore, the Miami-Dade school district includes all of the schools within the ROI. The Miami-Dade School District and Miami-Dade County government are separate entities.

Like many states, Florida seeks to ensure that all students in the state receive comparable educational opportunities, regardless of the relative wealth of each student's school district, and has established a funding equalization process to accomplish this goal. "In 1973, the Florida Legislature enacted the Florida Education Finance Program (FEFP) and established the state policy on equalized funding to guarantee to each student in the Florida public education system the availability of programs and services appropriate to his or her educational needs that are substantially equal to those available to any similar student notwithstanding geographic differences and varying local economic factors (FSBA 2012)." The FEFP is the primary mechanism for funding the operating costs of Florida school districts. Funding is based on the number of full-time equivalent students, and considers variations in several factors when determining funding for each district. A detailed description of the FEFP equation used to determine school district allocations is found at the Florida School Board Association website (FSBA 2012).

School funding comes primarily from local, state, and federal government sources. Local funding is from property taxes on properties located within the school district. State funding is by legislative appropriation, with the major source of revenue being the state sales tax. Federal funding is coordinated by the Florida Department of Education. School districts receive funds from the federal government directly and through the state as an administering agency, and may receive funds under a variety of programs from agencies such as the Department of Labor, Veterans Administration, Department of Interior, Department of Education, Department of Defense, and Department of Agriculture. Table 2.5-21 shows the Miami-Dade School District's revenues by source for the 2000–2001 to 2009–2010 school years. As the table shows, over this

10-year period, the state contribution has steadily declined from 53.4 percent to 28.2 percent, while the local portion has risen from 37.2 percent to 54.0 percent. The change in contribution proportions between state and local funding is a result of legislative action in 2004 that changed the funding formula for large school districts such as the Miami-Dade School District (Iatarola 2004). As a result, the state contribution declined and local contributions increased to make up the difference. The federal contribution has also risen, from 9.5 percent to 17.9 percent. In the 2009–2010 school year, Miami-Dade schools had total revenues of $3.5 billion. Figure 2.5-10 illustrates these trends.

2.5.2.3.6 Local Revenues and Expenditures

Over 83 percent of the current Turkey Plant employees live in Miami-Dade County, which is the ROI. The county's extensive retail opportunities ensure that Turkey Point Plant workers would purchase a large portion of their goods and services within the county. Therefore, Miami-Dade is the county most affected by project and worker expenditures and subsequent sales tax collections. Neither the city of Homestead nor Florida City, home to 43 percent of current Turkey Point plant employees, imposes a local sales tax, but both levy a tax on real and personal property. Local revenues and expenditures by Miami-Dade County and the cities of Homestead and Florida City are briefly described below.

Miami-Dade County

As shown in Table 2.5-22, in 2011, Miami-Dade County government had $1.3 billion in total revenues. The county received 76.4 percent of its revenues from ad valorem (property) taxes, 5.1 percent from gas taxes, and 4.5 percent from sales taxes. Figure 2.5-11 illustrates the proportion from each revenue source. (As noted previously, the Miami-Dade school district is a separate taxing entity.)

The county's expenditures for 2011 totaled $1.2 billion, as shown in Table 2.5-22. Public safety was the largest expenditure, accounting for 43.2 percent. Health and human services accounted for 15.2 percent, general government for 14.7 percent, and transportation for 14.1 percent. Figure 2.5-12 shows the expense breakout.

City of Homestead

Table 2.5-23 presents 2001 through 2010 revenues and expenditures for the city of Homestead. In 2010, the city had total revenues of $58.5 million and expenditures of $54.5 million, resulting in a surplus of $4.1 million, substantially more than the previous year's surplus of $600,000. Figure 2.5-13 illustrates the changes in revenues, expenditures, and the total tax levy from 2001 to 2010, and shows that all have grown substantially since 2002. Revenues and expenditures dropped in 2007 and 2008 from 2006 levels.

In 2010, 37.8 percent of Homestead's revenues were from property taxes, with 33.9 percent coming from intergovernmental sources with 2.6 percent from licenses and permits. Figure 2.5-14 illustrates the proportion from each revenue source.

Public safety was Homestead's largest expenditure in 2010, accounting for 47.2 percent of the total. General government accounted for 22.8 percent, capital outlay for 15.5 percent, and parks and recreation for 7.2 percent. Figure 2.5-15 outlines the expense breakout.

Table 2.5-24 presents the assessed value of Homestead's real and personal property from 2001 to 2010, along with the total tax levy for each year. The assessed value of real property increased by more than fivefold (not adjusted for inflation) over that decade, while the amount of total tax levy more than quadrupled.

Table 2.5-25 shows the history of millage rates over that decade. Rates for the city of Homestead, the school district, the county, and the state have declined somewhat, while the special district millages have fluctuated. Overall, the total property tax rate for Homestead property owners has declined from 26.2640 (dollars per $1000 of taxable property value) to 23.1774.

City of Florida City

Table 2.5-26 presents 1998 through 2007 revenues and expenditures for the city of Florida City. In 2007, the city had total revenues of $14.7 million and expenditures of $11.6 million, resulting in a surplus of $3.1 million, slightly less than the previous year's surplus of $3.2 million. Figure 2.5-16 illustrates the revenues and expenditures over the past decade, along with the total tax levy (values are not adjusted for inflation). Since 2001, both revenues and expenditures have generally grown, although they declined between 2003 through 2004, 2004 through 2005, and 2006 through 2007. The surplus of revenue over expenditures has gradually increased during most years. The total tax levy grew steadily, increasing at a faster rate between 2004 and 2006, but increasing only slightly between 2006 and 2007.

In 2007, 41.5 percent of Florida City's revenues were from taxes, 20.6 percent came from charges for services, and 13.2 percent came from intergovernmental sources. Figure 2.5-17 illustrates the proportion from each revenue source.

General government was Florida City's largest expenditure in 2007, accounting for 34.2 percent of the total. Public safety accounted for 22.1 percent, capital outlays for 20.2 percent, public works for 19.0 percent, and parks and recreation for 3.4 percent. Figure 2.5-18 illustrates the breakout of expenses.

Table 2.5-27 presents the assessed value of Florida City's real and personal property from 1998 to 2007, along with the total tax levy for each year. The assessed value of real property more than

quadrupled (not adjusted for inflation) over that decade, while the amount of total tax levy increased by about fivefold.

Table 2.5-28 shows the history of millage rates over that decade. Rates for the city of Florida City have increased, while the school district, the county, and the state have declined and special district millages have fluctuated. Overall, the total property tax rate for Florida City property owners has declined from 28.8620 (dollars per $1000 of taxable property value) to 27.1998.

2.5.2.4 Land Use

The Turkey Point plant property is located in southeastern Miami-Dade County and consists of approximately 9400 acres of land. It is located approximately 4.5 miles east of the southeastern municipal limits of Homestead, adjacent to Biscayne Bay and Card Sound. Homestead is the closest population center of 25,000 or more. As shown in Table 2.5-3, 43 percent of FPL's current workforce resides in the Homestead and Florida City area. Based on the percentage of the existing workforce that lives in Homestead and Florida City, this area is described in addition to Miami-Dade County. Section 2.2 provides tables and maps displaying land use categories and breakdowns for the Turkey Point plant property, vicinity, and the 50-mile radius.

Laws adopted during the 1984–86 period established Florida's growth management system, including the adoption of a state comprehensive plan. This system requires regional planning councils to prepare and adopt comprehensive regional policy plans. Amendments mandated that specific level-of-service standards for traffic, mass transit, parks, water, sewer, solid waste, and drainage be included in local comprehensive plans and that no development orders can be issued when the adopted levels of service would not be met (MDC 2006). Chapter 163 of the Florida Statutes requires consistency between the local plan, the applicable regional plan, and the state comprehensive plan, and all development regulations and orders must be consistent with the adopted local comprehensive plan (FDCA 2008a, FDCA 2008b, and MDC 2006).

2.5.2.4.1 Florida's State Comprehensive Plan

Chapter 187 of Title XIII of the Florida Statutes is the state of Florida's designated comprehensive plan. The plan provides long-range policy guidance for the orderly social, economic, and physical growth of the state and is reviewed biennially by the state legislature.

The comprehensive plan encourages the centralization of commercial, governmental, retail, residential, and cultural activities within downtown areas and promotes directing development to those areas that have in place, or have agreements to provide, the land and water resources, fiscal abilities, and service capacity to accommodate growth in an environmentally acceptable manner.

2.5.2.4.2 South Florida Regional Planning District

The South Florida Regional Planning Council has regional planning responsibilities for Broward, Miami-Dade, and Monroe Counties (SFRPC 2004), while the Southwest Florida Regional Planning Council is responsible for Collier County and five other counties (SWFRPC 2004). State legislation passed in 1993 recognized that the regional planning council is Florida's only multipurpose regional entity that is in a position to plan for and coordinate intergovernmental solutions to growth-related problems on greater-than-local issues. This legislation requires each regional planning council to develop and periodically update a strategic regional policy plan (SFRPC 2004).

2.5.2.4.3 Miami-Dade County

Miami-Dade County has more than 2420 square miles of land and water, of which almost 510 square miles have been developed for urban uses. The land use portion of the Miami-Dade County Comprehensive Development Master Plan (CDMP) includes a map for 2015–2025 which shows recommended land uses by major categories. Each of these categories is interpreted locally through zoning designations (MDC 2006).

Miami-Dade County covers a land area of 1946 square miles (1,245,440 acres). In 2007, approximately 5 percent of the land area of Miami-Dade County consisted of farms and ranches (Subsection 2.2.3). There are 281,172 acres of urban or built up land, 98,200 acres of agricultural land, 16,094 acres of rangeland, 61,069 acres of upland forest, 20,088 acres of water, 837,446 acres of wetland, and 3881 acres of barren land.

The Miami-Dade County CDMP provides broad parameters for the county government to do detailed land use planning and zoning activities (MDC 2006). The CDMP applies to incorporated and unincorporated areas, addressing primarily the unincorporated areas and the county's jurisdictional responsibilities in the 35 municipalities. The CDMP cannot supersede authority of incorporated municipalities to exercise all powers relating solely to their local affairs, provided that four fundamental growth management components of the CDMP serve as minimum standards for zoning, service, and regulation to be implemented through all municipal comprehensive plans and land development regulations (MDC 2006). The four fundamental growth management components are:

1. The urban development boundary, urban expansion area boundaries, and the CDMP provisions that prescribe allowable land uses and public services and facilities outside the urban development boundary.

2. The Policies for Development of Urban Centers contained in the text of the land use element.

3. The Population Estimates and Distributions as mapped in the land use element.

4. Policies require the county to maintain and use its authority as provided by the Miami-Dade County Charter to maintain, site, construct and operate public facilities in incorporated and unincorporated areas of the county.

The plan encourages development in a contiguous pattern centered around a network of high-intensity urban centers well-connected by multimodal, intra-urban transportation facilities and in locations that optimize efficiency in public service delivery and conservation of valuable natural resources (MDC 2006).

Miami-Dade County zoning code mandates that the county must plan for and manage its population growth and provide the best possible distribution of land uses, by type and density, to meet the needs of the present and future resident and tourist populations in a manner that would maintain or improve the quality of the environment (Miami-Dade Code 2008). It also regulates the subdivision of land in both the incorporated and unincorporated areas of the county (Miami-Dade Code 2008).

2.5.2.4.4 City of Homestead

Homestead is the closest incorporated municipality with a population of 25,000 or more (Section 2.1). The city of Homestead is entirely surrounded by unincorporated Miami-Dade County, except for a common border with Florida City to the south and west. Homestead is comprised of approximately 15 square miles (Homestead EAR 2007). Homestead has 4755 acres of developed land and 4914 acres of undeveloped (vacant) land. Specifically, the city has 690 acres of land under construction zoned for residential purposes, 83 acres under construction for commercial uses, and 424 acres of open land.

There are currently 5525 acres of urban or built up land, 2241 acres of agricultural land, 440 acres of rangeland, 138 acres of upland forest, 400 acres of water, 250 acres of wetland, and 160 acres of transportation, communications, and utilities.

Homestead’s comprehensive plan is intended to provide effective, long-term future direction for redevelopment and new growth (Homestead CP 2005). The city also has neighborhood development and redevelopment plans.

The Homestead comprehensive plan is organized into ten plan elements and six sub-elements, including the future land use map contained in the future land use element. This comprehensive plan was approved by the Homestead city council for transmittal to the Florida Department of Community Affairs on September 5, 2000 (Homestead CP 2005).

Homestead has established an official zoning ordinance. One purpose of the ordinance is to conserve the value of buildings and encourage the most appropriate use of land within the incorporated area by designating specific uses of land, such as various residential and commercial designations (Homestead Code 2008). Homestead has undeveloped land designated for planned unit developments, which allows mixed uses including residential and commercial (Homestead Code 2008). In addition, mobile home parks are only permitted in areas zoned as residential mobile home (RMH), which total 88 acres in Homestead (Homestead Code 2008).

2.5.2.4.5 City of Florida City

Florida City is 8 miles west of the Turkey Point plant property (Section 2.1). It is bordered by unincorporated Miami-Dade County to the west and south, and shares a common border with Homestead to the north and east. Florida City consists of approximately 3.2 square miles. In 2005, there were 1126 acres of developed land and 837 acres of undeveloped or vacant land (Florida City EAR 2006). Specifically, the city has 66 acres of land under construction zoned for residential purposes, 6 acres under construction for commercial uses, and 255 acres of open land.

There are currently 1473 acres of urban or built up land, 266 acres of agricultural land, 60 acres of rangeland, 64 acres of upland forest, 47 acres of water, 95 acres of wetland, and 57 acres of transportation, communications, and utilities.

Florida City uses comprehensive planning as a means to direct development and redevelopment in a positive manner such that the community benefits and service levels are maximized. (Florida City EAR 2006). The city's comprehensive plan was adopted in 1991 with an evaluation and appraisal report completed in 1996. Another evaluation and appraisal report was completed in 2005 (Florida City EAR 2006).

Florida City has established zoning ordinances. One purpose of the ordinances is to encourage the most appropriate and convenient use of land in accordance with the adopted Comprehensive Development Master Plan and in the public interest (FCC 2008). Florida City has subdivision zoning codes that are intended to aid in coordinating land development in the community and to assist with implementing the master plan. (FCC 2008). In addition, mobile home parks are only permitted in areas zoned as R-T, which total 40 acres in Florida City (FCC 2008).

2.5.2.5 Aesthetics and Recreation

This subsection characterizes the visual aesthetics and recreational facilities and opportunities in the 50-mile region. Other aesthetics variables, including noise, odors, and vibrations, are discussed in Subsection 4.4.1.

2.5.2.5.1 Aesthetics

The Turkey Point plant property lies in an unincorporated area in Miami-Dade County, Florida, approximately 8 miles east of Florida City and 4.5 miles east of the southeastern municipal limits of Homestead. The Units 6 & 7 plant area is currently at an elevation of approximately –2.4 to 0.8 feet (NAVD 88). The topography of the area consists of flat mud lands and lies within the Floridian plateau. The Units 1 & 2 emissions stacks are the tallest structures on the property, approximately 400 feet tall.

There are some sensitive visual resources in the vicinity (within 6 miles) of the plant property. There are residential neighborhoods in Homestead. A portion of Biscayne National Park, including the visitor's center, lies within 6 miles to the east. There is a municipally-owned recreational area in the plant area vicinity, Homestead Bayfront Park. In addition, a privately owned recreational venue, Homestead Miami Speedway, is approximately 5 miles northwest of the plant property. Although the topography surrounding the plant property is relatively flat and sparsely populated with trees, there is sufficient vegetation to screen the existing units from area roadways and recreational areas on land.

SW 344th Street/Palm Drive and SW 328th Street/N. Canal Street provide the best opportunity for the public to view the existing units from roadways. However, trees and scrub growth aid in screening the units, including the emissions stacks, from area roadways. Because of the vegetation, the existing units and emission stacks are not visible from most points in Biscayne National Park and Homestead Bayfront Park. The emission stacks may be visible from some upper level seats in the grand stand at the Homestead-Miami Speedway. The existing units are fully visible from Biscayne Bay.

Beyond the six mile radius, on land, the existing units are not visible and, therefore, have no visual aesthetics considerations. Over the waters in Biscayne Bay however, the units can be clearly seen. There are no facility-generated noises, odors, or vibrations experienced outside the boundaries of the plant property, and hence, no recreational venue in the vicinity, ROI, or fifty-mile region, is affected by these aesthetic variables.

2.5.2.5.2 Recreation

Public and private recreational opportunities and facilities abound in the region. The metropolitan character of south Florida, including Miami-Dade and Broward Counties, means there is a wide range of leisure choices. In addition, the area is a major recreation tourist destination. Monroe County, a portion of which is also within the region (Figure 2.1-4), is famous as the home of the Florida Keys. Recreational opportunities in the region include, but are not limited to, festivals, specialized tourist attractions (zoos, botanical gardens, art and cultural museums, etc), spectator sports, participatory sports, beaches, and parks. Select recreational opportunities in the region

and more specifically in the cities of Homestead and Florida City are discussed below. Recreational areas in the vicinity are shown on Figure 2.5-19. Select recreational venues in the 50-mile radius are shown on Figure 2.5-20.

Festivals — The Region

Large and small municipalities and special interest organizations in the region host countless festivals throughout the year. Many reflect the region's rich cultural heritage. Among the two largest festivals in the region are the Italian Renaissance Festival in Miami, which drew 80,000 attendees in 2008 (SFS-S 2009) and the Orange Bowl Festival, also in Miami, which centers around the Orange Bowl football game on New Year's night.

Festivals — Homestead and Florida City

There are three major festivals in the Homestead and Florida City area. The Homestead Rodeo, "It's more than a sport … It's a lifestyle", is held each January. The 60th annual Rodeo in 2009 had approximately 27,500 spectators. The Annual Super Chili Bowl Cook-Off and Outhouse Race is held each February and draws about 2000 participants. The Dade County Farm Bureau Annual Barbeque and "Fun" Raiser is held in April and draws 1200 participants.

Specialized Attractions — The Region

The region has several popular specialized attractions that provide a recreational outlet. Among the more popular attractions, in terms of attendance, is the Miami Seaquarium which has more than 300,000 guests a year and the Miami MetroZoo with 750,000 visitors a year. The region also has the largest botanical garden in the continental United States, the Fairchild Tropical Garden, in Coral Gables.

There are many venues for concerts and theatrical performances in the region. There are also large libraries, historical museums, memorials, and several regional museums and galleries which reflect the varied culture of the region.

Specialized Attractions — Homestead and Florida City

Homestead has several popular specialized attractions that provide recreational opportunities. The Everglades Alligator Farm in Homestead is home to almost 3000 alligators as well as local and exotic snakes. Homestead is also the home of the Fruit and Spice Park, the only one of its kind in the USA which features over 500 varieties of fruits, herbs, spices, and nuts (DoT 2008). In addition, Coral Castle is a park that consists of over 1,100 tons of carved coral rock built by one man over a thirty-year period. Also known as Rock Gate, Coral Castle is listed on the National Register of Historic Places (AM 2009).

Recreational Sports for the Spectator — The Region

The region offers a variety of spectator sports at both the professional and collegiate level. The Miami Dolphins of the National Football League play their home games in Sunlife Stadium (aka Pro Player Dolphin Stadium, Miami Gardens Stadium) which is also home to the University of Miami Hurricanes. The stadium seats 75,540 for football and soccer and 38,560 for baseball (DS 2009). The American Airlines Arena houses the professional basketball team, the Miami Heat. The arena seats approximately 20,000 for basketball (AAA 2009). The Florida Panthers of the National Hockey League play at the BankAtlantic Center, which seats 19,250 (FPT 2009). The Florida International University Golden Panthers play at the Golden Panther Arena which has seating capacity of approximately 5000 (FIU 2009). The Miami Marlins major league baseball team is now playing at the new Marlins Park, a natural grass playing field with 37,000 seats (MM 2012).

Popular spectator sports in the area are horse and auto racing. Calder Race Course in Miami offers thoroughbred racing. Calder Race Course had a 2006 track attendance of 690,270. Other spectator sports include golf tournaments, greyhound races, horse shows, regattas, soccer matches, and tennis tournaments.

Recreational Sports for the Spectator — Homestead and Florida City

One of the region's major sporting events is the Grand Prix of Miami, which draws an estimated 85,000 over three days (Miami Today 2003) is held at the Homestead Miami Speedway in Homestead. The Speedway is approximately 5 miles from the Units 6 & 7 plant area. The grandstand seats 65,000 spectators. The Speedway hosts race car and motorcycle events throughout the year (HMS 2008).

Recreational Sports for the Participant — The Region

A complete range of outdoor sports activities is available year-round in the region at numerous public and private facilities. Within the region, Miami-Dade County offers more than 20 public golf courses. Nearly 500 tennis courts for day and evening play are located in many parks and recreation areas throughout the region; in addition, most hotels have their own tennis facilities. There are opportunities to participate in water sports including scuba and skin diving, snorkeling, windsurfing, waterskiing, and recreational boating in the region's lakes, rivers and in Biscayne Bay. Fishing is popular. A fresh water fishing license is required for anyone between the ages of 15 and 65 years. No license is required for salt water fishing, but minimum size and bag limits apply (FWC 2008). In addition, there are many opportunities for camping.

The Florida Keys are also known for sport fishing (fishing tournaments and angling opportunities), boating, sailing, kayaking, and ecotours (FK 2009).

Recreational Sports for the Participant — Homestead and Florida City

Participatory recreational opportunities in the Homestead and Florida City area are available in the area's two dozen municipal parks. These parks are described below in "Parks-Homestead and Florida City."

Beaches — The Region

There are 21 public beaches in Miami-Dade County alone. There are five public beaches in Broward County. Virtually all of the residents of Monroe County within the region live in the Keys and have ocean access. There are five public beaches in Monroe County that are within the 50-mile region. (CTG 2009)

Beaches — Homestead and Florida City

Homestead Bayfront Park has a public beach. The park offers picnic tables and barbeque grills, shelters, food/drink concession stands, restrooms and showers, and fishing (CTG 2009). The Homestead Bayfront Park is located next to Biscayne National Park which offers a beach, fishing, picnic areas, and a playground (FNAI 2008). The Biscayne National Park entrance is approximately 3 miles north of the plant property.

Parks (National, National Wildlife Refuges, and State Parks) — The Region

There are eight federal, state, and privately managed, wildlife management areas, preserves, national wildlife refuges, and sanctuaries within 50 miles of Units 6 & 7 (Figure 2.5-20). Tables 2.5-29 and 2.5-30 list locations, acreages, and other information for these facilities located within the 50-mile region.

Big Cypress National Preserve consists of 720,561 acres of swamp (FNAI 2008). The park offers hiking, hunting, and off-road vehicle use. Everglades National Park is primarily comprised of internationally important wetlands that are home to rare and endangered species such as the American crocodile, Florida panther, and West Indian manatee (NPS 2008b). The park covers 1,508,533 acres (FNAI 2008). In August 2010, the South Florida Water Management District took ownership of 26,800 acres of land formerly owned by United States Sugar Corporation and preserved the option to acquire 153,200 acres of additional land (SFWMD 2011). Also, the National Park Service is evaluating the possible acquisition of 320 acres within the park "expansion area" (The Everglades National Park Protection and Expansion Act of 1989) from FPL (NPS 2011). Recreational opportunities in the park include camping, hiking, boating, and wildlife viewing.

There are 11 state parks within 50 miles of Turkey Point. These parks offer an array of activities such as camping, fishing, hiking, wildlife viewing, scuba diving, snorkeling, boating, picnicking,

and historic lighthouse tours. Table 2.5-30 lists the park's distance from Units 6 & 7 to the various state parks and other information.

Among the more visited parks managed by the state or the U.S. Park Service in the region are Bill Baggs Cape Florida State Park, John Pennekamp Coral Reef State Park, John U. Lloyd Beach State Park, Oleta River State Park, Big Cypress National Preserve, and Everglades National Park. Bill Baggs Cape Florida State Park is the home of the oldest standing structure in Miami-Dade County, a lighthouse. Visitors come to the park to sunbathe, swim, bike, kayak, fish and picnic on over a mile of Atlantic beachfront. (FPS 2008). John Pennekamp Coral Reef State Park near Key Largo in the Florida Keys has the only living coral reef in the United States. Visitors to the park can swim, snorkel, surf fish, canoe, and scuba dive (FPS 2008).

Parks (National, National Wildlife Refuges, and State Parks) — Homestead and Florida City

The Biscayne National Park visitor's center is approximately 3 miles north of Units 6 & 7. Biscayne National Park protects a "rare combination of aquamarine waters, emerald islands, and fish-bejeweled coral reefs" (NPS 2008a). It covers an area of approximately 173,000 acres, 95 percent of which is water (FNAI 2008). Visitors can view wildlife, snorkel, scuba dive, canoe, camp, hike, and fish.

There are no state-owned recreational properties within 6 miles of the Units 6 & 7 plant area.

Parks (County, Local, Municipal) — The Region

There are over 400 county and local parks within the 50-mile region. Among the recreational activities that can be pursued in many of the parks are picnicking, canoeing, boating, hiking, camping, fishing, swimming, basketball, softball, handball, racquetball, and bike trails.

Parks (County, Local, Municipal) — Homestead and Florida City

The city of Homestead has 16 community, municipal, neighborhood, or special use parks (CHF 2012) and Florida City has 5 city parks (Iler Planning Group 2005). Among the recreational activities that can be pursued in many of the parks are picnicking, canoeing, boating, hiking, camping, fishing, swimming, basketball, softball, handball, racquetball, and bike trails.

2.5.2.6 Housing

Within Miami-Dade County, residential areas are found in cities, towns, smaller communities, and in the unincorporated portions of the county. Most of the housing is concentrated in the municipalities throughout the county, including the Homestead and Florida City area. The residential distribution of current Turkey Point employees is presented in Subsection 2.5.1 and Table 2.5-3. Approximately 43 percent of the current Turkey Point workers live in the Homestead and Florida City area. An additional 40 percent of the current workforce lives outside the

Homestead and Florida City area, but within Miami-Dade County, primarily in Miami. The ROI is densely populated and residential clusters abound in the many incorporated and unincorporated communities.

2.5.2.6.1 Permanent Housing

Table 2.5-31 provides information about housing units and housing characteristics for Miami-Dade County for 2000 and 2005-2009. In 2005-2009, there were 962,935 total housing units in the ROI, an increase of 13 percent or 110,657 units since 2000. Of the occupied units in 2005-2009, 482,841 (58 percent) were owner-occupied and 345,090 (42 percent) were renter-occupied. For the ROI in 2005-2009, the vacancy rate of the owner-occupied units was 3.7 percent, and the vacancy rate for the renter-occupied units was 8.0 percent. Rental units include housing such as single-family units, multifamily units, apartments, or mobile homes that, if occupied are not owner-occupied, and if vacant are “for rent.” In 2009, 368,533 single-family homes were located in Miami-Dade County. The mean construction date of these units is 1973. A large concentration of condominiums, 345,654 units (22 percent of the state of Florida) was located in Miami-Dade County in 2009 (UF 2010).

Of the 852,278 total units within the ROI in 2000, approximately 9 percent (75,504 units) were vacant (USCB 2008). However, of the 962,935 total units within the ROI in 2005-2009, 14 percent (135,004 units) were vacant. In 2009, 42 percent of the condominiums in Miami-Dade County were owner-occupied (UF 2010).

Of the occupied units, approximately 42 percent were rental units in 2005-2009, the same percentage as in 2000. In 2000, the majority of rental units in the ROI had a monthly rental rate below $750 with a median rent of $647 per month. The median monthly rate increased to $965 in 2005-2009 (dollars are not adjusted for inflation). Of the 852,278 housing units in Miami-Dade County in 2000, 15,338 were mobile homes, approximately 1.8 percent of the county’s housing units (USCB 2000b). Within Miami-Dade County in 2005-2009, there were 15,085 mobile homes. This is a 1.6 percent decrease in the number of mobile homes since 2000.

Housing characteristics in the Homestead and Florida City area are detailed in Table 2.5-32. In 2005-2009, 23,994 housing units were located in the Homestead and Florida City area. Approximately 17 percent (4,046) of these units were vacant. Approximately 57 percent of the occupied units are rental units. In August 1992, Hurricane Andrew hit Miami-Dade County, devastating areas in the southern portion of the county, particularly the Homestead and Florida City area. In 2000, there were 335 mobile homes in the Homestead and Florida City area; however, in 1990, there were 929 mobile homes in this same area, indicating a decrease of 64 percent of the mobile home stock in the decade that experienced Hurricane Andrew (USCB 1990).

There were 12,637 building permits for privately owned residential units (single and multifamily units) were issued in the Homestead and Florida City area from 2001 to 2010, nearly doubling the area's 2000 total housing inventory. There were 128,120 permits issued in Miami-Dade County for 2001–2010 (Table 2.5-33).

The median value of homes in Miami-Dade County increased from 2000 to 2005-2009. In 2005-2009, the largest portion of the owner-occupied housing inventory in Miami-Dade County was valued in the range of $300,000 to $499,999. In 2005-2009, approximately 28 percent of the owner-occupied housing in the county was valued at less than $199,999 (USCB 2000b). In 2000, the median value of an owner-occupied house was $124,000 (USCB 2010b). In 2005-2009, the median value of an owner-occupied house was $277,200 (USCB 2010b). This is an increase of 124 percent for the 2000 to 2005-2009 period.

The median value for an owner-occupied home in Homestead was $88,200 in 2000, and the median value for a owner-occupied home in Florida City was $70,200 (USCB 2000b). As shown in Table 2.5-32, the median value of an owner-occupied house was $216,500 in Homestead and $171,300 in Florida City in 2005-2009. These values reflect an increase of 145 percent and 144 percent respectively of the 2000 values.

2.5.2.6.2 Seasonal Housing

The U.S. Census Bureau defines seasonal housing as a housing unit held for occupancy only during limited portions of the year; such as a weekend home, winter residences, beach cottage, ski cabin, or a time-share condominium.

In 2010, there were 38,302 housing units for seasonal, recreational, or occasional use in Miami-Dade County (Table 2.5-31). Seasonal housing is a part of an area's "vacant housing." Of those housing units for seasonal, recreational, or occasional use in the ROI, 175 were in the Homestead and Florida City area (Table 2.5-32).

2.5.2.6.3 Recreational Vehicle Parks with Hookups

There are at least nine recreational vehicle parks or campgrounds in Miami-Dade County. These identified parks and campgrounds have 1587 spaces with full hookups for private recreational vehicles in the ROI. Approximately 68 percent of these spaces are in the Homestead and Florida City area (Table 2.5-34). Because most of the recreational vehicle parks are privately owned, the average yearly capacity was not available.

2.5.2.6.4 Hotels and Motels

In 2011, there were approximately 361 hotels/motels with 47,642 rooms available in the ROI (Table 2.5-35). In the South Dade region, which includes the Homestead and Florida City area, 27 hotels/motels with approximately 1928 rooms were available in 2011.

Because many areas of Miami-Dade County are tourist attractions, the room rates and the occupancy rates vary in different regions of the county during different seasons of the year. The room rates in December 2011 ranged from $75.76 per night in South Dade to $206.54 per night in Miami Beach (GMCVB 2012).

2.5.2.7 Public Services and Community Infrastructure

Public services and community infrastructure include public water supply and wastewater treatment systems, law enforcement and fire departments, medical facilities, and schools. Schools are described in Subsection 2.5.2.8. The other services and infrastructures are described below.

2.5.2.7.1 Public Water Supply and Wastewater Treatment Systems

As described in Subsection 2.5.2, the ROI consist of Miami-Dade County. Since 43 percent of the current Turkey Point workforce reside in the Homestead and Florida City area, the description of public services and community infrastructure details this area in addition to the ROI. Table 2.5-36 details major public water suppliers in the county, their rated capacities, and their daily average annual flow measured in 2005. Table 2.5-38 details wastewater treatment facilities in the county. The public water suppliers and the wastewater treatment facilities in the Homestead and Florida City area are included in the table. Currently, there is sufficient water supply for peak demand in all of the major water supply facilities and in most of the wastewater treatment facilities. The water supply facilities that serve the Homestead and Florida City area have excess production capacity, as does the wastewater facility that serves Florida City.

2.5.2.7.1.1 Public Water Supply

The Florida Department of Environmental Protection (FDEP) is involved in managing the quality and quantity of water through its relationship with the state's five water management districts; Northwest Florida Water Management District, Suwannee River Water Management District, St. Johns River Water Management District, South Florida Water Management District (SFWMD), and Southwest Florida Water Management District (FDEP 2008) (Figure 2.5-21).

The South Florida Water Management District (SFWMD) is a regional governmental agency that oversees the water resources in the southern half of Florida, covering 16 counties from Orlando to the Florida Keys and serving a population of 7.5 million residents. It is the largest of Florida's

five water management districts and is responsible for water supply planning for each region within its jurisdiction. SFWMD's mission is to manage and protect water resources of the region by balancing and improving water quality, flood control, natural systems and water supply.

The SFWMD serves local governments by supporting efforts to safeguard existing natural resources and meet future water demands through one of the four water supply planning areas. The four water supply planning areas are the Upper East Coast, the Lower East Coast, the Lower West Coast, and the Kissimmee Basin. The planning areas are generally defined by the drainage divides of major surface water systems in South Florida. The Lower East Coast (LEC) Planning Area of the SFWMD encompasses approximately 6100 square miles that includes all of Miami-Dade, Broward and Palm Beach Counties, most of Monroe County, and the eastern portions of Hendry and Collier Counties. The SFWMD, through the LEC planning area, provides regional oversight to these specific counties for water demand projections, assessment of existing and projected resource conditions, and formulation of strategies to meet urban, agricultural and environmental water needs (SFWMD 2005).

Miami-Dade County is one of ten counties in the LEC planning area. Miami-Dade County's water is provided by five suppliers: the Miami-Dade Water and Sewer Department, the city of North Miami, the city of North Miami Beach, the city of Homestead and the city of Florida City. The Miami-Dade Water and Sewer Department (MDWASD) provides drinking water to approximately two million customers in Miami-Dade County (Figure 2.5-22) and draws drinking water from the Biscayne Aquifer. The MDWASD is composed of three water treatment facilities: the Hialeah-Preston Water and Sewer Department (WASD), serving the northern part of Miami-Dade County, the Alexander Orr, Jr. WASD, serving the central and portions of the southern part of Miami-Dade County and the South Dade WASD, serving the southern part of Miami-Dade County. The MDWASD has plans for the construction and operation of the South Miami Heights (SMH) Water Treatment Plant in the South Dade area, which is scheduled to come online in 2012. The MDWASD has a 20 year water use permit issued by the SFWMD which limits its annual allocation to 149,106 million gallons and its monthly maximum allocation to 13,047 million gallons (SFWMD 2010). These allocations are further limited by a wellfield operational plan, described in Limiting Condition 27 of the water use permit (MDWASD 2008).

The city of North Miami supplies water within its municipal boundary as well as outside of its municipal boundary to certain northern parts of unincorporated Miami-Dade County. The city of North Miami Beach supplies water within its municipal boundary as well as outside its municipal boundaries to certain northern parts of unincorporated Miami-Dade County. The city of Homestead provides water within its municipal boundary and for a portion of unincorporated Miami-Dade County, including the Redavo development, from 6 city-owned withdrawal wells. The city of Homestead also has an agreement with the MDWASD to provide some water service within portions of Homestead municipal boundary. Florida City also provides water to portions of

unincorporated Miami-Dade County as a water supplier. Florida City provides water service within its incorporated boundaries from 4 production wells (MDWASD 2008).

In 2007, the total daily average demand of water supplied by these five major suppliers in Miami-Dade County was 398.03 million gallons per day (MGD) or 74.74 percent of total capacity (Table 2.5-36).

Demand, Supply, Additional Water Needs, and Water Management Strategies

In 2005, the SFWMD analyzed projected use by type. In this study, the county's total water demand was projected to increase by 33 percent, from 526.22 mgd in 2005 to 699.9 mgd in 2025 (Table 2.5-37). Thermoelectric power use accounted for the largest increase of projected demand through 2025. Municipal demand was projected to experience an increase by approximately 27 percent over the same period, from 380.92 mgd to 483.10 mgd. Agricultural irrigation self-supplied demand was expected to decline by 2.70 percent, from 92.7 mgd to 90.2 mgd. Thermoelectric power self supplied demand will increase 3224 percent from 2.1 mgd to 69.8 mgd (SFWMD 2005).

The two water systems in the Homestead and Florida City area currently have a combined facility capacity of 20.90 mgd. The total population served by both Homestead and Florida City water systems is estimated to increase from 57,951 in 2005 to 110,278 in 2025 (SFWMD 2005). This would be an estimated 90 percent increase in population since 2005. The projected water demands in 2025 for both the Homestead and Florida water systems are estimated to exceed the current rated capacity of these systems. The projected finished water demand in 2025 for the Homestead water system would be 122 percent of the current rated capacity. The projected finished water demand in 2025 for the Florida City water system would be 104 percent of the current rated capacity (SFWMD 2005).

The major water supply source for all of the existing water treatment systems in Miami-Dade County is from the surficial (also known as Biscayne) and Floridan aquifers (MDWASD 2008). While the Biscayne aquifer is highly productive with high-quality freshwater in some areas of the county (in the vicinity of the Turkey Point plant property, the water is saline, see Subsection 2.3.3), it is generally shallow, located within 200 feet of ground surface, and is connected to surface water systems, including canals, lakes, and wetlands (SFWMD 2005).

Groundwater from the Floridan aquifer is used to blend brackish and fresh water at water treatment plants in order to extend the water supply. Alexander Orr water treatment plant is currently using this process. Blending of groundwater from the Floridan aquifer is also proposed at the Hialeah Preston water treatment plant. The design capacity of the Hialeah Preston Upper Floridan aquifer wells is 12.50 mgd with a total designed installed capacity of 295 mgd, and is proposed to be operational by 2010 (MDWASD 2008).

The SFWMD, local governments, and utilities have been working closely with the Florida Department of Community Affairs to project water demands and propose viable alternative water supply projects. Water management strategies for the Miami-Dade county plan include, but are not limited to, a more coordinated use of conservation and alternative water supply projects, such as reverse osmosis plants, and reclaimed water systems. In total, these strategies could provide 98.3 mgd of additional water supply to Miami-Dade County by the year 2025, at a total capital cost of approximately $989,460,000 (SFWMD 2005).

In 2010, the SFWMD approved the renewal and modification of a water use permit for the public water supply for the MDWASD service area serving 2,787,451 persons in the year 2030. Modifications were recommended for several well fields and the delay of timelines for two projects (Hialeah Reverse Osmosis plant and South Miami Heights WTP). Also included were allocation changes to decrease the yearly raw water supply system allocation from 152,741 million gallons to 149,106 million gallons to meet the water supply needs through 2030.

2.5.2.7.1.2 Wastewater Treatment Systems

Wastewater is the spent or used water from homes, communities, farms, and businesses. Wastewater includes both domestic sewage and industrial waste from manufacturing sources. Wastewater treatment in the region is provided by local jurisdictions and primarily regulated by the FDEP. Wastewater treatment capacity depends on two factors: water supply and the availability of infrastructure. There is currently excess capacity in most of the wastewater treatment systems within Miami-Dade County.

Capacity for Wastewater Treatment

Table 2.5-38 details public wastewater treatment facilities located within the ROI, the average annual flow rates reported for May 2007 through April 2008, the permitted capacity, and their flow as a percent of the design capacity.

Infrastructure for Wastewater Treatment

In the event that capacity limits may be approached or exceeded, Florida Administrative Code Section 62-600.405 directs that:

> “When the three-month average daily flow for the most recent three consecutive months exceeds 50 percent of the permitted capacity of the treatment plant or reuse and disposal systems, the permittee shall submit to the Department a capacity analysis report. [Section 62-600.405(3)]”

An evaluation of the data listed in Table 2.5-38 indicates that the wastewater systems for the city of Homestead, MDWASD South District, MDWASD North District, and MDWASD Central District are in excess of the 50 percent flow value described above.

Currently, Homestead wastewater treatment plant uses the MDWASD system as backup and excess flows are diverted to the county wastewater treatment facilities. These excess flows are included in the South District water treatment plant flows reports.

The wastewater treatment facility for Homestead currently shows 102 percent capacity; however, the city's proposed 10-Year Water Supply Facilities Work Plan identifies and details the construction of a 3.45 mgd high level disinfectant wastewater treatment plant upgrade. The proposed expanded wastewater treatment plant will have the capacity to handle 9.45 mgd, which will provide enough capacity through at least 2030.

The wastewater created in Miami-Dade County is either treated at the public wastewater treatment facilities listed in Table 2.5-38, or is handled by privately owned and operated septic systems. These septic systems are likely to be found in unincorporated areas of Miami-Dade County.

MDWASD handles Florida City's wastewater and they are currently below the design capacity. Capacity modifications are the responsibility of MDWASD.

2.5.2.7.2 Law Enforcement, Fire, and Emergency Management

Law Enforcement

The Miami-Dade County police department serves the entire county including all the municipalities. However, each incorporated city is also served by their own police department as in Homestead and Florida City under the Miami-Dade County Police Department.

In 2010, 2980 officers were employed in the Miami-Dade County Police Department. Law enforcement in the Homestead and Florida City area is served through the Miami-Dade County Police Department.

In 2010, 135 officers were employed in the Homestead and Florida City areas police departments. Table 2.5-39 summarizes the number of law enforcement personnel in Miami-Dade County, Homestead, and Florida City.

Fire

Table 2.5-40 provides fire protection personnel data for the departments in Miami-Dade County as of 2010. All of the firefighters in these departments, with the exception of those serving the Everglades National Park, are active, career firefighters.

The Homestead and Florida City area is served by the Miami-Dade County Fire and Rescue. As of 2010, approximately 2070 firefighters were active throughout 65 fire stations located in the Homestead and Florida City service area.

The public protection classification system is a national system used by the insurance services office to reflect a community's local fire protection for property insurance rating purposes. The insurance services office is an advisory organization that serves the property and casualty insurance industry by providing inspection services, insurance coverage for development, and statistical services. The public fire protection of a city, town, or area is graded using the insurance services office fire suppression rating schedule. The insurance services office classifies communities from 1 (the most preferred) to 10 (the least preferred). Communities are graded on water distribution, fire department equipment and manpower, and fire alarm facilities, among other things. The overall public protection classification rating for Miami-Dade County is 4. The overall public protection classification for Homestead and Florida City was 4.

2.5.2.7.3 Medical

Table 2.5-41 presents hospital use data in Miami-Dade County. Miami-Dade County has 10,497 physicians (AMA 2011), 31 hospitals, 8420 staffed beds, and a hospital census (the average number of in-patients receiving care each day) of 4010 (AHA 2006).

A majority (23) of the hospitals located within the ROI are classified as "General and Surgical" hospitals. Three hospitals are listed as certified trauma centers (Shands at University of Florida, Jackson Memorial Hospital, and Miami Children's Hospital). Four hospitals are listed as rehabilitation, while two are long-term acute care, one is children's general, one is eye, ear, nose and throat, and one other specialty hospital.

2.5.2.8 Education

2.5.2.8.1 Public Schools — Pre-Kindergarten through 12

This subsection describes the enrollment, capacity, and facilities of public schools in the ROI. The state of Florida divides the school districts by county. The Miami-Dade County Public School District (M-DCPS) covers all of the ROI and is ranked fourth largest in student population among school districts in the United States (M-DCPS 2011a). M-DCPS is further divided into five regional centers and nine districts. The Homestead and Florida City area is a part of District IX.

The Florida Legislature enacted the FEFP and equalized funding to guarantee each student receives the same programs and services regardless of geographical and local economic differences. Subsection 2.5.2.3 describes school revenue sources and other fiscal issues.

Miami-Dade County Public School District

The M-DCPS has a total of 435 schools (M-DCPS 2011a). There are 213 elementary schools, 79 middle schools, 46 K-8 schools, 68 high schools, 24 alternate or special schools, and 5 combined schools (M-DCPS 2011a). For the school year 2010-2011, M-DCPS had a kindergarten through Grade 12 total enrollment of 347,133 students. This is an approximately 4 percent decrease from the 2005-2006 school enrollments. Student enrollment has consistently decreased since 2001-2002 with the exception of 2009-2010 when there was a very small increase from 2008-2009 (M-DCPS 2011a). In the school year 2006-2007, the district relied on 2193 portable units to handle excess student enrollment (M-DCPS 2007). The district has construction and expansion projects underway for an additional 13,746 student stations to accommodate enrollment with a completion date of 2015-2016. Table 2.5-42 lists the various projects and capacities. Of the student population in M-DCPS, 91.4 percent are racial and/or ethnic minorities. Students enrolled in the English for Speakers of Other Languages Program totaled 62,838 (18.1 percent of the 2010-2011 enrollments) (M-DCPS 2011a).

All publicly funded Florida pre-kindergarten through Grade 12 schools are required to meet Florida Department of Education (FDOE)-mandated average student class size. The mandated class sizes vary depending on the grade level: Pre-kindergarten through grade 3 = 18 students, Grades 4 through 8 = 22 students, and Grades 9 through 12 = 25 students by the 2010-2011 school year (FDOE 2002). The M-DCPS class size for the 2010–2011 school year for kindergarten through Grade 3 was 13.9, Grades 4 through 8 was 16.6, and Grades 9 through 12 was 20.2 (FDOE 2012). Therefore, M-DCPS met the state-mandated average classroom size for all grades.

Homestead and Florida City Area

Approximately 43 percent of the current Turkey Point workforce resides within the Homestead and Florida City area. Therefore, special focus has been given to the schools within District IX which includes the Homestead and Florida City area. District IX has 76 schools. For the 2010-2011 year, the public schools in the Homestead and Florida City area had an enrollment of 55,860 students (M-DCPS 2011a). Recent initiatives within the Miami Dade County Public School system have eliminated overcrowding in the Homestead and Florida City area (M-DCPS 2008).

2.5.2.8.2 Private Schools – Pre-Kindergarten through 12

Miami-Dade County

In the 2009-2010 school year, Miami-Dade County had a total of 301 private schools (NCES 2012b), which includes all grade levels from pre-kindergarten through 12. In that same school year, the private schools in Miami-Dade county had a total enrollment of 61,161 (NCES 2012b). Capacity levels are not available.

Homestead and Florida City

In the 2009-2010 school year, the Homestead and Florida City area had a total of 16 private schools (NCES 2012b), which include all grade levels from pre-kindergarten through 12. In the same school year, the private schools in the Homestead and Florida City area had a total enrollment of 2263 (NCES 2012b). Capacity levels are not available.

2.5.2.8.3 Post-Secondary Institutions

There are 12 colleges or universities that are accredited by the Southern Association of Colleges and Schools (SACS) to award various certificates and degrees ranging from associate to doctoral. There are also a large number of vocational schools that offer professional and paraprofessional training within 50 miles of Units 6 & 7. Table 2.5-43 lists the colleges' distance from Homestead, type of college, awards offered, and the 2007 student enrollment.

2.5.3 HISTORIC PROPERTIES

2.5.3.1 Applicable Federal, State, and Local Historic Preservation Regulations

Because the NRC, a federal agency, would issue the combined licenses for Units 6 & 7, the project is subject to review and consultation under the *National Historic Preservation Act* (16 U.S.C. § 470 et seq.). In particular, Section 106 of the Act applies, along with the section's implementing regulations, 36 CFR Part 800, which direct the lead federal agency to consider the potential effects of proposed projects on historic properties and to enact measures to avoid, reduce, or mitigate those effects. This regulation applies to historic properties, which are those cultural resources determined potentially eligible or eligible for listing on the National Register of Historic Places.

The state of Florida's Statutes, Title XVIII, Chapter 267, *Historical Resources*, provides Florida's state policy regarding historical resources, and outlines the role of the Division of Historical Resources. Florida Statutes, Title XLVI, Chapter 872, *Offenses Concerning Dead Bodies and Graves*, Section 5, *Unmarked Human Burials*, addresses the protection and treatment of human remains and associated burial artifacts found on public or private lands, including submerged lands.

The *Metropolitan Miami-Dade County Historic Preservation Ordinance* (Miami-Dade County Ordinance 81-13 Chapter 16-A) was adopted to ensure the protection, enhancement, and perpetuation of properties of historical, cultural, archaeological, paleontological, aesthetic, and architectural merit that represent distinctive elements of the county's cultural, social, economic, political, scientific, religious, prehistoric, and architectural history. It applies to all incorporated and unincorporated parts of the county, except for municipalities that enact their own ordinance that is at least as prescriptive as the county ordinance. The ordinance establishes the Miami-Dade

County, Office of Planning and Zoning, Office of Historic Preservation and its Historic Preservation Board. The board designates important properties and archaeological and paleontological zones, and if projects are proposed that will affect those properties or zones, the project cannot go forward without a board-issued certificate of appropriateness or certificate to dig.

The city of Homestead is the only certified local government with an historic preservation ordinance in the project area. The city of Homestead enacted its own *Historic Preservation Ordinance* 2005-11-37. Very similar to the county ordinance, the Homestead ordinance establishes the Homestead Historic Preservation Board, which designates historical, archaeological, or architectural properties of merit and issues certificates of appropriateness for any projects that could affect designated properties.

2.5.3.2 Consultation with the Florida Division of Historical Resources

FPL initiated consultation by letter with the Florida Division of Historical Resources, the executive director of which is the State Historic Preservation Officer (SHPO), for the proposed project. FPL has submitted survey reports and work plans to the SHPO (FPL 2009a, FPL 2009b, FPL 2009c, and FPL 2009d) for consultation on the Site and associated non-linear facilities, as detailed in Subsection 2.5.3.3.1, and received concurrence from the SHPO on the recommendations made by FPL in the work plans. FPL will continue consultation with the SHPO in accordance with Section 106 of the National Historic Preservation Act for the offsite linear facilities, as described in Subsection 2.5.3.3.2. Results of continued SHPO consultation, including reports of surveys and investigations, and all original and current correspondence between FPL and SHPO is contained in Appendix 2.5A. Future correspondence will be provided to the NRC.

2.5.3.3 Cultural Resource Reports and Work Plans

FPL has prepared and submitted several reports and work plans to the SHPO, including the following:

- *Cultural Resource Assessment Survey for the Turkey Point Units 6 & 7 Site, Associated Non-Linear Facilities, and Spoils Area on Plant Property* (FPL 2009a).
- *Cultural Resource Assessment Survey Work Plan for the Turkey Point Units 6 & 7 Site and Associated Non-Linear Facilities* (FPL 2009b).
- *Preliminary Cultural Resources Report for the Turkey Point Units 6 & 7 Associated Linear Facilities* (FPL 2009c).
- *Cultural Resource Assessment Survey Work Plan for the Turkey Point Units 6 & 7 Associated Linear Facilities* (FPL 2009d).

All cultural resource work plans and reports were conducted and prepared by personnel who meet or exceed the professional qualifications as stipulated in the *Secretary of the Interior's Standards and Guidelines for Archeology and Historic Preservation* (36 CFR Part 61) (48FR44716-44742).

The results of these reports, contents of the work plans, recommendations for further work, and SHPO correspondence are discussed in the following paragraphs.

2.5.3.3.1 Units 6 & 7 Site and Associated Non-Linear Facilities

A Cultural Resource Assessment Survey (FPL 2009a) of the Site and associated non-linear facilities was prepared by FPL and submitted in June 2009 as part of the Turkey Point Units 6 & 7 Site Certification Application (FPL 2009e). This survey addressed the potential for historic properties within the following potentially impacted areas:

- Turkey Point Units 6 & 7 Site
- Nuclear Administration Building, Training Building and Parking Area
- Radial Collector Wells
- FPL Reclaimed Water Treatment Facility and Delivery Pipelines to the Plant Area
- FPL-Owned Fill Source
- Equipment Barge Unloading Area
- Heavy Haul Road on Plant Property
- Spoils Areas on Plant Property

The locations of these areas are depicted in Figure 3.9-1.

The Areas of Potential Effects (APEs) for the historic resources survey considered direct as well as secondary or indirect effects. The APE for direct effects included areas within the footprints of the Site and associated non-linear facilities. The APE for potential indirect effects is defined as the area within which potential visual, audible, or atmospheric impacts from the improvements could be observed. The highest proposed structure will be 400 feet tall, which will not exceed the current height of the structures associated with the existing units. Also considered is the relatively flat topography and the undeveloped character of the surrounding area. Based on these factors, an indirect effects APE of one-half mile from the proposed site was recommended.

The survey (FPL 2009a) included a review of Pre-Contact and Historic cultural history; an environmental overview; a description of land use history, including research from Government Land Office historic plat maps and historic aerial photographs of the area; and the results of background research into previously recorded cultural resources. The background research included a search of the Florida Master Site File and review of Miami-Dade County and local inventories. No previously recorded properties or locally-designated sites are located within or adjacent to (within 100 feet) of the APEs, and research determined that, prior to 1963, the area surrounding the site was undeveloped.

A pedestrian survey and subsurface shovel testing were conducted during the months of October 2008, December 2008, March 2009, and April 2009. A total of 21 shovel tests were judgmentally excavated in the following areas: two within the Site, four within the radial collector well area, five within the FPL reclaimed water treatment facility area, and 10 within the FPL-owned fill source area. These subsurface tests resulted in stratigraphic sequences consistent with land modification, disturbance, and inundation. No artifacts, features, or cultural material were identified in any of the shovel tests conducted during the survey. The field investigations confirmed that the locations of the Site and associated non-linear facilities have a low probability for archaeological sites. The results of the field investigations are detailed below.

Site

The area along the southern edge of the Site was examined to determine whether any remnants of a possible hammock, as suggested by the historic plat map, existed. The survey confirmed that this area consisted of a spoil pile from the canal bordering the property to the south. An area of slightly higher elevation on the spoil pile appeared to be in the approximate location of the possible hammock. A shovel test was excavated in that location and revealed that the strata consisted of 30 cm of spoil overlying black peat. Water was encountered at 60 cm below the surface. A second shovel test was excavated to the north of the spoil pile in an area containing mangroves. This shovel test consisted of brown muck and water, which was evident at the surface. The remainder of the Site consisted of mudflats, some of which were too low or unstable to walk on or through. The mudflats are frequently inundated and have been impacted by flooding and hurricanes over the years.

Nuclear Administration Building, Training Building and Parking Area

The nuclear administration building, training building and parking area are located within the plant property in an area dominated by mangrove and coastal plain willow. This area is considered to have a low probability for archaeological sites. Given the wet environmental conditions, the results of the survey, and the lack of previously recorded sites within or adjacent to the Turkey Point plant property and the Everglades Mitigation Bank, subsurface testing was not deemed necessary.

Radial Collector Wells

Four test excavations conducted within the radial collector well corridor demonstrated an average 40 cm deposit of limestone fill before the shovel test was inundated with groundwater, indicating that this area is man-made land.

FPL Reclaimed Water Treatment Facility and Delivery Pipelines to the Plant Area

The area proposed for the FPL reclaimed water treatment facility consisted of dwarf mangroves and sawgrass with clusters of Australian pines. One of the Australian pine clusters was tested and showed a black muck to a depth of about 40 cm underlain by water. A line of five shovel tests was placed running along the northern area resulting in a white-ashy muck to a grayish brown colored muck and water was encountered very close to the surface.

The delivery pipeline to the plant follows an existing access road south of the facility; crosses fill areas and roadways and goes underneath the existing discharge canal before ending at the southwest portion of the Site. This area is considered to have a low probability for archaeological sites. Given the existing conditions, the results of the survey, and the lack of previously recorded sites within or adjacent to the Turkey Point plant property and the Everglades Mitigation Bank, subsurface testing was not deemed necessary.

FPL-Owned Fill Source

Archaeological testing within the FPL-owned fill source revealed gray brown loamy clay, which ranged in depth from approximately 10 to 30 cm below the surface, over limerock. No archaeological material was identified.

Equipment Barge Unloading Area

The equipment barge unloading area is located within the plant property to the north of the Site in land currently classified as electric power facilities. A portion of the existing barge unloading area will be expanded. This area is considered to have a low probability for archaeological sites. Given the existing conditions, the results of the survey, and the lack of previously recorded sites within or adjacent to the Turkey Point plant property and the Everglades Mitigation Bank, subsurface testing was not deemed necessary.

Heavy Haul Road on Plant Property

The heavy haul road is an existing heavy haul road located within the plant property. The only improvements will be to improve the road for additional weight. This area is considered to have a low probability for archaeological sites. Given the existing conditions and the lack of proposed ground disturbance, no subsurface testing was deemed necessary.

Spoils Areas on Plant Property

Spoils generated from de-mucking the Site will be deposited onto existing spoils berms adjacent to the Grand Canal (main return canal) and the southern boundary of the industrial wastewater facility. The existing berms consist of limestone taken from the adjacent canals. This area is considered to have a low probability for archaeological sites. Given the existing conditions and the lack of proposed ground disturbance, subsurface testing was not deemed necessary.

A Cultural Resource Assessment Survey Work Plan (FPL 2009b) was submitted to SHPO in June 2009 that summarized the results of the *Cultural Resource Assessment Survey* (FPL 2009a). Based on the results of the survey, which included both historical research and field survey, the recommendation that no further field investigations or research are needed for these construction areas was proposed to SHPO. Additional recommendations included continued coordination with the Miami-Dade County Office of Historic and Archaeological Resources, consultation with five federally recognized tribes (see Subsection 2.5.3.4) regarding the results of the archaeological field assessment, and development of an Unanticipated Finds Plan and associated Contractor Training Program.

SHPO concurred with the recommendations of the Work Plan in July 2009 (FDOS Jul 2009a). The letter of concurrence has been attached as Appendix 2.5A. FPL will implement the Work Plan recommendations prior to construction on the site and associated non-linear facilities.

2.5.3.3.2 Units 6 & 7 Associated Linear Facilities

A Preliminary Cultural Resources Report for the Turkey Point Units 6 & 7 Associated Linear Facilities (FPL 2009c) was prepared by FPL and submitted in June 2009 as part of the Turkey Point Units 6 & 7 Site Certification Application (FPL 2009e). This survey addressed the potential for historic properties within the following potentially impacted areas:

- New transmission lines going north and west from the Clear Sky substation (the East Preferred Corridor and West Preferred/Secondary Corridors) and the Levee substation expansions.
- Reclaimed water delivery pipelines from the MDWASD South District Wastewater Treatment Plant to the FPL reclaimed water treatment facility (reclaimed water delivery pipelines).
- Access roads and bridges to Units 6 & 7 (access roads and bridges).
- Potable water pipelines from MDWASD potable water transmission main to Units 6 & 7 (potable water pipelines).

The locations of these areas are depicted in Figures 2.2-5 (transmission and reclaimed water corridors) and 3.9-1.

The Preliminary Cultural Resources Report (FPL 2009c) researched a direct effects APE of 100 feet from the associated linear facilities to identify any previously recorded archaeological sites. An indirect APE for potential visual effects is defined as the area within which the improvements could be observed. For this preliminary report, the indirect APE was defined as 500 feet from the associated linear facilities to identify any previously recorded historic structures, resource groups, bridges, and cemeteries. No previously recorded resources were located within the direct or indirect APEs for the reclaimed water delivery pipeline, potable water pipelines, access roads, or bridges. For the West Preferred/Secondary corridors, three previously recorded archaeological sites are located with the direct APE and three resource groups (a trail, a canal, and a railway) cross the corridors. Also, two historic structures are located between 100 and 500 feet of the corridors. For the East Preferred Corridor, the direct APE contains two archaeological sites, 82 historic structures, 12 resource groups, and one historic bridge. The indirect APE includes an additional 109 historic structures, one resource group, and one historic bridge.

Based on the results of the *Preliminary Cultural Resources Report* (FPL 2009c), a *Cultural Resource Assessment Survey Work Plan* (FPL 2009d) was prepared by FPL and submitted to SHPO for their review and concurrence with the recommendation for further surveys and investigations. The areas considered include the western and eastern transmission lines, the reclaimed water and potable water pipelines, and the access roads and bridges. The APE for direct effects would be the construction corridors for the transmission lines, the reclaimed water and potable water pipelines, access road rights-of-way, and any associated staging or laydown areas. Only the transmission lines would have an indirect APE because the other work areas would be at or below the ground surface. This indirect APE for the transmission lines would be determined in consultation with the SHPO after conduct of a reconnaissance visual survey. The SHPO agreed (FDOS Jul 2009b) with the recommendation proposed in the Work Plan (FDEP 2009d). The SHPO response is included in Appendix 2.5A.

Specific recommendations for offsite linear facilities with which the SHPO concurred include the following:

Archaeological and Historic Survey and Identification Plan for Access Roads and Bridges

- Historic access roads and bridges will be surveyed prior to construction.
- No archaeological survey will be necessary for existing roads with no proposed widening.
- Visual surveys of all roads will be conducted to identify areas of high archaeological probability within new roads or areas of road widening.

- Standard archaeological surveys will be conducted in areas of high archaeological potential. Testing will be conducted at 25-meter intervals within the APE.

Archaeological Survey and Identification Plan for the Transmission Line Corridors, the Reclaimed Water Delivery Pipelines and the Potable Water Pipelines

- Surveys will be conducted prior to construction.
- The APE for archaeological survey will be confined to the construction corridor and associated staging areas.
- Visual surveys will be conducted of the APE to refine areas of high archaeological probability.
- All previously recorded archaeological sites within the APE will be field verified and re-evaluated. Updated Florida Master Site File (FMSF) forms will be completed for each previously recorded site.
- A reconnaissance level survey will be conducted for previously surveyed areas that do not meet current professional standards. In areas that have not been previously surveyed, a standard archaeological survey will be conducted of high and moderate probability zones. Testing will be conducted at 25-meter and 50-meter intervals respectively, with judgmental testing of low probability zones. Shovel testing will be confined to the APE.

Historic Resource Survey and Identification Plan for the Transmission Line Corridors, the Reclaimed Water Delivery Pipelines, and Potable Water Pipelines

- Surveys will be conducted prior to construction.
- A standard historic resource survey will be conducted to identify resources in areas that have not been previously surveyed. FMSF forms will be completed for newly identified resources.
- All previously recorded historic districts and individual resources in the APE will be field verified. Each individual building or structure within the boundaries of a previously recorded historic district will not be field verified. Updated FMSF forms will be completed only if substantial changes have occurred since a resource's initial recording, including: demolition, change in National Register status, and change in original massing.
- The boundaries of both previously recorded and newly identified historic districts will be noted and recorded on FMSF forms. Individual buildings within the historic district will not be recorded.

- A reconnaissance level historic resource survey will be conducted of the APE for indirect impacts of the transmission line corridors. This APE will be determined in consultation with the SHPO's office.

Other recommendations with which the SHPO concurred include continual tribal coordination and the development of an Unanticipated Finds Plan and Contractor Training for the non-linear facilities prior to construction. FPL will implement the Work Plan recommendations prior to construction of the associated linear facilities. When field investigations have been completed, a report of the results will be submitted, along with recommendations on effects to historic properties, to the SHPO for consultation under Section 106 of the NHPA. The report, recommendations on effect, and the SHPO's response will be provided to the NRC.

2.5.3.4 Native American Consultation

Five federally-recognized tribes with cultural affiliation to Florida have been notified about the Units 6 & 7 project. These tribes include: Miccosukee Tribe of Indians of Florida, the Seminole Tribe of Florida, the Muskogee Creek Indians, the Poarch Band of Creek Indians, and the Seminole Nation of Oklahoma. A meeting was held by FPL with the land management of the Miccosukee Tribe on January 9, 2009 to discuss the project. The Miccosukee Tribe of Indians of Florida and the Seminole Tribe of Florida have reservations in the State of Florida. Consultations will be held with these five tribes regarding the results of any archaeological field investigations conducted for the project. Letters and responses received from the tribes have been included in Appendix 2.5A.

2.5.3.5 Significant Cultural Resources within 10 Miles

There are seven types of designations in the project region of interest to recognize and protect significant historic and prehistoric properties; two are federal, three are state, and two are local designations. The National Park Service designates areas as National Historic Landmarks and lists properties on the National Register of Historic Places. The Florida Division of Historical Resources offers three designations: State Archeological Landmark, Florida Heritage Site, and Florida Heritage Landmark. In addition, the Miami-Dade County Historic Preservation Board and the Homestead Historic Preservation Board each maintain a listing of significant cultural resources within their respective jurisdictions.

A search of records maintained by the National Park Service, Florida Division of Historical Resources, Miami-Dade County, and city of Homestead was conducted to identify significant cultural resources located within 10 miles of Units 6 & 7. The research identified 290 individual resources and five resource groups in the search area. These resources are summarized below, and are listed with details in Tables 2.5-44 through 2.5-47.

Within the search area are 22 archaeological sites, most are located in Key Largo and Elliott Key. None are located within the Turkey Point plant property. The sites date to both prehistoric and historic periods, and include middens, refuse dumps, road segments, artifact scatters, and habitations. One site is listed on the National Register of Historic Places and one site is listed by the Miami-Dade Historic Preservation Board.

Two historic cemeteries are located within the 10-mile search area. One is in Naranja and one in Miami. Both date to the early 20th century and the latter is listed by the Miami-Dade Historic Preservation Board.

The search area contains 266 recorded historic period structures, of which 34 have been designated as destroyed (likely by hurricanes). These resources are found mostly in Homestead, followed by Florida City and South Dade County. The other towns with historic structures in the search area are Goulds, Leisure City, Miami, Modello, and Naranja. None are located within the Turkey Point plant property. Most of the historic structures are residences, though public and commercial buildings are also represented. Nine of the structures are listed on the National Register of Historic Places, while 19 have been designated as significant by the Miami-Dade Historic Preservation Board and 8 have been designated by the Homestead Historic Preservation Board.

There are five resource groupings within the 10-mile search area. One is an archaeological district located offshore on Islandia. This district contains both prehistoric and historic resources and is listed on the National Register of Historic Places. Another is an historic district located in Goulds. It is listed by the Miami-Dade Historic Preservation Board, but has not been evaluated for National Register of Historic Places eligibility. Two other historic districts, located in Homestead and in Key Largo, are both listed on the National Register of Historic Places. Finally, there is a railway located in Miami that has not been evaluated for listing.

2.5.3.6 Significant Cultural Resources within 1.2 Miles of Offsite Areas

A search of records maintained by the National Park Service, Florida Division of Historical Resources, Miami-Dade County, and city of Homestead was conducted to identify significant cultural resources located within 1.2 miles of the transmission lines, substations, and reclaimed water pipelines. The research identified 178 individual resources and five resource groups in the search area. These resources are summarized below, and are listed with details in Tables 2.5-48 through 2.5-51.

Within the search area are 58 archaeological sites, six of which have been destroyed since recording. Most of the sites are in the search area surrounding the northern portion of the proposed transmission lines, in unincorporated Dade County west of the developed metropolitan area from Everglades National Park north to the area around Pennsuco substation. Other

locations include Alladin City, Florida City, Goulds, Hialeah, Hialeah Gardens, Homestead, Medley, Miami, and Pennsuco. The sites date to both prehistoric and historic periods, and include campsites, roads, habitations, artifact scatters, middens, burials, a quarry, and a mound. None are listed on the National Register of Historic Places; however, nine sites are listed by the Miami-Dade Historic Preservation Board.

The northern-most portion of the eastern transmission line corridor is located within the North Bank and West Bank Archaeological Zones designated by the City of Miami. The same portion of the eastern transmission line corridor is also located less than 500 feet west of the City of Miami's South Bank Archaeological Zone.

Only one historic cemetery is located within the 1.2-mile search area. It is an African-American cemetery located in Miami. It dates to the early 20th century and is listed by the Miami-Dade Historic Preservation Board.

The search area contains 303 recorded historic period structures, of which one has been designated as destroyed (likely by hurricanes). These resources are found mostly in the search areas surrounding the northern half of the proposed Turkey Point-to-Davis transmission line, along the Davis-to-Miami line, and in unincorporated Dade County west of Florida City and Homestead. The other places with historic structures in the search area are Florida City, Goulds, Homestead, Longview, Medley, Miami, and Pennsuco. Most of the historic structures are residences, though public and commercial buildings are also represented. Four of the structures are listed on the National Register of Historic Places, while 21 have been designated as significant by the Miami-Dade Historic Preservation Board.

There are 16 resource groupings within the 1.2-mile search area. Ten of the groupings are linear resources, mostly roads, which extend through multiple towns. Five groupings are districts and one grouping is a multiple property submission. Seven of the resource groups have been determined potentially eligible for listing on the National Register of Historic Places. Two resource groups are listed on the Register: the Calle Ocho and the MacFarlane Homestead Historic District.

2.5.4 ENVIRONMENTAL JUSTICE

2.5.4.1 Methodology

Environmental justice is defined as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies (U.S. EPA 2008). Concern that minority and/or low-income populations might be bearing a disproportionate share of adverse health and environmental impacts led to Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations.*

This order directs federal agencies to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low income populations (EO 1994). The Council on Environmental Quality has provided guidance for addressing environmental justice (CEQ 1997). The NRC has also issued guidance on environmental justice analysis in *Procedural Guidance for Preparing Environmental Assessments and Considering Environmental Issue*s. NRC guidance was used to determine the minority and low-income composition in the environmental impact area.

The NRC concluded that a 50-mile radius could reasonably be expected to contain the area of potential impact and that the state was appropriate as the geographic area for comparative analysis. The NRC methodology identifies minority and low-income populations within the 50-mile region and then determines if these populations could receive disproportionately high adverse impacts from the proposed action. This approach was adopted for identifying the minority and low-income populations and associated impacts that could be caused by the proposed action. While this section identifies the locations of minority and low income populations in the area surrounding the plant property, the potential adverse impacts to these groups from construction and operation are identified and described in Chapters 4 and 5, respectively.

The ArcGIS®[1] 10.0 software was used with 2005-2009 American Community Survey (ACS) data to determine minority and low-income populations by block group within 50 miles of Units 6 & 7 (i.e., the environmental impact area), which is located in Miami-Dade County. A census block group is a geographic unit used by the USCB, hierarchically between the census tract and census block. A block group generally contains 600 to 3000 people. For the environmental justice analysis of Units 6 & 7, a block group in the analysis set was included if any part of its area fell within 50 miles. There are 1627 block groups that meet this criterion (Table 2.5-52). Consistent with the NRC guidance, the geographic area for comparative analysis was defined as the state of Florida.

2.5.4.2 Minority Populations

The NRC *Procedural Guidance for Preparing Environmental Assessments and Considering Environmental Issues* defines minority categories as: American Indian/Alaskan Native races, Asian race, Native Hawaiian/Other Pacific Islander races, Black races, and Hispanic ethnicity. Additionally, the guidance states that “Other” race may be considered a separate category and requires that the multiracial and aggregate racial minority categories be analyzed separately. The

1. ArcGis is a registered trademark of Environmental Systems Research Institute, Inc.

guidance also indicates that a significant minority population exists if either of two conditions is met:

- The minority population of a block group or environmental impact area exceeds 50 percent.
- The minority population of a block group or environmental impact area is a significantly greater proportion than the minority population in the geographic comparison area. “Significantly greater” is defined as at least 20 percentage points.

Each minority group’s proportion of each of the 1627 block groups was calculated in the 50-mile radius using 2005-2009 ACS data, and each minority group’s proportion of the population in the state of Florida was also calculated. If the percentage of any minority population in a block group exceeded 50 percent of the total population in that block group, or if it surpassed the state’s percentage for that minority category by 20 percentage points or more, that block group qualified as containing a “significant” minority population. Some block groups contained more than one significant minority population.

For this analysis, Florida was the geographic comparison area. According to 2005-2009 ACS census data for the state of Florida (Table 2.5-52), 15.4 percent of the state’s population is Black, 0.3 percent is American Indian/Alaska Native, 2.3 percent is Asian, 0.05 percent is Native Hawaiian/Other Pacific Islander, 3.6 percent is Other, 1.8 percent is multiracial (two or more races), and 20.6 percent of the state’s population is of Hispanic ethnicity. Persons of Hispanic ethnicity may be of any race.

Table 2.5-52 provides the block group analysis results and Figures 2.5-24 through 2.5-30 show the locations of block groups with significant minority populations. There are 411 block groups within 50 miles of Units 6 & 7 with a significant Black population. Units 6 & 7 lie within the closest block group (Figure 2.5-24). Of these 411 block groups, 92 are in Broward County (more than 36 miles from the plant area) and the remaining 319 are in Miami-Dade County.

There is only one block group with a significant American Indian or Alaskan Native population within 50 miles of Units 6 & 7. It is in Broward County, approximately 42 miles north-northeast, adjacent to the Hollywood Indian Reservation. The Hollywood Reservation is one of six reservations of the Seminole Tribe of Florida. As the Seminole Tribe of Florida Headquarters, the reservation offers many commercial enterprises including a restaurant, casinos, and a museum.

Four Miccosukee Indian Reservations--Tamiami Trail (Miami-Dade County), Alligator Alley (Broward County), and two at Krome Avenue (Miami-Dade County)--also lie within 50 miles. There are over 640 people enrolled in the Miccosukee Tribe. The Tamiami Trail Reservation, which consists of four parcels of land, is 40 miles west of Miami and is presently the site of most tribal operations and the center of the Miccosukee Indian population. One parcel is under a

50-year use permit from the National Park Service, which expires on January 24, 2014. The other three parcels were originally dedicated to the Miccosukee by the state of Florida and have since acquired federal reservation status. These areas are used for commercial development. The tribe also has a perpetual lease from the state of Florida for 189,000 acres, which is part of the South Florida Water Management District's Conservation Area 3A South. The tribe is allowed to use this land for hunting, fishing, frogging, subsistence agriculture, and to carry on the traditional Miccosukee way of life. Alligator Alley is the largest of the Miccosukee Tribe's reservations, comprising approximately 75,000 acres. This land consists of 20,000 acres with potential for development and 55,000 acres of wetlands. The reservation contains a modern service station plaza, a police substation, and 13,000 acres of land that is leased for cattle grazing. There are two reservations located at the intersection of Krome Avenue and Tamiami Trail. One (25 acres) is the site of the Miccosukee Indian gaming facility and the Miccosukee resort and convention center. The second reservation area (less than 1 acre) is the site of the Miccosukee tobacco shop (Miccosukee Tribe of Indians of Florida 2012).

Figure 2.5-25 shows the locations of the single American Indian or Alaskan Native block group, the Hollywood Indian Reservation, and the Miccosukee Indian Reservations.

There are six block groups with a significant Asian minority population, all within Miami-Dade County. The closest of these is approximately 22 miles north of Units 6 & 7. Figure 2.5-26 shows the locations of these block groups. There are 22 block groups with a significant *Other* races population. The closest is approximately 15 miles north-northeast of Units 6 & 7. The locations of these block groups are shown on Figure 2.5-27. Two block groups within 50 miles have significant multiracial minority populations, both are in Miami-Dade County. The closest of these is approximately 10 miles north-northwest of Units 6 & 7. These block groups' locations are shown on Figure 2.5-28. Within the 50-mile radius, 443 block groups contain significant aggregate minority racial populations (Figure 2.5-29). The closest of these is the block group containing the Turkey Point plant property.

There are 843 block groups (58 in Broward County, 783 in Miami-Dade County, and 2 in Monroe County) that contain significant Hispanic ethnicity minority populations (Figure 2.5-30).

Seasonal, agricultural (migrant) workers may make up a portion of the minority population within 50 miles. While migrant worker populations are not available from USCB, the U.S. Department of Agriculture has collected information on farms that employ migrant labor. Farms in the following Florida counties, which fall wholly or partially within the 50-mile radius, employ migrant labor: Broward (24 farms), Collier (31), and Miami-Dade (234). There are no farms in Monroe County that employ migrant labor (USDA 2007).

2.5.4.3 Low-Income Populations

The NRC guidance defines low-income households based on statistical poverty thresholds. A block group is considered low income if either of the following two conditions is met:

- The low-income population of a block group or environmental impact area exceeds 50 percent.
- The low-income population of a block group or environmental impact area is a significantly greater proportion than the low income population in the geographic comparison area. “Significantly greater” is defined as at least 20 percentage points.

The proportion of low-income households was calculated in each block group within 50 miles relative to the total households in that block group. For this analysis, Florida is the geographic comparison area. For the state of Florida as a whole, it was determined that 12.5 percent of households are low income (Table 2.5-52). Within 50 miles of Units 6 & 7, 231 block groups have a significant low-income population. Table 2.5-52 identifies and Figure 2.5-31 locates the significant low-income block groups, 212 of which are in Miami-Dade County and 19 in Broward County. There are no significant low-income block groups in Collier or Monroe County.

2.5.4.4 Potential for Disproportionate Impacts

Local government officials, staff of social welfare agencies, and the Miccosukee Indian Tribe were contacted concerning unusual resource dependencies or practices or health conditions that could result in potentially disproportionate impacts to minority and low-income populations. Contacts with multiple government entities in Miami-Dade County were attempted.

Many agencies had no information concerning activities and health issues of minority populations. Interviews were conducted with the Community Action Agency, Miami-Dade Office of Community Advocacy, Miami-Dade County Community and Economic Development, Countywide Healthcare Planning, Metro Miami Action Plan Trust, and the Miami-Dade Black Advisory Board. No agency reported dependencies or practices, such as subsistence agriculture, hunting, or fishing, or preexisting health conditions through which the populations could be disproportionately or adversely affected by the proposed project. Several agencies alluded to the extreme urban nature of the study area and implied that there was no possibility of any subsistence activity on the part of any group.

Contact with the Miccosukee Indian Tribe reported that the Indians residing in the reservation within the 50-mile radius do not depend on hunting, fishing, or gardening for subsistence. The Miccosukee Tribe does lease land from the SFWMD for hunting, fishing, frogging, agriculture, and to carry on the traditional Miccosukee way of life. However, most tribal members rely on modern means to meet their food needs.

February 20, 2009

Ms. Laura Kammerer
Florida Department of State
Division of Historical Resources
RA Gray Building, 4th floor
500 S. Bronough St.
Tallahassee FL 32399-0250

SUBJECT: Florida Power & Light Company Turkey Point Units 6 & 7 Project, Miami Dade County, Florida

Dear Ms. Kammerer:

Florida Power & Light Company (FPL) is preparing permit and license applications to the U.S. Nuclear Regulatory Commission (NRC), the Florida Department of Environmental Protection (FDEP) and the United States Army Corps of Engineers (USACE) to allow construction and operation of two new nuclear units and associated project features at our existing Turkey Point property in Miami-Dade County, Florida (the "proposed action").

This project will require federal approval by the NRC and USACE. Therefore, consistent with Section 106 of the National Historic Preservation Act (NHPA) of 1966 (Public Law 89-665, as amended), as implemented by 36 CFR 800 (Protection of Historic Properties, effective January 2001), a cultural resource assessment is in progress. Moreover, this project is being conducted in accordance with F.A.C. Electrical Power Plant Siting Act and as prescribed by DEP Form 62-11.211(1), F.A.C. Accordingly, the cultural resource assessment will comply with Chapter 267, Florida Statutes (Florida Historical Resources Act), the minimum field methods, data analysis, and Chapter 1A-46 (Archaeological and Historical Report Standards and Guidelines), F.A.C.

Janus Research is assisting FPL with the cultural resource investigations and will be contacting your office on FPL's behalf to obtain required information as needed. A cultural resource assessment (CRA) survey of the proposed power plant site and facilities associated with the project is in progress. A copy of this report will be submitted with the Site Certification Application. A CRA survey of additional facilities associated with the proposed project (e.g., transmission lines) will be conducted once final routes and locations are selected. Field work in areas where FPL does not control the property may have to wait until the final right of way is secured. Copies of the CRA report for associated facilities will be forwarded to you office when completed and post SCA submittal.

The Turkey Point property is located in Miami-Dade County, Florida, adjacent to Biscayne Bay and Card Sound, about 25 miles south of Miami (Figure 1). The total, non-contiguous property area is approximately 11,000 acres. The developed portion of the property includes a natural gas fueled generating unit; two oil/gas-fired generating units, and two nuclear-powered generating units. This proposed action would further develop approximately 300 acres of the property west and south of these existing units, primarily within an existing cooling canal /industrial wastewater treatment facility. In addition, FPL will construct (1) pipelines to convey dual cooling water supplies (reclaimed and saltwater) to new cooling towers, (2) power transmission lines to connect the new units with the regional electric grid, and (3) a reclaimed water treatment facility to condition the reclaimed water for cooling water uses. In addition, because fill material is necessary for the unit foundations, FPL is proposing to place fill sourced from a commercial mine and/or nearby FPL-owned property approximately 4 miles northwest of the proposed site. These areas are shown in Figures 2 and 3. Figures 2A and 2B include the project features in the vicinity of the proposed plant area. Figure 3 also provides an expanded view of the area showing the proposed transmission corridor.

Please note that an Unanticipated Finds Plan will be in place prior to construction in the unlikely event that any cultural remains are encountered during construction. In the event that human remains, archeological or historical objects are found during construction or maintenance activities, all activity that might disturb the human remains will cease in accordance with the provisions of Chapter 872.05. In addition, if historical or archeological artifacts are discovered, notification will be made to the Florida Department of Environmental Protection Southeast District Office and Bureau of Historical Preservation, Division of Historical Resources Office.

Thank you for your attention to this request; I will follow up with you to confirm receipt and to address any questions or concerns you may have. Should you need to talk to me earlier, please reach me by telephone at 561-691-2808.

Sincerely,

Matthew J. Raffenberg

Manager, Environmental Licensing

FLORIDA DEPARTMENT OF STATE
Kurt S. Browning

Re: DHR Project File No.: 2009-3841 / Received by DHR: June 30, 2009
Cultural Resource Assessment Survey for the Turkey Point Units 6 & 7 Site, Associated Non-Linear Facilities, and Spoils Areas on Plant Property, Miami-Dade County, Florida

Dear Ms. Hoffman:

Our office received and reviewed the above referenced survey report in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 C.F.R., Part 800: Protection of Historic Properties for assessment of possible adverse impact to cultural resources (any prehistoric or historic district, site, building, structure, or object) listed, or eligible for listing, in the National Register of Historic Places (NRHP).

In October 2008, December 2008, March 2009, and April 2009, Janus Research conducted an archaeological and historical Phase I survey of the proposed Turkey Point Units 6 & 7 site, associated non-linear facilities, and spoils areas on plat property on behalf of the Florida Power & Light Company. Janus Research identified no cultural resources within the project area during the investigation.

Our office finds the submitted report complete and sufficient in accordance with Chapter 1A-46, *Florida Administrative Code.* Based on the information provided, it is the opinion of this office that the proposed development will have no effect on historic properties. However, we also concur with Janus Research that, prior to construction, an unanticipated finds plan should be developed to outline the procedures and identify personnel to be contacted if significant archaeological material or human remains are encountered during construction.

If you have any questions concerning our comments, please contact Samantha Earnest, Historic Preservationist, by electronic mail at *swearnest@dos.state.fl.us*, or by telephone at 850-245-6333 or 800-847-7278.

Sincerely,

Laura A. Kammerer

Re: DHR Project File No.: 2009-3838 / Received by DHR: June 25, 2009
Cultural Resource Assessment Survey Work Plan for the Turkey Point Units 6 & 7 Site and Associated Non-Linear Facilities
Miami-Dade County, Florida

Dear Mr. Raffenberg:

Our office received and reviewed the above referenced work plan in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 C.F.R., Part 800: Protection of Historic Properties for assessment of possible adverse impact to cultural resources (any prehistoric or historic district, site, building, structure, or object) listed, or eligible for listing, in the National Register of Historic Places (NRHP).

In October 2008, December 2008, March 2009, and April 2009, Janus Research conducted an archaeological and historical Phase I survey of the proposed Turkey Point Units 6 & 7 site, associated non-linear facilities, and spoils areas on plat property on behalf of the Florida Power & Light Company. This survey was submitted to this office in June 2009 (DHR Project File No. 2009-3841). Janus Research identified no cultural resources within the project area during the investigation. As a result, the above referenced work plan included the following recommendations:

1. No further field investigations of the site or associated non-linear facilities are recommended.
2. A copy of the final survey results should be sent to the five federally recognized tribes with cultural affiliation to Florida.
3. Prior to construction, an unanticipated finds plan should be developed to outline the procedures and identify personnel to be contacted if significant archaeological material or human remains are encountered during construction.

Based on the information provided, our office concurs with these recommendations as outlined in the work plan.

Re: DHR Project File No.: 2009-3839 / Received by DHR: June 25, 2009
Cultural Resource Assessment Survey Work Plan for the Turkey Point Units 6 & 7 Associated Linear Facilities
Miami-Dade County, Florida

Dear Mr. Raffenberg:

Our office received and reviewed the above referenced work plan in accordance with Section 106 of the National Historic Preservation Act of 1966, as amended, and 36 C.F.R., Part 800: Protection of Historic Properties for assessment of possible adverse impact to cultural resources (any prehistoric or historic district, site, building, structure, or object) listed, or eligible for listing, in the National Register of Historic Places (NRHP).

In 2009, Janus Research conducted background research to identify previously recorded archaeological resources within 100 feet and historic cultural resources within 500 feet of the associated linear facilities, and to identify areas of high, medium, and low probability for the presence of unrecorded cultural resources. As a result of this analysis, Janus Research has made the following recommendations:

1. Archaeological and Historic Survey and Identification Plan for Access Roads and Bridges:

    a. Historic access roads and bridges will be surveyed prior to construction.
    b. No archaeological survey will be necessary for existing roads with no proposed widening.
    c. A visual survey of all roads will be conducted to identify areas of high archaeological probability within new roads or areas of road widening.
    d. A standard archaeological survey will be conducted of these high probability areas. Testing will be conducted at 25-meter intervals within the area of potential effect (APE).

2. Archaeological Survey and Identification Plan for the Transmission Line Corridors, Reclaimed Water Delivery Pipelines, and Potable Water Pipelines

    a. Surveys will be conducted prior to construction.
    b. The APE for the survey will be confined to the construction corridor and associated staging areas.

c. The APE will be subjected to a visual survey to refine archaeological probability areas.
d. All previously recorded archaeological sites in the APE will be field verified and re-evaluated. Updated Florida Master Site File (FMSF) forms will be completed for each previously recorded site.
e. A reconnaissance level survey will be conducted for previously surveyed areas that do not meet current professional standards.
f. In areas that have not been previously surveyed, a standard archaeological survey will be conducted of high and moderate probability zones. Testing will be conducted at 25-meter and 50-meter intervals respectively, with judgmental testing of low probability zones. Shovel testing will be confined to the APE.

3. Historic Resource Survey and Identification Plan for the Transmission Line Corridors, Reclaimed Water Delivery Pipelines, and Potable Water Pipelines

a. Surveys will be conducted prior to construction.
b. A standard historic resource survey will be conducted to identify resources in areas that have not been previously surveyed. FMSF forms will be completed for newly identified resources.
c. All previously recorded historic districts and individual resources in the APE will be field verified. Individual structures or buildings within the boundaries of a previously recorded historic district will not be field verified. Updated FMSF forms will be completed only if substantial changes have occurred since a resource's initial recording, including: demolition, change in National Register status, and change in original massing.
d. The boundaries of both previously recorded and newly identified historic districts will be noted and recorded on FMSF forms. Individual buildings within the historic district will not be recorded.
e. A reconnaissance level historic resource survey will be conducted of the APE for indirect impacts of the transmission line corridors. This APE will be determined in consultation with our office.

4. A copy of the final survey report should be sent to the five federally recognized tribes with cultural affiliation to Florida.

5. Due to the proximity of the project to Tribal lands associated with the Florida-resident Seminole Tribe of Florida and the Miccosukee Tribe of Indians of Florida, a meeting is recommended prior to the initiation of field investigations. The purpose of this meeting will be to review the project, address any comments resulting form the project notification letters previously sent to the Tribes, and to identify any cultural issues, sacred areas, or traditional use areas within the APE. Further coordination is recommended to resolve any potential concerns should any such issues be identified during the survey.

6. Prior to construction, an unanticipated finds plan should be developed to outline the procedures and identify personnel to be contacted if significant archaeological material or human remains are encountered during construction.

7. Section 106 consultation will be conducted with this office to identify and resolve any adverse effects to significant resource.

Based on the information provided, our office concurs with these recommendations as outlined in the work plan. We look forward to receipt of the final survey report for review and comment.

If you have any questions concerning our comments, please contact Samantha Earnest, Historic Preservationist, by electronic mail at *swearnest@dos.state.fl.us*, or by telephone at 850-245-6333 or 800-847-7278.

Sincerely,

Laura A. Kammerer

SUBJECT: Information Sharing Supporting Section 106 of the *National Historic Preservation Act* for the Proposed Turkey Point Units 6 & 7 On-Site Project Facilities, Florida

Florida Power and Light Company (FPL) has submitted a Combined Operating License (COL) Application to the Nuclear Regulatory Commission (NRC) to construct and operate nuclear power Unit 6 & 7 at the Turkey Point site, located east of Homestead, Florida. The Unit 6 & 7 project would provide clean, safe and reliable power to meet the needs of FPL's customers. As part of its COL Application, FPL included an environmental report to assist the NRC prepare an environmental impact statement (EIS) under the *National Environmental Policy Act*. The decision by the NRC on whether to issue the license for construction and operation of Units 6 & 7 meets the definition of an "undertaking" under the *National Historic Preservation Act* (NHPA) and its implementing regulations 36 CFR Part 800.16(y).

FPL has shared project information with the Florida Division of Historical Resources (DHR) and the Florida State Historic Preservation Officer for this proposed project. Specifically a final cultural resources assessment (CRA) report of on-site areas and associated non- linear facilities and a preliminary CRA report on the associated linear facilities were submitted to the DHR as part of FPL's Site Certification Application (SCA).

By recommendation from the DHR, FPL hereby offers to share project information with potentially interested Tribes to assist us in identifying important cultural resources that could be present in the vicinity of the proposed undertaking. Attached is the CRA report addressing the on-site areas and other non-linear associated facilities affected by the proposed undertaking. Linear facilities (namely access roads, transmissions lines, and water pipelines) are being permitted as corridors in the SCA process. Therefore, the CRA report for the project's linear facilities will be shared with you after placement of those facilities is finalized.

Description of the Proposed Project

The project would add two new nuclear generating units and supporting facilities at a site within the existing Turkey Point plant property boundaries. The Project includes the construction and operation of Turkey Point Unit 6 & 7 on the site as well as new transmission lines and other off-site associated linear and non-linear facilities.

FPL's Turkey Point plant property comprises approximately 11,000 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead, and bordered by Biscayne Bay to the east. The existing Turkey Point Plant consist of two nominal 400-megawatt (MW) natural gas/oil steam electric generating units (Units 1 & 2); two nominal 700-MW nuclear units (Units 3 & 4); and a nominal 1,150 MW natural gas-fired combined-cycle unit (Unit 5). The existing closed- loop cooling canals and industrial wastewater facility occupy approximately 5,900 acres. The location of the Turkey Point plant property is shown in Figure 1.

The site for Turkey Point Units 6 & 7 is south of Units 3 &4 and occupies approximately 300-acres within the industrial wastewater facility. Two nuclear generating units, each with an approximate electrical out put of 1,100 MWe (net), including supporting buildings, facilities and equipment will be located on the site, along with a laydown area. Proposed off-Site associated facilities include: nuclear administration building, training building and parking area; an FPL reclaimed water treatment facility and reclaimed water pipelines; radial collector wells and delivery pipelines; equipment barge unloading area; an FPL–owned fill source; transmission lines and system improvements within Miami-Dade County; access roads and bridges; and a potable water pipeline. The site and proposed off-site associated facilities are shown in Figures 2 to 5. Because the linear facilities are being permitted as corridors, the areas shown on these figures is actually larger than the areas that will be impacted by actual construction and operation of the linear facilities.

Information Sharing with the Florida Division of Historical Resources

On February 20, 2009, FPL notified the DHR that it was commencing a CRA of on-site areas and would be contacting the SHPO to obtain required information as needed. On June 25, 2009, FPL forwarded to DHR its CRA survey work plans for the on- and off-site project areas. In that submittal, FPL requested concurrence that (1) the determination and definition of the Areas of Potential Effect (APEs) are appropriate for the project and (2) implementation of the work plans would constitute a reasonable and good-faith effort to carry out appropriate identification efforts of historic properties that could potentially be impacted by the project. On July 13, 2009, the DHR concurred with all the recommendations provided by FPL in the on-and off-site CRA survey work plans. The DHR recommended that the final CRA survey results be sent to the five federally-recognized tribes with cultural affiliation to Florida.

On June 30, 2009, as part of the Site Certification Application, FPL submitted its final CRA report of on-site areas and associated non-linear facilities and the preliminary CRA report on the associated linear facilities to the DHR. On July 10, 2009, DHR found FPL's final CRA report of on-site areas and associated non-linear facilities complete and sufficient in

accordance with Chapter 1A-46 F.A.C. The DHR offered its opinion that the project would have no effect on historic properties and recommended that the CRA report of on-site areas and associated non-linear facilities be sent to the five federally recognized tribes with cultural affiliation to Florida.

Information Sharing with Potentially Interested Tribes

The purpose of this letter is to share information with potentially interested Tribes in accordance with Section 106 of the NHPA and 36 CFR Part 800.2(c)(2)(ii). The NRC will conduct formal NHPA consultation with Tribes per Federal government-to-government guidance during the preparation of the environmental impact statement. However both the NRC and the DHR have encouraged FPL to share information with Tribes to identify tribal concerns for important cultural resources that could potentially be impacted by the proposed project. On March 20, 2009, FPL submitted a letter to the Miccosukee Tribe of Indians of Florida sharing initial project information.

FPL welcomes your input and comments on the proposed undertaking and the cultural properties of importance to you. FPL is requesting your review of this information so that you can identify concerns about cultural resources, present views about the proposed undertaking's potential effects on such properties, and participate in the resolution of adverse effects. FPL is particularly interested in any information you may have regarding resources, traditional cultural places, sites, or properties of tribal importance that may be adversely affected by the proposed project. This information will assist FPL in identifying important cultural resources in the project area. FPL requests a written response to this information review by January 29, 2010.

Mr. Matthew Raffenberg is FPL's environmental permitting lead and will be your contact for this information sharing request. Please reach Mr. Raffenberg at (561) 691-2808 or by email matthew.raffenberg@fpl.com if you have any questions about this information.

Sincerely,

Barbara Linkiewicz

December 16, 2009

SUBJECT: Information Sharing Supporting Section 106 of the *National Historic Preservation Act* for the Proposed Turkey Point Units 6 & 7 On-Site Project Facilities, Florida

Dear Mrs. Bear:

Florida Power and Light Company (FPL) has submitted a Combined Operating License (COL) Application to the Nuclear Regulatory Commission (NRC) to construct and operate nuclear power Unit 6 & 7 at the Turkey Point site, located east of Homestead, Florida. The Unit 6 & 7 project would provide clean, safe and reliable power to meet the needs of FPL's customers. As part of its COL Application, FPL included an environmental report to assist the NRC prepare an environmental impact statement (EIS) under the *National Environmental Policy Act*. The decision by the NRC on whether to issue the license for construction and operation of Units 6 & 7 meets the definition of an "undertaking" under the *National Historic Preservation Act* (NHPA) and its implementing regulations 36 CFR Part 800.16(y).

FPL has shared project information with the Florida Division of Historical Resources (DHR) and the Florida State Historic Preservation Officer for this proposed project. Specifically a final cultural resources assessment (CRA) report of on-site areas and associated non- linear facilities and a preliminary CRA report on the associated linear facilities were submitted to the DHR as part of FPL's Site Certification Application (SCA).

By recommendation from the DHR, FPL hereby offers to share project information with potentially interested Tribes to assist us in identifying important cultural resources that could be present in the vicinity of the proposed undertaking. Attached is the CRA report addressing the on-site areas and other non-linear associated facilities affected by the proposed undertaking. Linear facilities (namely access roads, transmissions lines, and water pipelines) are being permitted as corridors in the SCA process. Therefore, the CRA report for the project's linear facilities will be shared with you after placement of those facilities is finalized.

Description of the Proposed Project

The project would add two new nuclear generating units and supporting facilities at a site within the existing Turkey Point plant property boundaries. The Project includes the construction and operation of Turkey Point Unit 6 & 7 on the site as well as new transmission lines and other off-site associated linear and non-linear facilities.

FPL's Turkey Point plant property comprises approximately 11,000 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead, and bordered by Biscayne Bay to the east. The existing Turkey Point Plant consist of two nominal 400-megawatt (MW) natural gas/oil steam electric generating units (Units 1 & 2); two nominal 700-MW nuclear units (Units 3 & 4); and a nominal 1,150 MW natural gas-fired combined-cycle unit (Unit 5). The existing closed- loop cooling canals and industrial wastewater facility occupy approximately 5,900 acres. The location of the Turkey Point plant property is shown in Figure 1.

The site for Turkey Point Units 6 & 7 is south of Units 3 &4 and occupies approximately 300-acres within the industrial wastewater facility. Two nuclear generating units, each with an approximate electrical out put of 1,100 MWe (net), including supporting buildings, facilities and equipment will be located on the site, along with a laydown area. Proposed off-Site associated facilities include: nuclear administration building, training building and parking area; an FPL reclaimed water treatment facility and reclaimed water pipelines; radial collector wells and delivery pipelines; equipment barge unloading area; an FPL–owned fill source; transmission lines and system improvements within Miami-Dade County; access roads and bridges; and a potable water pipeline. The site and proposed off-site associated facilities are shown in Figures 2 to 5. Because the linear facilities are being permitted as corridors, the areas shown on these figures is actually larger than the areas that will be impacted by actual construction and operation of the linear facilities.

Information Sharing with the Florida Division of Historical Resources

On February 20, 2009, FPL notified the DHR that it was commencing a CRA of on-site areas and would be contacting the SHPO to obtain required information as needed. On June 25, 2009, FPL forwarded to DHR its CRA survey work plans for the on- and off-site project areas. In that submittal, FPL requested concurrence that (1) the determination and definition of the Areas of Potential Effect (APEs) are appropriate for the project and (2) implementation of the work plans would constitute a reasonable and good-faith effort to carry out appropriate identification efforts of historic properties that could potentially be impacted by the project. On July 13, 2009, the DHR concurred with all the recommendations provided by FPL in the on-and off-site CRA survey work plans. The DHR recommended that the final CRA survey results be sent to the five federally-recognized tribes with cultural affiliation to Florida.

On June 30, 2009, as part of the Site Certification Application, FPL submitted its final CRA report of on-site areas and associated non-linear facilities and the preliminary CRA report on the associated linear facilities to the DHR. On July 10, 2009, DHR found FPL's final CRA

report of on-site areas and associated non-linear facilities complete and sufficient in accordance with Chapter 1A-46 F.A.C. The DHR offered its opinion that the project would have no effect on historic properties and recommended that the CRA report of on-site areas and associated non-linear facilities be sent to the five federally recognized tribes with cultural affiliation to Florida.

Information Sharing with Potentially Interested Tribes

The purpose of this letter is to share information with potentially interested Tribes in accordance with Section 106 of the NHPA and 36 CFR Part 800.2(c)(2)(ii). The NRC will conduct formal NHPA consultation with Tribes per Federal government-to-government guidance during the preparation of the environmental impact statement. However both the NRC and the DHR have encouraged FPL to share information with Tribes to identify tribal concerns for important cultural resources that could potentially be impacted by the proposed project. On March 20, 2009, Janus Research, on behalf of FPL, submitted a letter to the Muscogee (Creek) Nation sharing initial project information.

FPL welcomes your input and comments on the proposed undertaking and the cultural properties of importance to you. FPL is requesting your review of this information so that you can identify concerns about cultural resources, present views about the proposed undertaking's potential effects on such properties, and participate in the resolution of adverse effects. FPL is particularly interested in any information you may have regarding resources, traditional cultural places, sites, or properties of tribal importance that may be adversely affected by the proposed project. This information will assist FPL in identifying important cultural resources in the project area. FPL requests a written response to this information review by January 29, 2010.

Mr. Matthew Raffenberg is FPL's environmental permitting lead and will be your contact for this information sharing request. Please reach Mr. Raffenberg at (561) 691-2808 or by email matthew.raffenberg@fpl.com if you have any questions about this information.

Sincerely,

Kathl S. Hoffm

SUBJECT: Information Sharing Supporting Section 106 of the *National Historic Preservation Act* for the Proposed Turkey Point Units 6 & 7 On-Site Project Facilities, Florida

Dear Mr. Steele:

Florida Power and Light Company (FPL) has submitted a Combined Operating License (COL) Application to the Nuclear Regulatory Commission (NRC) to construct and operate nuclear power Unit 6 & 7 at the Turkey Point site, located east of Homestead, Florida. The Unit 6 & 7 project would provide clean, safe and reliable power to meet the needs of FPL's customers. As part of its COL Application, FPL included an environmental report to assist the NRC prepare an environmental impact statement (EIS) under the *National Environmental Policy Act*. The decision by the NRC on whether to issue the license for construction and operation of Units 6 & 7 meets the definition of an "undertaking" under the *National Historic Preservation Act* (NHPA) and its implementing regulations 36 CFR Part 800.16(y).

FPL has shared project information with the Florida Division of Historical Resources (DHR) and the Florida State Historic Preservation Officer for this proposed project. Specifically a final cultural resources assessment (CRA) report of on-site areas and associated non- linear facilities and a preliminary CRA report on the associated linear facilities were submitted to the DHR as part of FPL's Site Certification Application (SCA).

By recommendation from the DHR, FPL hereby offers to share project information with potentially interested Tribes to assist us in identifying important cultural resources that could be present in the vicinity of the proposed undertaking. Attached is the CRA report addressing the on-site areas and other non-linear associated facilities affected by the proposed undertaking. Linear facilities (namely access roads, transmissions lines, and water pipelines) are being permitted as corridors in the SCA process. Therefore, the CRA report for the project's linear facilities will be shared with you after placement of those facilities is finalized.

Description of the Proposed Project

The project would add two new nuclear generating units and supporting facilities at a site within the existing Turkey Point plant property boundaries. The Project includes the construction and operation of Turkey Point Unit 6 & 7 on the site as well as new transmission lines and other off-site associated linear and non-linear facilities.

FPL's Turkey Point plant property comprises approximately 11,000 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead, and bordered by Biscayne Bay to the east. The existing Turkey Point Plant consist of two nominal 400-megawatt (MW) natural gas/oil steam electric generating units (Units 1 & 2); two nominal 700-MW nuclear units (Units 3 & 4); and a nominal 1,150 MW natural gas-fired combined-cycle unit (Unit 5). The existing closed- loop cooling canals and industrial wastewater facility occupy approximately 5,900 acres. The location of the Turkey Point plant property is shown in Figure 1.

The site for Turkey Point Units 6 & 7 is south of Units 3 &4 and occupies approximately 300-acres within the industrial wastewater facility. Two nuclear generating units, each with an approximate electrical out put of 1,100 MWe (net), including supporting buildings, facilities and equipment will be located on the site, along with a laydown area. Proposed off-Site associated facilities include: nuclear administration building, training building and parking area; an FPL reclaimed water treatment facility and reclaimed water pipelines; radial collector wells and delivery pipelines; equipment barge unloading area; an FPL–owned fill source; transmission lines and system improvements within Miami-Dade County; access roads and bridges; and a potable water pipeline. The site and proposed off-site associated facilities are shown in Figures 2 to 5. Because the linear facilities are being permitted as corridors, the areas shown on these figures is actually larger than the areas that will be impacted by actual construction and operation of the linear facilities.

Information Sharing with the Florida Division of Historical Resources

On February 20, 2009, FPL notified the DHR that it was commencing a CRA of on-site areas and would be contacting the SHPO to obtain required information as needed. On June 25, 2009, FPL forwarded to DHR its CRA survey work plans for the on- and off-site project areas. In that submittal, FPL requested concurrence that (1) the determination and definition of the Areas of Potential Effect (APEs) are appropriate for the project and (2) implementation of the work plans would constitute a reasonable and good-faith effort to carry out appropriate identification efforts of historic properties that could potentially be impacted by the project. On July 13, 2009, the DHR concurred with all the recommendations provided by FPL in the on-and off-site CRA survey work plans. The DHR recommended that the final CRA survey results be sent to the five federally-recognized tribes with cultural affiliation to Florida.

On June 30, 2009, as part of the Site Certification Application, FPL submitted its final CRA report of on-site areas and associated non-linear facilities and the preliminary CRA report on the associated linear facilities to the DHR. On July 10, 2009, DHR found FPL's final CRA

report of on-site areas and associated non-linear facilities complete and sufficient in accordance with Chapter 1A-46 F.A.C. The DHR offered its opinion that the project would have no effect on historic properties and recommended that the CRA report of on-site areas and associated non-linear facilities be sent to the five federally recognized tribes with cultural affiliation to Florida.

Information Sharing with Potentially Interested Tribes

The purpose of this letter is to share information with potentially interested Tribes in accordance with Section 106 of the NHPA and 36 CFR Part 800.2(c)(2)(ii). The NRC will conduct formal NHPA consultation with Tribes per Federal government-to-government guidance during the preparation of the environmental impact statement. However both the NRC and the DHR have encouraged FPL to share information with Tribes to identify tribal concerns for important cultural resources that could potentially be impacted by the proposed project. On March 20, 2009, Janus Research, on behalf of FPL, submitted a letter to the Seminole Tribe of Florida sharing initial project information.

FPL welcomes your input and comments on the proposed undertaking and the cultural properties of importance to you. FPL is requesting your review of this information so that you can identify concerns about cultural resources, present views about the proposed undertaking's potential effects on such properties, and participate in the resolution of adverse effects. FPL is particularly interested in any information you may have regarding resources, traditional cultural places, sites, or properties of tribal importance that may be adversely affected by the proposed project. This information will assist FPL in identifying important cultural resources in the project area. FPL requests a written response to this information review by January 29, 2010.

Mr. Matthew Raffenberg is FPL's environmental permitting lead and will be your contact for this information sharing request. Please reach Mr. Raffenberg at (561) 691-2808 or by email matthew.raffenberg@fpl.com if you have any questions about this information.

Sincerely,

Kathleen S. Hoffman

December 16, 2009

SUBJECT: Information Sharing Supporting Section 106 of the *National Historic Preservation Act* for the Proposed Turkey Point Units 6 & 7 On-Site Project Facilities, Florida

Dear Mr. Thrower:

Florida Power and Light Company (FPL) has submitted a Combined Operating License (COL) Application to the Nuclear Regulatory Commission (NRC) to construct and operate nuclear power Unit 6 & 7 at the Turkey Point site, located east of Homestead, Florida. The Unit 6 & 7 project would provide clean, safe and reliable power to meet the needs of FPL's customers. As part of its COL Application, FPL included an environmental report to assist the NRC prepare an environmental impact statement (EIS) under the *National Environmental Policy Act*. The decision by the NRC on whether to issue the license for construction and operation of Units 6 & 7 meets the definition of an "undertaking" under the *National Historic Preservation Act* (NHPA) and its implementing regulations 36 CFR Part 800.16(y).

FPL has shared project information with the Florida Division of Historical Resources (DHR) and the Florida State Historic Preservation Officer for this proposed project. Specifically a final cultural resources assessment (CRA) report of on-site areas and associated non- linear facilities and a preliminary CRA report on the associated linear facilities were submitted to the DHR as part of FPL's Site Certification Application (SCA).

By recommendation from the DHR, FPL hereby offers to share project information with potentially interested Tribes to assist us in identifying important cultural resources that could be present in the vicinity of the proposed undertaking. Attached is the CRA report addressing the on-site areas and other non-linear associated facilities affected by the proposed undertaking. Linear facilities (namely access roads, transmissions lines, and water pipelines) are being permitted as corridors in the SCA process. Therefore, the CRA report for the project's linear facilities will be shared with you after placement of those facilities is finalized.

Description of the Proposed Project

The project would add two new nuclear generating units and supporting facilities at a site within the existing Turkey Point plant property boundaries. The Project includes the construction and operation of Turkey Point Unit 6 & 7 on the site as well as new transmission lines and other off-site associated linear and non-linear facilities.

FPL's Turkey Point plant property comprises approximately 11,000 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead, and bordered by Biscayne Bay to the east. The existing Turkey Point Plant consist of two nominal 400-megawatt (MW) natural gas/oil steam electric generating units (Units 1 & 2); two nominal 700-MW nuclear units (Units 3 & 4); and a nominal 1,150 MW natural gas-fired combined-cycle unit (Unit 5). The existing closed- loop cooling canals and industrial wastewater facility occupy approximately 5,900 acres. The location of the Turkey Point plant property is shown in Figure 1.

The site for Turkey Point Units 6 & 7 is south of Units 3 &4 and occupies approximately 300-acres within the industrial wastewater facility. Two nuclear generating units, each with an approximate electrical out put of 1,100 MWe (net), including supporting buildings, facilities and equipment will be located on the site, along with a laydown area. Proposed off-Site associated facilities include: nuclear administration building, training building and parking area; an FPL reclaimed water treatment facility and reclaimed water pipelines; radial collector wells and delivery pipelines; equipment barge unloading area; an FPL–owned fill source; transmission lines and system improvements within Miami-Dade County; access roads and bridges; and a potable water pipeline. The site and proposed off-site associated facilities are shown in Figures 2 to 5. Because the linear facilities are being permitted as corridors, the areas shown on these figures is actually larger than the areas that will be impacted by actual construction and operation of the linear facilities.

Information Sharing with the Florida Division of Historical Resources

On February 20, 2009, FPL notified the DHR that it was commencing a CRA of on-site areas and would be contacting the SHPO to obtain required information as needed. On June 25, 2009, FPL forwarded to DHR its CRA survey work plans for the on- and off-site project areas. In that submittal, FPL requested concurrence that (1) the determination and definition of the Areas of Potential Effect (APEs) are appropriate for the project and (2) implementation of the work plans would constitute a reasonable and good-faith effort to carry out appropriate identification efforts of historic properties that could potentially be impacted by the project. On July 13, 2009, the DHR concurred with all the recommendations provided by FPL in the on-and off-site CRA survey work plans. The DHR recommended that the final CRA survey results be sent to the five federally-recognized tribes with cultural affiliation to Florida.

On June 30, 2009, as part of the Site Certification Application, FPL submitted its final CRA report of on-site areas and associated non-linear facilities and the preliminary CRA report on the associated linear facilities to the DHR. On July 10, 2009, DHR found FPL's final CRA

report of on-site areas and associated non-linear facilities complete and sufficient in accordance with Chapter 1A-46 F.A.C. The DHR offered its opinion that the project would have no effect on historic properties and recommended that the CRA report of on-site areas and associated non-linear facilities be sent to the five federally recognized tribes with cultural affiliation to Florida.

Information Sharing with Potentially Interested Tribes

The purpose of this letter is to share information with potentially interested Tribes in accordance with Section 106 of the NHPA and 36 CFR Part 800.2(c)(2)(ii). The NRC will conduct formal NHPA consultation with Tribes per Federal government-to-government guidance during the preparation of the environmental impact statement. However both the NRC and the DHR have encouraged FPL to share information with Tribes to identify tribal concerns for important cultural resources that could potentially be impacted by the proposed project. On March 20, 2009, Janus Research, on behalf of FPL, submitted a letter to the Poarch Band of Creek Indians sharing initial project information.

FPL welcomes your input and comments on the proposed undertaking and the cultural properties of importance to you. FPL is requesting your review of this information so that you can identify concerns about cultural resources, present views about the proposed undertaking's potential effects on such properties, and participate in the resolution of adverse effects. FPL is particularly interested in any information you may have regarding resources, traditional cultural places, sites, or properties of tribal importance that may be adversely affected by the proposed project. This information will assist FPL in identifying important cultural resources in the project area. FPL requests a written response to this information review by January 29, 2010.

Mr. Matthew Raffenberg is FPL's environmental permitting lead and will be your contact for this information sharing request. Please reach Mr. Raffenberg at (561) 691-2808 or by email matthew.raffenberg@fpl.com if you have any questions about this information.

Sincerely,

Kathleen S. Hoffman

SUBJECT: Information Sharing Supporting Section 106 of the *National Historic Preservation Act* for the Proposed Turkey Point Units 6 & 7 On-Site Project Facilities, Florida

Dear Ms. Deere:

Florida Power and Light Company (FPL) has submitted a Combined Operating License (COL) Application to the Nuclear Regulatory Commission (NRC) to construct and operate nuclear power Unit 6 & 7 at the Turkey Point site, located east of Homestead, Florida. The Unit 6 & 7 project would provide clean, safe and reliable power to meet the needs of FPL's customers. As part of its COL Application, FPL included an environmental report to assist the NRC prepare an environmental impact statement (EIS) under the *National Environmental Policy Act*. The decision by the NRC on whether to issue the license for construction and operation of Units 6 & 7 meets the definition of an "undertaking" under the *National Historic Preservation Act* (NHPA) and its implementing regulations 36 CFR Part 800.16(y).

FPL has shared project information with the Florida Division of Historical Resources (DHR) and the Florida State Historic Preservation Officer for this proposed project. Specifically a final cultural resources assessment (CRA) report of on-site areas and associated non- linear facilities and a preliminary CRA report on the associated linear facilities were submitted to the DHR as part of FPL's Site Certification Application (SCA).

By recommendation from the DHR, FPL hereby offers to share project information with potentially interested Tribes to assist us in identifying important cultural resources that could be present in the vicinity of the proposed undertaking. Attached is the CRA report addressing the on-site areas and other non-linear associated facilities affected by the proposed undertaking. Linear facilities (namely access roads, transmissions lines, and water pipelines) are being permitted as corridors in the SCA process. Therefore, the CRA report for the project's linear facilities will be shared with you after placement of those facilities is finalized.

Description of the Proposed Project

The project would add two new nuclear generating units and supporting facilities at a site within the existing Turkey Point plant property boundaries. The Project includes the construction and operation of Turkey Point Unit 6 & 7 on the site as well as new transmission lines and other off-site associated linear and non-linear facilities.

FPL's Turkey Point plant property comprises approximately 11,000 acres in unincorporated southeast Miami-Dade County, Florida, east of Florida City and the City of Homestead, and bordered by Biscayne Bay to the east. The existing Turkey Point Plant consist of two nominal 400-megawatt (MW) natural gas/oil steam electric generating units (Units 1 & 2); two nominal 700-MW nuclear units (Units 3 & 4); and a nominal 1,150 MW natural gas-fired combined-cycle unit (Unit 5). The existing closed- loop cooling canals and industrial wastewater facility occupy approximately 5,900 acres. The location of the Turkey Point plant property is shown in Figure 1.

The site for Turkey Point Units 6 & 7 is south of Units 3 &4 and occupies approximately 300-acres within the industrial wastewater facility. Two nuclear generating units, each with an approximate electrical out put of 1,100 MWe (net), including supporting buildings, facilities and equipment will be located on the site, along with a laydown area. Proposed off-Site associated facilities include: nuclear administration building, training building and parking area; an FPL reclaimed water treatment facility and reclaimed water pipelines; radial collector wells and delivery pipelines; equipment barge unloading area; an FPL–owned fill source; transmission lines and system improvements within Miami-Dade County; access roads and bridges; and a potable water pipeline. The site and proposed off-site associated facilities are shown in Figures 2 to 5. Because the linear facilities are being permitted as corridors, the areas shown on these figures is actually larger than the areas that will be impacted by actual construction and operation of the linear facilities.

Information Sharing with the Florida Division of Historical Resources

On February 20, 2009, FPL notified the DHR that it was commencing a CRA of on-site areas and would be contacting the SHPO to obtain required information as needed. On June 25, 2009, FPL forwarded to DHR its CRA survey work plans for the on- and off-site project areas. In that submittal, FPL requested concurrence that (1) the determination and definition of the Areas of Potential Effect (APEs) are appropriate for the project and (2) implementation of the work plans would constitute a reasonable and good-faith effort to carry out appropriate identification efforts of historic properties that could potentially be impacted by the project. On July 13, 2009, the DHR concurred with all the recommendations provided by FPL in the on-and off-site CRA survey work plans. The DHR recommended that the final CRA survey results be sent to the five federally-recognized tribes with cultural affiliation to Florida.

On June 30, 2009, as part of the Site Certification Application, FPL submitted its final CRA report of on-site areas and associated non-linear facilities and the preliminary CRA report on the associated linear facilities to the DHR. On July 10, 2009, DHR found FPL's final CRA

report of on-site areas and associated non-linear facilities complete and sufficient in accordance with Chapter 1A-46 F.A.C. The DHR offered its opinion that the project would have no effect on historic properties and recommended that the CRA report of on-site areas and associated non-linear facilities be sent to the five federally recognized tribes with cultural affiliation to Florida.

Information Sharing with Potentially Interested Tribes

The purpose of this letter is to share information with potentially interested Tribes in accordance with Section 106 of the NHPA and 36 CFR Part 800.2(c)(2)(ii). The NRC will conduct formal NHPA consultation with Tribes per Federal government-to-government guidance during the preparation of the environmental impact statement. However both the NRC and the DHR have encouraged FPL to share information with Tribes to identify tribal concerns for important cultural resources that could potentially be impacted by the proposed project. On March 20, 2009, Janus Research, on behalf of FPL, submitted a letter to the Seminole Nation of Oklahoma sharing initial project information.

FPL welcomes your input and comments on the proposed undertaking and the cultural properties of importance to you. FPL is requesting your review of this information so that you can identify concerns about cultural resources, present views about the proposed undertaking's potential effects on such properties, and participate in the resolution of adverse effects. FPL is particularly interested in any information you may have regarding resources, traditional cultural places, sites, or properties of tribal importance that may be adversely affected by the proposed project. This information will assist FPL in identifying important cultural resources in the project area. FPL requests a written response to this information review by January 29, 2010.

Mr. Matthew Raffenberg is FPL's environmental permitting lead and will be your contact for this information sharing request. Please reach Mr. Raffenberg at (561) 691-2808 or by email matthew.raffenberg@fpl.com if you have any questions about this information.

Sincerely,

Kathl. S. Hoffman

Subject: Proposed Turkey Point Units 6 & & On-site Project Facilities, Miami-Dade County, Florida

To Whom It May Concern:

The Seminole Tribe of Florida Tribal Historic Preservation Office (STOF-THPO) has received the **Florida Power and Light Company's** correspondence concerning the aforementioned project. The STOF-THPO has no objection to your findings at this time. However, the STOF-THPO would like to be informed if cultural resources that are potentially ancestral or historically relevant to the Seminole Tribe of Florida are inadvertently discovered during the construction process. We thank you for the opportunity to review the information that has been sent to date regarding this project. Please reference to ***THPO-005028*** for any related issues.

We look forward to working with you in the future.

Sincerely,

Direct routine inquiries to:

Willard Steele,
Tribal Historic Preservation Officer
Seminole Tribe of Florida

Anne Mullins
Compliance Review Supervisor

2.6 GEOLOGY

The geological conditions at the Units 6 & 7 plant area are summarized in this section. The information is subdivided into three categories: physiography, stratigraphy, and structural geology.

The geological information in this section is based on the information contained in FSAR Subsection 2.5.1.

2.6.1 GEOLOGICAL CONDITIONS

The Turkey Point plant property is located within the Atlantic Coastal Plains physiographic province (Figure 2.6-1). Elevation of the ground surface in the 200-mile radius site region varies from 3 feet below MSL to 345 feet above MSL (FDEP 2008).

2.6.1.1 Physiography

The Turkey Point plant property is located within Miami-Dade County, Florida, approximately 25 miles south of Miami, 8 miles east of Florida City, and 9 miles southeast of Homestead, Florida. The plant property is located within the Southern Slope sub-province of the Southern Zone physiographic subregion of the Florida Platform within the Atlantic Coastal Plain physiographic province (Figure 2.6-1) (Randazzo and Jones 1997 and White 1970).

Surficial deposits at Units 6 & 7 consist of organic muck and the Miami Limestone (Figure 2.6-2). The organic muck is the dominant sediment type, whereas the Miami Limestone is located surficially in the northwestern portion of the plant area.

The plant area is at or near sea level with an existing elevation of –2.4 to 0.8 feet (NAVD 88) and is generally flat. The plant area is flat and uniform throughout with the exception of the vegetated depressions. The vegetative depressions are surficial dissolution features within the Miami Limestone and are described in FSAR Subsections 2.5.1, 2.5.3, and 2.5.4.4.

2.6.1.2 Stratigraphy

Strata sampled during the Units 6 & 7 subsurface investigation are shown in Figure 2.6-3 as they occur from the ground surface to a depth beneath the plant area. Most of the 88 borings drilled penetrate the Miami Limestone, Key Largo Limestone, and Fort Thompson Formation to a depth up to 125 feet. Thirty-four deeper borings penetrated into the underlying Tamiami Formation at approximately 115 feet and continued to a depth of approximately 150 feet. Two deep borings, B-601 and B-701, penetrated into the Peace River Formation of the Hawthorn Group at depths ranging from 216 to 224 feet, respectively. Boring B-701 advanced into the Arcadia Formation of the Hawthorn Group at a depth of 455 feet before terminating at a final depth of 615.5 feet.

2.6.1.3 Structural Geology

The Turkey Point plant property lies on the stable Florida carbonate platform, and no faults or folds are mapped within 25 miles. The plant property is on a tectonically stable region characterized by extremely low rates of seismicity. New data including geologic mapping and bedding attitudes inferred from lithologic contacts in boreholes indicate flat, planar bedding in Pleistocene and older units and an absence of geologic structures within the plant property. No topographic features within the vicinity of the plant area indicate the presence of surface faulting.

Based on an analysis of aerial imagery, Grossman's Hammock is the only lineament within the 25-mile radius site vicinity. Grossman's Hammock is a north-south-trending vegetated rock reef 8 miles long. Based on ground penetrating radar analysis, there is no faulting associated with this feature (Kruse et al. 2000). Crone and Wheeler (2000) and Wheeler (2006) classify Grossman's Hammock as a non-tectonic feature.

No geomorphic features or lineaments associated with faulting within the plant property were identified during analysis of aerial imagery. The lineament analysis did identify linear and ellipsoidal/circular features associated with changes in vegetation within the 5- and 0.6-mile radii of the plant area. These features are loci of more highly concentrated vegetation. These features are likely the result of the surficial dissolution of the limestone bedrock and are described in detail in FSAR Subsection 2.5.3.8.2. There is no geomorphic expression of these features or other evidence that would indicate tectonic faulting associated with these vegetation lineaments. Data obtained during site characterization indicated the absence of collapse sinkholes in the plant area.

Results of the subsurface exploration program at the plant area reveal continuous, horizontal stratigraphy, which precludes the presence of faults, folds, or structures related to tectonic deformation.

2.7 METEOROLOGY, AIR QUALITY, AND NOISE

This section describes the regional and local climatological, meteorological, and air quality characteristics applicable to Units 6 & 7. This section also provides site-specific meteorological information for use in evaluating construction and operational impacts. This section concludes with a brief description of existing noise-generating sources at the Turkey Point plant property and predicted noise levels relative to estimated background conditions.

2.7.1 REGIONAL CLIMATOLOGY

This section identifies sources of climatological data used to characterize various aspects of the climate representative of the region around Units 6 & 7, describes large-scale general climatic features and regional air quality, and their relationship to conditions at Turkey Point (Subsection 2.7.1.2). This section also summarizes normal, mean, and extreme values of several standard weather parameters (Subsection 2.7.1.3).

2.7.1.1 Data Sources

Sources of data used to characterize local and regional climatological conditions pertinent to Units 6 & 7 include the National Weather Service (NWS) at its Miami International Airport first-order station and 16 nearby cooperative network land-based reporting stations. The cooperative network stations are located within approximately 50 miles of Units 6 & 7. In addition, historical data is available from measurements made at the current meteorological monitoring stations operated in compliance with RG 1.23 and RG 1.206 under the established meteorological monitoring program in support of existing Units 3 & 4 and located on the Turkey Point plant property close to the Units 6 & 7 plant area.

The referenced land-based cooperative network locations of climatological observing stations are in Broward, Monroe, Miami-Dade, and Collier counties in Florida. Table 2.7-1 identifies the specific stations and their approximate distance and direction from the midpoint between Units 6 & 7. Figure 2.7-1 illustrates these station locations relative to Units 6 & 7.

The objective of selecting nearby, offsite climatological monitoring stations is to determine mean and extreme values, as measured at those locations, that are reasonably representative of conditions that would be expected to be observed at Units 6 & 7. The 50-mile radius shown in Figure 2.7-1 provides a relative indication of the distance between the climate stations and Units 6 & 7.

The identification of stations to be included was based on the following general considerations:

- Proximity to the plant area (i.e., within the nominal 50-mile radius indicated above, to the extent practical)

- Coverage in all directions surrounding the plant area (to the extent possible)

- Where more than one station exists for a given direction relative to the plant area, a station was chosen if it contributed one or more extreme conditions (e.g., rainfall, snowfall, maximum and/or minimum temperatures) for that general direction or added content for describing climatic conditions in the plant area

Nevertheless, if an overall extreme precipitation or temperature condition was identified for a station located within a reasonable distance beyond 50 miles, and that event was considered to be reasonably representative for the plant area, such stations were also included, regardless of directional coverage.

Normal (i.e., 30-year average), mean, and extreme values of temperature, rainfall, and snowfall are based on the following references: (NCDC Feb 2009a), (NCDC 2004), (NCDC Feb 2002a), (NCDC Feb 2006), (USU 2008), (SERCC Jun 2008a and SERCC Jun 2008b).

First-order NWS stations also record measurements, typically every hour, of other weather elements, including winds, several indicators of atmospheric moisture content (i.e., relative humidity, dew point, and wet bulb temperatures), and barometric pressure, as well as other observations when those conditions occur (e.g., fog, thunderstorms). The long-term (30 years) data from the NWS Miami International Airport first-order station was used to describe the general climatic conditions at Units 6 & 7. This is the closest first-order station to Turkey Point. Table 2.7-2, excerpted from the 2008 local climatological data (LCD) annual summary for the Miami International Airport, Florida NWS station, presents the long-term characteristics of these parameters.

Additional data sources were also used in describing the climatological characteristics of the plant area and region, including, among others, the following references: (ASCE 2005), (NOAA-CSC 2008), (NCDC Sep 2002b), (NCDC 2009b, NCDC 2008c and NCDC 2008d), (Wang and Angell Apr 1999), (USDA 2007).

2.7.1.2 General Climate Description

The location of Units 6 & 7 would be on the lower east coast of Florida within the Atlantic Coastal Ridge, which is a flat stretch of land that borders both the Atlantic Ocean and the Gulf of Mexico (see Figure 2.1-2). The Units 6 & 7 plant area is relatively flat with an approximate finished grade elevation of 25.5 feet (North American Vertical Datum 1988 [NAVD 88]). Topographic features within 5 miles and 50 miles of the plant area are addressed in Subsection 2.7.4.6. Elevations within 50 miles of the plant area range from approximate elevation –2.5 feet (NAVD 88) to the north-northeast to an approximate elevation of 86 feet (NAVD 88) to the north. Biscayne Bay is directly east of Units 6 & 7.

The state of Florida is divided into seven climate divisions by the National Oceanic and Atmospheric Administration (NOAA). A climate division represents a region within a state that is as climatically homogeneous as possible. The Units 6 & 7 plant area is located within the Lower East Coast Division (Division 6), which includes most of Miami-Dade, Broward, Palm Beach, and Martin counties (NOAA 2008a). The general climate in this division is classified as subtropical maritime (or humid subtropical) and is characterized by long and warm summers, with abundant rainfall, followed by mild, dry winters. The chief factors that govern the climate are latitude, land and water distribution, prevailing winds, storms, pressure systems, and ocean currents. The wet season, which is hot and humid, lasts from May to October, when it gives way to the dry season. The dry season features mild temperatures with some invasions of colder air, which is when little winter rainfall occurs with the passing of a cold front (NCDC Feb 2006).

The Azores-Bermuda high-pressure system (NCDC Feb 2006) exerts a powerful influence on the weather during the winter months. Within high-pressure systems, air is subsiding, and as a consequence, precipitation cannot take place. The Azores-Bermuda high remains over the Sahara Desert throughout the year, but extends over Florida during the winter. As the water around the peninsula warms in the spring, the high-pressure system over Florida weakens and the summer rains begin. Some years, the influence of the Azores-Bermuda high-pressure system is greater than others, so even in the Units 6 & 7 area; rain may fall in the winter. Because of the clockwise circulation around the western extent of the Azores-Bermuda high pressure and the proximity of the Atlantic Ocean, maritime tropical air mass characteristics prevail much of the year. Together, these factors govern late spring, summer, and early fall temperature and precipitation patterns. Florida does not experience the potential for high air pollution because it does not contain heavy industry or the climate and topographical conditions that cause air stagnation.

The El Niño-Southern Oscillation is a physical phenomenon that occurs in the equatorial Pacific Ocean where the water temperature oscillates between being unusually warm (El Niño) and unusually cold (La Niña). El Niño and La Niña are among the strongest drivers of the climate of North America, with impacts that vary across different regions. These oceanic events shift the position of the jet streams across the continent, which act to steer the fronts and weather systems. The southeast United States experiences particularly strong long-term weather shifts, with Florida feeling the greatest impacts. El Niño typically brings 30 to 40 percent more rainfall and cooler temperatures to Florida in the winter, while La Niña brings a warmer and much drier than normal winter and spring. La Niña is frequently a trigger to periodic drought in Florida (NCDC Feb 2006).

The marine influence of the Atlantic Ocean is evidenced by the low daily range of temperature and the rapid warming of cold air masses that pass to the east of the state. The regional area is subject to winds from the east and southeast about half of the time, and in several specific respects has a climate whose features differ from farther inland. One of the features is the annual

precipitation for the area. During the early morning hours, more rainfall occurs along the beach areas than at Miami International Airport, while during the afternoon, the reverse situation is true (NCDC Feb 2009a). The Miami International Airport lies approximately 9 miles inland. Monthly precipitation exhibits a cyclical pattern, with the predominant maximum occurring in the summer months and the minimum occurring during the winter months (see Table 2.7-2).

The region is subject to sea/land breeze circulations, local winds that are driven by the differential heating of the air over the ocean and over the land surface. In south Florida, the existence and intensity of the sea breeze depends largely on seasonal and latitudinal factors as well as on the time of day. Sea/land breeze circulations influence local temperature, humidity, wind speed, stability, and wind direction and precipitation. The most notable sea breeze impacts are a shift in wind to the onshore direction, an increase in wind speed, a decrease in temperature, and an increase in humidity.

An even more striking difference appears in the annual number of days with temperatures reaching 90°F or higher, with inland stations having four times more than the beach areas. Minimum temperature contrasts are also particularly marked under proper conditions, with the difference between inland locations and the beach areas frequently reaching to 15 degrees or more, especially in the winter. Freezing temperatures occur occasionally in the inland suburban areas and farming districts, but rarely near the ocean (NCDC Feb 2009a).

Hurricanes affect the area often enough that they are an annual concern within the FPL service area. The months of greatest frequency are September and October. Destructive tornadoes are rare. Funnel clouds are occasionally sighted offshore and a few touch the ground briefly but significant damage is seldom reported. Waterspouts (tornadoes over water) are often visible from the beaches during the summer months; however, significant damage is seldom reported. Further information regarding tornadoes, hurricanes, and tropical cyclones is provided in Subsection 2.7.3. The months of June, July, and August have the highest frequency of dangerous lightning events (NCDC Feb 2009a).

2.7.1.3 Normal, Mean, and Extreme Climatological Conditions

This subsection addresses normal and period-of-record mean and extreme values for several standard weather elements representative of this climate setting (i.e., temperature, atmospheric water vapor, precipitation, and wind conditions). All references to seasonal periods in this subsection pertain to winter (December, January, February), spring (March, April, May), summer (June, July, August), and fall (September, October, November).

As indicated previously, Table 2.7-2 presents the more extensive set of meteorological measurements and observations made at the Miami International Airport, NWS Station, located approximately 25 miles north of Units 6 & 7. For comparison, Table 2.7-3 summarizes the annual

normal daily maximum, minimum, range, and mean temperatures, as well as the normal annual rainfall and snowfall totals for Miami International Airport and 16 nearby cooperative network reporting stations. Table 2.7-4 summarizes the climatological extremes for maximum and minimum temperatures and maximum 24-hour and monthly rainfall and snowfall for Miami International Airport, and 16 nearby cooperative network reporting stations.

Long-term periods of record for temperature and precipitation for the climatological observing stations, as well as summaries of the latest 30-year station normal values from 1971 through 2000, are readily available from the National Climatic Data Center (NCDC).

2.7.1.3.1 Temperature

Daily mean temperatures are based on the average of the daily mean maximum and mean minimum temperature values. The annual daily normal temperatures are similar over the area, ranging from 73.8°F at the Fort Lauderdale Experiment Station weather observing station to 78.4°F at the Hialeah weather observing station (see Table 2.7-3), which are separated by a distance of approximately 18 miles.

Diurnal (day-to-night) temperature ranges, as indicated by the differences between the daily mean maximum and minimum temperatures, however, are more variable, ranging from 9.0°F at the Miami Beach weather observing station to 19.8°F at the Oasis Ranger Station (NCDC Feb 2002a). In general, diurnal temperature ranges among the one NWS and the 16 nearby cooperative weather observer stations are greater at those stations farther from the Atlantic Ocean and adjacent bays, and are less for those stations closer to those waters (see Figure 2.7-1).

On a monthly basis, the local climate data (LCD) summary for the Miami International Airport indicates that the daily normal dry bulb temperature is highest during July (83.7°F) and reaches a minimum (68.1°F) in January (NCDC Feb 2009a).

As Table 2.7-4 indicates, extreme maximum temperatures recorded in the vicinity of the Units 6 & 7 plant area at land-based stations have ranged from 96°F to 104°F, with the highest reading observed at the Flamingo Ranger Station on June 24, 1998. The record high temperatures for the Homestead Experiment Station (100°F), Miami 12 SSW (98°F), Miami International Airport (98°F), Royal Palm Ranger (102°F), and Tavernier (98°F) weather observing stations have been reached on two or three occasions.

The extreme minimum temperatures in the vicinity of the Units 6 & 7 plant area have ranged from 21°F to 42°F, with the lowest reading on record observed at the Pompano Beach weather observing station on February 9, 1995 (SERCC Jun 2008b).

The extreme maximum and minimum temperature data, and the historical station records that they are based on, indicate that synoptic-scale conditions can be responsible for periods of record-setting heat. Synoptic-scale conditions can also be responsible for cold air outbreaks that tend to affect the overall Turkey Point plant property. The general similarity of the respective extremes suggests that these statistics are representative of the Turkey Point site area (SERCC Jun 2008b; NCDC 2004). However, as with the variation in the weather observing station diurnal temperature ranges noted above, proximity to the water has a moderating influence on normal and extreme maximum and minimum temperatures as well.

2.7.1.3.2 Atmospheric Water Vapor

Based on a 25-year period of record, the LCD summary for the Miami International Airport NWS station (see Table 2.7-2) indicates that the mean annual wet bulb temperature is 69.6°F, with a seasonal maximum during the period June through September and a seasonal minimum during the winter months (December through February). The highest monthly mean wet bulb temperature is 76.4°F in August; the lowest monthly mean value (62.0°F) occurs during January (NCDC May 2009).

Based on a 25-year period of record, the LCD summary shows a mean annual dew point temperature of 67.1°F, also reaching its seasonal maximum and minimum during the summer (August 74.4°F) and winter (January 59.1°F), respectively (NCDC Feb 2009a).

The 30-year period of record of normal daily relative humidity averages 73 percent annually, typically reaching its diurnal maximum in the early morning (approximately 7:00 a.m.) and its diurnal minimum during the midday (around 1:00 p.m.). There is less variability in this daily pattern with the passage of weather systems, persistent cloud cover, and precipitation. Nevertheless, this daily pattern is evident throughout the year. The LCD summary shows that average early morning (7:00 a.m.) relative humidity levels are equal to or greater than 83 percent from June through February and are not much lower during the remaining months of the year (NCDC Feb 2009a).

2.7.1.3.3 Precipitation

Normal annual rainfall totals for the 17 nearby observing stations listed in Table 2.7-3 vary greatly, ranging from 44.8 inches at the Tavernier (Monroe County) observing station (approximately 31 miles to the south-southwest of the Units 6 & 7) to 66 inches at the Hialeah station (approximately 27 miles to the north) (SERCC Jun 2008b).

The LCD summary of normal rainfall totals for Miami International Airport indicates that the seasonal maximum occurs during the summer through early fall (June through September). This 4-month period accounts for approximately 54 percent (31.34 inches) of the total annual precipitation (58.53 inches). With the exception of July (5.79 inches), the normal monthly rainfall

during this 4-month period is greater than 8 inches. The maximum overall normal monthly total rainfall occurs during August (8.63 inches) (NCDC March 2009b).

Historical precipitation extremes (i.e., rainfall and snowfall) are presented in Table 2.7-4 for the 17 nearby climatological observing stations. Based on the maximum 24-hour and monthly precipitation totals recorded among these stations and, more importantly, the areal distribution of these stations around the Turkey Point plant property, the data are reasonably representative of the extremes of rainfall and snowfall that might be expected to be observed at the Units 6 & 7 plant area.

The overall highest 24-hour rainfall total in the area, 15.1 inches, occurred on August 26, 2005, at the Perrine 4 W cooperative weather observing station (SERCC Jun 2008a), approximately 13 miles north-northwest of the Units 6 & 7 plant area. This extreme rainfall event was directly associated with Hurricane Katrina (see Subsection 2.7.3.5).

The overall highest monthly rainfall total in the area, 34.4 inches during October 1965, was recorded at the Pompano Beach cooperative observing station (USU 2008), located approximately 57 miles to the north-northeast of Units 6 & 7. This total represents the accumulation of 12 days of measurable precipitation during that month, with approximately 86 percent being recorded on October 14 (6.75 inches), October 15 (12.7 inches), and October 31 (10.01 inches). This monthly record rainfall was not associated with any hurricanes or tropical storms (USU 2008). Further information on extreme rainfall events in the area is presented in Subsection 2.7.4.1.2.

While snow is far from common in southeast Florida, it does fall there from time to time. Snow has never been reported at the Miami International Airport. However, snow was reported on January 19, 1977 in Homestead, Florida, where the southeastern municipal limit is approximately 4.5 miles west of the Turkey Point plant property. The total snowfall noted in the data records was estimated to be 0.05 inches (USU 2008). However, notes made by the station observer indicate that the snow melted before reaching the ground (NOAA Jan 1977). This was during one of the worst mid-1970s cold waves and snow fell that day in several parts of Dade County, Florida, but not at the NWS office at the Miami Airport, which is why the official records do not report snow.

The LCD for Miami International Airport (Table 2.7-2) indicates a trace of snow in May 1998. It is important to note that the snowfall data reported on the LCD comprises all forms of frozen precipitation, including hail. A review of data records for Miami International Airport on May 6, 1998 indicates that the minimum temperature for this day was 70°F. As a result, the trace amount reported on the Miami International Airport LCD was determined to be hail.

See Subsection 2.7.4.1.2 for more details regarding these events and a description of other station precipitation records.

2.7.1.3.4 Wind Conditions

Based on a 30-year period of record, the LCD summary for the Miami International Airport NWS station (Table 2.7-2) indicates that the annual prevailing wind direction (i.e., the direction from which the wind blows most often) is from 120 degrees (i.e., from the southeast). Monthly prevailing winds are from the southeast during the late winter through mid-spring (February through April) and again during the period summer through early fall (June through September). During October and November, the prevailing wind direction backs to more easterly. The prevailing winds are more northerly during the winter months (December through January) (NCDC Feb 2009a). These characteristics are further enhanced by the establishment of the Bermuda high in the summer, and the passage of northerly cold fronts in the winter (see Subsection 2.7.1.2).

Based on a 25-year period of record, the Miami International Airport LCD summary shows an annual mean wind speed of approximately 8.7 mph. On a seasonal basis, the highest average wind speeds occur during the spring (approximately 9.7 mph) and are lowest during the summer months (approximately 7.6 mph). On average, the LCD indicates that the highest monthly average wind speed (approximately 10.1 mph) occurs during March (NCDC Feb 2009a).

Characteristics of extreme wind conditions for design basis purposes are described in Subsection 2.7.3.3. An onsite Turkey Point meteorological monitoring program is operated in support of Units 3 & 4 for the purpose of climatological characterization as related to the dispersion of radioactive and nonradioactive effluents released into the atmosphere. Wind data summaries, based on data obtained from the Turkey Point meteorological monitoring program, are addressed in Subsections 2.7.4.3 and 2.7.4.4.

2.7.2 AIR QUALITY

This subsection addresses current ambient air quality conditions in the area and region (e.g., the compliance status of various air pollutants), projected air quality conditions resulting from the operation of Units 6 & 7, and the climatology of restrictive dispersion conditions in the region. The pollutants that are currently monitored in the region are nonradiological and include parameters such as particulate matter and select gaseous pollutants, and are described in Subsection 2.7.2.1. Based on plant design, construction, and operating basis considerations, Subsection 2.7.2.2 addresses projected air quality conditions during the operation of Units 6 & 7 and what sources would contribute to nonradiological emissions. Subsection 2.7.2.3 characterizes climatological conditions in the area and region that may be restrictive to atmospheric dispersion.

2.7.2.1 Regional Air Quality Conditions

The Turkey Point plant property is located within the Southeast Florida Intrastate Air Quality Control Region. This region includes Broward County, Dade County, Indian River County, Martin County, Monroe County, Okeechobee County, Palm Beach County, and St. Lucie County (U.S. EPA Jul 2008a). The Units 6 & 7 plant area is located in extreme southeastern Miami-Dade County. The Southeast Florida Intrastate Air Quality Control Region is in attainment for all criteria air pollutants (U.S. EPA Jul 2008b). Attainment areas are areas where the ambient levels of criteria air pollutants are designated as being “better than, unclassifiable/attainment, or cannot be classified or better than” the EPA-promulgated National Ambient Air Quality Standards (NAAQS). Criteria pollutants are those for which NAAQS have been established: sulfur dioxide, particulate matter (i.e., PM_{10} and $PM_{2.5}$, which are particles with nominal aerodynamic diameters less than or equal to 10.0 and 2.5 microns, respectively), carbon monoxide, nitrogen dioxide, ozone (1-hr and 8-hr); and lead (U.S. EPA Jul 2007).

There are three pristine areas in the state of Florida designated as *Mandatory Class I Federal Areas Where Visibility is an Important Value.* They include the Chassahowitzka Wilderness Area, Everglades National Park, and St. Marks Wilderness Area (U.S. EPA Jul 2008c). The Everglades National Park is the closest of the Class I areas, located approximately 13 miles west of the Units 6 & 7. The Chassahowitzka Wilderness Area and St. Marks Wilderness Area are located over 250 miles northwest of the Turkey Point plant property.

In addition to Class I federal areas, there are two national parks and a national wildlife refuge in the vicinity of the Turkey Point plant property that are PSD Class II federal areas. Biscayne National Park is immediately north and east of the Turkey Point plant property while the Biscayne Bay Aquatic Preserve is northeast, east, and southeast of the property. Homestead Bayfront Park is a recreational park approximately 1.7 miles north of the Units 6 & 7 plant area. The Biscayne Trail is approximately 2 miles north of the plant area. The Everglades Mitigation Bank is southwest of the Turkey Point plant property.

2.7.2.2 Projected Air Quality Conditions

The Units 6 & 7 steam supply systems and other related radiological systems would not be sources of criteria pollutants or other air toxics. Supporting equipment (e.g., diesel generators, fire pump engines), and other nonradiological emission-generating sources (e.g., cooling towers, storage tanks, and related equipment) or activities would not be significant sources of criteria pollutant emissions (see Sections 3.6 and 5.5).

Supporting equipment would only be operated on an intermittent test or emergency-use basis. Therefore, these emission sources would not impact ambient air quality levels in the vicinity of the Turkey Point plant property, nor would they be a significant factor in the design and operation

of Units 6 & 7. The combination of insignificant emissions and the relatively large separation distance from the Turkey Point plant property to the Chassahowitzka Wild and St. Marks Wilderness Class I areas would not result in a significant impact on visibility as a result of project construction and facility operations.

These nonradiological emission sources would be regulated by the Florida Department of Environmental Protection (FDEP) as required under the Florida Administrative Code (F.A.C.), Title 62, Chapters 4 through 297 depending on the source type, source emissions, and permitting requirements for construction and operation.

Emission-generating sources and activities related to construction of Units 6 & 7, potential impacts, and mitigation measures are addressed in Subsection 4.4.1.2. Nonradiological emission-generating sources associated with routine facility operations are addressed further in Subsection 3.6.3.1. Characteristics of these proposed emission sources and the potential effects on air quality and visibility associated with their operation are addressed in Subsections 5.8.1 and 5.3.3, respectively.

2.7.2.3 Restrictive Dispersion Conditions

Atmospheric dispersion can be described as the horizontal and vertical transport and diffusion of pollutants released into the atmosphere. Horizontal and vertical dispersion of a pollutant along the downwind trajectory from a source is controlled primarily by wind direction variation, wind speed, and atmospheric stability.

In general, lower wind speeds represent less turbulent airflow, which is restrictive to both horizontal and vertical dispersion. And, although wind direction tends to be more variable under lower wind speed conditions (which increases horizontal transport), air parcels containing pollutants often recirculate within a limited area, thereby increasing cumulative exposure.

Major air pollution episodes are usually related to the presence of stagnating high-pressure weather systems (or anticyclones) that influence a region with light and variable wind conditions for 4 consecutive days or more. An updated air stagnation climatology report titled Air Stagnation Climatology for the United States (Wang and Angell 1999) has been published with data for the continental United States based on more than 50 years of observations. In this study, stagnation conditions were defined as 4 or more consecutive days when meteorological conditions were conductive to poor dispersion. Although inter-annual frequency varies, the data in Figures 1 and 2 of that report indicates that, on average, the region surrounding Units 6 & 7 can expect approximately 20 days per year with stagnation conditions, or approximately 4 cases or less per year, with a mean duration of 5 days or less for each case (Wang and Angell Apr 1999).

Air stagnation conditions primarily occur during an “extended” summer season (May through October). This is a result of the weaker pressure and temperature gradients, and therefore

weaker wind circulations, during this period (as opposed to the winter season). Based on Wang and Angell Figures 17 to 67, the highest incidence of air stagnation is recorded between July and September, typically reaching its peak during August, when the Bermuda high-pressure system establishes. As the LCD summary in Table 2.7-2 for Miami International Airport indicates, this 3-month period coincides with the lowest monthly mean wind speeds during the year. Air stagnation is at a relative minimum within the “extended” summer season during May and June (Wang and Angell Apr 1999).

The dispersion of air pollutants is also a function of the mixing height. The mixing height (or depth) is defined as the height above the surface through which relatively vigorous vertical mixing takes place. Lower mixing heights (and wind speeds), therefore, are a relative indicator of more restrictive dispersion conditions. The United States Department of Agriculture (USDA) Forest Service Ventilation Climate Information System (USDA 2007) reports statistical data for mean monthly morning and afternoon mixing heights and wind speeds for locations in the contiguous United States, Alaska, and Hawaii. The data used to compute the statistics is based on observations for the period 1961–1990 for mixing heights and 1959–1998 for wind speed. Monthly statistics for these parameters include minimum, maximum, and mean values, average wind direction, and most frequent wind direction and are based on the longitude and latitude of the Units 6 & 7 plant area.

Table 2.7-5 summarizes minimum, maximum, and mean morning and afternoon mixing heights and surface wind speeds on a monthly, seasonal, and annual basis for the area. As atmospheric sounding measurements are still only made from a relatively small number of observation stations, these statistics represent model-derived values within the interactive database for a specific location (USDA 2007)—in this case, the Turkey Point plant property. The seasonal and annual values listed in Table 2.7-5 were derived as weighted means based on the corresponding monthly values.

From a climatological standpoint, the lowest morning mixing heights occur in the summer, and the highest morning mixing heights occur during the spring. The afternoon mixing heights reach a seasonal minimum in the fall and a maximum during the spring due to more intense daytime heating.

The wind speeds listed in Table 2.7-6 representing the location of the Units 6 & 7 plant area are reasonably consistent with the LCD summary for Miami International Airport in Table 2.7-2, in that the lowest mean wind speeds are shown to occur during the summer. This period of minimum wind speeds also coincides with the “extended” summer season described by Wang and Angell (Wang and Angell Apr 1999) that is characterized by relatively higher air stagnation conditions.

2.7.3 SEVERE WEATHER

This subsection addresses severe weather phenomena that affect the Turkey Point area and region and that are considered in the design and operating bases for Units 6 & 7. These phenomena and observed properties include:

- The frequencies of thunderstorms and lightning (Subsection 2.7.3.1)
- Observed and probabilistic extreme wind conditions (Subsection 2.7.3.2)
- Tornadoes and related wind and pressure characteristics (Subsection 2.7.3.3)
- The frequency and magnitude of hail, snowstorms, and ice storms (Subsection 2.7.3.4)
- Tropical cyclones and related effects (Subsection 2.7.3.5)

2.7.3.1 Thunderstorms and Lightning

Thunderstorms can occur in the area at any time during the year. Based on a 61-year period of record, Miami International Airport averages approximately 73 thunderstorm-days (i.e., days on which thunder is heard at an observing station) per year (see Table 2.7-2). On average, August has the highest monthly frequency of occurrence—approximately 15 days. Annually, 74 percent of thunderstorm-days are recorded during June, July, August, and September. From November through March, a thunderstorm might be expected to occur approximately 1 to 2 days per month (NCDC Feb 2009a).

The mean frequency of lightning strokes to earth can be estimated using a method attributed to the Electric Power Research Institute (EPRI), as reported by the USDA Rural Utilities Service (USDA Aug 1998). This methodology assumes a relationship between the average number of thunderstorm-days per year (T) and the number of lightning strokes to earth per square mile per year (N), where:

$N = 0.31T$

Based on the average number of thunderstorm-days per year (73) at Miami International Airport (see Table 2.7-2), the frequency of lightning strokes to earth per square mile is approximately 23 per year for the site area. This estimate of frequency is somewhat lower than the mean of the 10-year (1989 to 1999) cloud-to-ground flash density of approximately 12 to 14 flashes/square-kilometers/year or 4.6 to 5.4 flashes/square-miles/year reported by the NWS for the area that includes Units 6 & 7. Considering the fact that the estimated cloud-to-ground flash density is based on both cloud-to-ground and cloud-to-cloud lightning flashes, the actual number of

lightning strokes to earth would be somewhat lower and more comparable to the estimate provided by the EPRI method (NSSL Jan 2006).

In order to estimate the frequency of lightning strokes on Units 6 & 7, a rectangular area of approximately 30 acres (0.047 square-miles) was identified to encompass the power blocks of both units. Given the estimated annual average frequency of lightning strokes to earth, the frequency of lightning strokes to Units 6 & 7 can be estimated as follows:

(23 lightning strokes/square-miles/year) x (0.047 square-miles) = 1.1 lightning strokes/year, or about once each year.

2.7.3.2 Extreme Winds

From a climatological standpoint, the frequency of peak wind speed gusts can be characterized from information in the *Climate Atlas of the United States* (NCDC Sep 2002b), which is based on observations made for the 30-year period of record from 1971 to 2000. Frequencies of occurrence were developed from values reported as the 5-second peak gust for the day. Mean annual occurrences of peak gusts greater than or equal to 50 mph, 40 mph, and 30 mph in the area range between 0.5 and 1.4 days per year, less than 9.5 days per year, and 40.5 and 50.4 days per year, respectively.

Estimating the wind loading on plant structures for design and operating bases considers the basic wind speed, which is the 3-second gust speed at 33 feet (10 meters) above the ground in Exposure Category C (ASCE 2005).

The basic wind speed is approximately 150 mph, as estimated by linear interpolation from the plot of basic wind speeds in Figure 6-1B of ASCE 7-05 (ASCE 2005) for that portion of the United States that includes the Units 6 & 7 plant area. The plant area is located in a hurricane prone region as defined in Section 6.2 of the ASCE-SEI design standard, that is, along the U.S. Atlantic Ocean and Gulf of Mexico coasts where the basic wind speed is greater than 90 mph (ASCE 2005).

From a probabilistic standpoint, this value is associated with a mean recurrence interval of 50 years. Section C6.0 (Table C6-3) of the ASCE-SEI design standard provides conversion factors for estimating 3-second-gust wind speeds for other recurrence intervals (ASCE 2005). Based on this guidance, the 100-year return period value is determined by multiplying the 50-year return period value by a scaling factor of 1.07, which yields a 100-year return period 3-second-gust wind speed of approximately 161 mph. Additionally, using the guidance of RG 1.221 (U.S. NRC Oct 2011), it was determined that the nominal 3-second wind gust speed that can be expected to occur at the Turkey Point site with a return period of 1.0E07 years is 260 mph. The 3-second gust wind speed was determined by digitizing the contours from Figure 1 of RG 1.221, and overlaying the Turkey Point site location.

2.7.3.3 Tornadoes

The design basis tornado characteristics applicable to structures, systems, and components important to safety include the following parameters as identified in RG 1.76:

- Maximum wind speed
- Translational speed
- Maximum rotational speed
- Radius of maximum rotational speed
- Pressure drop
- Rate of pressure drop

Based on Figure 1 of RG 1.76 and the coordinates for the midpoint between the Units 6 & 7 shield buildings (see FSAR Subsection 2.1.1.2), the Turkey Point plant property is located within Tornado Intensity Region II. The design basis tornado characteristics for Tornado Intensity Region II (RG 1.76, Revision 1) that apply to the plant property are:

- Maximum wind speed = 200 mph
- Translational speed = 40 mph
- Maximum rotational speed = 160 mph
- Radius of maximum rotational speed = 150 feet
- Pressure drop = 0.9 pounds per square inch (psi)
- Rate of pressure drop = 0.4 psi/sec

Revision 1 of RG 1.76 retains the 1E-07 exceedance probability for tornado wind speeds, the same as the original version of that RG. Revision 2 of NUREG/CR-4461 describes the relationship between the previous use of the original Fujita scale of wind speed ranges for different tornado intensity classifications and the Enhanced Fujita Scale wind speed ranges in the revised analysis of tornado characteristics. That document was the basis for most of the technical revisions to RG 1.76.

Tornadoes observed within a 2-degree latitude and longitude square, centered on the Units 6 & 7 plant area, are used to characterize their frequency of occurrence from a climatological

standpoint. The data was obtained from the NCDC *Storm Events* database of tornado occurrences by location, date, and time; starting and ending coordinates; Fujita-scale wind speed classification (or F-scale); Pearson-scale path length and path-width dimensions (or P-scale); and other storm-related statistics (NCDC 2008c).

The 2-degree square area for this evaluation includes all or portions of six counties in Florida. All tornado occurrences within the 2-degree latitude/longitude square were included. Through the nearly 58-year period from 1950 through 2007, the records in the database indicate that a total of 297 tornadoes occurred within the 2-degree latitude/longitude square (NCDC 2008c).

Tornado F-scale classifications (with corresponding wind speed range based on the original Fujita scale of wind speeds) and respective frequencies of occurrence are as follows:

Tornado F-Scale Classification	Corresponding Wind Speed Range in Meters Per Second	Respective Occurrences
F5	≥117 (261–318 mph)	0
F4	93 to 116 (207–260 mph)	0
F3	70 to 92 (158–206 mph)	4
F2	50 to 69 (113–157 mph)	17
F1	33 to 49 (73–112 mph)	65
F0	18 to 32 (40–72 mph)	211

Twelve of the tornadoes are assigned an undefined F-scale magnitude of “F” in the *Storm Events* database, because the begin location and end location are both unknown and most have no description of the incident available. and are assumed to be comparable to an F0 classification (NCDC 2008c).

Tornadoes have occurred in the area during every month of the year with a peak frequency occurring in the summer. On a monthly basis, the greatest number of events has been recorded in June, followed by the second-highest count during August, followed by the third highest count during May. The smallest amount of the tornadoes have occurred during the winter months (NCDC 2008c).

Tornadoes that occur over a body of water are called waterspouts. Waterspouts probably occur more frequently in the Florida Keys than anywhere else in the world (NWS Jan 2007). Waterspouts are generally broken into two categories: fair weather waterspouts and tornadic waterspouts. Tornadic waterspouts are simply tornadoes that form over water, or move from land to water. They have the same characteristics as a land tornado (NWS Jan 2007). The maximum rotational wind speed of waterspouts has been estimated to be as high as 219 miles per hour (AMS Mar 1977). Fair weather waterspouts are quite common over south Florida’s coastal waters from late spring to early fall. The term “fair weather” comes from the fact that this type of waterspout forms during fair and relatively calm weather, often during the early to mid-morning

and sometimes during the late afternoon. Waterspouts can move onshore and become tornadoes and cause significant damage and injuries to people. However, typically, fair weather waterspouts dissipate rapidly when they make landfall, and rarely penetrate far inland (NWS Jan 2007).

It is estimated that the Florida Keys area experiences 50 to 500 waterspouts each year. In terms of waterspouts per unit area, the most active region after the Florida Keys is the entire southeast Florida coast from Stuart, Florida to Homestead, Florida (AMS Mar 1977). Conventional data-reporting sources for the Florida Keys area likely underestimate the actual yearly waterspout population. This tendency is likely present in the storm data compiled by the NCDC for the Florida Keys (Monroe County), which only reports 421 waterspouts for the period of record January 1, 1950 through April 30, 2008 (NCDC 2008b). The tendency for underreporting in the Florida Keys may be attributed to the fact that much of the population is concentrated in a few areas of much higher density, such as the city of Key West, and the duration of a waterspout is only approximately 14 minutes.

2.7.3.4 Hailstorms, Snowstorms, and Ice Storms

Frozen precipitation in the area typically occurs in the form of hail. The frequency of occurrence and characteristics of these types of weather events are based on the following two references: the latest version of *The Climate Atlas of the United States* (NCDC Sep 2002b), which has been developed from observations made over the 30-year period of record from 1961 to 1990, and the NCDC *Storm Events* database for Florida (NCDC 2009b) based on observations for the period of January 1950 to May 2008.

Though hail can occur at any time of the year in the area and is associated with well-developed thunderstorms, it has been observed primarily during late spring and the summer months (May through August), reaching a peak during May, and occurring least often from late fall through the winter months (December, January, and February) (NCDC 2008c).

The *Climate Atlas* (NCDC Sep 2002b) indicates that most of Miami-Dade County can expect, on average, hail with diameters of 0.75 inch or greater approximately one day per year. The *Climate Atlas* also shows a similar frequency in the eastern portions of the adjacent Broward County. However, a relatively lower frequency of occurrence is indicated for the west portion of Broward County and the extreme western and southern portions of Miami-Dade County (less than 0.5 days per year). Other nearby counties of Collier and Monroe, which are directly adjacent to the Gulf of Mexico, can expect 0.75-inch or greater hail about 0.5 days or less per year. The *Climate Atlas* indicates that the occurrence of hail with diameters greater than or equal to 1.0 inch is relatively less frequent over the area and confined to the northeastern portion of Miami-Dade County and the southeastern portion of Broward County (NCDC Sep 2002b).

NCDC cautions that hailstorm events are point observations and somewhat dependent on population density. This may explain the areal extent of higher frequencies around Miami-Dade and Broward Counties, and what could be interpreted as generally lower frequencies of occurrence in the other nearby counties. The slightly higher annual mean frequency of approximately 0.5 to 1 day per year with hail greater than or equal to 0.75 inch in diameter is considered to be a representative indicator for the Turkey Point site.

Hailstorm events within Miami-Dade and surrounding counties have generally reported maximum hailstone diameters ranging between 1.75 and 4.0 inches. Golf ball-size hail (approximately 1.75 inches in diameter) is not a rare occurrence, having been observed numerous times in the area (NCDC 2009b). However, in terms of extreme hailstorm events, the NCDC *Storm Events* database indicates that grapefruit- to softball-size hail (approximately 4.0 to 4.5 inches in diameter, respectively) was observed on March 29, 1963 (4.0 inches), in Miami-Dade County. The exact location of this event is unknown (NCDC 2009b).

Winters bring no accumulation of snowfall in southeastern Florida. Snow has never been reported at the Miami International Airport; however, snow was reported in January 1977, in Homestead, Florida. The total snowfall was estimated to be only 0.05 inches (USU 2008). However, notes made by the station observer indicate that the snow melted before reaching the ground (NOAA Jan 1977). This was during one of the worst mid-1970s cold waves and snow fell that day in several parts of Dade County, Florida, but not at the NWS office at the Miami International Airport, which is why the official records do not reflect the reports of snow.

The *Storm Events* database for Florida (NCDC 2009b) indicates that ice storms have not been reported in Broward, Collier, Monroe, or Miami-Dade Counties in the period January 1, 1950 through March 31, 2009. In addition, the *Climate Atlas* (NCDC Sep 2002b) indicates that the mean numbers of days per year with frozen precipitation in all counties of southeastern Florida is zero.

2.7.3.5 Tropical Cyclones

Tropical cyclones include not only hurricanes and tropical storms, but systems classified as tropical depressions, subtropical storms, subtropical depressions, and extratropical storms. This characterization considers all “tropical cyclones” (rather than systems classified only as hurricanes and tropical storms) because storm classifications are generally downgraded once landfall occurs and the system weakens, although they may still result in significant rainfall and extreme wind events as they travel through the region.

NOAA’s Coastal Services Center (NOAA-CSC) provides a comprehensive historical database, extending from 1851 through 2007, of tropical cyclone tracks based on information compiled by the National Hurricane Center. This database indicates that a total of 53 tropical cyclone centers

or storm tracks (including extratropical storms) have passed within 100 nautical miles of Turkey Point, during this historical period (NOAA-CSC 2007). Storm classifications and respective frequencies of occurrence spanning this 157-year period of record are:

- Hurricanes — Category 5 (3), Category 4 (10), Category 3 (13), Category 2 (8), Category 1 (16)

- Extratropical storms — 3

Wind speeds (1-minute average) corresponding to each of the Saffir-Simpson Hurricane categories are listed below:

Saffir-Simpson Hurricane Categories	
Classification	Wind Speed (mph)
Category 1	74–95
Category 2	96–110
Category 3	111–130
Category 4	131–155
Category 5	>155

Tropical cyclones have occurred as early as June and as late as November. During the months of August through October, hurricanes occur with increasing frequency. Three Category 5 hurricanes tracked within 100 nautical miles of Turkey Point. Two were no-named hurricanes occurring in September of 1935 and September of 1947. Hurricane Andrew, the third Category 5 hurricane, occurred in August 1992.

Tropical cyclones are responsible for at least 14 separate rainfall records among the 17 NWS and cooperative observer network stations listed in Table 2.7-4, which includes eight 24-hour (daily) rainfall totals and 6 monthly rainfall totals (see Table 2.7-4). On August 26, 2005, a 24-hour record was set at the Perrine 4 W cooperative observing station as a result of Hurricane Katrina (15.1 inches) (SERCC Jun 2008a).

Monthly station records were established due to partial contributions from the following tropical cyclones (NOAA-CSC 2008):

- Hurricane Donna and Tropical Storm Florence in September 1960 (21.95 inches at Dania 4 WNW; 27.54 inches at Miami 12 SSW; 24.4 inches at Miami International Airport; and 29.5 inches at Perrine 4 W).

  Hurricane Donna was responsible for unprecedented damage as it moved along a path through the coastal areas of southern and western Florida. The first advisories for Donna were given on September 2, 1960 when it was located about 700 miles west of the Lesser

Antilles and had maximum winds estimated at 135 mph. The hurricane tracked west-northwestward and on September 10 moved into the central Florida Keys. The last report from the Tavenier station estimated the wind speed to be 135 mph. Wind gusts of 97 mph were reported at the Miami Airport Tower (NOAA-CSC 2008).

Florence intensified into a tropical storm on September 18, 1960 north of Puerto Rico and moved westward. Wind speeds reached 50 to 55 mph. The storm weakened the next day as it moved westward to the Florida Straits and just north of Cuba, then moved slowly northward over southern Florida on September 23 and 24 with accompanying heavy rains before turning northwestward and then into the Gulf of Mexico (NOAA-CSC 2008). This tropical storm was responsible for the 24-hour maximum rainfall (8.4 inches) at the Miami Beach cooperative observing station.

As indicated above, significant amounts of rainfall can still be associated with a tropical cyclone once the system moves inland. Wind speed intensity, however, noticeably decreases as the system passes over terrain and is subjected to increased frictional forces. Examples of such effects associated with some of the more intense tropical cyclones that have passed within 100 nautical miles of Turkey Point are:

- Hurricane Andrew (August 1992). Hurricane Andrew (Category 5) caused an estimated $26 billion in damage in the United States making it the most expensive natural disaster at that time in the United States. Andrew dropped sufficient rain to cause local floods even though the hurricane was relatively small and generally moved fast. Rainfall totals in excess of four to seven inches were recorded in southeast Florida. At landfall in southern Miami-Dade County, Florida, the central pressure was 922 millibars, which was the third lowest this century (after the 1935 Florida Keys Labor Day storm and Hurricane Camille in 1969) for a land falling hurricane in the U.S. The storm devastated Miami-Dade County then moved northwest across the Gulf of Mexico to make a second landfall in a sparsely populated area of south-central Louisiana as a Category 3 storm on August 26. Hurricane Andrew is historic because this is the first time that a hurricane significantly affected a commercial nuclear power plant. The eye of the storm, with sustained winds of up to 145 mph and gusts of 175 mph, passed over the Turkey Point plant property and caused extensive onsite and offsite damage. However, there was no damage to the safety-related systems of Units 3 & 4 except for minor water intrusion and some damage to insulation and paint (USNRC 1993).

- Hurricane Katrina (August 2005). Katrina was one of the strongest storms to impact the coast of the United States during the last 100 years. Hurricane Katrina developed initially as a tropical depression on August 23, 2005 and strengthened into Tropical Storm Katrina the next day. It then moved slowly along a northwesterly then westerly track through the Bahamas, increasing in strength during this time. A few hours before landfall in south Florida on August 25, Katrina strengthened to become a Category 1 hurricane. Landfall occurred between

Hallandale Beach and North Miami Beach, Florida, with maximum sustained winds of 81 mph. The storm continued to move southwest across the tip of the Florida peninsula. Katrina was responsible for the maximum reported 24-hour rainfall (15.1 inches) at the Perrine 4 W cooperative station on August 26, 2005 (SERC Jun 2008a). This observation agrees with an analysis conducted by NOAA's Climate Prediction Center that showed parts of the region received heavy rainfall, more than 15 inches in some locations, which caused localized flooding (NOAA-CSC 2008).

2.7.4 LOCAL METEOROLOGY AND TOPOGRAPHY

Data acquired by the NWS at its Miami International Airport, first-order station 16, and nearby cooperative network reporting stations, as compiled and summarized by the NCDC, the Utah State GIS Climate Search, Southeast Regional Climate Center (USU 2008; NCDC Feb 2002a; NCDC Sep 2002b; SERCC Jun 2008a and SERCC Jun 2008b), were used to characterize normals and period-of-record means and extremes of temperature, rainfall, and frozen precipitation in the vicinity of Units 6 & 7. Subsection 2.7.1.1 identifies the sources of these climatological summaries and other data resources. The approximate distances and directions of these climatological observing stations relative to the Units 6 & 7 plant area are listed in Table 2.7-1; their locations are shown in Figure 2.7-1.

As indicated in Subsection 2.7.1.1, first-order NWS stations also record measurements, typically every hour, of other weather elements, including winds, relative humidity, dew point, and wet bulb temperatures, barometric pressure, and other observations when those conditions occur (e.g., fog, thunderstorms).

Besides using data from these nearby climatological observing stations, measurements from the tower-mounted meteorological monitoring system that currently supports Units 3 & 4 were also used to characterize dispersion conditions. Refer to Subsections 6.4.2 and 6.4.3 for a description of relevant details about this pre-application monitoring program, including: tower location; terrain features and elevations in the vicinity of Units 6 & 7; instrumentation and measurement levels; data recording and processing; and system operation, maintenance, and calibration activities.

Sea breezes are an almost daily occurrence during the summer. However, their strength and degree of inland penetration vary daily depending on the direction and speed of the prevailing wind. Sea/land breeze circulations influence local temperature, humidity, wind speed, and wind direction and precipitation. The most notable sea breeze impacts are a shift in wind to the onshore direction, an increase in wind speed, a decrease in temperature, and an increase in humidity.

2.7.4.1 Normal, Mean, and Extreme Values

Subsection 2.7.1.3 summarizes normals and period-of-record means and extremes for several standard weather elements (i.e., temperature, atmospheric water vapor, precipitation, and wind conditions).

To substantiate that mean and extreme values at these stations, based on their long-term records of observations, are representative of conditions that might be expected at the Units 6 & 7 plant area, this subsection provides additional details regarding the individual station records from which the values presented in Subsection 2.7.1.3 were obtained.

Historical extremes of temperature, rainfall, and snowfall are listed in Table 2.7-4 for the NWS first-order station and cooperative observing stations in the Turkey Point area.

2.7.4.1.1 Temperature

Characteristics of the normal daily maximum and minimum temperatures, the daily mean temperatures, and the diurnal temperature ranges for the nearby climatological observing stations that make such measurements are addressed in Subsection 2.7.1.3.1 and presented in Table 2.7-3. The overall maximum and minimum temperature extremes observed in the Turkey Point area are summarized in Subsection 2.7.1.3.1 as well.

Extreme maximum temperatures recorded in the region have ranged from 96°F to 104°F for land-based observations, with the highest reading observed at the Flamingo Ranger Station on June 24, 1998. As Table 2.7-4 and the accompanying notes show, the record high temperature for several stations have been reached on two or three occasions, e.g., Homestead Experiment Station, Miami 12 SSW, Miami International Airport, Royal Palm Ranger Station, and Tavernier (NCDC 2004; NCDC Feb 2002a; NCDC July 2005; NCDC Feb 2006; USU 2008; SERCC Jun 2008a).

Extreme minimum temperatures in the region have ranged from 21°F to 42°F, with the lowest reading on record observed at the Pompano Beach cooperative station (approximately 57 miles to the north-northeast) on February 9, 1995. More noteworthy, though, Table 2.7-4 and the accompanying notes indicate that record low temperatures were also set at the NWS Miami International Airport, Flamingo Ranger Station, Miami Beach, Perrine 4 W, Tamiami Trail 40 Mile Bend, and Tavernier stations during a cold wave outbreak on December 24 and 25, 1989. Record minimum temperatures for the Fort Lauderdale, Fort Lauderdale Experiment Station, Miami 12 SSW, and Royal Palm Ranger cooperative stations were all set on January 20, 1977 (NCDC Feb 2002a; NCDC 2004; NCDC July 2005; NCDC Feb 2006; SERCC Jun 2008a; USU 2008).

The extreme maximum and minimum temperature data indicates that synoptic-scale conditions responsible for periods of record-setting excessive heat as well as significant cold air outbreaks

tend to affect the overall Turkey Point area. The similarity of the respective extremes and their dates of occurrence suggest that these statistics are reasonably representative of the temperature extremes that might be expected to be observed at the Units 6 & 7 plant area.

2.7.4.1.2 Atmospheric Water Vapor

Annual, seasonal, and monthly characteristics of the wet bulb and dew point temperatures, along with relative humidity (including diurnal variations), based on measurements at the nearby Miami International Airport NWS station are described in Subsection 2.7.1.3.2.

2.7.4.1.3 Precipitation

Characteristics of the normal annual rainfall and snowfall totals for the 17 nearby land-based climatological observing stations reporting precipitation are described in Subsection 2.7.1.3.3 and presented in Table 2.7-3. The overall maximum daily and monthly totals observed in the Turkey Point area for these forms of precipitation are summarized in Subsection 2.7.1.3.3 as well.

Because precipitation is a point measurement, mean and extreme statistics, such as individual storm event, or daily or cumulative monthly totals vary from station to station. Assessing the variability of precipitation extremes across the area, in an effort to evaluate whether the available long-term data are representative of conditions at the site, largely depends on station coverage.

Historical precipitation extremes (rainfall and snowfall) are presented in Table 2.7-4 for the 17 nearby climatological observing stations**.** Maximum recorded 24-hour rainfall totals range from 7.5 inches at the Tamiami Trail 40 Mile Bend station, 38 miles northwest of the Turkey Point plant property, to 15.1 inches at the Perrine 4 W observing station, approximately 13 miles to the north-northwest. The maximum 24-hour rainfall total at the Perrine 4 W cooperative weather observing station (SERCC Jun 2008a) was directly associated with Hurricane Katrina. Maximum monthly rainfall totals range from 17.5 inches at Miami Beach, approximately 28 miles to the northeast, to 34.4 inches at the Pompano Beach observing station, approximately 57 miles to the north-northeast (USU 2008).

The 34.4 inches during October 1965 recorded at Pompano Beach represents the accumulation of 12 days of measurable precipitation during that month, with approximately 86 percent being recorded on October 14 (6.75 inches), October 15 (12.7 inches), and October 31 (10.01 inches). During the 2-day period of October 14 and 15, heavy rainfall was brought about by lifting of conditionally unstable layers of air to saturation as a result of a stationary front lingering over extreme southern Florida (NHRL Apr 1967; NOAA 2008b). On October 31, 1965, a persistence easterly wind flow off of the ocean resulted in occasional showers and thunderstorms (NOAA 2008b).

In general, when monthly rainfall records are established at a given weather observing station, regardless of their cause(s), significant amounts of precipitation are usually measured at most of the other stations in the site area, particularly when associated with the passage of tropical cyclones. This is usually not the case for maximum 24-hour rainfall records because of the occurrence of more local-scale events such as thunderstorms. For the 24-hour rainfalls from Table 2.7-4, the four most inland stations relative to easterly storms (Flamingo Ranger Station, Oasis Ranger Station, Royal Palm Ranger Station, and Tamiami Trail 40 Mile Bend) report significantly less rainfall than the other stations. They average 8.33 inches while the balance averages 11.73 inches. It is true that not all of the coastal stations report high consistently, but it is true the inland stations report low consistently.

Snow is far from common in southeast Florida and has never been reported at the Miami International Airport. However, snow was reported on January 19, 1977, in Homestead, Florida. The total snowfall was estimated to be 0.05 inches (USU 2008). This was during one of the worst mid-1970s cold waves and snow fell that day in several parts of Miami-Dade County, Florida, but not at the NWS office at the Miami International Airport, which is why the official records do not reflect the snow.

2.7.4.2 Fog

The closest station to the Turkey Point plant property at which observations of fog are made and routinely recorded is the Miami International Airport NWS station, approximately 25 miles to the north. The 2009 LCD summary for this station (Table 2.7-2) indicates an average of approximately 5 days per year of heavy fog conditions, based on a 45-year period of record. The NWS defines heavy fog as fog that reduces visibility to one-quarter mile or less.

On a seasonal basis, heavy fog conditions occur most often during the winter months (December through February), reaching peak frequency in January, and averaging 0.9 days per month. Heavy fog conditions occur least from May through September, averaging much less than one day per month (NCDC Feb 2009a).

The frequency of heavy fog conditions at the Units 6 & 7 plant area would be expected to be very similar to the Miami International Airport NWS station observations because of their proximity to each other (about 25 miles). This is consistent with the low frequency of occurrence reported in *The Climate Atlas of the United States* (NCDC Sep 2002b), which indicates an annual average frequency of 5.5 to 10.4 days per year in the area that includes the Turkey Point plant property. The seasonal variation is very similar to that in the 2009 LCD for the Miami International Airport NWS station (NCDC Feb 2009a).

Enhancement of naturally occurring fog conditions resulting from the operation of the Units 6 & 7 circulating water system and service water system cooling towers is addressed in Subsection 5.3.3.1.

2.7.4.3 Average Wind Direction and Wind Speed Conditions

The distribution of wind direction and wind speed is an important consideration when characterizing the dispersion climatology of a site. Long-term average wind motions at the macro- and synoptic scales (i.e., on the order of several thousand down to several hundred kilometers) are influenced by the general circulation patterns of the atmosphere at the macroscale and by large-scale topographic features (e.g., land-water interfaces such as coastal areas). These characteristics are addressed in Subsection 2.7.1.2.

Site-specific or microscale (i.e., 2 kilometers or less) wind conditions, while they may reflect these larger-scale circulation effects, are influenced primarily by local and, to a lesser extent, meso- or regional-scale (i.e., up to approximately 200 kilometers) topographic features. Wind measurements at these smaller scales are available from the onsite Units 3 & 4 meteorological monitoring program, and these were compared to data recorded at the Miami International Airport NWS station.

A description of the Units 3 & 4 meteorological monitoring program is provided in Section 6.4. Wind direction and wind speed measurements are made at two levels on a guyed 60-meter primary instrumented tower (the lower level at 10 meters and the upper level at 60 meters).

Figures 2.7-2 through 2.7-13 present annual and seasonal wind rose plots (i.e., graphical distributions of the direction from which the wind is blowing) and wind speeds for each of 16, 22.5-degree compass sectors centered on north, north-northeast, northeast, etc., for the 10- and 60-meter levels based on measurements for three annual periods (2002, 2005, and 2006). These years were selected as a period of data that is defendable, representative, and complete, but not older than 10 years from the date of the application, in accordance with RG 1.23.

As shown in Figure 2.7-2, the wind direction distribution at the 10-meter level generally follows an easterly orientation on an annual basis. The prevailing wind (i.e., the direction from which the wind blows most often) is from the east; with approximately 41 percent of the winds blowing from the east-northeast through east-southeast sectors. Conversely, winds from the west-northwest through west-southwest sectors occur approximately 7 percent of the time.

Seasonally, winds from the southeast quadrant predominate during the spring and summer seasons (March through August) (Figures 2.7-4 and 2.7-5). During the winter season, the prevailing wind direction shifts to the north-northwest because of increased cold frequency of frontal passages. Winds from the northeast quadrant predominate during the fall season

(September through November) (Figure 2.7-6). Plots of individual monthly wind roses at the 10-meter measurement level are presented in Figure 2.7-7, Sheets 1 to 12.

Wind rose plots based on measurements at the 60-meter level are shown in Figures 2.7-8 through 2.7-13. By comparison, wind direction distributions for the 60-meter level are fairly similar to the 10-meter level wind roses on composite annual and seasonal bases in terms of the predominant directional quadrants and variation over the course of the year. Plots of individual monthly wind roses at the 60-meter measurement level are presented in Figure 2.7-13, Sheets 1 to 12.

Wind information summarized in the LCD for the Miami International Airport NWS station (Table 2.7-2) indicates a prevailing southeast wind direction on an annual basis, as well as seasonal variations (NCDC Feb 2009a), that appear to be somewhat similar to the 10-meter level wind flow at the Turkey Point plant property. A comparison of monthly prevailing wind directions for both locations indicates that the prevailing winds are generally within the same quadrant at both locations. Differences between the two wind direction distributions are attributable to many factors such as topographic setting, sensor exposure, instrument threshold and accuracy, and length of record.

Table 2.7-6 summarizes seasonal and annual mean wind speeds based on measurements from the upper and lower levels of the meteorological tower operated in support of Units 6 & 7 during annual periods in 2002, 2005, and 2006, and from wind instrumentation at the Miami International Airport NWS station based on a 24-year period of record (NCDC Feb 2009a). The elevation of the wind instruments at the Miami International Airport NWS station is reasonably comparable to the lower level measurements at the Turkey Point plant property.

Annually, mean wind speeds at the 10- and 60-meter levels are 3.8 and 5.6 meters per second, respectively, at the Turkey Point plant property. The annual mean wind speed at the Miami International Airport (3.9 meters per second), is almost identical to the 10-meter level at Turkey Point, differing by only 0.1 meters per second. Seasonal average wind speeds at Miami International Airport are very similar throughout the year except during the winter and spring seasons when speeds average approximately 0.3 meters per second higher than those at Turkey Point. Seasonal mean wind speeds for both locations follow the same pattern described in Subsection 2.7.2.3 in relation to the seasonal variation of relatively higher air stagnation and restrictive dispersion conditions in the region. It should be noted that this is only a qualitative comparison since short term conditions at Turkey Point are compared to long-term trends at Miami.

There were few calm winds recorded by the Units 3 & 4 meteorological monitoring system at the 10-meter level and the 60-meter level during the annual periods in 2002, 2005, and 2006. [Note: Wind speeds greater than 0.5 mph (starting threshold of sensor) are considered non-calm winds.

However, 42 hours of actual calm conditions occurred over the 2002, 2005, and 2006 periods. These hours, however, were not considered valid and were not used in the meteorological data set.]

2.7.4.4 Wind Direction Persistence

Wind direction persistence is a relative indicator of the duration of atmospheric transport from a specific sector width to a corresponding downwind sector width that is 180 degrees opposite. Atmospheric dilution is directly proportional to the wind speed (other factors remaining constant). When combined with wind speed, a wind direction persistence/wind speed distribution further indicates the downwind sectors with relatively more or less dilution potential (higher or lower wind speeds, respectively) associated with a given transport wind direction.

Tables 2.7-7 and 2.7-8 present wind direction persistence/wind speed distributions (in hours) based on measurements from the Units 3 & 4 meteorological monitoring program for three annual periods (2002, 2005, and 2006). The distributions account for durations ranging from 1 hour to 48 hours for wind directions from 22.5-degree upwind sectors centered on each of the 16 standard compass radials (i.e., north, north-northeast, northeast, etc.) and for wind speed groups greater than or equal to 5, 10, 15, 20, 25, 30, 35, and 40 mph. Distributions are provided for wind measurements made at the lower (10-meter) and the upper (60-meter) tower levels, respectively, identified in the preceding subsection.

At the 10-meter level, the longest persistence period is 36 hours for winds from the east-northeast and southeast sectors. The durations appear only in the lowest two wind speed groups for wind speeds greater than or equal to 5 and 10 mph. Persistence periods lasting for at least 12 hours are indicated for several direction sectors for wind speeds greater than or equal to 5, 10, 15 and 20 mph, including winds from the northeast through south directions; and periods of 12 hour durations are also indicated from the north and north-northwest sectors for wind speed groups greater than or equal to 5 and 10 mph. For wind speeds greater than or equal to 25 mph, maximum persistence is limited to 4 hours.

At the 60-meter level, the longest persistence period is 36 hours and occurs for winds from the northeast, east-northeast, and north-northwest sectors (Table 2.7-8) for wind speeds greater than or equal to 5 and 10 mph and from the northeast sector for wind speeds greater than or equal to 15 and 20 mph. For wind speeds greater than or equal to 25 mph, maximum persistence periods are limited to 12 hours for winds from the northeast and east-southeast sectors.

2.7.4.5 Atmospheric Stability

Atmospheric stability is a relative indicator of the potential diffusion of pollutants released into the ambient air. Atmospheric stability is based on the delta temperature (ΔT) method defined in Table 1 of Revision 1 to RG 1.23.

The method classifies stability based on the temperature change with height (i.e., the difference in °C per 100 meters or ΔT). Stability classifications are assigned according to the following criteria:

- Extremely Unstable (Class A): $\Delta T \leq -1.9°C$
- Moderately Unstable (Class B): $-1.9°C < \Delta T \leq -1.7°C$
- Slightly Unstable (Class C): $-1.7°C < \Delta T \leq -1.5°C$
- Neutral Stability (Class D): $-1.5°C < \Delta T \leq -0.5°C$
- Slightly Stable (Class E): $-0.5°C < \Delta T \leq +1.5°C$
- Moderately Stable (Class F): $+1.5°C < \Delta T \leq +4.0°C$
- Extremely Stable (Class G): $+4.0°C < \Delta T$

The diffusion capacity is greatest for extremely unstable conditions and decreases progressively through the remaining unstable, neutral, and stable classifications.

During the 3-year period of record that includes calendar years 2002, 2005, and 2006 at Turkey Point, ΔT was determined from the difference between temperature measurements made at the 60- and 10-meter tower levels. Seasonal and annual frequencies of atmospheric stability class and associated 10-meter level mean wind speeds for this period of record are presented in Table 2.7-9.

The data in Table 2.7-9 indicates a predominance of neutral stability (Class D) and slightly stable (Class E) conditions throughout the year, 28.5 percent and 36.5 percent of the time for these stability classes, respectively, and 65 percent combined. Extremely unstable conditions (Class A) are more frequent during the spring and occur least often during the summer and autumn months. Such extremely unstable conditions are attributed to relatively lower mean wind speeds and greater insolation in the summer and higher mean wind speeds and lesser insolation in the spring. Extremely stable conditions (Class G) are most frequent during the winter (approximately 10 percent of the time), owing in part to increased radiational cooling at night, and occur least often during the summer months.

Joint frequency distributions of wind speed and wind direction by atmospheric stability class and for all stability classes combined for the 10-meter and 60-meter wind measurement levels at Turkey Point are presented in Table 2.7-10 and Table 2.7-11 respectively, for the 3-year period of record that includes calendar years 2002, 2005, and 2006. The 10-meter level joint frequency distributions are used to evaluate short-term dispersion estimates for accidental atmospheric

releases (see Subsection 2.7.5) and to evaluate long-term diffusion estimates of routine releases to the atmosphere (see Subsection 2.7.6).

2.7.4.6 Topographic Description

The Turkey Point plant property is an 9400-acre tract in a rural area of Miami-Dade County, Florida. Units 6 & 7 would be constructed on 218 acres south of Units 3 & 4. The combined power block footprints of Units 6 & 7 encompass an area of approximately 6 acres. The finished grade of Units 6 & 7 is approximately elevation 25.5 feet (NAVD 88).

Terrain features within 50 miles, based on digital map elevations, are illustrated in Figure 2.7-1. Terrain elevation profiles along each of the 16 standard 22.5-degree compass radials out to a distance of 50 miles are shown in Figure 2.7-14, Sheets 1 through 6. Because Units 6 & 7 are relatively close to one another and because of the distance covered by these profiles, the locus of these radial lines is the center point between the Units 6 & 7 power block buildings.

The Turkey Point plant property lies on the lower east coast of Florida within the Atlantic Coastal Ridge, which is generally a flat stretch of land that borders the Atlantic Ocean. The terrain within 50 miles is generally flat with elevations decreasing to the west through the south as the Florida Everglades and adjacent bay waters are reached. Terrain elevations tend to increase to the west-northwest through the north-northeast from the plant area with maximum relief of up to approximately 60 feet relative to the finished plant grade. Figure 2.7-1 indicates that the highest elevation within 50 miles is 86.12 feet above MSL (this spot elevation does not fall along one of the 16 standard direction radials presented in Figure 2.7-14). Figure 2.7-1 also indicates that the lowest elevation within 50 miles, 2.49 feet below MSL, is to the northeast of the Turkey Point plant property.

More detailed topographic features within 5 miles of Units 6 & 7, also based on digital map elevations, are shown in Figure 2.7-15. Terrain within this radial distance primarily consists of flat plains with very little elevation change relative to nominal plant grade.

While there would be clearing, grubbing, excavation, leveling, and landscaping activities associated with the construction of Units 6 & 7 (see Section 3.9), these alterations to the existing terrain would be localized and would not represent a significant change to the flat to gently rolling topographic character of the vicinity or the surrounding area. Neither the mean and extreme climatological characteristics of the area nor the meteorological characteristics of the Turkey Point plant property and vicinity would be affected as a result of plant construction.

The dimensions and operating characteristics of the facilities associated with Units 6 & 7, including paved, concrete, or other improved surfaces, are insufficient to generate discernible, long-term effects to local- or microscale meteorological conditions, or to the mean and extreme climatological characteristics of the area addressed previously in Subsection 2.7.4.1.

Wind flow would be altered in areas immediately adjacent to and downwind of larger structures. However, these effects would likely dissipate within ten structure heights downwind of the intervening structure(s). Similarly, while ambient temperatures immediately above any improved surfaces could increase, these temperature effects will be too limited in their vertical profile and horizontal extent to alter local-, area-, or regional-scale mean or extreme ambient temperature patterns.

Units 6 & 7 would use mechanical draft cooling towers as a means of heat dissipation during normal operation. Potential meteorological effects as a result of the cooling towers could include localized enhanced ground-level fogging, cloud shadowing and precipitation enhancement, and increased ground-level humidity. These localized effects are addressed in Subsections 5.3.3.1 and 5.3.3.2.

2.7.5 SHORT-TERM DIFFUSION ESTIMATES

2.7.5.1 Regulatory Basis and Technical Approach

To evaluate potential health effects of postulated design basis accidents at Units 6 & 7, the NRC-sponsored PAVAN computer code (NUREG/CR-2858) was used to estimate relative ground-level atmospheric concentrations (X/Q) at the exclusion area boundary (EAB) and low population zone (LPZ) for postulated accidental releases of radioactive material. According to Subsection B of RG 1.23, the recommended meteorological data for a combined license which does not reference an early site permit is a consecutive 24-month period of data that is defendable, representative, and complete, but not older than 10 years from the date of application.

The 2002, 2005, and 2006 period of data taken was determined to be the best available (using validated data with least data substitution), representative (tower and sensor siting in accordance with RG 1.23, Revision 1), and complete (with annualized composite data recovery of 90 percent), without being older than 10 years. Because RG 1.23, Revision 1 specifies that more years of data is preferable, three years (i.e., 2002, 2005, and 2006) of data was used in characterizing the atmospheric conditions for Units 6 & 7.

According to 10 CFR Part 100, it is necessary to consider the doses for various time periods immediately following the onset of a postulated ground-level release at the EAB and for the duration of the exposure for the LPZ and the population center distances. Therefore, the relative atmospheric dispersion factors (X/Qs) are estimated for various time periods ranging from 2 hours to 30 days.

Meteorological data was used to determine various postulated accident conditions as recommended in RG 1.145. Compared to an elevated release, a ground-level release usually results in higher ground-level concentrations at downwind receptors as a result of less dispersion and shorter traveling distances. The ground-level release scenario provides a bounding case,

and none of the release heights are higher than 2.5 times the height of the nearby reactor building, elevated releases were not considered.

The PAVAN program implements the guidance provided in RG 1.145. Primarily, the code computes X/Q values at the EAB and LPZ for each combination of wind speed and atmospheric stability class for each of 16 downwind direction sectors (i.e., north, north-northeast, northeast, etc.). The X/Q values calculated for each direction sector are then ranked in descending order, and an associated cumulative frequency distribution is derived based on the frequency distribution of wind speeds and stabilities for the complementary upwind direction sector. The X/Q value that is equaled or exceeded 0.5 percent of the total time becomes the maximum sector-dependent X/Q value.

The calculated X/Q values were also ranked independently of wind direction to develop a cumulative frequency distribution for the entire site. The PAVAN program then selects the X/Qs that equaled or exceeded 5 percent of the total time.

The larger of the two values (i.e., the maximum sector-dependent 0.5 percent X/Q or the overall site 5 percent X/Q value) is used to represent the X/Q value for a 0–2 hour time period. To determine X/Qs for longer time periods, the program calculates an annual average X/Q value using the procedure described in RG 1.111. The program then uses logarithmic interpolation between the 0–2 hour X/Qs for each sector and the corresponding annual average X/Q to calculate the values for intermediate time periods (i.e., 0–8 hours, 8–24 hours, 1–4 days, and 4 – 30 days). As suggested in NUREG/CR-2858, each of the sector-specific 0–2 hour X/Q values provided in the PAVAN output file were examined for “reasonability” by comparing them with the ordered X/Q values presented in the model output.

The PAVAN model was configured to calculate offsite X/Q values assuming both “wake credit allowed” and “wake credit not allowed”. Several sector distances from the power block area (PBA) to the EAB (NE, ENE, E, SE, and ESE) are within the building wake influence zone. No building wake credit was taken for EAB receptors within the building wake influence zone to ensure conservative results. Also, because the LPZ is farther away from the units than the EAB, the “wake-credit not allowed” scenario of the PAVAN results was used for the X/Q analyses at both the EAB and the LPZ.

The following input data and assumptions were used in the PAVAN modeling analysis:

- Meteorological data: 3-year (2002, 2005, and 2006) onsite joint frequency distributions of wind speed, wind direction, and atmospheric stability
- Wind sensor height: 10 meters (33 feet)
- Vertical temperature difference: (10 meters–60 meters)

- Number of wind speed categories in joint frequency distributions: 13
- Minimum reactor building cross-sectional area: 2636 square meters
- Type of release: Ground-level (model-designated)
- Distances from release point to EAB for all downwind sectors
- Distances from release point to LPZ for all downwind sectors

The PAVAN model uses building cross-sectional area and containment height to estimate wake-related X/Q values. If the EAB and the LPZ are both located beyond the building wake influence zone, these two input parameters have no effect in calculating the non-wake X/Q values.

The joint frequency distribution (JFD) input to the PAVAN dispersion modeling analysis are presented in Table 2.7-10 (see also Subsection 2.7.4.4 for additional information). There were no hours of calm wind conditions at the 10-meter measurement level during the period of record.

2.7.5.2 PAVAN Modeling Results

For modeling convenience, Units 6 & 7 were conservatively treated as one unit in estimating the shortest distance to each boundary receptor in each direction. This was done by using a source boundary which encloses both Units 6 & 7. Using the source boundary approach, the shortest distance from the source boundary to the EAB is presented in Table 2.7-12 for each of the 16 direction sectors.

The maximum direction-dependent 0.5 percent X/Q value and the overall 5 percent X/Q value were conservatively estimated using the source boundary concept. Similarly, the shortest distances from the source boundary to the LPZ were used in the PAVAN modeling run to determine the X/Q values at the LPZ.

Based on the PAVAN modeling results, the maximum 0-2 hour, 0.5 percent, direction-dependent X/Q value was compared with 5 percent overall site 0-2 hour X/Q value at the EAB. The higher of the two was used as the proper X/Q at the EAB for each time period. The same approach was used to determine the proper X/Qs at the LPZ.

Tables 2.7-13 (EAB without and with wake credit) and 2.7-14 (LPZ with no wake credit) present the X/Qs for each of the 16 downwind sectors for the appropriate time period(s). The overall site 5 percent X/Q (s/m^3) value at either the EAB (with or without wake credit for select sectors) or the

LPZ is higher than the sector-dependent 0.5 percent X/Q (s/m^3) value. These values are summarized below.

Receptor Location	X/Q 0–2 hours	X/Q 0–8 hours	X/Q 8–24 hours	X/Q 1–4 days	X/Q 4–30 days	X/Q Annual Average
EAB	4.19E-04	+	+	+	+	+
DCD Value	5.1E-04	Not provided	Not provided	Not provided	Not provided	Not provided
LPZ	+	1.87E-5	1.25E-5	5.25E-6	1.51E-6	+
DCD Value	Not provided	2.2E-04	1.6E-04	1.0E-04	8.0E-05	Not provided

Table Notes: + The value is not provided because there is no equivalent DCD value.

As required in Section 7.1, below are the 50 percent X/Q values at the EAB and LPZ:

Receptor Location	X/Q 0–2 hours	X/Q 0–8 hours	X/Q 8–24 hours	X/Q 1–4 days	X/Q 4–30 days	X/Q Annual Average
EAB	1.89E-04	1.38E-04	1.18E-04	8.40E-05	5.15E-05	2.83E-05
LPZ	9.18E-06	5.29E-06	4.02E-06	2.21E-06	9.39E-07	3.29E-07

2.7.6 LONG-TERM (ROUTINE) DIFFUSION ESTIMATES

2.7.6.1 Regulatory Basis and Technical Approach

This subsection provides estimates of annual average atmospheric dispersion factors (X/Q values) and relative dry deposition factors (D/Q values) to a distance of 50 miles (80 kilometers) for annual average release limit calculations and person-rem estimates.

The NRC-sponsored XOQDOQ computer program (NUREG/CR-2919) was used to estimate X/Q and D/Q values from routine releases of gaseous effluents to the atmosphere. The XOQDOQ computer code has the primary function of calculating annual average X/Q and D/Q values at receptors of interest (e.g., EAB, nearest milk animal, nearest resident, nearest vegetable garden, and nearest meat animal).

The XOQDOQ dispersion model implements the assumptions outlined in RG 1.111. The program assumes that the material released to the atmosphere follows a Gaussian distribution around the plume centerline. In estimating concentrations for longer time periods, the Gaussian distribution is assumed to be evenly distributed within a given directional sector. A straight-line trajectory is assumed between the release point and all receptors.

Since the NRC-sponsored XOQDOQ model was used in the analysis, diffusion parameters (σ_y and σ_z) as specified in RG 1.145 and implemented by the XOQDOQ code were used in estimating the X/Q and D/Q values. The following input data and assumptions was used in the XOQDOQ modeling analysis:

- Meteorological data: 3-year (2002, 2005, and 2006) onsite joint frequency distributions of wind speed, wind direction, and atmospheric stability (see Table 2.7-5)
- Type of release: Ground-level
- Wind sensor height: 10 meters
- Vertical temperature difference: (10 meters–60 meters)
- Number of wind speed categories: 13
- Release height: 10 meters
- Minimum Shield Building cross-sectional area: 2636 square meters
- Shield Building height: 69.7 meters above grade
- Distances from the release point to the nearest residence, EAB, vegetable garden, milk animal, and meat animal

No residential milk cows have been identified within 5 miles of the Turkey Point plant property, and no dairies have been identified within 50 miles. It was conservatively assumed that all residents have a vegetable garden and are raising beef cattle for residential consumption.

The AP1000 standard plant design was used to calculate the minimum building cross-sectional area as called for in NUREG/CR-2919 for evaluating building downwash effects on dispersion. Therefore, based on the width (43.3 meters) and height above grade (60.9 meters – normalized for building taper) of the shield building, the cross-sectional area (normalized to a rectangle) of the shield structure was calculated to be 2636 square meters.

Distances from Units 6 & 7 to various receptors of interest (i.e., nearest residence, meat animal, EAB, and vegetable garden) are presented in Table 2.7-15.

As described in Subsection 2.7.5, site-specific meteorological data covering the 3-year period of record (2002, 2005, and 2006) was used to quantitatively evaluate diffusion estimates. Therefore, the lower level (10 meters) joint frequency distributions of wind speed, wind direction, and atmospheric stability (based on 60 meter and 10 meter data) were used as input in the XOQDOQ modeling analysis.

2.7.6.2 XOQDOQ Modeling Results

Table 2.7-16 summarizes the maximum relative concentration and relative deposition (i.e., X/Q and D/Q) values predicted by the XOQDOQ model for identified sensitive receptors of interest in

the area as a result of routine releases of gaseous effluents. The listed maximum X/Q values reflect several plume depletion scenarios that account for radioactive decay: no decay and the default half-life decay periods of 2.26 and 8 days.

The overall maximum annual average X/Q value with no decay is 1.70E-05 seconds/cubic meter and occurs at the EAB along the south-southeast, southeast, and west sectors as a result of releases from the PBA. The maximum annual average X/Q values (along with the direction and distance of the receptor locations relative to Units 6 & 7) for the other sensitive receptor types are:

- 1.4E-07 seconds/cubic meter for the nearest resident occurring in the north sector at a distance of 2.7 miles

- 9.6E-08 seconds/cubic meter for the nearest vegetable garden occurring in the northwest sector at a distance of 4.8 miles

Tables 2.7-17 and 2.7-18 summarize the annual average X/Q values (for no decay) and D/Q values, respectively, for the 22 standard radial distances between 0.25 miles and 50 miles, and for the 10 distance-segment boundaries between 0.5 miles and 50 miles downwind along each of the 16 standard direction radials separated by 22.5 degrees. Table 2.7-19 summarizes X/Q values and D/Q values for the receptors of interest.

2.7.7 NOISE

An ambient noise monitoring survey was performed in June 2008 to assess the existing ambient noise in areas adjacent to the Turkey Point units. The purpose of the noise survey was to determine baseline noise impacts at and around the Units 6 & 7 plant area, at the Turkey Point plant property boundary, and offsite receptors. The location of the noise monitoring sites is shown in Figure 2.7-16. The receptors of primary concern are the nearest residences to the northwest, the day care facility to the west, and Homestead Bayfront Park to the north.

The field effort to collect the baseline noise level data was conducted on June 3 and 4, 2008, during the daytime and nighttime. The survey consisted of measuring the background noise levels at eight locations both onsite and offsite spanning a 2-day period.

Six of the eight monitoring locations (monitoring sites S1, S4, S5, S6, S7, and S8) were selected to delineate the existing noise levels produced by the existing units as well as other noise sources at the Turkey Point plant property boundary and at the nearest public receptors. Additionally, monitoring sites S2 and S3 were selected to delineate the existing onsite noise levels produced solely by the existing units and were located on the transmission line to the northwest of Unit 5. Monitoring sites S4 and S5 were located approximately 1.6 miles northwest and 2 miles north, respectively, from the existing units. These monitoring sites were chosen to

delineate the noise levels at or near the plant property boundaries, and are the closest public access to Turkey Point. Monitoring sites S6, S7, and S8 were located at the day-care facility to the west, at the Homestead Bayfront Park entrance, and at the nearest residence, respectively. Monitoring site S1 was located at the southeast corner of the Homestead Miami Speedway. Background measurements for Units 6 & 7 were collected while Units 1, 2, 3, 4, and 5 were operating at base load.

The baseline daytime sound pressure level (noise level equivalent [Leq]) measurements for the monitoring locations within and near the Turkey Point plant property boundary (monitoring sites S2, S3, S4, and S5) ranged from a low of 44 dBA at site S5 to a high of 68 dBA at site S3. The nighttime Leq measurements ranged from a low of 47 dBA at site S5 to a high of 67 dBA at site S3. These monitoring sites are closest to Unit 5, which had an audible contribution. Also contributing to the observed sound levels were transient noise sources such as traffic, birds, insects, and wind.

The baseline daytime Leq measurements for the monitoring locations beyond the plant property boundary (monitoring sites S1, S6, S7, and S8) ranged from a low of 46 dBA at site S7 to a high of 67 dBA at site S8. The contributing audible noise sources to the highest observed noise levels at site S8, the nearest residence, were transient noises that included traffic, birds, insects, and wind. The nighttime Leq measurements beyond the plant property boundary ranged from a low of 41 dBA at site S7 to a high of 56 dBA at site S1. The contributing audible noise sources to the highest observed noise levels at site S1 were transient noises that included insects, wind noise, and traffic.

SECTION 2.8: RELATED FEDERAL PROJECT ACTIVITIES
TABLE OF CONTENTS

2.8 RELATED FEDERAL PROJECT ACTIVITIES 2.8-1

2.8.1 LAND ACQUISITION AND USE 2.8-1
2.8.2 COOLING WATER SOURCE AND SUPPLY 2.8-2
2.8.3 PROJECTS AFFECTING CONSTRUCTION OR OPERATION 2.8-2
2.8.4 PLANS OR COMMITMENTS RESULTING IN SIGNIFICANT POWER PURCHASES 2.8-3
2.8.5 OTHER FEDERAL ACTIVITIES 2.8-3

2.8 RELATED FEDERAL PROJECT ACTIVITIES

The purpose of this section is to identify any federal activities that are related to the construction and operation of Units 6 & 7 in Miami-Dade County, Florida. This section describes the cumulative impacts due to other related federal activities and determines the possible need for another federal agency to participate in the preparation of the environmental impact statement as a cooperating agency. In accordance with 10 CFR Part 51 Subpart A, related activities that may result in cumulative impacts that are under state or local agency jurisdiction are described. However, actions related only to the granting of licenses, permits, or approvals by other federal agencies for Units 6 & 7 are not considered in this review because such activities typically have an independent environmental review, in accordance with NUREG-1555.

In accordance with NUREG-1555, the following impact categories (federal/state/local) were identified:

- Actions associated with acquisition and/or use of the proposed site and transmission corridors or of any offsite property needed for the project
- Projects that will be required either to provide an adequate source of plant cooling water or to ensure an adequate supply of cooling water over the lifetime of the new units
- Projects or activities that must be completed as a condition of plant construction or operation
- Projects that are contingent on construction and operation of the new units
- Agency plans or commitments that will result in significant new power purchases that would be applicable to the analysis used to justify the need for power associated with Units 6 & 7

2.8.1 Land Acquisition and Use

The Florida Electrical Power Plant Siting Act, Sections 403.501-403.518, Florida Statutes, mandates a site certification process for obtaining a single site-related license that will include state, regional, and local requirements for construction and operation of a power plant and associated facilities of the type and magnitude being proposed. Pursuant to these statutes, the environmental impacts of the construction of Units 6 & 7 and associated linear and non-linear facilities will be reviewed by the state of Florida and other local and regional bodies. Although these are state-led processes, the potential cumulative impacts of these offsite actions, with regard to both construction and operation, need to be considered as part of related activities.

Transmission corridor alternatives considered for Units 6 & 7 will involve the Department of the Interior and the U.S. Army Corps of Engineers, depending on the corridor selected.

There will also be coordination with Everglades National Park and Biscayne National Park, as necessary, regarding possible impacts to the current Everglades restoration project being performed adjacent to the Turkey Point plant property.

2.8.2 Cooling Water Source and Supply

Currently, there are two natural gas/oil conventional boiler units (Units 1 & 2), two pressurized water nuclear reactors (Units 3 & 4), and one combined-cycle natural gas unit (Unit 5) located on the Turkey Point plant property.

Units 1 through 4 use the cooling canals of the industrial wastewater facility for cooling. Unit 5 uses mechanical draft cooling towers for heat dissipation. These towers receive water from the Upper Floridan aquifer for use as makeup water and route their blowdown to the industrial wastewater facility. Potable water from the Miami-Dade County water supply system, a municipal water source, is provided for potable and service water use for Units 1 through 5 and would also be used for Units 6 & 7.

Two sources of makeup water are planned to replace cooling tower blowdown for Units 6 & 7. One source would be water reclaimed for reuse after processing by the Miami-Dade Water and Sewer Department, conveyed via pipelines to the Turkey Point plant property. An onsite FPL reclaimed water treatment facility would further treat the reclaimed water for use in the cooling system. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, a second source for makeup water would consist of radial collector wells that would withdraw saltwater from under Biscayne Bay. The wells would be located on the Turkey Point peninsula, east of the existing units. Blowdown from the circulating water system would be transferred to a common blowdown sump before being discharged to deep injection wells.

In summary, there are no known planned federal projects or activities that Units 6 & 7 require to meet cooling water requirements, and no federal projects or activities are required to ensure continuous water supply over the plant lifetime.

2.8.3 Projects Affecting Construction or Operation

There are no federal projects or activities that must be completed as a condition of, or are contingent on, Units 6 & 7 construction or operation.

State and/or local projects or activities that must be completed as a condition of, or are contingent on, Units 6 & 7 construction or operation include road improvements and installation of the reclaimed water and potable water pipelines.

2.8.4 Plans or Commitments Resulting in Significant Power Purchases

As described in Chapter 8, there is a demonstrated need for power generated by the proposed project. FPL's reliability analysis did not identify plans or commitments for significant new power purchases from any federal, state, or local agency.

2.8.5 Other Federal Activities

Two related federal activities associated with Units 3 & 4 are potential federal-related activities that may need to be considered for cumulative impacts. A power uprate for Units 3 & 4 is scheduled for 2012, and the construction of an independent spent fuel storage installation is scheduled for 2009.

CHAPTER 3 PLANT DESCRIPTION

3.1 EXTERNAL APPEARANCE AND PLANT LAYOUT

3.1.1 EXISTING SITE

The 218-acre Units 6 & 7 plant area is located within the approximately 9400-acre Turkey Point plant property in Miami-Dade County, Florida, approximately 25 miles south of Miami, 8 miles east of Florida City, and 9 miles southeast of Homestead, Florida. Units 1 through 5 occupy approximately 195 acres on the Turkey Point plant property.

Units 1 & 2 are each 400 MWe (nominal) natural gas/oil steam electric generating units that have been in service since 1967 (Unit 1) and 1968 (Unit 2), respectively. Units 3 & 4 are 700 MWe (nominal) pressurized water reactor nuclear units that have been in service since 1972 (Unit 3) and 1973 (Unit 4), respectively. Turkey Point Unit 5 is a nominal 1150 MWe (nominal) natural gas combined-cycle unit that began operating in 2007. All five of the steam electric generating units lie within the developed area of the Turkey Point plant property. An aerial photograph showing the five existing power generating units is provided as Figure 3.1-1.

A closed-loop system of canals is used by Units 1 through 4 to provide cooling. This system is a permitted industrial wastewater facility. The industrial wastewater facility is a closed-loop system of recirculating canals occupying an area of approximately 5900 acres on the Turkey Point plant property. Unit 5 uses mechanical draft cooling towers for heat dissipation. These towers receive water from the Upper Floridan aquifer for use as makeup water and route their blowdown to the cooling canals of the industrial wastewater facility.

3.1.2 PROPOSED SITE

The Westinghouse AP1000 plant design has been selected for Units 6 & 7 (approximately 1100 MWe each, net output power), a nuclear plant design certified under 10 CFR Part 52, Subpart B. The location of the new units would be directly south of Units 3 & 4 in the northeast portion of the industrial wastewater facility, with Biscayne Bay to the east. An aerial photograph of the Units 6 & 7 plant area showing the existing generating units (Units 1 through 5) in the background is provided in Figure 3.1-2. Figure 3.1-3 shows the plot plan with major structures identified. Figure 2.7-15 provides topographical features within a 5-mile radius around Units 6 & 7.

Units 6 & 7 would share the primary and backup meteorological towers with Units 3 & 4. The current meteorological tower locations are shown on Figure 6.4-1 and Figure 6.4-2. (The backup meteorological tower would be relocated during Units 6 & 7 construction to a suitable area on the Turkey Point plant property.) The radioactive liquid release points and the radioactive gaseous release points for the new units are presented in Section 3.5. The nonradioactive liquid release

points and the nonradioactive gaseous release points for the new units are presented in Section 3.6.

The new AP1000 units and support facilities are designed around a Westinghouse standardized unit approach. Each AP1000 unit consists of five principal structures:

1. Nuclear island
2. Turbine building
3. Annex building
4. Diesel generator building
5. Radwaste building

The structures that make up the nuclear island include the containment building, shield building, and auxiliary building. The foundation for the nuclear island will be an integral basemat that supports these buildings. The containment building will be a free-standing steel containment vessel with elliptical upper and lower heads. It will be surrounded by the shield building. The shield building will be a structure that, in conjunction with the internal structures of the containment building, provides the required shielding for the reactor coolant system and the other radioactive systems and components housed in the containment building.

The auxiliary building will be a reinforced concrete structure that wraps around approximately 70 percent of the circumference of the shield building. The primary function of the auxiliary building is to provide protection and separation for the mechanical and electrical equipment located outside of the containment building. The main control room will be contained within the auxiliary building. The auxiliary building will provide protection to safety-related equipment from the consequences of either a postulated internal or external event. The auxiliary building will also provide shielding for the radioactive equipment and piping that is housed within the building.

The turbine building will be a rectangular steel column and beam structure with its long axis oriented radially from the containment building. The turbine building will house the turbine, generator, and associated mechanical and electrical systems.

The annex building will be a combination reinforced concrete and steel-framed structure with insulated metal siding. The annex building will provide the main personnel entrance to the power block. The building also will contain the control support area, machine shop, the ancillary diesel generators, other electrical equipment and various heating, ventilation, and air conditioning systems.

The diesel generator building will be a single-story, steel-framed structure with insulated metal siding. The building will house two diesel generators to provide backup power in the event of disruption of the normal power source.

The radwaste building will be a steel-framed structure. The radwaste building will house low-level liquid radwaste holdup tanks and processing system. The building will include facilities for segregated storage of various categories of waste before processing, for processing by mobile systems, and for storing processed waste in shipping and disposal containers.

For each unit, the closed-cycle circulating water system (CWS) would consist of three mechanical draft cooling towers, an open channel (flume) with a pump intake structure, and the two sources of makeup water for the cooling towers. The primary source of makeup water for the cooling towers would be treated reclaimed water from the Miami-Dade Water and Sewer Department (MDWASD). The other source available for makeup water to the CWS would be saltwater via substratum radial collector wells. Saltwater would be used when a sufficient supply and/or quality of treated reclaimed water is unavailable. The CWS cooling towers would be situated at the southern end of the Units 6 & 7 plant area. Blowdown flow from the cooling towers would be directed to a common blowdown sump before being discharged to deep injection wells. A description of the CWS, including deep injection wells, is provided in Section 3.4.

In addition to the CWS cooling towers, Units 6 & 7 will include one service water system cooling tower (a 2-cell tower) for each unit. These mechanical draft cooling towers will occupy an area of approximately 0.5 acre per unit and will be located near the turbine building. The source of makeup water for the service water cooling towers would be potable water from the MDWASD potable water supply.

Additional plant structures would include warehouses, nuclear administration building, training building, other offices and buildings, security buildings, parking areas, sanitary waste treatment plant, switchyard, and transmission towers. A reclaimed water treatment facility, makeup water reservoir, and pipelines would be constructed for treating, storing, and delivering the reclaimed water from the MDWASD.

Units 6 & 7 would be constructed from materials architecturally similar to Units 1 through 4. The overall goal would be to provide an aesthetically pleasing effect. An artist’s rendition of Units 6 & 7 with the existing Units 1 through 5 is provided in Figure 3.1-4. Photographs that show the new units from several vantage points are included as Figures 3.1-5 and 3.1-6. Figure 3.1-5 shows the expected view from the local transportation corridor-SW 344th Street/Palm Drive. Figure 3.1-6 shows the expected view from Biscayne Bay.

Figure 3.1-6 Visual Rendering From Biscayne Bay

3.2 REACTOR POWER CONVERSION SYSTEM

Two Westinghouse AP1000 units are proposed for Units 6 & 7. The architect-engineer has not yet been selected. Major components for each unit include a single reactor pressure vessel, two steam generators, and four reactor coolant pumps for converting reactor thermal energy into steam. A single high-pressure turbine and three low-pressure turbines drive a single electric generator. Figure 3.2-1 provides a simplified diagram of the reactor power conversion system.

The reactor contains a matrix of fuel rods assembled into 157 mechanically identical fuel assemblies along with control and structural elements. A fuel assembly consists of 264 fuel rods in a 17 x 17 square array. The assemblies, containing various fuel enrichments, are configured into the core arrangement located and supported by the reactor internals. The reactor internals also direct the flow of the coolant past the fuel rods. The coolant and moderator is light water at a normal operating pressure of 2250 psia. The fuel, internals, and coolant are contained within a heavy-walled reactor pressure vessel.

The fuel rods consist of enriched uranium, in the form of cylindrical pellets of sintered uranium dioxide contained in ZIRLO™[1] tubing, with an initial fuel cycle enrichment of 2.35 to 4.45 weight percent U-235. The average concentration of U-235 in reloads is 4.54 weight percent. The total weight of uranium dioxide is 211,588 pounds as shown in DCD Table 4.1-1 (WEC 2011). Reload core designs, as well as the initial cycle design, are anticipated to operate approximately 18 months between refueling, accumulating an average burnup of discharged fuel of approximately 50,553 megawatt-days per metric ton of uranium (MWD/MTU), with a cycle burnup of approximately 21,000 MWD/MTU. The NRC has approved maximum fuel rod average burnup of 60,000 MWD/MTU. Extended burnup to 62,000 MWD/MTU has been established as described in DCD Subsection 4.3.1.1.1. The total fuel capacity for each unit is approximately 84.5 MTU.

The ZIRLO tubing is plugged and seal-welded at the ends to encapsulate the fuel. An axial blanket comprised of fuel pellets with reduced enrichment may be placed at each end of the enriched fuel pellet stack to reduce the neutron leakage and to improve fuel use.

The AP1000 reactor is connected to two steam generators via two primary hot leg pipes and four primary cold leg pipes. A reactor coolant pump is located in each primary cold leg pipe to circulate pressurized reactor coolant through the reactor core. The coolant flows through the reactor core, making contact with the fuel rods containing the enriched uranium dioxide fuel. As the coolant passes through the core, heat from the nuclear fission process is transferred from the fuel rods to the coolant. The heat is transported to the steam generators by the circulating reactor coolant and passes through the steam generator tubes to heat the feedwater from the secondary

1. ZIRLO is a registered trademark of Westinghouse Electric Company.

system. Reactor coolant is pumped back to the reactor by the reactor coolant pumps, where it is reheated to start the heat transfer cycle over again. Inside the steam generators, the heat from the primary system is transferred through the tube walls to convert the incoming feedwater from the secondary system into steam. The steam is transported from the steam generators by the main steam piping to drive the high-pressure and low-pressure turbines connected to the electric generator. After passing through three low-pressure turbines, the steam is condensed back to water by cooled water circulating inside the tubes of three main condensers. The heat rejected in the main condensers is removed by the circulating water system. The condensate is then preheated and pumped back to the steam generators as feedwater to repeat the steam cycle.

Transportation of fuel and waste is addressed in Section 3.8.

3.2.1 ENGINEERED SAFETY FEATURES

Engineered safety features protect the plant workers and the public in the event of an accidental release of radioactive fission products from the reactor coolant system. The engineered safety features function to localize, control, mitigate, and terminate such accidents and to maintain radiation exposure levels to the public below applicable limits and guidelines, such as those in 10 CFR Part 20 and 10 CFR Part 100. The following subsections define the engineered safety features.

3.2.1.1 Containment

The containment vessel is a free-standing cylindrical steel vessel with ellipsoidal upper and lower heads. It is surrounded by a Seismic Category I reinforced concrete shield building. The function of the containment vessel, as part of the overall containment system, is to contain the release of radioactivity following postulated design basis accidents. The containment vessel also functions as the safety-related ultimate heat sink by transferring the heat associated with accident sources to the surrounding environment. The following paragraph details this safety-related feature.

Passive Containment Cooling System: The function of the passive containment cooling system is to maintain the containment air temperature below a specified maximum value and to reduce the containment temperature and pressure following a postulated design basis event. The passive containment cooling system removes thermal energy from the containment atmosphere. The passive containment cooling system also serves as the safety-related ultimate heat sink for other design basis events and shutdowns. The passive containment cooling system limits the release of radioactive material to the environment by reducing the pressure differential between the containment atmosphere and the external environment. This diminishes the driving force for leakage of fission products from the containment to the atmosphere in the event of a postulated design basis accident.

3.2.1.2 Containment Isolation System

The major function of the containment isolation system of the AP1000 is to provide containment isolation to allow the normal or emergency passage of fluids through the containment boundary while preserving the integrity of the containment boundary, if required. This prevents or limits the escape of fission products that may result from postulated accidents. Containment isolation provisions are designed so that fluid lines penetrating the primary containment boundary are isolated in the event of an accident. This minimizes the release of radioactivity to the environment.

3.2.1.3 Passive Core Cooling System

The primary function of the passive core cooling system is to provide emergency core cooling following postulated design basis events. The passive core cooling system provides reactor coolant system makeup and boration during transients or accidents where the normal reactor coolant system makeup supply from the chemical and volume control system is lost or is insufficient. The passive core cooling system provides safety injection to the reactor coolant system to provide adequate core cooling for the complete range of loss of coolant accident events up to, and including, the double-ended rupture of the largest primary loop reactor coolant system piping. The passive core cooling system provides core decay heat removal during transients, accidents, or whenever the normal heat removal paths are lost.

3.2.1.4 Main Control Room Emergency Habitability System

The main control room emergency habitability system is designed so that the main control room remains habitable following a postulated design basis event. With a loss of all alternating current power sources, the habitability system maintains an acceptable environment for continued operating staff occupancy.

3.2.1.5 Fission Product Control

Post-accident safety-related fission product control for the AP1000 is provided by natural removal processes inside containment, the containment boundary, and the containment isolation system. The natural removal processes, including various aerosol removal processes and pool scrubbing, remove airborne particulates and elemental iodine from the containment atmosphere following a postulated design basis event.

3.2.2 TURBINE GENERATOR

The turbine generator serves no safety-related function and therefore has no nuclear safety design basis. The turbine generator system is designed to convert the thermal energy of the steam flowing through the turbine into rotational mechanical work, which rotates a generator to

provide electrical power. It consists of a double-flow, high-pressure cylinder (high-pressure turbine) and three double-flow, low-pressure cylinders (low-pressure turbines) that exhaust to the condenser. It is a six-flow, tandem compound, 1800 rpm reheat unit. The turbine system includes stop, control, and intercept valves directly attached to the turbine and in the steam flow path, crossover and crossunder piping between the turbine cylinders and the moisture separator reheater. This design is provided as the reference design in DCD Chapter 10. The manufacturer of the turbine generator system has not yet been selected.

Each turbine generator has an output of approximately 1200 MWe for each reactor thermal output of 3415 MWt. The generator rating is 1,375,000 kVA with a power factor of 0.9. Plant electrical consumption (station and auxiliary service loads) is approximately 108 MWe or approximately 9 percent of generator output at rated power. The systems of the turbine cycle have been designed to meet the maximum expected turbine generator conditions. The net electrical power is addressed in FSAR Section 1.1.

The significant design features and performance characteristics for the major steam and power conversion system components are listed in DCD Table 10.1-1. Turbine generator design parameters are listed in DCD Table 10.2-1.

The main condenser is a three-shell, single-pass, multi-pressure, spring-supported unit with a total surface area of 12.36E5 square feet or 4.12E5 square feet per shell available for heat transfer. Each shell is located beneath its respective low-pressure turbine. The condenser rejects approximately 7.54E9 Btu/hour of waste heat to the circulating water system. The condenser is equipped with titanium tubes. The titanium material provides good corrosion and erosion resisting properties. Additional main condenser design data is presented in DCD Table 10.4.1-1.

In a multi-pressure condenser, the condenser shells operate at slightly different pressures and temperatures. Condensate in the low-pressure condenser shell drains through internal piping to the high-pressure (hottest) shell where it is slightly heated and mixed with condensate of the high pressure shell. This condensate then flows through a single outlet to the suction of the condensate pumps.

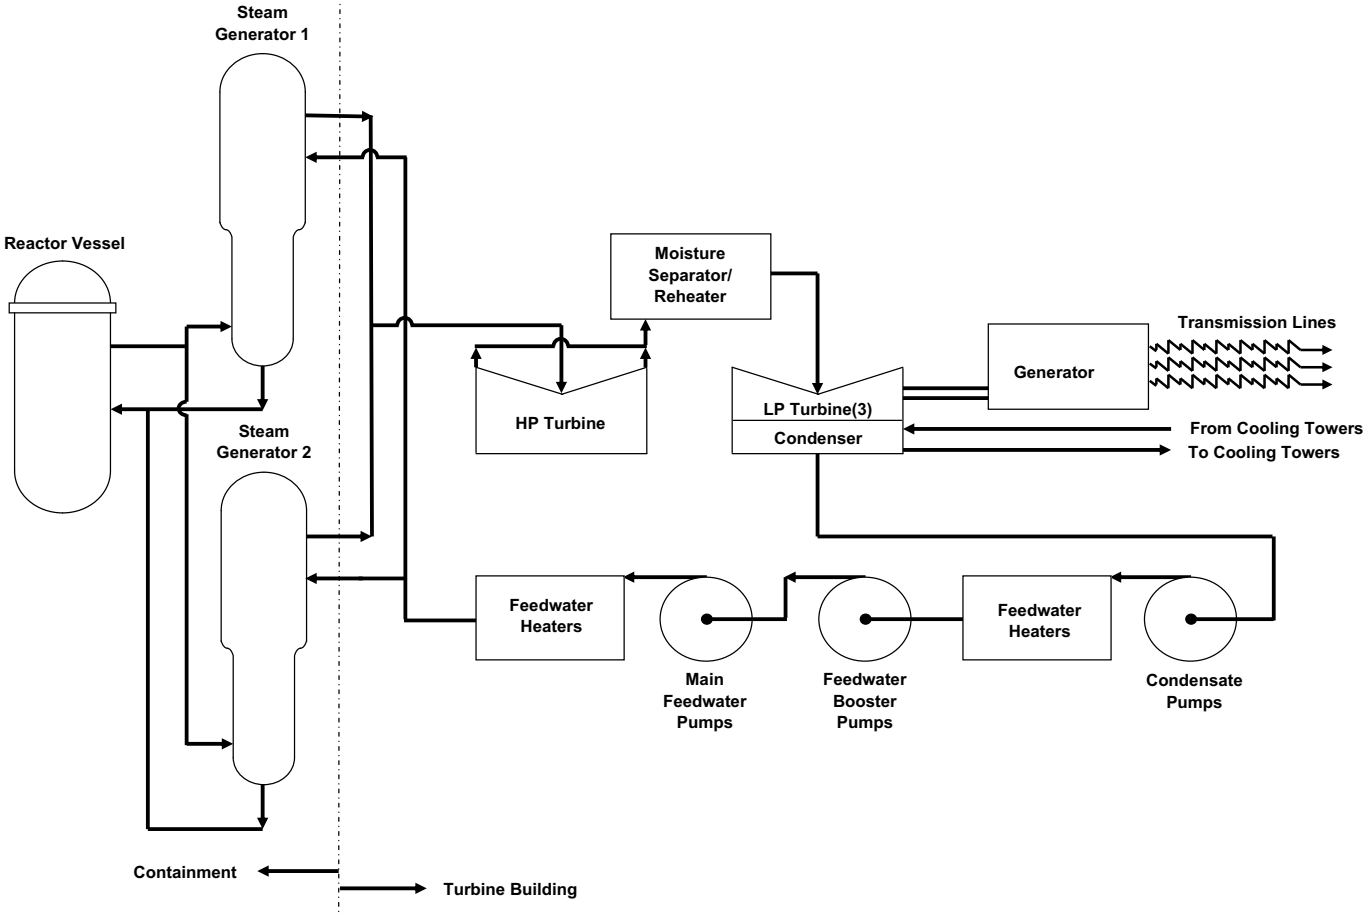
Figure 3.2-1 Simplified Diagram of Reactor Power Conversion



3.3 PLANT WATER USE

Plant water use for Units 6 & 7 is based on two AP1000 units. Consumption and treatment requirements are determined from the DCD (WEC 2011) water quality guidelines and site characteristics. Reclaimed water from the Miami-Dade Water and Sewer Department (MDWASD) would supply makeup water for the circulating water system of Units 6 & 7. When reclaimed water cannot supply the quantity and/or quality of water needed for the circulating water system, additional makeup water would be saltwater supplied from radial collector wells. The circulating water system would be designed to accommodate 100 percent supply from reclaimed water, saltwater, or a combination of the two sources. The ratio of water supplied by the two makeup water sources would vary based on the availability of reclaimed water from the MDWASD. Makeup water for the service water system would be supplied by the MDWASD potable water supply. This water would also be the source for potable water, the demineralized water system, fire protection, and miscellaneous water users. Effluents would be discharged to the Boulder Zone via deep injection wells permitted by the Florida Department of Environmental Protection (FDEP) underground injection control program.

3.3.1 WATER CONSUMPTION

Each unit would use closed-cycle, mechanical draft cooling towers for both circulating water system cooling and service water system cooling. Makeup water would be required to replenish circulating water system and service water system water lost to evaporation, drift, and blowdown.

For makeup to the circulating water system, reclaimed water would be supplied to the FPL reclaimed water treatment facility from the MDWASD. In accordance with FDEP regulations (Florida Administrative Code 62-610.668), MDWASD would be required to provide high-level disinfection of reclaimed water before industrial use by FPL in open cooling towers. The FPL reclaimed water treatment facility would be designed to further treat the reclaimed water from MDWASD prior to use in the circulating water system. The FPL reclaimed water treatment facility would include pumps, trickling filters, clarifiers, deep bed filters, and solids-handling equipment to reduce the levels of iron, magnesium, oil and grease, total suspended solids, nutrients, and silica to usable levels for the circulating water system.

From the FPL reclaimed water treatment facility, the treated reclaimed water would be piped to and stored in the makeup water reservoir before being pumped to the circulating water system cooling tower basins for each unit. Additional circulating water makeup would be saltwater supplied from radial collector wells. The wells would be located on the Turkey Point peninsula, east of the existing units. These wells would provide water to the circulating water system cooling tower basins. Saltwater would be used in instances where sufficient supply and/or quality of reclaimed water from the MDWASD would be unavailable to Units 6 & 7.

The MDWASD potable water supply would provide makeup water for the service water cooling towers of each unit. Additionally, the MDWASD potable water supply would also provide water for the potable water system, fire protection system, the demineralized water system, and other miscellaneous users for each unit. Water balances for this arrangement are provided by data listed in Tables 3.3-1 and 3.3-2 in conjunction with Figure 3.3-1. Hydrologic and water use impacts of this arrangement are addressed in Section 5.2.

Tables 3.3-1 and 3.3-2 define normal and maximum water use for two units based on AP1000 design parameters and site-specific characteristics. Table 3.3-1 assumes reclaimed water is supplied as the source of makeup to the circulating water system. Table 3.3-2 assumes reclaimed water is unavailable and, therefore, saltwater is supplied as the source of makeup to the circulating water system. Evaporation and drift estimates for the circulating water and service water cooling towers are based on site characteristics and AP1000 design parameters for the cooling systems included in Tables 3.4-1 and 3.4-2.

3.3.1.1 Plant Water Demand

Tables 3.3-1 and 3.3-2 provide the total water use estimate for Units 6 & 7. These tables include normal and maximum flows for corresponding streams defined in Figure 3.3-1. Water demand includes makeup water for the circulating water and service water systems and water supply for potable water, fire protection, and the demineralized water system. Normal values listed are expected values for normal plant operation with the two units in operation. Maximum values are those expected for extreme conditions with the two units in operation. The maximum values would not be concurrent. Fire water usage is based on monthly average use required to maintain fire protection system availability.

3.3.1.2 Plant Water Discharges

Tables 3.3-1 and 3.3-2 also provide cooling water and wastewater discharge estimates for the two units. These include losses from both the service water and circulating water systems of each unit through cooling tower water evaporation and drift, as well as rejection of blowdown from the cooling towers. The water balances provided by the data listed in Tables 3.3-1 and 3.3-2 in conjunction with Figure 3.3-1 include estimates for the wastewater flows from the two units, including radiological effluent discharges, sanitary waste, miscellaneous drains, and demineralizer waste discharges. Normal values listed are expected values for normal plant operation with two units in operation. Maximum values are those expected for extreme conditions with two units in operation. Flow rates given are not necessarily concurrent.

The cooling tower blowdown and wastewater from Units 6 & 7 would be discharged to the Boulder Zone via deep injection wells. A blowdown sump serving Units 6 & 7 would collect effluent streams including cooling tower blowdown, wastewater retention basin effluents, and raw

water required for liquid radwaste dilution for discharge to the Boulder Zone. Processed liquid radioactive effluents would be batch-discharged to the Boulder Zone through the blowdown sump effluent stream.

During the construction phase, the wastewater system collects system wastes produced during miscellaneous system flushing. Wastes would be treated to meet permit limits before discharge to the blowdown sump for subsequent discharge to the Boulder Zone. Alternatively, drain wastes may be released to an existing suitable site facility or collected in tanks and disposed of in accordance with local regulation using appropriate licensed haulers.

3.3.2 WATER TREATMENT

Water treatment would be performed to maintain satisfactory water quality for plant use and discharge from the plant to the environment as permitted by state and local regulations. Representative chemicals for water treatment to control biofouling and algae, to adjust pH, inhibit corrosion and scale formation, for disinfection and for dechlorination are identified in Section 3.6. The effluent from water treatment would be within the limits of the FDEP underground injection control program.

3.3.2.1 Cooling Tower Makeup

Reclaimed water from the MDWASD would be treated at the FPL reclaimed water treatment facility and used as circulating water system cooling tower makeup. This treatment would occur before storage in the makeup water reservoir. The makeup water for the circulating water cooling towers would be treated to prevent biofouling in the raw water supply piping to the circulating water cooling towers. Reclaimed water and saltwater would have separate chemical treatments for use in the cooling towers.

Additional treatment for biofouling, scaling, and suspended matter, with biocides, antiscalants, and dispersants would be performed as needed for the circulating water system and service water system. Treatment for the circulating water system (reclaimed water and saltwater) would occur through injection of chemicals from a local chemical feed system into system piping. Treatment for the service water system would occur through injection of chemicals from the turbine island chemical feed system into system piping. Cooling water chemistry would be controlled by the addition of chemicals and maintaining the proper cycles of concentration.

3.3.2.2 Demineralized Water

The MDWASD potable water supply would provide water for the demineralized water system of each unit. This water would be treated by filtration and primary and secondary demineralization processes, which produces in highly purified water for various plant systems. Reverse osmosis would be the primary demineralization treatment process designed to reduce dissolved solids,

salts, and organics. In the secondary stage of purification, the treated water would pass through an electrodeionization system where dissolved carbon dioxide and most of the remaining ions would be removed. Spent resin would be removed and replaced.

Discharges from systems using demineralized water for makeup would be routed to the wastewater retention basin or the liquid radwaste system before discharge.

3.3.2.3 Potable Water System

The potable water system would provide a water supply for domestic use and human consumption. Water provided from the MDWASD potable water supply would be supplied to the potable water distribution system for each unit. This water would meet federal, state, and local water quality standards and would not need to be pretreated.

3.3.2.4 Fire Protection Water System

The fire protection water system of each unit would be used for fire suppression and as a backup supply of water to other water systems, including the passive containment cooling system. The system would consist of storage tanks, pressure maintenance equipment, and a distribution system. The MDWASD potable water supply would be the source of water for the fire protection water system. This water would meet federal, state and local water quality standards and would not need to be pretreated.

(a) Streams are shown in Figure 3.3-1.
(b) The flow rate values (in gpm) are for two AP1000 units.
(c) Flows are not necessarily concurrent. Maximum case is defined as the maximum overall water use for Units 6 & 7. Some streams are affected by other flow rates and not all streams would be at maximum flow conditions. For example, dilution supply for liquid radwaste discharge flow is inversely proportional to circulating water system cooling tower blowdown. Additional information is provided in Note (e).
(d) Fire water use is based on monthly average use required to maintain fire protection system availability.
(e) The liquid radwaste discharge flow may be up to 150 gpm (for two units). However, given the liquid radwaste activity level, the discharge flow rate would be controlled to be compatible with the available dilution flow.
(f) The service water cooling towers are assumed operating at four cycles of concentration. Flows are determined by weather conditions and water chemistry.
(g) The service water system and circulating water system cooling tower drifts are conservatively assumed to be 0.0005 percent of the cooling tower water flow.
(h) Concentrated blowdown from the service water system would be routed to the circulating water system. The blowdown from the circulating water system will therefore include the additional input from the service water system blowdown.
(i) During maximum flow for overall water use, MDWASD potable water supply makeup to the service water system increases while makeup to CWS is unchanged. This results in more service water system blowdown to CWS and thus, more CWS cooling tower blowdown. Since alternate dilution supply for liquid radwaste discharge is inversely proportional to CWS cooling tower blowdown, there would be less reclaimed water dilution. Additionally, since makeup to CWS is unchanged and the alternate dilution supply for liquid radwaste discharge is decreased, less reclaimed water supply is required.
(j) The circulating water cooling towers are assumed operating at four cycles of concentration. Flows are determined by weather conditions and water chemistry.
(k) Wastewater would be recirculated within the FPL reclaimed water treatment facility. Discharge would occur when facility drains are required.

(h) Concentrated blowdown from the service water system would be routed to the circulating water system. The blowdown from the circulating water system will therefore include the additional input from the service water system blowdown.
(i) The circulating water cooling towers are assumed operating at one and a half cycles of concentration. Flows are determined by weather conditions and water chemistry.
(j) Wastewater would be recirculated within the FPL reclaimed water treatment facility. Discharge would occur when facility drains are required.

Figure 3.3-1 Water Balance Diagram (Sheet 1 of 2)

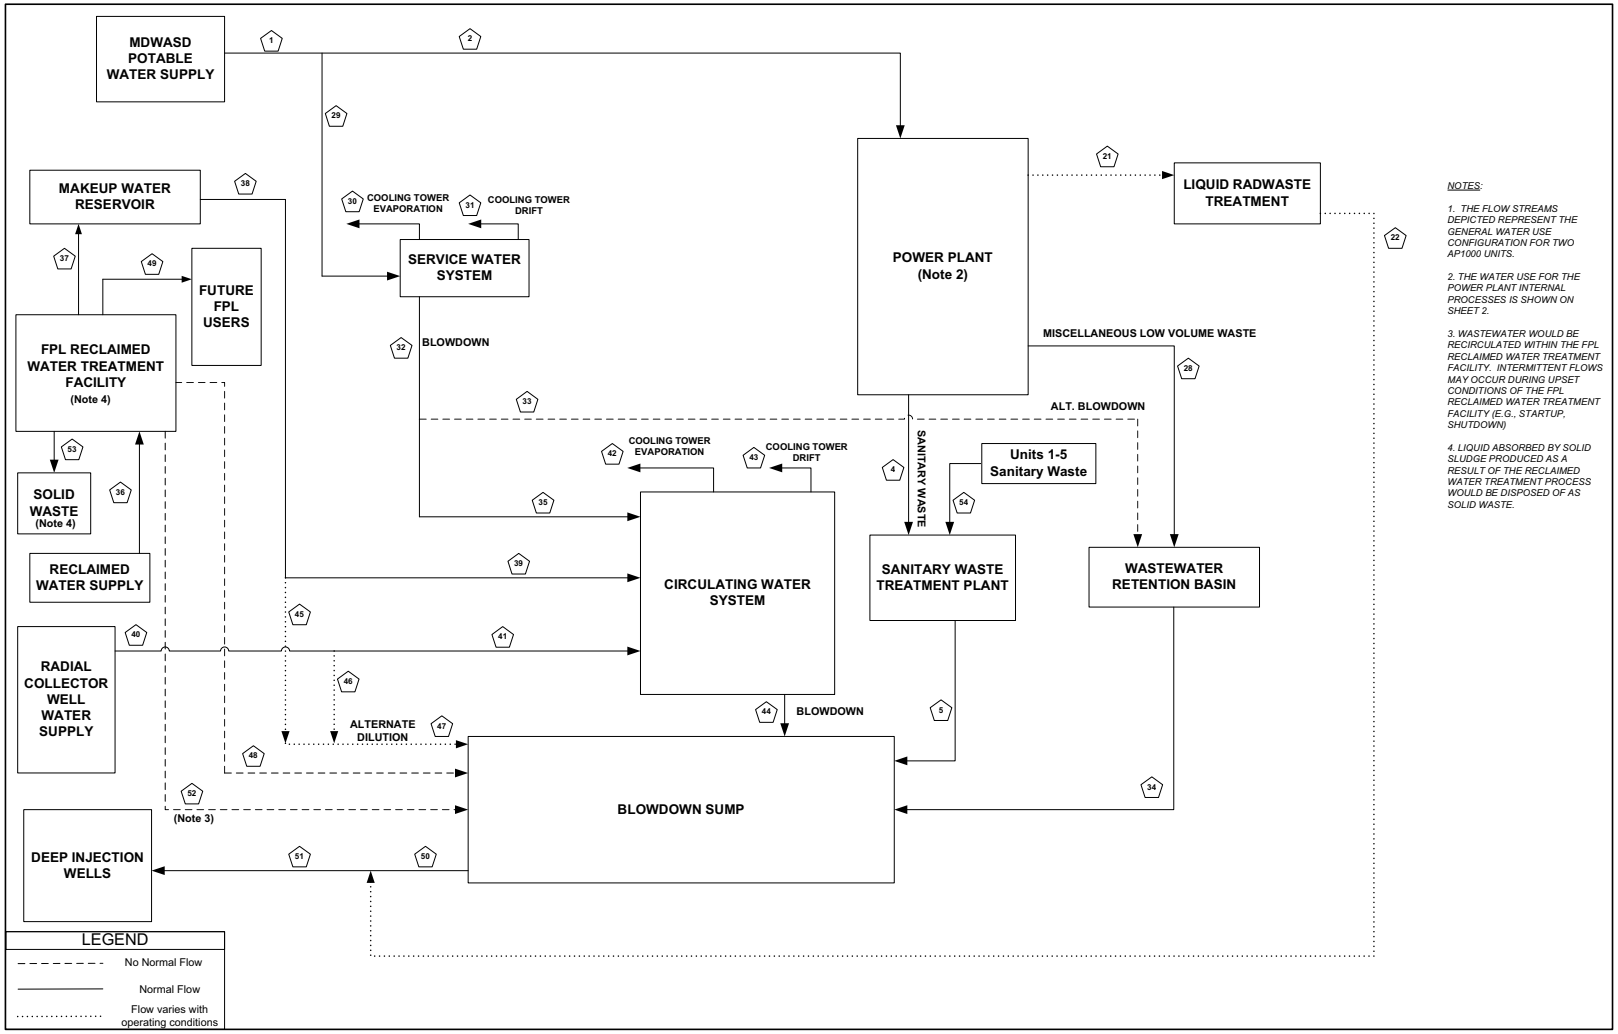

Figure 3.3-1 Water Balance Diagram (Sheet 2 of 2)

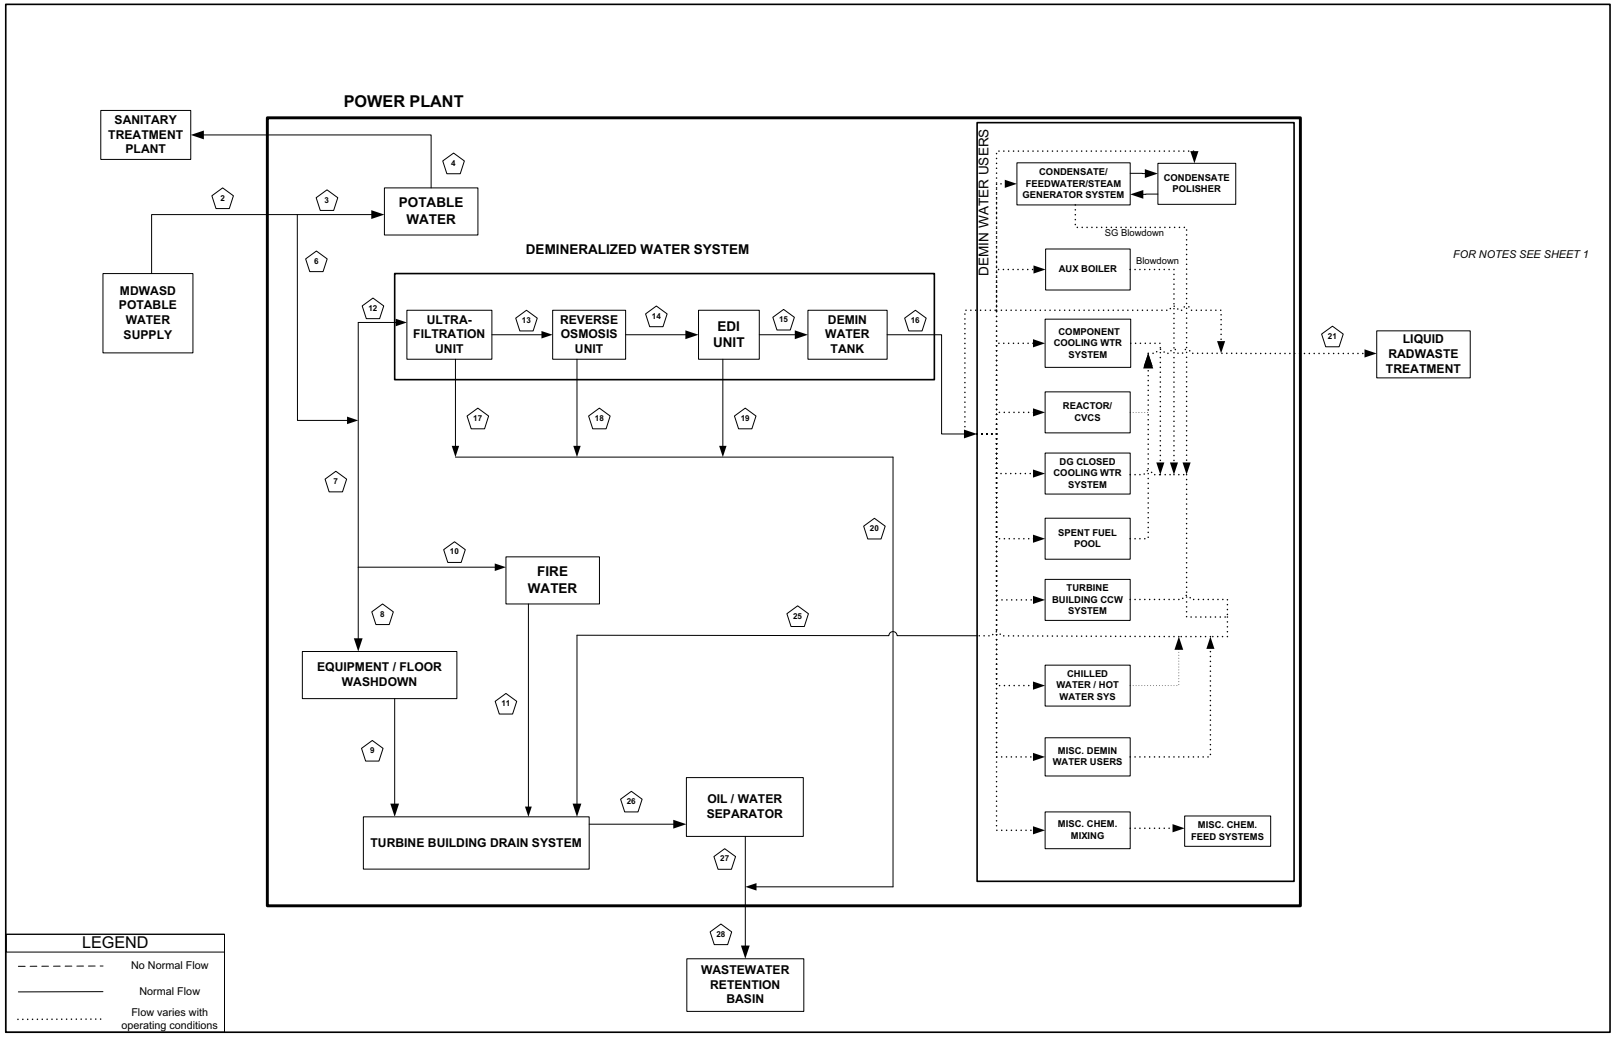

3.4 COOLING SYSTEM

Units 6 & 7 cooling systems, operational modes, and components design parameters were determined from the DCD (WEC 2011), site-specific characteristics, and engineering evaluations. The plant cooling systems and the operational modes are described in Subsection 3.4.1. Component descriptions for the raw water system and makeup water supply options are presented in Subsection 3.4.2. These parameters were used to evaluate the environmental impacts from cooling system operation. The plant cooling systems would have makeup water from the reclaimed water supply, potable water supply, and saltwater supply. Blowdown from the plant would ultimately be discharged to the deep injection wells on the plant property. Figure 3.4-1 is a simplified cooling water system flow diagram for Units 6 & 7. The circulating water system and service water system along with associated systems locations are shown in Figure 3.1-3.

3.4.1 DESCRIPTION AND OPERATIONAL MODES

The cooling system selected for Units 6 & 7 will transfer waste heat generated as a by-product of each unit's electrical power generation to the environment. Site-specific characteristics were used in addition to the AP1000 design parameters to evaluate the impacts for Units 6 & 7 to the environment. Units 6 & 7 will be equipped with two cooling systems that transfer heat to the environment from primary and secondary systems during different modes of plant operation for each unit. These systems will be the circulating water system and the service water system. There will be five operational modes:

- Normal operation (full load)
- Cooldown
- Refueling (full core offload)
- Plant startup
- Minimum to support shutdown cooling and spent fuel cooling

3.4.1.1 Normal Plant Cooling

3.4.1.1.1 Circulating Water System

Each AP1000 unit will have a circulating water system that will be used to dissipate 7540E06 Btu/hour as condenser heat load, 86E06 Btu/hour as turbine building cooling water heat load, and 1.61E06 Btu/hour as condenser vacuum pump heat load, for a total of 7628E06 Btu/hour for one unit. The waste heat rejected from the condenser, turbine building closed cooling water heat exchangers, and condenser vacuum pump seal water heat exchangers would be 1.53E10

Btu/hour for two units. The circulating water system for Units 6 & 7 would use a closed cycle, wet cooling system via mechanical draft cooling towers for heat dissipation.

The heated cooling water from the condenser, turbine building closed cooling water system heat exchangers, and condenser vacuum pump seal water heat exchangers would flow through return piping to the distribution header of the mechanical draft cooling towers. The heated cooling water would be circulated to the spray headers of the wet mechanical draft cooling towers, where the heat content of the cooling water would be transferred to the ambient air via evaporative cooling and conduction. Mechanical fans would provide airflow past the water droplets as they fall through the tower fill, rejecting heat to the atmosphere. After passing through the cooling tower, the cooled water collects in the tower basin and would be pumped back to the condenser, turbine building closed cooling water system heat exchangers, and condenser vacuum pump seal water heat exchangers completing the closed cycle cooling water loop.

The circulating water system would consist of three 33-1/3-percent-capacity circulating water pumps, three mechanical draft cooling towers, and associated piping, valves, and instrumentation for each unit. The circulating water pumps flow rate would be approximately 660,100 gpm per unit. The water would be pumped through the condenser, turbine building closed cooling water heat exchangers, and condenser vacuum pump seal water heat exchangers (all in parallel), and then to the mechanical draft cooling towers to dissipate heat to the atmosphere.

Makeup water would compensate for water losses during plant operation from circulating water system evaporation, drift, and blowdown. Three circulating water cooling towers are estimated to have evaporation water losses of approximately 14,400 gpm per unit during normal plant operation. Drift loss for the circulating water system is described in Subsection 5.3.3. The raw water makeup system would supply makeup water that would come from reclaimed water and/or saltwater sources. The design parameters for each makeup water source are addressed in the following paragraphs.

Reclaimed Water

Reclaimed water would be provided from the Miami-Dade Water and Sewer Department (MDWASD) for makeup water to the circulating water system. The maximum reclaimed water makeup rate to the circulating water system would be approximately 19,200 gpm per unit. This is based on maintaining four cycles of concentration in the cooling towers. Blowdown from the circulating water system would be transferred to a common blowdown sump before being discharged to the deep injection wells. The normal operating blowdown rate at four cycles of concentration would be approximately 4860 gpm per unit.

Saltwater

Saltwater would be used as makeup from the radial collector wells for the circulating water system when a sufficient quantity and/or quality of reclaimed water is not available. The maximum saltwater makeup rate to the circulating water system would be approximately 43,200 gpm per unit. This is based on maintaining 1.5 cycles of concentration in the cooling towers. Blowdown from the circulating water system would be transferred to a common blowdown sump before being discharged to the deep injection wells. The normal operating blowdown rate for saltwater at 1.5 cycles of concentration would be approximately 28,860 gpm per unit.

Combination of Reclaimed Water and Saltwater

When reclaimed water is not available in a sufficient quantity, a combination of reclaimed and saltwater would be used as a source of cooling water. The ratio of water supplied by the two makeup water sources would vary based on the availability of reclaimed water from the MDWASD. The makeup water and the blowdown rates for this combined usage would be within the flow rates identified above.

3.4.1.1.2 Service Water System

Each unit will have a nonsafety-related service water system to provide cooling water to the component cooling water system heat exchangers in the turbine building. The system will consist of a dedicated closed cycle system with a mechanical draft cooling tower to dissipate heat. Service water will be pumped to the component cooling water heat exchangers for heat removal.

Heated service water will return to the distribution header of the mechanical draft cooling tower. Mechanical fans will provide airflow past the water droplets as they fall through the tower fill, rejecting heat from the service water to the atmosphere. The cooled water will be collected in the tower basin and returned to the pump suction for recirculation through the system. Table 3.4-1 provides nominal service water flows and heat loads at the various operating modes for the service water system.

The service water cooling towers are estimated to have evaporation water losses of approximately 366 gpm during normal conditions and approximately 1248 gpm during cooldown conditions for two units. Blowdown flow from the service water towers would be discharged to the circulating water system cooling tower basin at a maximum flow rate of up to approximately 415 gpm for two units. The blowdown would be directed to the wastewater retention basin as necessary. A maximum makeup water flow rate of approximately 1664 gpm for two units will be required to accommodate a maximum of approximately 624 gpm per unit

evaporation rate and approximately 208 gpm per unit blowdown rate. Makeup water to the service water cooling towers would be potable water from the MDWASD.

Drift loss would be minimal for the service water system cooling tower. Maximum service water system blowdown and makeup rates are based on maintaining four cycles of concentration in the cooling tower.

3.4.1.2 Operational Modes

The circulating water system would be used to provide plant cooling during plant startup, normal plant operations, and plant cooldown. The maximum heat load removed by the circulating water system would be during normal plant operation mode and would bound the water makeup, evaporation, and discharge rates for the other operational modes.

The service water system would be used to provide heat removal from the component cooling water system during modes of normal operation, including startup, normal plant operations, cooldown, minimum to support shutdown cooling and spent fuel cooling, and refueling. The maximum heat load removed by the service water system would be during the cooldown mode and would bound the water makeup, evaporation, and discharge rates for the other operational modes.

3.4.1.3 Additional information

3.4.1.3.1 Station Load Factor

The units are expected to operate at a maximum capacity factor of 93 percent, taking into consideration scheduled outages and other plant maintenance. On a long-term basis, an average heat load of approximately 1.26E14 Btu/year (annualizing 93 percent of the maximum rated heat load of 1.55E10 Btu/hour) would be dissipated to the atmosphere.

3.4.1.3.2 Antifouling Treatment

Circulating water chemistry would be maintained by a local chemical feed system. The local chemical feed equipment will inject the required chemicals into the circulating water at the circulating water system cooling tower basin. This would be in an effort to maintain a noncorrosive, nonscale-forming condition and would limit the biological film formation that reduces the heat transfer rate in the cooling towers, condenser, and the heat exchangers supplied by the circulating water system. Additional biocide and algaecide would be provided at the cooling towers to allow for local treatment in the cooling towers, as required. Addition of biocide treatment chemicals would also be provided by chemical feed injection metering pumps into the makeup water pipelines to control biological fouling.

The plant service water system chemistry would be maintained by the turbine island chemical feed system. The turbine island chemical feed system equipment would inject the required chemicals into the service water system in an effort to maintain a noncorrosive, nonscale-forming condition. This would also limit the biological film formation that reduces the heat transfer rate in the cooling towers, condenser, and the heat exchangers supplied by the service water system. Chemicals and biocides would be injected into service water pump discharge piping in the turbine building.

The chemicals and biocides used in the circulating water and service water systems are presented in Table 3.6-1.

3.4.2 COMPONENT DESCRIPTIONS

3.4.2.1 Raw Water System

The raw water system for Units 6 & 7 would be the source of makeup water for the circulating water system, service water system, and other systems demand as described in detail in Section 3.3. The raw water would be supplied from different sources depending on the availability of each source and the makeup water requirements for each system. The raw water supplies for the circulating water system makeup would be from reclaimed water and/or saltwater sources. The raw water for the service water system makeup would be potable water provided by the MDWASD.

The following paragraphs describe the different raw water system supplies for makeup water for the circulating water system and the service water system.

3.4.2.1.1 Circulating Water System Makeup Water

3.4.2.1.1.1 Raw Water Makeup Supply from Reclaimed Water

Reclaimed water would be provided for use as makeup water to the circulating water system from the MDWASD. In accordance with FDEP regulations (Florida Administrative Code 62-610.668), MDWASD would be required to provide high-level disinfection of reclaimed water before industrial use in open cooling towers.

The reclaimed water would be further treated at the FPL reclaimed water treatment facility to further reduce levels of iron, magnesium, oil and grease, total suspended solids, nutrients, and silica to suitable levels for the circulating water system. The treated reclaimed water would then be supplied to the makeup water reservoir. The makeup water reservoir would be used as storage for the circulating water systems. Three 50-percent capacity pumps for each unit would transfer reclaimed water from the makeup water reservoir to the circulating water systems providing the required makeup.

3.4.2.1.1.2 Raw Water Makeup Supply from Saltwater

Saltwater would be supplied by radial collector wells, with caissons located on the Turkey Point peninsula, east of the existing units.

Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The design for a typical radial collector well is illustrated in Figure 3.4-2. The wells would be designed and located to induce recharge from Biscayne Bay. The general location of the radial collector wells are shown in Figure 3.1-3.

There would be four 33 1/3 percent radial collector wells (30,000 gpm capacity per well). Three wells would meet the makeup water requirements for the circulating water systems; the fourth would be an installed spare. Two 50 percent pumps (15,000 gpm capacity per pump) in each well caisson would transfer the saltwater to the circulating water systems.

3.4.2.1.2 Service Water System Makeup Water

The MDWASD potable water system would provide water to the raw water storage tank. The raw water storage tank is common for the two units. Two 100 percent raw water ancillary transfer pumps for each unit would transfer the required makeup water to the service water system. The demineralized water system, potable water system, and firewater system would use potable water supplied from the MDWASD.

3.4.2.2 Final Plant Discharge

The cooling towers blowdown and other site wastewater streams would be collected in a common blowdown sump and injected through the deep injection wells. Biocides and chemical additives in the discharge stream are addressed in detail in the Section 3.6. The deep injection wells would meet the requirements established in the underground injection control program permits. Treated liquid radwaste would be diluted with the blowdown sump discharge flow, as depicted in Figure 3.4-1, at a rate required to maintain the required dilution rate. Additional information on liquid radwaste is addressed in Section 3.5. The maximum sump discharge flow for two units when 100 percent reclaimed water is used would be approximately 12,764 gpm, and the maximum sump discharge flow for two units when 100 percent saltwater is used would be approximately 58,922 gpm. The treated radwaste stream would be mixed with the blowdown sump pump discharge before being discharged in the deep injection wells. Figure 3.4-3 is a typical Class I injection well design.

3.4.2.3 Heat Dissipation System

3.4.2.3.1 Circulating Water System

The circulating water system would use three mechanical draft cooling towers as a normal heat sink for each unit. The cooling towers would use fiberglass-reinforced plastic structural members and casing. The circulating water system cooling towers would be octagonal and would rise approximately 67 feet above the top of the basin curb. Internal construction materials could include fiberglass-reinforced plastic or polyvinyl chloride for piping laterals, reinforced thermosetting resin for spray nozzles, and polyvinyl chloride for fill and drift eliminator materials. Mechanical draft towers use mechanical fans to generate airflow across sprayed water to reject heat to the atmosphere. Six mechanical draft cooling towers would be required to dissipate a maximum waste heat load of up to 1.53E10 Btu/hour from the two units, would operate with approximately a 7.1°F approach temperature, and would provide a less than 91°F return temperature at design ambient conditions. Table 3.4-2 provides specifications of the circulating water system cooling towers.

3.4.2.3.2 Service Water System

The service water system will have a cooling tower that is a rectilinear mechanical draft structure for each unit. The cooling tower is a counterflow-induced draft tower and is divided into two cells. Each cell uses one fan, located in the top portion of the cell, to draw air upward through the fill counter to the downward flow of water. Each fan is driven by a two-speed electrical motor through a gear reducer. During normal power operation, one cell is inactive and water flow to that cell is shut off by a motor-operated isolation valve. One operating service water pump supplies flow to the operating cell. When the service water system is used to support plant shutdown cooling, both tower cells are normally placed in service along with both service water pumps for increased cooling capacity.

Table 3.4-1 provides system flow rates and the expected heat duty for various operating modes of the service water tower. The service water tower will maintain a maximum 93.5°F return temperature to the component cooling water system heat exchangers during normal operation mode. Temperature rise through the component cooling water system heat exchangers would be approximately 20°F during normal operation and approximately 33°F during cooldown operation based on the heat transfer rates defined in Table 3.4-1. Each unit's service water system cooling tower would be adjacent to the turbine building occupying an area of approximately 0.5 acre.

3.5 RADIOACTIVE WASTE MANAGEMENT SYSTEM

Radioisotopes are produced during the operation of nuclear reactors, through the processes of fission and activation. Fission products have the potential to enter the reactor coolant system by diffusion or by way of defects in the fuel cladding. The primary cooling water may contain dissolved or suspended corrosion products and nonradioactive materials from plant components that can be activated in the reactor core as the water passes through the core. These radioisotopes can exit the reactor coolant either by plant systems designed to remove impurities, by small leaks that occur in the reactor coolant system (RCS) and auxiliary systems, or by breaching of systems for maintenance. Therefore, each plant generates radioactive waste that can be liquid, solid, or gaseous.

Radioactive waste management systems will be designed to minimize releases from reactor operations to values ALARA. These systems will be designed and maintained to meet the requirements of 10 CFR Part 20 and 10 CFR Part 50, Appendix I. Requirements for the design of these systems, and the plant effluents used to determine the maximum individual population doses from normal plant operations, are provided in Section 5.4. Lastly, environmental impacts resulting from management of low-level wastes are expected to be bounded by the NRC's findings in 10 CFR 51.51 (b).

The information presented in this section is for a single unit. The design for a second unit would be the same and the data given in this section would double for a second unit.

3.5.1 LIQUID RADIOACTIVE WASTE MANAGEMENT SYSTEM

The liquid radioactive waste management systems for each unit include the systems that will be used to process and dispose of liquids containing radioactive material. These include:

- Steam generator blowdown processing system
- Radioactive waste drain system
- Liquid radioactive waste system

The liquid radioactive waste system will be designed to control, collect, process, handle, store, and dispose of liquid radioactive waste generated as the result of normal operation, including anticipated operational occurrences.

The liquid radioactive waste system will provide holdup capacity as well as permanently installed processing capacity of 75 gpm through the ion exchange/filtration train. This will be adequate capacity to meet the anticipated processing requirements of the plant. The projected flows of

various liquid waste streams to the liquid radioactive waste system under normal conditions are identified in DCD Table 11.2-1 (WEC 2011).

The liquid radioactive waste system design could accept equipment malfunctions without affecting the capability of the system to handle both anticipated liquid waste flows and possible surge load due to excessive leakage.

The liquid radioactive waste system, shown in DCD Figure 11.2-1, will include tanks, pumps, ion exchangers, and filters. The liquid radioactive waste system is designed to process, or store for processing by mobile equipment, radioactively contaminated wastes in four major categories:

- Borated, reactor-grade, wastewater — this input will be collected from the RCS effluents received through the chemical and volume control system (CVS), primary sampling system sink drains, and equipment leakoffs and drains.

- Floor drains and other wastes with potentially high suspended solids content — this input will be collected from various building floor drains and sumps.

- Detergent wastes — this input will come from the plant hot sinks and showers, and some cleanup and decontamination processes. It generally has low concentrations of radioactivity.

- Chemical wastes — this input will come from the laboratory and other relatively small volume sources. It may be mixed hazardous and radioactive wastes or other radioactive wastes with high dissolved solids content.

Nonradioactive secondary-system waste normally would not be processed by the liquid radioactive waste system. Secondary system effluent will be handled by the steam generator blowdown processing system and by the turbine building drain system. However, radioactivity could enter the secondary systems from steam generator tube leakage. If significant radioactivity were detected in secondary side systems, blowdown would be diverted to the liquid radioactive waste system for processing and disposal.

3.5.1.1 Waste Input Streams

3.5.1.1.1 RCS Effluents

The effluent subsystem will receive borated and hydrogen-bearing liquid from two sources: the reactor coolant drain tank and the CVS. The reactor coolant drain tank will collect leakage and drainage from various primary systems and components inside containment. Effluent from the CVS will be produced mainly as a result of RCS heatup, boron concentration changes, and RCS level reduction for refueling.

Input collected by the effluent subsystem would normally contain hydrogen and dissolved radioactive gases. Therefore, it will be routed through the liquid radioactive waste system vacuum degasifier before being stored in the effluent holdup tanks.

The liquid radioactive waste system vacuum degasifier could also be used to degas the RCS before shutdown by operating the CVS in an open loop configuration. This would be done by taking one of the effluent holdup tanks out of normal waste service and draining it. Then normal CVS letdown would be directed through the degasifier to the dedicated effluent holdup tank. From there, it would be pumped back to the suction of the CVS makeup pumps with the effluent holdup tank pump. The makeup pumps would return the fluid to the RCS in the normal fashion. This process would be continued as necessary for degassing the RCS.

The input to the reactor coolant drain tank would potentially be at high temperature. Therefore, provisions will be made for recirculation through a heat exchanger for cooling. The tank will be inerted with nitrogen and vented to the gaseous radwaste system (WGS). Transfer of water from the reactor coolant drain tank will be controlled to maintain an essentially fixed tank level to minimize tank pressure variation.

RCS effluents from the CVS letdown line or the reactor coolant drain subsystem will pass through the vacuum degasifier, where dissolved hydrogen and fission gases will be removed. These gaseous components will be sent via a water separator to the WGS. A degasifier discharge pump will then transfer the liquid to the currently selected effluent holdup tank. If flows from the letdown line and the reactor coolant drain tank are routed to the degasifier concurrently, the letdown flow would have priority and the drain tank input would be automatically suspended. In the event of abnormally high degasifier water level, inputs would be automatically stopped by closing the letdown control and containment isolation valves.

The effluent holdup tanks will vent to the radiologically controlled area ventilation system and, in abnormal conditions, may be purged with air to maintain a low hydrogen gas concentration in the tanks' atmosphere. Hydrogen monitors are included in the tanks' vent lines to alert the operator of elevated hydrogen levels.

The contents of the effluent holdup tanks will be recirculated and sampled, recycled through the degasifier for further gas stripping, returned to the RCS via the CVS makeup pumps, discharged to the mobile treatment facility, processed through the ion exchangers, or directed to the monitor tanks for discharge without treatment. Processing through the ion exchangers will be the normal mode.

The liquid radioactive waste system will process waste with an upstream filter followed by four ion exchange resin vessels in series. Any of these vessels could be manually bypassed and the order of the last two can be interchanged to provide complete usage of the ion exchange resin.

The top of the first vessel will normally be charged with activated carbon, to act as a deep bed filter and remove oil from floor drain wastes. Moderate amounts of other wastes could also be routed through this vessel. It could be bypassed for processing of relatively clean waste streams. This vessel will be somewhat larger than the other three, with an extra sluice connection to allow the top bed of activated carbon to be removed. This feature will be associated with the deep bed filter function of the vessel; the top layer of activated carbon collects particulates, and the ability to remove it without disturbing the underlying zeolite bed minimizes solid waste production.

The second, third, and fourth beds will be in identical ion exchange vessels that will be selectively loaded with resin depending on prevailing plant conditions.

After deionization, the water will pass through an after-filter where radioactive particulates and resin fines will be removed. The processed water will then enter one of the monitor tanks. When one of the monitor tanks is full, the system will automatically realign to route processed water to another tank.

The contents of the monitor tank will be recirculated and sampled. In the unlikely event of radioactivity in excess of operational targets, the tank contents would be returned to a waste holdup tank for additional processing.

Normally, however, the radioactivity will be well below the discharge limits, and the dilute boric acid will be discharged for dilution to the circulating water blowdown. The discharge flow rate will be set to limit the boric acid concentration in the circulating water blowdown stream to an acceptable concentration for local requirements. Detection of high radiation in the discharge stream will stop the discharge flow and operator action will be required to reestablish discharge. The raw water system, which provides makeup for the circulating water system, will be used as a backup source for dilution water when cooling tower blowdown is not available for the discharge path.

3.5.1.1.2 Floor Drains and Other Wastes with Potentially High Suspended Solid Contents

Potentially contaminated floor drain sumps and other sources that tend to be high in particulate loading will be collected in the waste holdup tank. Additives may be introduced to the tank to improve filtration and ion exchange processes. Tank contents may be recirculated for mixing and sampling. The tanks will have sufficient holdup capability to allow time for realignment and maintenance of the process equipment.

The wastewater will be processed through the waste pre-filter to remove the bulk of the particulate loading. Next, it will pass through the ion exchangers and the waste after-filter before entering a monitor tank. The monitor tank contents will be sampled and, if necessary, returned to a waste holdup tank or recirculated directly through the filters and ion exchangers.

Wastewater meeting the discharge limits will be discharged to the circulating water blowdown through a radiation detector that will stop the discharge if high radiation is detected.

3.5.1.1.3 Detergent Wastes

The detergent wastes from the plant hot sinks and showers will contain soaps and detergents. These wastes are generally not compatible with the ion exchange resins. The detergent wastes will not be processed and will be collected in the chemical waste tank. If the detergent waste activity is low enough, the wastes will be discharged without processing.

When sufficient detergent wastes are produced and processing is necessary, mobile processing equipment is brought into one of the radwaste building mobile systems facility truck bays provided for this purpose.

3.5.1.1.4 Chemical Wastes

Inputs to the chemical waste tank normally will be generated at a low rate. These wastes will be only collected; no internal processing will be provided. Chemicals could be added to the tank for pH or other adjustment. Because the volume of these wastes will be low, they can be treated using mobile equipment or by shipment offsite.

3.5.1.1.5 Steam Generator Blowdown

Steam generator blowdown will normally be accommodated within the steam generator blowdown system. If steam generator tube leakage results in significant levels of radioactivity in the steam generator blowdown stream, this stream would be redirected to the liquid radioactive waste system for treatment before discharge. In this event, one of the waste holdup tanks would be drained to prepare it for blowdown processing. The blowdown stream will be brought into that holdup tank, and continuously or in batches pumped through the waste ion exchangers. The number of ion exchangers in service will be determined by the operator to provide adequate purification without excessive resin usage. The blowdown will then be collected in a monitor tank, sampled, and discharged in a monitored fashion.

3.5.1.2 Radioactive Releases

Liquid waste will be produced both on the primary side (primarily from adjustment of reactor coolant boron concentration and from reactor coolant leakage) and the secondary side (primarily from steam generator blowdown processing and from secondary side leakage). Primary and secondary coolant activity levels will be based on operating plant experience.

Except for RCS degasification in anticipation of shutdown, primary side effluents will not be recycled for reuse. Primary side effluents will be routed to the liquid radwaste system for

processing. Fluid recycling will be provided for the steam generator blowdown fluid which is normally returned to the condensate system.

The liquid waste will be discharged from the monitor tank in a batch operation, and the discharge flow rate will be restricted as necessary to maintain an acceptable concentration when diluted by the circulating water discharge flow.

The annual average release of radionuclides from the plant is determined using the PWR-GALE code. The PWR-GALE code models releases that use source terms derived from data obtained from the experience of operating PWRs. The code input parameters used in the analysis are listed in DCD Table 11.2-6. The annual releases for a single unit are presented in DCD Table 11.2-7.

The total releases include an adjustment factor of 0.16 curies per year to account for anticipated operational occurrences. The adjustment uses the same distribution of nuclides as the calculated releases.

3.5.1.3 Doses

As described in Subsection 5.4.1.1, the maximum individual and population doses due to normal plant operation are not evaluated.

3.5.1.4 Cost Benefit Analysis of Population Doses

As described in FSAR Subsection 11.2.3.5, the liquid effluent pathways are not evaluated and no cost benefit analysis has been performed.

3.5.2 GASEOUS RADIOACTIVE WASTE MANAGEMENT SYSTEM

During reactor operation, radioactive isotopes of xenon, krypton, and iodine will be created as fission products. Some of these radionuclides will be released to the reactor coolant. Subsequent leakage of reactor coolant results in a release to the containment atmosphere of these noble gases. Airborne releases will be limited both by restricting reactor coolant leakage and by limiting the concentrations of radioactive noble gases and iodine in the RCS.

Iodine will be removed by ion exchange in the CVS. Removal of the noble gases from the RCS would not normally be necessary because the gases would not build up to unacceptable levels when fuel defects are within normally anticipated ranges. If noble gas removal were required because of high RCS concentration, the CVS can be operated in conjunction with the liquid radwaste system degasifier to remove the gases.

The WGS will be designed to perform the following major functions:

- Collect gaseous wastes that are radioactive or hydrogen-bearing
- Process and discharge the waste gas, keeping offsite releases of radioactivity within acceptable limits

In addition to the WGS release pathway, release of radioactive material to the environment will occur through the various building ventilation systems. The estimated annual release includes contributions from the major building ventilation pathways.

The WGS will be designed to receive hydrogen-bearing and radioactive gases generated during process operation. The radioactive gas flowing into the WGS will enter as trace contamination in a stream of hydrogen and nitrogen.

WGS inputs are:

- Letdown diversion for dilution, RCS with maximum hydrogen concentration
- Letdown diversion for RCS degassing
- Reactor coolant drain tank liquid transfer to maintain proper reactor coolant drain tank level
- Reactor coolant drain tank gas venting

3.5.2.1 System Description

3.5.2.1.1 General Description

The WGS, as shown on DCD Figures 11.3-1 and 11.3-2, will be a once-through, ambient temperature, activated carbon delay system. The system will include a gas cooler, a moisture separator, an activated carbon-filled guard bed, and two activated carbon-filled delay beds. Also included in the system will be an oxygen analyzer subsystem and a gas sampling subsystem.

DCD Table 11.3-2 lists the key design parameters for the WGS components.

The radioactive fission gases entering the system will be carried by hydrogen and nitrogen gas. The primary influent source will be the liquid radwaste system degasifier. The degasifier will extract both hydrogen and fission gases from the CVS letdown flow that is diverted to the liquid radwaste system or from the reactor coolant drain tank discharge.

Reactor coolant degassing will not be required during power operation with fuel defects at or below the design basis level of 0.25 percent. However, the WGS will periodically receive influent when CVS letdown is processed through the liquid radwaste system degasifier during RCS dilution and volume control operations. Because the degasifier is a vacuum type and

requires no purge gas, the maximum gas influent rate to the WGS from the degasifier will equal the rate that hydrogen enters the degasifier (dissolved in liquid).

The other major source of input to the WGS will be the reactor coolant drain tank. Hydrogen dissolved in the influent to the reactor coolant drain tank will enter the WGS either via the tank vent or the liquid radwaste system degasifier discharge.

The tank vent would normally be closed, but can be periodically opened on high pressure to vent the gas that has come out of solution. The reactor coolant drain tank liquid would normally discharge to the liquid radwaste system via the degasifier, where the remaining hydrogen would be removed.

The reactor coolant drain tank will be purged with nitrogen gas to discharge hydrogen and fission gases to the WGS before operations requiring tank access. The reactor coolant drain tank will also be purged with nitrogen gas to dilute and discharge oxygen after tank servicing or inspection operations which allow air to enter the tank.

Influents to the WGS will first pass through the gas cooler where they will be cooled to about 40°F by the chilled water system. Moisture formed due to gas cooling will be removed in the moisture separator.

After leaving the moisture separator, the gas will flow through a guard bed that protects the delay beds from abnormal moisture carryover or chemical contaminants. The gas will then flow through two delay beds in series where the fission gases undergo dynamic adsorption by the activated carbon and are thereby delayed relative to the hydrogen or nitrogen carrier gas flow. Radioactive decay of the fission gases during the delay period significantly reduces the radioactivity of the gas flow leaving the system.

The activated carbon volume will be twice the theoretical amount required to achieve the holdup times given in DCD Table 11.3-1.

The effluent from the delay bed will pass through a radiation monitor and discharges to the ventilation exhaust duct. The radiation monitor will be interlocked to close the WGS discharge isolation valve on high radiation. The discharge isolation valve will also close on low ventilation system exhaust flow rate to prevent the accumulation of hydrogen in the aerated vent.

3.5.2.1.2 System Operation

During normal operation, the WGS will usually not be in operation. When there is no waste gas inflow to the system, the discharge isolation valve closes which will maintain the WGS at a positive pressure, preventing the ingress of air during the periods of low waste gas flow. When

the WGS is in use, its operation will be passive, using the pressure provided by the influent sources to drive the waste gas through the system.

The largest input to the WGS will be from the liquid radwaste system degasifier, which processes the CVS letdown flow when diverted to the liquid radwaste system and the liquid effluent from the liquid radwaste system reactor coolant drain tank.

The CVS letdown flow will be diverted to the liquid radwaste system only during dilutions, borations, and RCS degassing in anticipation of shutdown. The design basis influent rate from the liquid radwaste system degasifier will be the full diversion of the CVS letdown flow, when the RCS is operating with maximum allowable hydrogen concentration. Because the liquid radwaste system degasifier is a vacuum type that operates without a purge gas, this input rate will be very small, approximately 0.5 standard cubic feet per minute (scfm).

The liquid radwaste system degasifier will also be used to degas liquid pumped out of the reactor coolant drain tank. The amount of fluid pumped out, and therefore the gas sent to the WGS, will depend on the input into the reactor coolant drain tank. This will be smaller than the input from the CVS letdown line.

The final input to the WGS will be from the reactor coolant drain tank vent. A nitrogen cover gas will be maintained in the reactor coolant drain tank. This input will consist of nitrogen, hydrogen, and radioactive gases. The tank operates at nearly constant level, with its vent line normally closed, so this input will be minimal. Venting will be required only after enough gas has evolved from the input fluid to increase the reactor coolant drain tank pressure.

The influent will first pass through a gas cooler. Chilled water will flow through the gas cooler at a fixed rate to cool the waste gas to about 40°F regardless of waste gas flow rate. Moisture formed due to gas cooling will be removed in the moisture separator, and collected water will be periodically discharged automatically. To reduce the potential for waste gas bypass of the gas cooler in the event of valve leakage, a float-operated drain trap will be provided that automatically closes on low water level.

The gas leaving the moisture separator will be monitored for temperature, and a high alarm will alert the operator to an abnormal condition requiring attention. Oxygen concentration will also be monitored. On a high oxygen alarm, a nitrogen purge will be automatically injected into the influent line.

The waste gas then will flow through the guard bed, where iodine and chemical (oxidizing) contaminants will be removed. The guard bed will also remove any remaining excessive moisture from the waste gas. The waste gas will flow through the two delay beds where xenon and krypton will be delayed by a dynamic adsorption process. The discharge line will be equipped with a

valve that automatically closes on either high radioactivity in the WGS discharge line or low ventilation exhaust duct flow.

The adsorption of radioactive gases in the delay bed will occur without reliance on active components or operator action. Operator error or active component failure will not result in an uncontrolled release of radioactivity to the environment. Failure to remove moisture before the delay beds (due to loss of chilled water or other causes) will result in a gradual reduction in WGS performance. Reduced performance will be indicated by high temperature and discharge radiation alarms. A high-high radiation signal will automatically terminate a discharge.

3.5.2.2 Radioactive Releases

Releases of radioactive effluent by way of the atmospheric pathway will occur due to:

- Venting of the containment that contains activity as a result of leakage of reactor coolant and as a result of activation of naturally occurring Ar-40 in the atmosphere to form radioactive Ar-41
- Ventilation discharges from the auxiliary building that contain activity as a result of leakage from process streams
- Ventilation discharges from the turbine building.
- Condenser air removal system (gaseous activity entering the secondary coolant as a result of primary to secondary leakage is released via this pathway).
- WGS discharges

These releases will be ongoing throughout normal plant operations and will be within the NRC release limits provided in 10 CFR Part 20 and 10 CFR Part 50, Appendix I. There will be no gaseous waste holdup capability in the gaseous waste management system and thus no criteria are required for determining the timing of releases or the release rates to be used.

3.5.2.2.1 Estimated Annual Releases

The annual average airborne releases of radionuclides from the plant are determined using the PWR-GALE code. The PWR-GALE code models releases using realistic source terms derived from data obtained from the experience of many operating pressurized water reactors. The code input parameters used in the analysis are provided in DCD Table 11.2-6. The expected annual releases for a single unit are presented in DCD Table 11.3-3.

3.5.2.2.2 Release Points

Airborne effluents will normally be released through the plant vent or the turbine building vent. The plant vent will provide the release path for containment venting releases, auxiliary building ventilation releases, annex building releases, radwaste building releases, and WGS discharge. The turbine building vents will provide the release path for the condenser air removal system, gland seal condenser exhaust and the turbine building ventilation releases.

3.5.2.3 Doses

The calculated maximum individual and population doses for normal plant operation are addressed in Section 5.4.

3.5.2.4 Cost Benefit Analysis of Population Doses

The site-specific cost-benefit analysis regarding population doses due to gaseous effluents during normal plant operation is addressed in FSAR Subsection 11.3.3.4. This FSAR subsection applies to the cost-benefit analysis for each unit. The dollar/person millirem reduction is included in the calculation for the cost-benefit analysis in the FSAR subsection.

3.5.3 SOLID RADIOACTIVE WASTE MANAGEMENT SYSTEM

Solid radioactive wastes will be produced in multiple ways at a nuclear power station. The waste could be either dry or wet solids, and the source could be an operational activity or maintenance function.

The solid radioactive waste management system will collect, process, and package solid radioactive wastes generated as a result of normal plant operation, including anticipated operational occurrences. The system will be designed to have sufficient capacity, based on normal waste generation rates, to ensure that maintenance or repair of the equipment does not impact power generation.

Operating procedures would encourage plant operators to segregate wastes to keep mixed wastes at a minimum. However, the waste handling system will be designed to allow handling and disposal of mixed waste, if it is created, as described below.

For each unit, the solid waste management system will be designed to collect and accumulate spent ion exchange resins and deep bed filtration media, spent filter cartridges, dry active wastes, and mixed wastes generated as a result of normal plant operation, including anticipated operational occurrences. The system will be located in the auxiliary and radwaste buildings. Processing and packaging of wastes will be by mobile systems in the auxiliary building truck bay and in the mobile systems facility part of the radwaste building. The packaged waste will be

stored in the auxiliary and radwaste buildings until it is shipped offsite to a licensed disposal facility.

The use of mobile systems for the processing functions will permit the use of the latest technology and avoid the equipment obsolescence problems experienced with installed radwaste processing equipment. The most appropriate and efficient systems could be used as they become available.

This system will not handle large, radioactive waste materials such as core components or radioactive process wastes from the plant's secondary cycle. However, the volumes and activities of the secondary cycle wastes are provided in this subsection.

3.5.3.1 System Description

The waste management system will include the spent resin system. The flows of wastes through the solid waste management system are shown in DCD Figure 11.4-1. The radioactivity of influents to the system will depend on reactor coolant activities and the decontamination factors of the processes in the CVS, spent fuel cooling system, and the liquid waste processing system.

The parameters used to calculate the estimated activity of the influents to the solid waste management system are listed in DCD Table 11.4-1. The AP1000 design has sufficient radwaste storage capacity to accommodate the maximum generation rate.

The radioactivity of the dry active waste would be expected to normally range from 0.1 curies per year to 8 curies per year with a maximum of about 16 curies per year. This waste will include spent HVAC filters, compressible trash, noncompressible components, mixed wastes, and solidified chemical wastes. These activities will be produced by relatively long-lived radionuclides (such as Cr-51, Fe-55, Co-58, Co-60, Nb-95, Cs-134 and Cs-137), and therefore, radioactivity decay during processing and storage will be minimal. These activities apply to the waste as generated and to the waste as shipped.

The estimated expected and maximum annual quantities of waste influents by source and form are listed in DCD Table 11.4-1 with disposal volumes. The annual radwaste influent rates are derived by multiplying the average influent rate (e.g., volume per month, volume per refueling cycle) by 1 year of time. The annual disposal rate is determined by applying the radwaste packaging efficiency to the annual influent rate. The influent volumes are conservatively based on an 18-month refueling cycle. Annual quantities based on a 24-month refueling cycle will be less than those for an 18-month cycle.

All radwaste that is packaged and stored will be shipped offsite for disposal. The AP1000 design does not include provisions for permanent storage of radwaste. Radwaste will be stored ready for shipment. Shipped volumes of radwaste for disposal are estimated in DCD Table 11.4-1 from the

estimated expected or maximum influent volumes by making adjustments for volume reduction processing and the expected container filling efficiencies. For drum compaction, the overall volume reduction factor, including packaging efficiency, is 3.6. For box compaction, the overall volume reduction factor is 5.4. These adjustments result in a packaged internal waste volume for each waste source, and the number of containers required to hold this volume is based on the container's internal volume. The disposal volume is based on the number of containers and the external (disposal) volume of the containers.

The disposal volumes of wet and dry wastes are approximately 547 and 1417 cubic feet/year, respectively as shown in DCD Table 11.4-1. The wet wastes shipping volumes include 510 cubic feet/year of spent ion exchange resins and deep bed filter activated carbon, approximately 20 cubic feet/year of volume reduced liquid chemical wastes and 17 cubic feet/year of mixed liquid wastes. The spent resins and activated carbon will be initially stored in the spent resin storage tanks located in the truck bay of the auxiliary building. When a sufficient quantity has accumulated, the resin will be sluiced into high-integrity containers in anticipation of transport for offsite disposal. Liquid chemical wastes will be reduced in volume and packaged into drums (20 cubic feet/year) and will be stored in the packaged waste storage room of the radwaste building. The estimated mixed liquid wastes will fill less than three drums per year (about 17 cubic feet/year) and will be stored on containment pallets in the waste accumulation room of the radwaste building until shipped offsite for processing.

The two spent resin storage tanks (275 cubic feet usable, each) and one high-integrity container in the spent resin waste container fill station at the west end of the truck bay of the auxiliary building will provide more than a year of spent resin storage at the expected rate, and several months of storage at the maximum generation rate. The expected radwaste generation rate is based on the following assumptions:

- All ion exchange resin beds are disposed of and replaced every refueling cycle
- The WGS activated carbon guard bed is replaced every refueling cycle
- The WGS delay beds are replaced every 10 years
- All wet filters are replaced every refueling cycle
- Rates of compactible and non-compactible radwaste, chemical waste, and mixed wastes are estimated using historical operating plant data

The maximum radwaste generation rate is based on:

- The ion exchange resin beds are disposed of based on operation with 0.25 percent fuel defects

- The WGS activated carbon guard bed is replaced twice every refueling cycle
- The WGS delay beds are replaced every 5 years
- All wet filters are replaced based upon operation with 0.25 percent fuel defects
- Expected rates of compactible and noncompactible radwaste, chemical waste, and mixed wastes are increased by about 50 percent
- Primary to secondary system leakage contaminates the condensate polishing system and blowdown system resins and membranes, and are replaced

The dry solid radwaste will include approximately 1383 cubic feet/year of compactible and non-compactible waste packed into about 14 boxes (90 cubic feet each) and about 10 drums per year. Drums will be used for higher activity compactible and noncompactible wastes. Compactible waste will include HVAC exhaust filter, ground sheets, boot covers, hairnets, etc. Noncompactible waste will include about 60 cubic feet/year of dry activated carbon and other solids such as broken tools and wood. Solid mixed wastes will occupy 7.5 cubic feet/year (one drum). The low activity spent filter cartridges may be compacted to about 3 cubic feet/year and will be stored in the packaged waste storage room. Compaction will be performed by mobile equipment or offsite. The volume of high activity filter cartridges will be about 22.5 cubic feet/ year and will be stored in portable processing or storage casks in the truck bay of the auxiliary building.

The total volume of radwaste to be stored in the radwaste building packaged waste storage room will be 1417 cubic feet/year at the expected rate and 2544 cubic feet/year at the maximum rate. The compactible and noncompactible dry wastes, packaged in drums or steel boxes, will be stored with the mixed liquid and mixed solid, volume reduced liquid chemical wastes, and the lower activity filter cartridges. The quantities of liquid radwaste stored in the packaged waste storage room of the radwaste building will consist of approximately 20 cubic feet of chemical waste and approximately 17 cubic feet of mixed liquid waste. The useful storage volume in the packaged waste storage room will be approximately 3900 cubic feet (10 feet deep, 30 feet long, and 13 feet high), which will accommodate more than one full offsite waste shipment using a tractor trailer truck. The packaged waste storage room will provide storage for more than 2 years at the expected rate of generation and more than a year at the maximum rate of generation. One four-drum containment pallet will provide more than 8 months of storage capacity for the liquid mixed wastes and the volume reduced liquid chemical wastes at the expected rate of generation and more than 4 months at the maximum rate.

FPL expects that, consistent with its current commercial agreements, a third-party contractor will process, store, own, and ultimately dispose of low-level waste generated as a result of

operations. Activities associated with the transportation, processing, and ultimate disposal of low-level waste are expected to comply with all applicable laws and regulations in order to assure the public's health and safety. In particular, the third-party contractor would conduct its operations consistent with NRC regulations (e.g., 10 CFR Part 20), which will assure that the radiological impacts from these activities would be small. Lastly, environmental impacts resulting from management of low-level wastes are expected to be bounded by he NRC's findings in 10 CFR 51.51 (b).

If needed, FPL would construct additional waste storage facilities onsite. Such facilities would be designed and operated pursuant to the guidance in Appendix 11.4-A of the Standard Review Plan, NUREG-0800.

A conservative estimate of solid wet waste includes blowdown material based on continuous operation of the steam generator blowdown purification system, with leakage from the primary to secondary system. The volume of radioactively contaminated material from this source is estimated to be 540 cubic feet/year. Although included here for conservatism, this volume of contaminated resin will be removed from the plant within the contaminated electrodeionization unit and not stored as wet waste.

The condensate polishing system will include mixed bed ion exchanger vessels for purification of the condensate as described in DCD Section 10.4.6. If the resins become radioactive, the resins would be transferred from the condensate polishing vessel directly to a temporary processing unit or to the temporary processing unit via the spent resin tank. The processing unit, located outside of the turbine building, would dewater and process the resins as required for offsite disposal. Radioactive condensate polishing resin would have very low activity. It would be packaged in containers as permitted by U.S. DOT regulations. After packaging, the resins may be stored in the radwaste building. Based on a typical condensate polishing system operation of 30 days per refueling cycle with leakage from the primary system to the secondary system, the volume of radioactively contaminated resin is estimated to be 206 cubic feet/year (one 309-cubic-foot bed per refueling cycle).

The parameters used to calculate the activities of the steam generator blowdown solid waste and condensate polishing resins are given in DCD Table 11.4-1. Based on the above volumes, the disposal volume is estimated to be 939 cubic feet/year.

DCD Tables 11.4-4 and 11.4-8 list the expected principal radionuclides in primary wastes and secondary wastes, respectively. These values represent the radionuclide content in these wastes as shipped.

The spent fuel storage facility is located in the auxiliary building fuel handling area and will house pools that provide storage space for the irradiated fuel. Each unit will have a separate pool with

capacity for 889 fuel assemblies. All portions of the spent fuel transfer operation will be completed underwater and the waterways will be deep enough to maintain adequate shielding above the fuel. The spent fuel pools will have access to a cask-loading pit for loading the spent fuel assemblies into transportation casks. The fuel-handling building will also house equipment for the decontamination of the shipping cask before it leaves the building. The DOE is responsible for the acceptance of title, subsequent transportation, and disposal of spent fuel in accordance with the Nuclear Waste Policy Act of 1982, as amended. FPL has executed a standard spent nuclear fuel disposal contract with DOE for Units 6 & 7.

3.6 NONRADIOACTIVE WASTE SYSTEMS

The following section provides descriptions of nonradioactive waste streams that would be expected from the operation of Units 6 & 7.

This section is divided into three subsections that evaluate these nonradioactive waste systems as follows:

- Effluents containing chemicals or biocides
- Sanitary system effluents
- Other effluents

3.6.1 EFFLUENTS CONTAINING CHEMICALS OR BIOCIDES

Proper water chemistry for plant operation requires the treatment of potable water, reclaimed water, and saltwater that would be used in the various plant water systems such as circulating water, service water, potable water, and demineralized water systems.

The waste effluent from the station demineralized water system, sanitary waste treatment plant, FPL reclaimed water treatment facility, filter backwash wastewater, and other nonradioactive drains throughout the station would be collected in the blowdown sump along with the blowdown from the circulating water and service water systems. The combined stream would be pumped to the deep injection wells. The combined stream would be controlled through engineering design and operational procedures to meet the requirements established in the underground injection control permits.

The effluent waste stream constituents and concentrations in the blowdown sump are identified in Table 3.6-2 for a reclaimed water supply as makeup to the circulating water system and Table 3.6-3 for a saltwater supply as makeup to the circulating water system. The characterization of the circulating water system blowdown is based on two makeup water cases that use either 100 percent reclaimed or 100 percent saltwater supply as makeup water. Saltwater from the radial collector wells would be used as makeup for the circulating water system when an adequate quantity and/or quality of reclaimed water is not available. Constituents in effluent discharge in the case of combined reclaimed and saltwater supply would be within the rates and limits described for each individual water supply.

The water treatment chemicals used in the circulating water system, service water system, FPL reclaimed water treatment facility, steam generator blowdown system, and demineralized water system are identified in Table 3.6-1. Table 3.6-1 shows the chemicals that would be used in each system, the estimated amount used per year, the frequency of use, and the chemical

concentration. The circulating water system chemicals are based on two cases of makeup water supply: 100 percent reclaimed or 100 percent saltwater. The quantity of chemical additives to the plant systems in the case of combined reclaimed and saltwater supply would be within the concentration of chemicals described for each individual water supply.

The systems that treat the water for plant operation are described in Subsection 3.3.2. The concentration factors for the CWS and service water system cooling systems are addressed in Section 3.4. The concentrations of material in the reclaimed water, saltwater, and potable water supplies are presented in Section 2.3. A description of the sources of reclaimed and saltwater supply is provided in Section 3.4. The airborne concentration of chemicals and solids in spray is addressed in Subsection 5.3.3. The discharge limits are presented in Subsection 5.5.1.1.

3.6.2 SANITARY SYSTEM EFFLUENTS

A sanitary waste system would be maintained onsite during the preconstruction, construction, and operation of Units 6 & 7. During construction, portable sanitary waste facilities would be used until the permanent sanitary waste treatment facility is functional, and as needed during the peak construction or outage activities to augment the permanent system. These temporary facilities may include centralized restroom and hand wash trailers in addition to single restroom units placed throughout the site, as necessary. The waste collected in these temporary facilities would be disposed of by a licensed sanitary waste disposal contractor.

Sanitary treatment would be provided by a packaged sanitary treatment plant located on the Units 6 & 7 plant area. The sanitary treatment plant would be designed to process sanitary effluent from Units 1 through 7 and would operate in compliance with applicable FDEP rules.

Units 6 & 7 will have a sanitary drainage system. The sanitary drainage system will collect sanitary waste from plant restrooms and locker room facilities and carries this waste to the sanitary treatment plant where it will be processed. The sanitary drainage system will not service facilities in radiologically controlled areas.

For Units 6 & 7, the sanitary treatment plant would be designed to accommodate 50 gallons per person per day for 500 people during normal operation per unit and 1000 people during plant shutdown per unit. The sanitary treatment plant would also be designed to accommodate the sanitary effluent from Units 1 through 5. The design flows for the sanitary system are provided in Tables 3.3-1 and 3.3-2.

The waste sludge generated by the sanitary treatment plant, estimated at 1300 gallons per day at 1.5—2 percent solids content, would be disposed of offsite via contract with a licensed waste transportation and disposal company. Offsite disposal methods may include land filling, incineration, land application, and/or further treatment at licensed facilities. The treated liquid effluent from the sanitary drainage system would be pumped to the blowdown sump where it

would be combined with other effluent streams, as described in Subsection 3.6.1. The combined effluent would be discharged to the deep injection wells.

3.6.3 OTHER EFFLUENTS

This subsection describes the other miscellaneous nonradioactive gaseous, liquid, and solid effluents not addressed in Subsection 3.6.1 or 3.6.2 that are discharged to the environment. The applicable state permits for the gaseous, liquid, and solid effluents are described in Section 1.2.

3.6.3.1 Gaseous Effluents

Each unit contains two standby diesel generators, two ancillary diesel generators, and one diesel-driven fire pump. During normal operation of the plant, the operation of this equipment is infrequent and typically limited to periodic testing. Plant operation would result in small amounts of nonradioactive gaseous emissions to the environment from the equipment associated with the plant auxiliary system. Table 3.6-4 shows the projected annual emissions (tons/year) from the diesel generators and the diesel-driven fire pumps. The standby diesel generators are located in the diesel generator building. The diesel-driven fire pump is located in the diesel-driven fire pump enclosure. The ancillary diesel generators are located in the annex building. Each standby diesel generator has a 60,000-gallon fuel oil storage tank and a 1300-gallon fuel oil storage day tank. The two ancillary diesel generators have a common 650-gallon fuel oil storage tank, and the diesel-driven fire pump has a 240-gallon fuel oil storage tank. The projected annual hydrocarbon emissions from the diesel storage tanks at Turkey Point Units 6 & 7 are shown in Table 3.6-5.

3.6.3.2 Liquid Effluents

The wastewater system collects and processes liquid effluent from equipment and floor drains from nonradioactive building areas, and is capable of handling the anticipated flow of wastewater during normal plant operation and during plant outages. A process diagram and flow rates of the water system are addressed in Section 3.3. The wastewater system:

- Removes oil and/or suspended solids from miscellaneous waste streams generated from the plant
- Collects system flushing wastes during startup before treatment and discharge
- Collects and processes fluid drained from equipment or systems during maintenance or inspection activities

- Directs nonradioactive equipment and floor drains that may contain oily waste to the building sumps and transfer their contents for disposal in accordance with applicable regulations and permit specifications

Wastes from the turbine building floor and equipment drains (which include laboratory and sampling sink drains, oil storage room drains, the main steam isolation valve compartment, auxiliary building penetration area, and the auxiliary building HVAC room) are collected in the two turbine building sumps. Drainage from the diesel generator building sumps, the auxiliary building nonradioactive sump, and the annex building sump is also collected in the turbine building sumps. The turbine building sumps provide a temporary storage capacity and a controlled source of fluid flow to the oil separator. A radiation monitor located on the common discharge piping of the sump pumps alarms upon detection of radioactivity in the wastewater. The radiation monitor also trips the sump pumps on detection of radioactivity to isolate the contaminated wastewater. Provisions are included for sampling the sumps. If necessary, the wastewater from the turbine building sumps will be diverted to the liquid radwaste system for processing and disposal.

The turbine building sump pumps route the wastewater from either of the two sumps to the oil separator for removal of oily waste. The diesel fuel oil area sump pump also discharges wastewater to the oil separator. A bypass line allows for the oil separator to be out of service for maintenance. The oil separator has a small reservoir for storage of the separated oily waste that flows by gravity to the waste oil storage tank. The waste oil storage tank provides temporary storage before shipment for offsite disposal. Turkey Point Units 3 & 4 generated approximately 1550 gallons of used oil in 2010. Based on this generation rate, Turkey Point Units 6 & 7 would produce approximately 1550 gallons of used oil. The used oil was transported offsite by a licensed contractor and recycled for heat reclamation. It is anticipated that similar practices would be followed for Units 6 & 7.

The wastewater from the oil separator and the condenser water box drains by gravity to the wastewater retention basin for settling of suspended solids and any required treatment before discharge. The wastewater basin transfer pumps route the basin effluent to the blowdown sump where it would be combined with the cooling tower blowdown streams as part of the final plant effluent described in Subsection 3.6.1.

Stormwater would be routed to the industrial wastewater facility.

3.6.3.3 Solid Effluents

Nonradioactive solid waste includes typical industrial wastes such as metal, wood, and paper, as well as process wastes such as nonradioactive resins, filters, and sludge. Solid waste debris would also be collected from cleaning cooling basin forebay screens and catch basin screens. A solid waste minimization program would be employed as described in Subsection 5.5.1. To the

extent practicable, scrap metal, lead acid batteries, paper, and other recyclable material would be recycled offsite at an approved recycling facility. The nonradioactive wastes that cannot be recycled would be disposed of in a permitted landfill. Based on FPL's current operating experience for the existing units, Units 6 & 7 would be expected to produce approximately 1000 tons annually of nonradioactive, nonhazardous solid waste per year.

The solid waste collected from the periodic cleaning of cooling basin forebay screens and catch basin screens would be disposed of in a permitted landfill.

Approximately 4800 pounds of nonradioactive hazardous waste was generated from Turkey Point Units 3 & 4 in 2010. The majority of this waste was expired paint and laboratory chemicals. Based on this current waste generation rate, Turkey Point Units 6 & 7 would be expected to generate approximately 4800 pounds annually of nonradioactive hazardous waste. These wastes would be collected and stored onsite until disposed of at an offsite licensed commercial waste facility or recovered at an offsite permitted recycling facility. Currently, the majority of the nonradioactive hazardous waste is incinerated at a permitted offsite facility.

The reclaimed water from the Miami-Dade Water and Sewer Department (MDWASD) would be processed through the FPL reclaimed water treatment facility before it can be used as makeup water to the circulating water cooling system**.** The FPL reclaimed water treatment facility would generate solid waste (i.e., sludge) from the treatment of reclaimed water from the MDWASD. Assuming a continuous supply of reclaimed water from the MDWASD and Units 6 & 7 are in normal operation, the estimated amount of sludge produced would be approximately 435 tons per day. If the reclaimed water is not available, the estimated amount of sludge would be less. A description of the FPL reclaimed water treatment facility is provided in Section 3.3. Sludge from the FPL reclaimed water treatment facility would be disposed of in a permitted landfill.

Table 3.6-1
Estimated Chemicals Added to Liquid Effluent Streams from Two Units

System	Chemical-Type/Specific	Amount Used (gallon/year)	Frequency of Use	Chemical Concentrations
FPL Reclaimed Water Treatment Facility	Ferric Chloride	2,190,000	Continuous	50 ppm
	Polymer	20,500	Continuous	1 ppm
	Lime	42,400[(c)]	Continuous	383 ppm
	Sulfuric Acid	380,000	Continuous	26.2 ppm
	Methanol	1,794,000	Continuous	30.61 ppm
	Sodium Bisulfite	85,500	Continuous	1.46 ppm
Circulating Water System[(a)]	Proprietary Scale Inhibitor, High Stress Polymer, Phosphinosuccinic Oligomer	244,400	Continuous	60 ppm
	Sodium Hypochlorite	214,500	Shock treatment 30 minutes per day	2 ppm
Circulating Water System[(b)]	Sodium Hypochlorite	215,000	Shock treatment 30 minutes per day	2 ppm
	Sodium Hypochlorite	352,000	Continuous	1 ppm
	Sulfuric Acid	883,000	Continuous	53 ppm
	Proprietary scale Inhibitor, High Stress Polymer	591,500	Continuous	25 ppm
	Proprietary Scale Inhibitor, Sodium Salt of Phosphonomethylate Diamine	472,500	Continuous	20 ppm
	Proprietary Scale Inhibitor, Silicate Inhibiting Polymer	6460[(d)]	Intermittent — during transition	35 ppm
Demineralizer Water System	Sulfuric Acid	10,800	Continuous	172.5 ppm
	Proprietary Scale Inhibitor, Phosphoric Acid	1,790	Continuous	6 ppm
	Sodium Bisulfite	2,740	Continuous	2.92 ppm
Service Water	Sodium Hypochlorite	7,130	Shock treatment 30 minutes per day	2 ppm
	Sulfuric Acid	78,200	Continuous	649 ppm
	Proprietary Phosphoric Acid Scale Inhibitor	1,020	Continuous	6 ppm
	Proprietary Dispersant, High Stress Polymer	510	Continuous	3 ppm
Steam Generator Blowdown System	Oxygen Scavenging/ Morpholine	800	Used as needed	To be determined during detailed design
	pH Adjustment/ Carbohydrazide	800	Used as needed	To be determined during detailed design
	pH Adjustment/ Hydrazine	800	Used as needed	To be determined during detailed design

(a) The chemicals provided are based on the case of makeup water for the circulating system of 100 percent reclaimed water from the Miami-Dade Water and Sewer Department.
(b) The chemicals provided are based on the case of makeup water for the circulating system of 100 percent saltwater from the radial collector wells.
(c) Lime quantity is tons per year instead of gallons per year.
(d) Proprietary Scale Inhibitor Polymer is gallons per transition instead of gallons per year.

Table 3.6-2
Reclaimed Water Estimated Constituents and Concentrations Discharged to Deep Injection Wells[a]

Constituent Name	Concentration (mg/L)
Ammonia as N	Not Calculated
BOD	Not Calculated

(a) Based on total fuel throughput of 27,802 gal/yr for each tank.
(b) Based on total fuel throughput of 278 gal/yr for each tank.
(c) Based on total fuel throughput of 1650 gal/yr for each tank.
(d) Hydrocarbon emissions from the diesel fuel oil storage tanks were calculated using the EPA TANKS Program (Version 4.0.9d).

3.7 POWER TRANSMISSION SYSTEM

This section provides a description of the design characteristics and interfaces of the power transmission system for Units 6 & 7. The FPL power transmission system consists of transmission lines and substations that link the various generation facilities, load centers, and grid interties within the FPL service territory at various voltages ranging from 69 kV to 500 kV. In Miami-Dade County at the location of Units 6 & 7, the existing transmission lines are 230 kV. The transmission lines, substation/switchyard, and associated structures and equipment for the new nuclear units are rated at transmission voltages of 230 kV and 500 kV. FPL owns and operates the transmission system for the new nuclear units. A description of the components and activities necessary to connect between Units 6 & 7 and the FPL transmission system is presented in this section.

3.7.1 SWITCHYARD INTERFACES

A new switchyard/substation on the Units 6 & 7 plant area would be used to transmit electrical power output from Units 6 & 7 to the FPL transmission system. The new substation would be known as the Clear Sky substation. The substation would consist of two sections, a 230 kV section and a 500 kV section. Units 6 & 7 would be connected to the 230 kV section of Clear Sky substation section via onsite underground transmission facilities. The plot plan (Figure 3.1-3) shows the location of the new substation.

The Clear Sky substation would be a "breaker-and-a-half" bus configuration. The breaker-and-a-half bus configuration enhances reliability by providing multiple current flow paths between the units and the transmission lines, allowing continued transmission with a bus out of service due to a fault or for maintenance.

The 500 kV section of the substation would be configured to accommodate two new transmission lines and two 230 kV/500 kV autotransformers. The 230 kV section of the substation would be connected to the 500 kV transmission lines through the autotransformers. The bus breakers on both sides of the autotransformers would provide protection.

The 230 kV section of the substation would be configured to accept four new 230 kV lines interconnecting to the transmission system with two new 230 kV transmission lines and a normally open (NO) line to supply an alternate feed of offsite power to the Turkey Point substation. This alternate feed would provide a path for offsite power between the substations in the event of loss of transmission either at the Clear Sky substation or the Turkey Point substation. The Turkey Point substation is the existing substation for Units 1 through 5. The fourth position would be available for any future requirements.

The 230 kV section of the substation will include one terminal for the Unit 6 generator step-up transformer connection, one terminal for the Unit 7 generator step-up connection, two terminals

for connection to the Unit 6 reserve auxiliary transformers, and two terminals for connection to the Unit 7 reserve auxiliary transformers.

3.7.2 TRANSMISSION SYSTEM

The Clear Sky substation would be connected to the FPL transmission system through two new 500 kV and three new 230 kV transmission lines. The details of these transmission lines and their termination points to the FPL transmission system are summarized below:

Transmission Line (kV)	Termination Point	Approximate Length (miles)	Thermal Rating (MVA)
Clear Sky-Levee # 1 (500 kV)	Levee 500 kV	43	3464
Clear Sky-Levee # 2 (500 kV)	Levee 500 kV	43	3464
Clear Sky-Davis (230 kV)	Davis 230 kV	19	1191
Clear Sky-Pennsuco (230 kV)	Pennsuco 230 kV	52	1191
Clear Sky-Turkey Point (230 kV)	Turkey Point (NO)	0.5	1191
Davis-Miami (230 kV)	Miami 230 kV	18	915

See Figures 9.4-13 and 9.4-14 for a general location map of these transmission lines.

3.7.2.1 Design Parameters

The 230 kV lines would be rated at 2990 amps. These lines would be constructed with a two-conductor bundle of 954-thousand-circular-mils aluminum conductor aluminum-clad steel reinforced (ACSR/AW) conductor and optical ground wire or overhead ground wire sized based on the available fault current.

The 230 kV transmission tower structures would be single pole concrete (a gray/white color), approximately 80–90 feet high above ground depending on span length and other design factors. The substation pulloff towers would be galvanized steel or concrete.

The 500 kV transmission lines would be constructed using guyed single-circuit concrete, tubular steel or galvanized lattice steel structures. Heights would range from 140-160 feet depending on span length and other design factors. If tubular steel structures are used, similar structures with larger gauge steel would be used where the transmission lines turn light angles (2–15 degree). Similarly, where the lines turn heavy angles (55–90 degrees), three-pole structures with guys and anchors would be used. Structures would be galvanized steel (silver-gray color) or concrete (gray/white color).

The 500 kV lines would be framed in a triangular configuration. The conductor for these lines would be a three-conductor bundle of 1272-thousand-circular-mils ACSR/AW conductor with a

nominal operating voltage of 500,000 volts. The maximum current rating for this conductor would be 4215 amperes. Span distance between structures would be approximately 900–1000 feet. Site-specific conditions during detailed design may require some variance from this distance to avoid and minimize impacts to wetlands or cultural resources.

The transmission lines would be designed to meet or exceed the clearance-to-ground requirements of C2-2007, the National Electrical Safety Code (NESC) (IEEE 2007). The 230 kV and 500 kV lines would be designed to keep the electric field at the conductor surface below corona inception. The electric field induced current from transmission lines would meet the allowable NESC code (IEEE 2007) and Florida Department of Environmental Protection Florida Administrative Code (F.A.C.) requirements.

3.7.3 TRANSMISSION LINE CORRIDORS

Approval of the proposed transmission line corridors is under the authority of the Florida Power Plant Siting Act. A route study and corridor selection process was performed for the new units under the requirements of this act. Specifically, the study area was defined, candidate routes were delineated, and routes evaluated using both qualitative and quantitative criteria. There are land use constraints and opportunities in the corridor selection. Examples of land use constraints in the selection of transmission corridors include airports. Examples of land use opportunities include roads, canals and other existing linear facilities. The corridor selection process involves both public meetings and meetings with various state agencies and affected local municipalities. The end result of the selection process was the identification of a preferred corridor to submit for licensing approval for each transmission line. Selection of transmission line corridors is described in Subsection 9.4.3. The proposed lengths, widths, and area of the preferred corridors (where known), including modification and use of existing rights-of-way where applicable, are also described in Subsection 9.4.3.

3.7.3.1 Transmission Line Corridor Ecological and Cultural Surveys

As part of the transmission corridor selection process, ecological and cultural resource surveys were performed along the proposed corridors. The results of the ecological and cultural or historical surveys are described in Section 2.4 and Subsection 2.5.3, respectively. Subsection 9.4.3 describes the process of corridor selection that minimized impacts to the surrounding environment, as stipulated in the PPSA. This process, which included both qualitative and quantitative criteria in the use of resource mapping and alternate route identification, was used as part of the corridor study area selection and ultimately the selection of the preferred corridor(s).

3.7.3.2 Transmission Corridor Maintenance

The safe and reliable operation of transmission lines and maintenance of the right-of-way and facilities would be achieved through regular inspection of the structures, insulators, access areas, and vegetation management in the rights-of-way. These inspections would consist of ground patrols (truck) and/or aerial (airplane/helicopter) patrols. Transmission lines normally require minimal maintenance. However, FPL would inspect the transmission lines regularly to look for problems caused by weather, vandalism, vegetation growth, etc.

In areas that are not in active agricultural cultivation, FPL would manage vegetation within the rights-of-way using a variety of methods, including trimming, mowing, and the use of growth regulators and herbicides targeting species that are incompatible with the safe access, operation, and maintenance of the transmission system.

FPL's right-of-way maintenance program is site-specific and follows standard industry practices. The exact manner in which maintenance would be performed would depend on location, type of terrain, and the surrounding environment. Vegetation removal would be minimized consistent with safe and reliable operation of the transmission lines. Each area of the right-of-way would be addressed based on site-specific vegetation. Endangered or threatened species, if present, would be considered and accommodated in the maintenance program. Growth regulators and herbicides, when selectively used, would meet federal, state, and local regulations.

3.7.3.3 Transmission System Operation

FPL is the transmission system operator and it constructs, owns, and operates all substation and transmission facilities between the plant and the point of interconnection. An interface agreement exists between FPL Transmission & Substation — Power Supply Department and FPL Turkey Point Units 1 through 5, which establishes the protocol to provide effective monitoring and oversight of all grid, switchyard and plant activities. This agreement would be updated to include Units 6 & 7. Power Supply Department directives implement the agreement. These directives facilitate prompt and effective communications between the transmission system operator and the plant operators. The transmission system operator regularly inspects switchyard(s) and performs regular maintenance and necessary repair or replacement of equipment.

FPL uses a real-time contingency analysis program that is used by FPL's transmission system operators in determining the security level of the transmission system under a number of outage contingency criteria. The program simulates a set of contingencies on the current power system and produces an output of system conditions for each defined contingency. The program provides an updated output every 5 minutes using real-time system conditions (e.g., real time line outages, real time breaker status, etc.). For each defined contingency simulated, specified elements are checked for limit violations (e.g., line overloads, voltage limits, reactive limits at

generator buses). All contingencies that cause violations are output along with the identification of the violations and information and magnitude of the violation. The output of the contingency analysis program is used continuously by the operators to make critical decisions in response to potential severe conditions.

3.7.3.4 Noise

Transmission lines and substations can produce noise from corona discharge (the electrical breakdown of air into charged particles). The noise, referred to as corona noise, occurs when air ionizes near irregularities, such as nicks, scrapes, dirt, or insects on the conductors. Corona noise is composed of both broadband noise, characterized as a crackling noise, and pure tones, characterized as a humming noise. Corona noise, which is greater with increased voltage, is also affected by weather. During dry weather, the noise level is low and often indistinguishable from background noise. In wet conditions, water drops collecting on conductors can cause louder corona discharges.

During rain showers, the corona noise would likely not be readily distinguishable from background noise. During very moist, non-rainy conditions, such as heavy fog, the resulting small increase in the background noise levels would not be expected to result in annoyance to adjacent residents.

Periodic maintenance activities, particularly vegetation management, would produce noise from mowing, bush-hogging, and tree and limb trimming and grinding. This noise, particularly from bush-hogging or helicopter patrol operation, would be loud enough to disturb adjacent residents. However, this would be of short duration during the day and an infrequent occurrence.

The noise levels resulting from transmission system operations would be in accordance with state and local code requirements. Actual decibel noise levels would be held to a minimum by proper sizing of conductors and the use of corona-free hardware.

Additional information regarding noise levels resulting from transmission system operation is provided in Subsections 5.6.3.4 and 5.8.1.1.

3.7.3.5 General Methods of Construction

Transmission line construction would occur as a series of tasks accomplished in sequence by different specialized crews. Construction phases would consist of right-of-way clearing, access road and pad construction (where necessary), line construction, and right-of-way restoration. Construction phases would follow standard industry practices and would be performed sequentially along the right-of-way such that activities in any one area would be short term.

Clearing would be required for construction of the transmission line structures, pads, and roads. In the structure/pad areas, the right-of-way would be cleared across the entire right-of-way width. Upland areas that are not heavily vegetated with trees would be mowed. All vegetation in the right-of-way whose mature height exceeds 14 feet would also be cleared. The machinery required for clearing would include bulldozers, shearing machinery, and chain saws.

The initial step of transmission line construction would be the installation of foundations, if required. Foundations would be either steel or concrete. The actual type would be determined during detailed design. For steel foundations, the caisson would be vibrated into the ground using a vibratory hammer suspended from a crane. For concrete foundations, a hole would be excavated using an augering machine. Reinforcing steel would then be installed, and concrete would be hauled and poured in place by concrete mixing trucks. For precast foundations, a backhoe would be used to excavate the hole. If concrete poles are used, they would be directly embedded without a separate foundation.

The structures would be framed and erected using cranes and other support vehicles. After the structures are set, wire-pulling equipment would be used to install conductors and overhead ground wires. Bulldozers, tractors, trailers, and light vehicles, as required, would also be used to support line construction. Helicopters could also be used as part of the conductor stringing operation.

F.A.C. 2008. Florida Administrative Code 62-814.450, Florida Department of Environmental Protection, June 2008. Available at http://www.dep.state.fl.us/legal/Rules/62-814/62-814.doc.

3.8 TRANSPORTATION OF RADIOACTIVE MATERIALS

Operation of new Units 6 & 7 would require transportation of unirradiated fuel, irradiated fuel (spent nuclear fuel), and radioactive waste. The subsections that follow describe transportation of these three types of radioactive materials.

Subsection 5.7.2 also addresses the conditions in 10 CFR 51.52 (a) (1) through (a) (5) regarding use of Table S-4 to characterize both the impacts of radioactive materials transportation and to provide an analysis of the radiological impacts from incident-free transportation of these materials. Section 7.4 addresses postulated radiological transportation accidents.

3.8.1 TRANSPORTATION OF UNIRRADIATED FUEL

Transportation of new fuel assemblies to the Turkey Point site from a fuel fabrication facility would be in accordance with DOT (49 CFR Parts 173, 178, and 397) and NRC regulations (10 CFR Part 71). The initial fuel loading will consist of 157 fuel assemblies per unit. On an annualized basis, refueling will require an average of 43 fuel assemblies per unit per year. The fuel assemblies would be fabricated at a fuel fabrication plant and shipped by truck to the Turkey Point site shortly before they would be required. The details of container design, shipping procedures, and transportation routings would be in accordance with DOT and NRC regulations and would depend on the requirements of the suppliers providing the fuel fabrication services. Truck shipments would not exceed 73,000 pounds, as governed by federal and/or state gross vehicle weight restrictions.

3.8.2 TRANSPORTATION OF IRRADIATED FUEL

Spent fuel assemblies would typically be discharged from each unit on an 18-month refueling cycle and would remain in the spent fuel pool at each unit for at least 5 years while short half-life isotopes decay. As described in Subsection 3.5.3, each unit will have a spent fuel pool with capacity for 889 assemblies, which is adequate to support 11 refueling cycles plus margin for one full core offload. After a sufficient decay period, the fuel would be removed from the pool, packaged in spent fuel shipping/storage casks, licensed in accordance with 10 CFR Part 72, and transferred to either an independent spent fuel storage installation facility onsite or an offsite disposal facility. Packaging of the fuel for offsite shipment would comply with applicable DOT (49 CFR Parts 173 and 178) and NRC regulations (10 CFR Part 71) for transportation of radioactive material. By law, the DOE is responsible for spent fuel transportation from reactor sites to a repository (Nuclear Waste Policy Act of 1982, as amended). DOE would determine the transport mode.

3.8.3 TRANSPORTATION OF RADIOACTIVE WASTE

As described in Subsection 3.5.3, low-level radioactive waste would be packaged to meet transportation and disposal site acceptance requirements. Packaging of waste for offsite shipment would comply with applicable DOT (49 CFR Parts 173 and 178) and NRC regulations (10 CFR Part 71) for transportation of radioactive material. The packaged waste would be stored on site on an interim basis before being shipped offsite to a licensed processing, storage, or disposal facility. Onsite storage for more than a year at the maximum rate of generation would be provided in the waste accumulation room of the radwaste building. Radioactive waste would be shipped offsite by truck.

FPL expects that, consistent with its current commercial agreements, a third-party contractor will process, store, own, and ultimately dispose of low-level waste generated as a result of operations. Activities associated with the transportation, processing, and ultimate disposal of low-level waste would comply with applicable laws and regulations in order to ensure the public's health and safety. In particular, the third-party contractor would conduct its operations consistent with NRC regulations (e.g., 10 CFR Part 20), which will ensure that the radiological impacts from these activities would be small. Lastly, environmental impacts resulting from transportation of low-level wastes are expected to be bounded by the NRC's findings in 10 CFR 51.52 (c).

3.9 PRECONSTRUCTION AND CONSTRUCTION ACTIVITIES

This section provides a conceptual description of preconstruction and construction activities for new Units 6 & 7. The description of activities pertinent to addressing potential impacts of plant construction and mitigative measures to prevent or minimize impacts, is presented in Chapter 4. Preconstruction and construction activities are addressed in this section. Transmission corridor and transmission line activities are presented in Section 3.7.

Preconstruction Activities

Upon receipt of necessary approvals, preconstruction activities would be initiated at the site before receipt of the COL including, for example, initial site excavation and build up, installing temporary facilities, construction support facilities, service facilities, utilities, upgrading the equipment barge unloading area, cooling water pipelines, bridges, road improvements, and other nonsafety-related structures, systems, and components.

COL Construction

Upon receipt of the COL, the construction activities described in 10 CFR 50.10(a)(1) (i-vii) could begin. Specifically, constructing the structures, systems, and components of the plant, such as the in-place erection of the containment and auxiliary buildings, placement of structure, system, and component equipment, etc., could begin.

Schedule

The construction schedule assumes approximately 69 months for preconstruction activities. Unit 6 construction would begin after receipt of the COL and would have an approximate 66-month duration for construction activities and a 6-month duration for fuel load and startup. Unit 7 safety-related construction would begin approximately 12 months after Unit 6 safety-related construction begins and would follow identical construction and fuel load/startup durations. Units 6 & 7 would initiate electric generation output in 2022 and 2023, respectively. Table 3.9-1 summarizes the projected major milestone dates for the preconstruction activities, COL construction, and startup and operations for Units 6 & 7.

Summary of Land Disturbances

The construction activities would comply with the state site certification conditions and the U.S. Army Corps permit requirements (see Section 1.2). Environmental best management practices would be implemented to minimize impacts during preconstruction and construction activities. Although soil or groundwater contamination is not anticipated at any of the onsite or offsite areas proposed for land disturbance (e.g., excavation, land clearing, grading), applicable guidelines and procedures contained in Florida Administrative Code (F.A.C.) Chapter 62-780

”Contaminated Site Cleanup Criteria” would be followed by FPL, including any required site assessments and other potential remedial actions. A summary of the major land disturbances on the plant property, in the vicinity, and the region is as follows:

Turkey Point Plant Property Land Disturbance

- Units 6 & 7 plant area including power blocks, makeup water reservoir, switchyard, deep injection wells, associated facilities, etc. (218 acres)
- Western laydown areas, including filling of dead-end canal (52 acres)
- Parking and nuclear administration and training buildings (32 acres)
- Security buildings and associated pull-off and parking areas (previously disturbed)
- Improvements/construction of the heavy haul road from the equipment barge unloading area to the Units 6 & 7 plant area (5 acres)
- Transmission infrastructure improvements (e.g., towers and bridges) (previously disturbed)
- Transmission laydown areas (3 acres)
- Sanitary waste pipeline from existing units to Units 6 & 7 plant area (previously disturbed)
- Equipment barge unloading area (0.75 acres)
- "A," "B," and "C" spoils areas (211 acres)
- Radial collector wells and associated facilities (3 acres), radial collector well laydown area (3 acres), and water supply pipelines to the Units 6 & 7 plant area (13 acres)
- FPL reclaimed water treatment facility (44 total acres; 29 acres of undisturbed land; 15 acres of disturbed land as part of west transmission corridor), reclaimed water supply pipelines to the facility from the Miami-Dade Water and Sewer Department South District Wastewater Treatment Plant, and water supply pipelines from the facility to the Units 6 & 7 plant area (zero acres of undisturbed land)
- Potable water pipelines (previously disturbed)

Vicinity Land Disturbance

- FPL-owned fill source (300 acres)

- Improvements to SW 328th Street/N. Canal Drive, SW 344th Street/Palm Drive, SW 359th Street, SW 137th Avenue, and SW 117th Avenue (128 acres, includes improvements on plant property)

Region Land Disturbance

- Corridor for 72-inch diameter (or equivalent) reclaimed water pipelines (1886 acres)
- Corridor for 30-inch diameter (or equivalent) potable water pipelines (327 acres)
- Transmission corridors, access roads, and substation upgrades (approximately 5872 acres). (Disturbed area is based on Tables 2.2-2, 2.2-3, and 2.2-4.)

Table 3.9-2 summarizes the major land disturbances. Section 4.1 further discusses the major land disturbances related to construction activities and mitigation measures.

3.9.1 PRECONSTRUCTION ACTIVITIES

Preconstruction activities would commence in the 2nd quarter of 2013. The activities that could be performed include the following:

- Clearing, grubbing, and spoils area establishment
- Access roads, heavy haul roads, and equipment barge unloading area improvement
- Construction security
- Construction utilities
- Construction facilities and preparation activities
- Site earthwork, including power block
- Makeup water reservoir, cooling towers, and pipelines
- Reclaimed water pipelines
- Potable water pipelines
- FPL reclaimed water treatment facility
- Radial collector wells, associated facilities, and pipelines
- Deep injection wells

- Module assembly areas

The Construction Utilization Plan, as depicted in Figure 3.9-1, (Sheets 1 through 4), illustrates the disturbed land areas and other construction features.

3.9.1.1 Clearing, Grubbing, and Spoils Area Establishment

Clearing would begin with the removal of trees to the minimum extent necessary. Scrub vegetation and brush removal would be accomplished through the use of appropriate and approved techniques. Offsite disposal of any organic materials would be through approved local and state waste disposal techniques.

Spoils areas would be established on the Turkey Point plant property south of the Units 6 & 7 plant area to allow dewatering of materials during construction of Units 6 & 7 from such activities as clearing, grubbing, and excavation (see Subsection 3.9.1.6). Three separate spoils areas, denoted as “A,” “B,” and “C” on Figure 3.9-1 (Sheet 3 of 4), would be established at the southern end of the industrial wastewater facility. Spoils areas “A” and “C” would be located on the western and eastern side of the main return canal, respectively, and each pile would be 4.6 to 5 miles long. Spoils area “B” would be established at the southern end of the industrial wastewater facility and would be approximately 1.8 miles in length. The total area for spoils area “A,” “B,” and “C” would be approximately 77 acres, 18 acres, and 116 acres, respectively, resulting in a total spoils capacity of approximately 2 million cubic yards. The estimated height of the spoils pile will be determined after the spoils storage area has been surveyed and a final dirt road width for the berms has been established. It is anticipated that the final spoils elevation will be approximately 16–20 feet NAVD 88.

Drainage from the spoils piles would be controlled through measures such as berms, riprap, sedimentation filters, and detention ponds before any water drainage to the industrial wastewater facility.

3.9.1.2 Access Road, Heavy Haul Road, and Equipment Barge Unloading Area Improvement

Construction traffic would access the Turkey Point plant property via various routes including SW 117th Avenue, SW 137th Avenue/Tallahassee Road, SW 328th Street/N. Canal Drive, SW 344th Street/Palm Drive, and SW 359th Street. Road improvements would include widening SW 328th Street/N. Canal Drive, SW 344th Street/Palm Drive (west of SW 137th Avenue/Tallahassee Road), and SW 117th Avenue (north of SW 344th Street/Palm Drive) from two lanes to four lanes. SW 359th Street, which is currently an unimproved rock road, will be improved to a three lane road west of SW 117th Avenue and a four lane road east of SW 117th Avenue. SW 137th Avenue/Tallahassee Road is currently an unimproved dirt road and would be improved to a three lane road. SW 117th Avenue (south of SW 344th Street/Palm Drive) is currently an unimproved dirt road and would be improved to a four lane road. Road improvements, including road

widening, additional turn lanes, signalization, etc. are described in Subsection 4.4.2.2.4.4. Figure 3.9-1 (Sheet 4) depicts the location of the roads.

The existing barge turning basin connects Biscayne Bay to the Turkey Point plant property, and would be used for module and component delivery. The turning basin is approximately 300 feet wide and 1200 feet long and is currently used for fuel deliveries for Units 1 & 2. There would be approximately 80 round-trip barge deliveries for modules and components for each unit over an approximately six-year duration. The existing equipment barge unloading area would be extended to approximately 90 feet by 150 feet (0.31 acres) and 9 feet deep, as part of a total disturbed area of 130 feet by 250 feet (0.75 acres), to accommodate heavy component offloading (Figure 3.9-1 [Sheet 2]). Limited dredging would likely be required as part of the upgrade.

The existing heavy haul road, originating at the equipment barge unloading area, would be improved and terminate at three distinct places on the Units 6 & 7 plant area, to facilitate unloading modules and components. The heavy haul road would be approximately 2 miles long and 24 feet wide and would disturb approximately 5 acres. The road would start at the equipment barge unloading area and extend generally west between Unit 5 and Units 1 & 2. The road would then extend generally south and cross over two new heavy haul bridges, one at the main cooling discharge canal and the other at the main cooling return canal. The heavy haul road would then terminate at three locations on the Units 6 & 7 plant area to allow for module and component delivery and placement (See Figure 3.9-1 [Sheet 1 of 4]). Culverts would be installed under the heavy haul road where required to maintain drainage patterns.

Until the heavy haul road bridges are completed, temporary bridge(s) would be installed over the main cooling discharge canal and the L-31E Canal to facilitate construction activities. These bridges would be removed after completion of the heavy haul bridges.

3.9.1.3 Construction Security

Construction security programs and features would be implemented as part of the site preparation activities. Security structures would include access control points and security stations. Temporary security measures would also be used.

Details of the site security plan are described in Part 8 of the COL Application.

3.9.1.4 Construction Utilities

Temporary utilities would include aboveground and underground infrastructure for power, lighting, communications, wastewater and waste treatment facilities, fire protection, and construction gases and air systems. The temporary utilities would support the construction site and associated activities, including construction offices, warehouses, storage and laydown areas, fabrication and

maintenance shops, the power block, the concrete batch plant facility, and test and calibration labs.

3.9.1.5 Construction Facilities and Preparation Activities

The parking lot, laydown, storage and fabrication areas, and the road system to accommodate the site construction traffic would be cleared, grubbed, graded, and appropriately surfaced. Construction facilities, including offices, warehouses, workshops, sanitary facilities, locker rooms, training facilities, storage facilities, and access facilities would be constructed.

The site of the concrete batch plant would be prepared for cement and aggregate unloading and storage. Cement storage silos and the concrete batch plant would be erected. Dry material storage facilities would use dust control measures as necessary to meet the requirements of the applicable permits and guidelines.

Activities to support preparation of the construction facilities include:

- Conducting property surveys to establish local coordinates and the placement of benchmarks for horizontal and vertical control
- Developing laydown areas by grading, stabilizing canals, and surfacing these areas
- Installing construction fencing
- Installing shop and fabrication areas
- Installing concrete work slabs for formwork laydown, module assembly
- Installing equipment maintenance and parking areas
- Installing fuel and lubricant storage areas
- Installing concrete pads for cranes and crane assembly

3.9.1.6 Earthwork — Units 6 & 7 Plant Area

Significant earthwork would be required to establish finish grades at the Units 6 & 7 plant area, especially to raise the power block (i.e., Nuclear Island) to its required finished-floor elevation of 26.0 feet NAVD 88. Approximately 7.7 million cubic yards of general area (Category II) backfill would be required to raise the existing grade elevation of approximately –1.0 feet NAVD 88 to the finished grade elevation adjacent to the power block of 25.5 feet NAVD 88. Also, backfilling around the major power block Seismic Category I (safety-related) embedded structures would

require approximately 130,000 cubic yards of safety-related (Category I) engineered structural backfill.

Approximate estimated fill requirements for the plant area and associated non-linear facilities and conceptual ranges for offsite transmission and access roads, are as follows:

Onsite areas:

- Plant Area (198 acres) 7.8 million cubic yards
- Reclaimed Water Treatment Facility (44 acres) 1.6 million cubic yards
- Laydown Areas (52 acres) 0.7 million cubic yards
- Nuclear Admin/Training/Parking Area (32 acres) 0.6 million cubic yards

Offsite Areas

- Transmission Roads and Pads 2.0–3.0 million cubic yards
- Access Roads 0.4–0.7 million cubic yards

Stabilization of the plant area perimeter to provide protection of the cooling canals of the industrial wastewater facility during excavation and removal of unsuitable material and placement of fill materials would progress in the following manner:

- To minimize potential impacts on the cooling canals, the Units 6 & 7 plant area would first be isolated from the industrial wastewater facility by installing temporary sheet piling. The sheet piling would be installed into the Miami Limestone Formation around the perimeter of the plant area with the top of the sheet piling extending somewhat above the adjacent existing grade elevation. After the area behind the sheet piling is backfilled, the sheet piling would be removed and re-used as this process moves around the perimeter of the plant area. Eventually additional erosion protection such as riprap would be installed along the perimeter of the plant area adjacent to the canals.

- After stabilizing the perimeter of the Units 6 & 7 plant area with sheet piles, the approximately 5-foot thick layer of the existing organic soil material, or “muck,” would be removed from the plant area and replaced with general area backfill to raise the surface above the maximum water levels expected in the industrial wastewater facility. An estimated 1.8 million cubic yards of muck would be removed (de-mucked), starting with a small area (approximately 20-foot wide) adjacent to (and inside of) the entire plant area perimeter. De-mucking would continue until the Miami Limestone Formation is exposed along the interior face of the sheet piling and replaced with backfill. De-mucking and placement of backfill would be carefully coordinated to minimize inflow of groundwater. The backfill would be placed and compacted

to an approximate elevation of 0 feet NAVD 88 to create a working base for a mechanically stabilized earth (MSE) wall. This wall would be constructed around the perimeter of the Units 6 & 7 plant area, excluding the south side of the plant area where the makeup water reservoir would provide the plant area exterior wall. The MSE wall would be designed to retain the interior soil mass while also resisting wave forces resulting from the probable maximum hurricane (PMH). The MSE wall would extend from its base at approximately 0.0 feet NAVD 88 to a height that would range from elevation 20.0 feet to 21.5 feet NAVD 88.

- To establish a dry construction working surface at an approximate elevation of 0.0 feet NAVD 88, the remaining portions of the Units 6 & 7 plant area would be de-mucked and backfill placed and compacted in a manner similar to the perimeter. This process would proceed simultaneously in multiple areas across the plant area, sequenced to facilitate subsequent excavation activities, and would continue until the entire layer of muck is excavated and the plant area is backfilled to elevation 0.0 NAVD 88, except for the designated makeup water reservoir area which would not be backfilled. (See Subsection 3.9.1.7 for a description of construction activities for the makeup water reservoir.) Backfill would be obtained from a combination of an FPL-owned fill source located on a 300-acre plot located near Homestead Air Reserve Base approximately 4.5 miles from the plant area or other regional sources. Reused material excavated from the plant area would be used as Category I structural backfill. Figure 3.9-1 (Sheet 4) depicts the location of the FPL-owned fill source.

- The muck removed during excavation would be transferred to designated spoils areas, as depicted on Figure 3.9-1 (Sheet 2). Material removed from the deeper excavations and evaluated as acceptable for reuse would be stored for common Category II or Category I structural backfill.

3.9.1.7 Makeup Water Reservoir, Cooling Towers, and Makeup Water Supply Pipelines

The makeup water reservoir (a reinforced concrete structure with a footprint of approximately 37 acres) would be located in the south end of the plant area. Six (6) mechanical draft cooling towers (three per unit) would be installed over the reservoir to maximize size of the reservoir. Site preparation, excavation and construction of the reservoir would include the following:

- The south perimeter of the plant area would be stabilized similar to the remainder of the plant area perimeter by driving sheet piles into the Miami Limestone Formation. In addition to restraining the return canals, this sheet piling would function as sacrificial formwork when the reservoir exterior wall is poured and only the exposed portion above approximate elevation 0.0 NAVD 88 would be removed.

- After stabilizing the canals, the muck behind the sheet piles would be excavated to the top of the Miami Limestone Formation and placed in the designated spoils areas.

- General area dewatering would not be required as the surface of the excavated area would be sealed by tremie concrete (if required) to minimize in-leakage of ground water. Local de-watering in the area of the deeper cooling tower foundations would be required and pressure grouting might be required to facilitate this dewatering.

- Concrete would be placed over the excavated area to form the reservoir base slab. The top of the base slab would be at elevation –2.0 feet NAVD 88. Reinforced concrete walls would then be constructed with the top elevation at 24.0 feet NAVD 88.

The circulating water system piping would be routed from the discharge of the circulating water pumps located on the north side of the makeup water reservoir, to the condenser in the turbine building and from the condenser to the cooling towers. The section of the circulating water piping extending beneath the condenser would require a deep excavation and local dewatering. The remaining sections of the circulating water piping would be above the Miami Limestone and would be installed as the plant area is backfilled and would not require dewatering. Completion of the circulating water system piping installation would coincide with the turbine building pedestal basemat placement.

Blowdown piping would be routed from the circulating water discharge header to the blowdown sump on the east side of the plant area. These lines would be installed above the Miami Limestone as the plant area is backfilled.

The reclaimed water pipelines would be routed from the FPL reclaimed water treatment facility to the west side of the makeup water reservoir. Excavation would be required between the FPL reclaimed water treatment facility and the plant area, but the pipelines would be above ground on the plant area.

The pipelines from the radial collector wells would require excavation on the Turkey Point peninsula and the existing berm east of the plant area, but would be above ground on the plant area.

3.9.1.8 Reclaimed Water Pipelines and Potable Water Pipelines

Reclaimed water supply pipelines would be constructed to supply reclaimed water to the FPL reclaimed water treatment facility. The buried pipelines (72-inch diameter or equivalent) would be constructed from the Miami-Dade Water and Sewer Department South District Wastewater Treatment Plant to the FPL reclaimed water treatment facilility on the Turkey Point plant property. The length of the pipelines would be approximately 9 miles. For about 6.5 miles of their length, the pipelines would be collocated with the existing Clear Sky-to-Davis transmission line right-of-way and adjacent road and canal rights-of-way. The remaining approximately 2.5 miles would be

located within a new pipeline corridor. The corridor for this pipeline is approximately 1886 acres. Figure 3.9-1 (Sheet 4 of 4) shows the location of the reclaimed water pipelines.

The FPL reclaimed water treatment facility (29 acres of additional disturbed land and 15 acres of disturbed land from the west transmission corridor) would be located northwest of the Units 6 & 7 plant area, as shown on Figure 3.9-1 (Sheet 2 of 4).

Potable water pipelines would be constructed to supply potable water to Units 6 & 7. The buried pipelines (30-inch diameter or equivalent) would originate from an existing MDWASD supply line at the intersection of SW 288th Street and SW 137th Avenue/Tallahassee Road and proceed south to SW 328th Street/N. Canal Drive. The pipelines would then run east along SW 328th Street/N. Canal Drive to SW 117th Avenue and then south towards SW 359th Street. At the intersection of SW 359th Street, the pipelines would run east to the Turkey Point plant property. The estimated length of the potable water pipelines would be 8 miles to the plant property. The corridor for this pipeline, which will run concurrent with road improvements at several locations, is 327 acres.

3.9.1.9 Radial Collector Wells

Radial collector wells would be constructed to supply approximately 86,400 gpm of makeup water to the circulating water system cooling towers. As shown on Figure 3.9-1 (Sheet 2 of 4), the well caissons would be located on the Turkey Point peninsula, east of the existing units. Each radial collector well would consist of a central reinforced concrete caisson extending below the ground level with laterals projecting from the caisson. The well laterals would be advanced horizontally a distance of up to 900 feet and installed at a depth of approximately 25 to 40 feet below the bottom of Biscayne Bay. The design for a typical radial collector well is illustrated in Figure 3.4-2. The wells would be designed and located to induce recharge from Biscayne Bay. The radial collector well locations are shown in Figure 3.1-3.

3.9.1.10 Deep Injection Wells

Twelve deep injection wells (ten primary and two backup) would be installed, by drilling, in the plant area to provide a means of disposal of treated wastewater, sanitary waste, blowdown, and treated liquid radioactive waste effluent. The deep injection wells would be 24-inch-diameter wells and would extend approximately 2900 to 3500 feet below grade. Six dual-zone monitoring wells would also be installed by drilling to approximately 1900 feet below grade. During the deep injection and monitoring well installation, a recirculation slurry tank will be utilized to separate the drill cuttings and sand from the slurry mixture in order to re-use the slurry and minimize waste. The slurry mixture is composed primarily of bentonite, which is a nonhazardous material that is widely used in water and monitoring well installation.

Upon completion of well installation activities, excess water will be pumped from the recirculation tank, settled, and released to the industrial wastewater facility. The waste slurry mixture will be hauled to the spoils storage area for disposal. The estimated amount of waste slurry for one deep injections well and one dual-zone monitoring well is approximately 600 cubic yards and 260 cubic yards, respectively, or 8,760 cubic yards for the complete system of 12 deep injection wells and 6 dual-zone monitoring wells. A concrete surface pad would complete each deep injection well installation. The location of the deep injection wells are shown on Figure 3.1-3.

3.9.1.11 Module Assembly

The AP1000 design uses a modularization construction approach. Module components would be fabricated offsite, shipped to the site via truck or barge, and assembled into complete modules before being set in the power block. Modules that arrive by barge would be transported to the power block area or offloaded in fabrication assembly areas.

3.9.2 COL CONSTRUCTION ACTIVITIES

The construction activities that would be performed after receipt of the COL, including the structural construction and completion of structures, systems, and components, are presented in the following subsections.

3.9.2.1 Earthwork — Units 6 & 7 Power Block

The power block footprint encompasses the nuclear and turbine island building areas, which include the following major buildings for each unit:

— Containment building

— Auxiliary building

— Annex building

— Radwaste building

— Turbine building

Site preparation, excavation and foundation preparation for the Units 6 & 7 power block areas would include the following:

- The two excavations for the containment and auxiliary buildings would extend to an approximate elevation of –35.0 feet NAVD 88 or to the top of competent rock in the Fort Thompson Formation. To permit construction of the deep foundations and to hydraulically isolate this excavation from horizontal groundwater flow, a permanent reinforced concrete

diaphragm “cutoff” wall would be constructed. It is anticipated that the diaphragm wall would be installed into the Key Largo Formation to a depth of approximately -60.0 feet NAVD 88 or just below a semi-confining layer in the Biscayne Aquifer. The top of the diaphragm wall would be at elevation 2.0 feet NAVD 88 or two feet above the construction working surface elevation of 0.0 feet NAVD 88.

- The cutoff wall will be constructed sequentially by excavating vertical panels, roughly 3 feet wide, by 12 to 14 feet long, by 60 feet deep to form the outer footprint of each deep nuclear island excavation. During excavation, each slot is kept filed with bentonite-base slurry, which counter balances the hydrostatic forces and lateral earth pressure. When the slot is completed, reinforcement is installed and concrete is placed through tremie pipes, displacing the excavation slurry to the top, where it is pumped to a mud pit for re-use. This installation approach, specifically the use of panels and recirculation of slurry material, will minimize the amount of slurry waste at the completion of wall installation. The remaining slurry will be dewatered and disposed of onsite at the spoils piles, located along the cooling canals of the industrial wastewater facility.

- After completion of this diaphragm wall, a horizontal seepage barrier, or grout plug, which prevents vertical seepage, approximately 25 feet thick, will be constructed from elevation -35 feet NAVD 88 to elevation -60 feet NAVD 88 by first drilling from the ground surface, and then grouting. The barrier will be integral with the diaphragm wall so that construction dewatering can be accomplished by use of sump pumps, or similar methodologies, located within the excavation.

- To install the grout plug, vertical boreholes will be drilled in a grid pattern and grouted in an iterative process, which is estimated to consist of four rounds of drilling and grouting, prior to excavation. Successive rounds of grouting will be performed by dividing the spacing of the previous round of boreholes used for grouting. The later rounds of grouting will experience lower grout “take” — that is, as formation voids and flow pathways are filled during the initial grouting rounds, the formation will “take” less grout. The use of this testing and remedial grouting phased approach, in addition to both overlapping criteria and a designed program to indicate completeness of the program — based on such factors as grout injection pressure, volume pumped into the formation, and observable seepage, if any — will determine the adequacy and completeness of the horizontal grouting program.

- A temporary dewatering system would be installed for the two power block area deep excavations. Drainage sumps would be installed at the bottom of the excavations from which surface drainage and/or accumulated groundwater would be pumped to the cooling canals of the industrial wastewater facility. The subsequent dewatering phases, known as the excavation phase and foundation construction, are further discussed in Section 4.2.

- Once construction of the diaphragm wall is completed around the planned deep foundation area, excavation of the existing material within its interior would commence using conventional methods (use of explosives would not be required). Excavated material not suitable for reuse would be transferred to the designated spoils areas, as depicted on Figure 3.9-1 (Sheet 2). Material removed from the excavation and evaluated as acceptable, would be stored on the plant area and used later as common Category II or Category I structural backfill.

- Lean concrete fill would be placed between the excavated surface of the Key Largo Limestone Formation at approximately -35.0 feet NAVD 88 and an approximate elevation of –16.0 feet NAVD 88. At this elevation, additional lean concrete fill, mud mat(s), and a waterproof membrane would provide an interface at –14.0 feet NAVD 88 for construction of the containment and auxiliary building reinforced concrete foundations. Category I structural fill would then be placed to prescribed compaction requirements in the annular space between the power block structures and the diaphragm wall. The Category I structural fill would extend to the top of the wall and additional Category I fill would be placed over Category II fill at a 1.5:1 horizontal to vertical slope past the diaphragm wall perimeter.

Once the power block area has been backfilled to the top of diaphragm wall, backfill of the remaining plant area would be completed in a sequence defined by the construction schedule. Finished grade of the plant area would slope up from an approximate elevation of 19.0 feet NAVD 88 (adjacent to the perimeter retaining wall) to elevation 25.5 feet NAVD 88 at the power block area near the center of the plant area. The slope of the finished grade would be approximately 0.5 percent from the exterior walls to the power block areas with contours and swales to allow drainage into the surrounding canals.

3.9.2.2 Structural Construction

Each AP1000 unit is a series of buildings and structures with systems installed within the structures. Much of the commodity installation would consist of prefabricated civil/structural, electrical, mechanical, and piping modules with field-installed interconnections. The balance of the field installation consists of bulk commodity installation. Power plants are typically constructed with the major mechanical and electrical equipment and piping systems installed in each respective elevation as the civil construction advances upward. Each power block consists of five major buildings. The following is a brief description of each major building, along with the approximate maximum height of each above plant grade. Table 3.9-1 summarizes the estimated durations for major power block construction activities.

As described in Subsection 3.9.2.1, the power block is an AP1000 consisting of the following steel and concrete buildings:

- Containment building
- Auxiliary building
- Annex building
- Radwaste building
- Turbine building

The buildings, including dimensions, are described in the following paragraphs.

Containment Building

The containment building is constructed of steel and concrete with two floor elevations below plant grade and one floor elevation above grade. The containment building is a circular building with a diameter of approximately 142 feet and a height above grade (note: local grade is defined as 25.5 foot NAVD 88) of approximately 229 feet. The major activities associated with the containment building construction following the basemat foundation placement include:

- Erecting the containment vessel modules
- Placing the walls, slabs, platforms, and reactor supports
- Installing the reactor pressure vessel, steam generators, and heat exchangers
- Setting the major mechanical and electrical equipment, piping, and valves
- Installing the fuel transfer tubes
- Setting the refueling machine and the containment building crane
- Setting the upper containment building roof structure

The remaining mechanical, piping, fire sprinklers system, HVAC, and electrical installations begin in the lower elevations and continue to the upper elevations. This is the case with each of the other buildings. The containment building has the longest construction duration.

Auxiliary Building

The auxiliary building abuts the containment building and has five floor elevations (two stories below grade and three stories above grade) and reaches a height of approximately 81 feet above plant grade. The footprint of this building is approximately 254 feet by 116 feet.

Annex Building

The annex building has three main floor elevations (all above grade) and reaches a height of approximately 83 feet above plant grade. The footprint of this building is approximately 285 feet by 132 feet.

Turbine Building

The turbine building has five main floor elevations (one below plant grade and four above) and reaches a height of approximately 146 feet above plant grade. The footprint of this building is approximately 310 feet by 156 feet.

The turbine building construction would begin with the installation of turbine generator pedestal basemat and the buried circulating water pipe, followed by installation of the turbine generator pedestal columns, steam condenser modules, and turbine generator pedestal deck. The turbine generator building would then be erected once the turbine generator pedestal is complete, followed by the turbine building crane. Installation and assembly of the turbine generator would then proceed.

Radwaste Building

The radwaste building has one floor elevation above grade and reaches a height of approximately 36 feet above plant grade. The footprint of this building is approximately 175 feet by 88 feet.

3.9.3 OTHER FACILITIES AND SITE COMPLETION

Other facilities to be constructed/installed include:

- Substation, transformers, and transmission lines
- Warehouses
- Tunnels and pipe chases
- Electrical and diesel generator buildings
- Hot and cold machine shop
- Sewage treatment facility
- Fire protection pump house
- Security stations, sally ports, protected area, and delay fence

- Administration building(s)
- Various yard tanks
- Hydrogen, nitrogen, oxygen, and carbon dioxide storage facilities

The common yard area construction would occur over the full construction duration from the start of site preparation. The necessary permits and authorizations would be acquired to ensure compliance with applicable rules and regulations (see Section 1.2).

After completion of major construction activities, the Units 6 & 7 plant area would be graded to an elevation of approximately 19 feet NAVD 88 at the perimeter, sloping to a finished grade elevation of 25.5 feet NAVD 88 at the power block area.

3.10 WORKFORCE CHARACTERIZATION

A characterization of the workforce for the construction and operation of Units 6 & 7 is needed to assess the environmental and socioeconomic impacts of new unit construction and operation, as described in Sections 4.4 and 5.8, respectively. This workforce characterization involves estimating the number of personnel for construction and operation of Units 6 & 7, workforce relocation, and commuting.

As presented in Section 3.9, the construction and operation of Units 6 & 7 would be executed in distinct phases, as summarized below:

- Preconstruction Activities
- Construction Activities
- Operation

The estimated workforce, characterization, and relocation/commuting are described in the following paragraphs.

3.10.1 CONSTRUCTION WORKFORCE CHARACTERIZATION

The construction workforce for preconstruction and Units 6 & 7 construction activities would generally consist of two components: field craft labor and field nonmanual labor. Field craft labor would be the largest component of the construction workforce, consisting of approximately 75 percent of the field workforce based on conventional PWR nuclear plant construction. This labor force would consist of various disciplines, including civil, electrical, mechanical, piping, and instrumentation personnel. This labor force would be used during the construction and startup of the units. Field nonmanual labor would make up the balance of the construction workforce, or approximately 25 percent, with the assumption that design engineering would be performed offsite. The field nonmanual labor workforce would be comprised of field management, field supervision, field engineers, quality assurance/quality control, environmental/safety and health, and administrative/clerical staff.

Table 3.10-1 illustrates the representative percentage ranges for each discipline for the field craft and field nonmanual labor categories for all construction activities. The skill set makeup is representative of conventional PWR nuclear power plant construction.

3.10.1.1 Preconstruction Activities Workforce

As described in Section 3.9, preconstruction activities could occur 39 months (start of 2nd quarter 2013 through end of 2nd quarter 2016) before the start of safety-related construction for Units 6 & 7. The onsite peak construction workforce is estimated to be approximately 1475

personnel during this time period, working 40 hours per week. Table 3.10-2 and Figure 3.10-1 summarize the workforce personnel requirements by month for preconstruction activities.

3.10.1.2 Units 6 & 7 Construction Activities

The AP1000 design uses a modular construction approach. The amount of modularization depends on the characteristics of the site, transportation route restrictions, and methods. Modularization shifts some of the onsite work (and workforce) to another offsite location, thereby decreasing the required onsite construction staff. The construction duration and estimated onsite workforce presented assumes offsite fabrication with onsite module assembly.

The total onsite construction workforce, assuming the sequential construction of two units, per the construction schedule presented in Section 3.9, is based on an estimated 20.5 jobhours per net kW of generating capacity. This estimate is based on conventional non-modular PWR construction projects started after 1974, with an adjustment in jobhours/net kW for offsite modular fabrication. The estimated net generating capacity (MWe) for each unit is 1100 MWe.

In order to begin commercial operation of Units 6 & 7 in 2022 and 2023, respectively, the construction schedule assumes a 66-month duration from the start of activities under NRC authority to Unit 6 fuel load, including 6 months for startup. Unit 7 safety-related construction would begin 12 months after Unit 6 safety-related construction initiation and would follow an identical activity and duration schedule. This results in a total schedule duration of 123 months. Based on this schedule and the jobhour/net kW criteria, the onsite, peak construction workforce for the construction of the two units is estimated to be 3950 people, working 40 hours per week. Table 3.10-2 and Figure 3.10-1 summarize the workforce requirements by month of Units 6 & 7 construction activities.

3.10.2 CONSTRUCTION WORKER RELOCATION AND COMMUTING

Several assumptions are used to bound the construction workforce composition with respect to workforce commuting and relocation. It is assumed that construction workers typically commute up to a maximum of 50 miles to the jobsite. The Units 6 & 7 plant area is within 50 miles of the greater Miami-Dade metropolitan area, a large population center. It is conservatively assumed that 50 percent of the construction field craft labor workforce would be available to the project from within 50 miles, or approximately 1481 local craft personnel (based on a peak construction workforce personnel number of 3950 and 75 percent field craft labor). The balance of the construction workforce (1481 personnel) is assumed to come from outside the 50-mile radius. These personnel would relocate within the 50-mile area to minimize their commute distance and seek temporary housing.

It is further assumed that 50 percent of the field nonmanual labor workforce (494 based on 25 percent field nonmanual labor) would relocate to the area from outside the 50-mile radius and seek permanent housing.

3.10.3 OPERATIONS WORK FORCE

A study commissioned by the U.S. Department of Energy (U.S. DOE May 2004) estimated the additional operations workforce for a new unit constructed at an existing site for various new reactor technologies. Applying the DOE study analysis to Units 6 & 7 for two AP1000 units, it is estimated that the onsite operations workforce would be 403 personnel for each unit, or 806 personnel for the purpose of this ER. Fifty percent of the operations workforce is assumed to be recruited and trained from outside the Miami-Dade metropolitan area.

It is assumed that operations staffing would begin approximately 2 years before fuel load of Unit 6 to allow time for simulator training and startup testing support and increase to the full complement of personnel at the time of Unit 7 operation. Figure 3.10-2 graphically illustrates the operations workforce by month. Figure 3.10-3 illustrates the combined construction and operations workforce, by month, through initiation of Units 6 & 7 commercial operation.

Technical Specifications

PLANT SPECIFIC TECHNICAL SPECIFICATIONS (PSTS)

The AP1000 Generic Technical Specifications (GTS) and Bases of the referenced DCD (See FSAR Table 1.6-201) Section 16.1 are incorporated by reference into these plant specific technical specifications (PSTS) with the following departures and/or supplements. Section A addresses the completion of the bracketed information from the DCD GTS and Bases in response to COL information item 16.1-1. Section B provides a complete copy of the PSTS and Bases suitable for enclosing with the Combined License.

Section A. PSTS and Bases Differences from the DCD GTS and Bases (PTN COL 16.1-1)

1. All generic bracketed items in the GTS and Bases have been completed. Plant-specific bracketed items are addressed in Section A.2.
2. The remaining bracketed items in the GTS and Bases are plant specific and are addressed as follows. PSTS pages reflecting each PSTS change to the DCD GTS and Bases are provided in the Section B clean copy.

GTS 4.1

The bracketed information in the GTS reads:
[Not applicable to AP1000 Design Certification. Site specific information to be provided by the COL applicant.]

Replace the bracketed information in the GTS with the following:
The site is located approximately 25 miles south of Miami, 8 miles east of Florida City, and 9 miles southeast of Homestead, Florida.

Justification:
Bracketed information is replaced to establish the site location consistent with the site location identified in FSAR Section 2.1.1.1.

GTS 4.1.1

The bracketed information in the GTS reads:

[This information will be provided by the combined license applicant.]

Replace the bracketed information in the GTS with the following:
The Site Boundary is shown in Figure 4.1-1. The Exclusion Area Boundary is shown in Figure 4.1-2.

Justification:
Bracketed information is replaced to establish Site Boundary and Exclusion Area Boundary for PTN consistent with the descriptions identified in FSAR Sections 2.1.1.2 and 2.1.2

GTS 4.1.2

The bracketed information in the GTS reads:
[This information will be provided by the combined license applicant.]

Replace the bracketed information in the GTS with the following:
The LPZ is defined by the 5 mile radius from the site center point as shown in Figure 4.1-1.

Justification:
Bracketed information is replaced to establish the LPZ for PTN consistent with the descriptions identified in FSAR Section 2.1.2.

GTS 5.1.1

The bracketed information in the GTS reads:
The [Plant Manager] shall be responsible for overall unit operations and shall delegate in writing the succession to this responsibility during his absence.

The [Plant Manager] or his designee shall approve, prior to implementation, each proposed test, experiment or modification to systems or equipment that affect nuclear safety.

Replace the bracketed information in the GTS with the following:
The plant manager shall be responsible for overall unit operations and shall delegate in writing the succession to this responsibility during his absence. The plant manager or his designee shall approve, prior to implementation, each proposed test, experiment or modification to systems or equipment that affect nuclear safety.

Justification:
Generic titles are used consistent with the FSAR organization description in FSAR Section 13.1 and with WOG STS Revision 3.1.

GTS 5.1.2

The bracketed information in the GTS reads:
The [Shift Supervisor (SS)] shall be responsible for the control room command function. During any absence of the [SS] from the control room while the unit is in MODE 1, 2, 3, or 4, an individual with an active Senior Reactor Operator (SRO) license shall be designated to assume the control room command function. During any absence of the [SS] from the control room while the unit is in MODE 5 or 6, an individual with an active SRO license or Reactor Operator license shall be designated to assume the control room command function.

Replace the bracketed information in the GTS with the following:
The shift manager (SM) shall be responsible for the control room command function. During any absence of the SM from the control room while the unit is in MODE 1, 2, 3, or 4, an individual with an active Senior Reactor Operator (SRO) license shall be designated to assume the control room command function. During any absence of the SM from the control room while the unit is in MODE 5 or 6, an individual with an active SRO license or Reactor Operator license shall be designated to assume the control room command function.

Justification:
Generic titles are used consistent with the FSAR organization description in Section 13.1.

GTS 5.2.1.a

The bracketed information in the GTS reads:
These requirements including the plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the [FSAR/QA Plan].

Replace the bracketed information in the GTS with the following:
These requirements including the plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the FSAR.

Justification:
FPL has established that these requirements will be documented in the FSAR.

GTS 5.2.1.b

The bracketed information in the GTS reads:
The [Plant Manager] shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant.

Replace the bracketed information in the GTS with the following:
The plant manager shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant.

Justification:
Generic titles are used consistent with the FSAR organization description in Section 13.1.

GTS 5.2.2

The bracketed information in the GTS reads:
REVIEWER'S NOTE – [Determination of the unit staff positions, numbers, and qualifications are the responsibility of the COL applicant. Input provided in WCAP-14694, Revision 0, for the MCR staff and WCAP-14655, Revision 1, for other than the MCR staff will be used in the determination. Each of the following paragraphs may need to be corrected to specify the plant staffing requirements.]

Remove the reviewer's note information in the GTS. There is no replacement language.

Justification:
The reviewer's note information for this specification is deleted because it is not intended to be a part of the plant specific technical specifications.

GTS 5.2.2

The bracketed information in the GTS reads:
[The unit staff organization shall include the following:
a. A non-licensed operator shall be assigned to each reactor containing fuel and an … b., c., d., e., f. …Policy Statement on Engineering Expertise on Shift.]

Remove the brackets and adopt the bracketed information in the GTS except that 5.2.2.d is omitted, 5.2.2.e and 5.2.2.f are renumbered as 5.2.2.d and 5.2.2.e, respectively, and reference to 5.2.2.f in 5.2.2.b is renumbered as 5.2.2.e.

Justification:
Generic TS bracketed information is applicable and adopted except for GTS 5.2.2.d which is no longer necessary due to revisions to Part 26 since the approval of the GTS. The removal of GTS 5.2.2.d is consistent with TSTF-511 identified by the NRC as an appropriate change to implement the revisions to Part 26 (See 73 FR 79923, Notice of Availability of Model Safety Evaluation, Model No Significant Hazards Determination, and Model Application for Licensees That Wish To Adopt TSTF-511, Revision 0, "Eliminate Working Hour Restrictions From TS 5.2.2 To Support Compliance With 10 CFR Part 26"). Deletion of 5.2.2.d requires renumbering of subsequent steps and associated references.

GTS 5.3

The bracketed information in the GTS reads:
- REVIEWER'S NOTE - [Minimum qualifications for members of the unit staff shall be specified by use of an overall qualification statement referencing an ANSI Standard acceptable to the NRC staff or by specifying individual position qualifications. Generally, the first method is preferable; however, the second method is adaptable to those unit staffs requiring special qualification statements because of unique organizational structures.]

Remove the reviewer's note information in the GTS. There is no replacement language.

Justification:
The reviewer's note information for this specification is deleted because it is not intended to be a part of the plant specific technical specifications.

GTS 5.3.1

The bracketed information in the GTS reads:
Each member of the unit staff shall meet or exceed the minimum qualifications of [Regulatory Guide 1.8, Revision 2, 1987, or more recent revisions, or ANSI Standards acceptable to the NRC staff].[The staff not covered by Regulatory Guide 1.8 shall meet or exceed the minimum qualifications of Regulations, Regulatory Guides, or ANSI Standards acceptable to NRC staff.]
Replace the bracketed information in the GTS with the following:
Each member of the unit staff shall meet or exceed the minimum qualifications of Regulatory Guide 1.8, Revision 3, 2000, with the following exception:
a. During cold license operator training through the first refueling outage, the Regulatory Position C.1.b of Regulatory Guide 1.8, Revision 2, 1987, applies: cold license operator candidates meet the training elements defined in ANSI/ANS 3.1-1993 but are exempt from the experience requirements defined in ANSI/ANS 3.1-1993.
Justification: There are no unit staff members with required qualifications not covered by those identified in Regulatory Guide 1.8, Revision 3. As such, the second sentence is unnecessary.
Qualification requirements are part of Regulatory Guide 1.8 however Revision 3 does not address cold license operators. Therefore, this exception is included.

GTS 5.6.1

The bracketed information in the GTS reads:
[The initial report shall be submitted by April 30 of the year following the initial criticality.]

Remove the brackets and adopt the bracketed information in the GTS.

Justification:
Generic TS bracketed information is applicable and adopted.

GTS 5.6.2

The bracketed information in the GTS reads:
The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements [in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979].

Remove the brackets and adopt the bracketed information in the GTS.

Justification:
Generic TS bracketed information is applicable and adopted.

GTS B3.3.1

The Bases for Specification 3.3.1 (Background) contain a Reviewer Note which addresses future confirmation of chosen setpoints.

Remove the reviewer note in the PSTS. There is no replacement language.

Justification:
The reviewer's note information for this specification is deleted because it is not intended to be a part of technical specifications.

GTS B3.3.2

The Bases for Specification 3.3.2 (Background) contain a Reviewer Note which addresses future confirmation of chosen setpoints.

Remove the reviewer note in the PSTS. There is no replacement language.

Justification:
The reviewer's note information for this specification is deleted because it is not intended to be a part of specifications.

GTS B3.6.8

The Bases for Specification 3.6.8 contain a bracketed figure which addresses the anticipated time prior to coolant inventory boiling under various conditions.

Remove the reviewer note in the PSTS. There is no replacement language.

Justification:
The information is applicable as provided since no major departures from the certified design have been taken.

Section B. Complete Copy of PSTS and Bases

A complete copy of the PSTS and Bases is provided in this section. The copy provided herein incorporates the plant specific information to replace GTS and Bases bracketed information as discussed in Section A above.

TABLE OF CONTENTS / REVISION SUMMARY Revision

1.0 USE AND APPLICATION
1.1 Definitions ..... FSAR 6
1.2 Logical Connectors ..... FSAR 6
1.3 Completion Times ..... FSAR 6
1.4 Frequency ..... FSAR 6

2.0 SAFETY LIMITS (SLs)
2.1 SLs ..... FSAR 6
2.2 SL Violations ..... FSAR 6

3.0 LIMITING CONDITIONS FOR OPERATION (LCO) APPLICABILITY ..... FSAR 6
3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY ..... FSAR 6

3.1 REACTIVITY CONTROL SYSTEMS
3.1.1 SHUTDOWN MARGIN (SDM) ..... FSAR 6
3.1.2 Core Reactivity ..... FSAR 6
3.1.3 Moderator Temperature Coefficient (MTC) ..... FSAR 6
3.1.4 Rod Group Alignment Limits ..... FSAR 6
3.1.5 Shutdown Bank Insertion Limits ..... FSAR 6
3.1.6 Control Bank Insertion Limits ..... FSAR 6
3.1.7 Rod Position Indication ..... FSAR 6
3.1.8 PHYSICS TESTS Exceptions – MODE 2 ..... FSAR 6
3.1.9 Chemical and Volume Control System (CVS) Demineralized Water Isolation Valves and Makeup Line Isolation Valves ..... FSAR 6

3.2 POWER DISTRIBUTION LIMITS
3.2.1 Heat Flux Hot Channel Factor ($F_Q(Z)$) (F_Q Methodology) ..... FSAR 6
3.2.2 Nuclear Enthalpy Rise Hot Channel Factor ($F^N_{\Delta H}$) ..... FSAR 6
3.2.3 AXIAL FLUX DIFFERENCE (AFD) (Relaxed Axial Offset Control (RAOC) Methodology) ..... FSAR 6
3.2.4 QUADRANT POWER TILT RATIO (QPTR) ..... FSAR 6
3.2.5 OPDMS-Monitored Parameters ..... FSAR 6

3.3 INSTRUMENTATION
3.3.1 Reactor Trip System (RTS) Instrumentation ..... FSAR 6
3.3.2 Engineered Safety Feature Actuation System (ESFAS) Instrumentation ..... FSAR 6
3.3.3 Post Accident Monitoring (PAM) Instrumentation ..... FSAR 6
3.3.4 Remote Shutdown Workstation (RSW) ..... FSAR 6
3.3.5 Diverse Actuation System (DAS) Manual Controls ..... FSAR 6

3.4 REACTOR COOLANT SYSTEM (RCS)
3.4.1 RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits ..... FSAR 6
3.4.2 RCS Minimum Temperature for Criticality ..... FSAR 6
3.4.3 RCS Pressure and Temperature (P/T) Limits ..... FSAR 6

TABLE OF CONTENTS / REVISION SUMMARY Revision

1.0 USE AND APPLICATION

1.1 Definitions

- NOTE -

The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

Term	Definition
ACTIONS	ACTIONS shall be that part of a Specification that prescribes Required Actions to be taken under designated Conditions within specified Completion Times.
ACTUATION DEVICE TEST	An ACTUATION DEVICE TEST is a test of the actuated equipment. This test may consist of verification of actual operation but shall, at a minimum, consist of a continuity check of the associated actuated devices. The ACTUATION DEVICE TEST shall be conducted such that it provides component overlap with the ACTUATION LOGIC TEST.
ACTUATION LOGIC TEST	An ACTUATION LOGIC TEST shall be the application of various simulated or actual input combinations in conjunction with each possible interlock logic state and the verification of the required logic output. The ACTUATION LOGIC TEST shall be conducted such that it provides component overlap with the ACTUATION DEVICE TEST.
AXIAL FLUX DIFFERENCE (AFD)	AFD shall be the difference in normalized flux signals between the top and bottom halves of a two-section excore neutron detector.
CHANNEL CALIBRATION	A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel so that it responds within the required range and accuracy to known values of the parameter that the channel monitors. The CHANNEL CALIBRATION shall encompass all devices in the channel required for OPERABILITY. Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an inplace qualitative assessment of sensor behavior and normal calibration of the remaining adjustable

1.1 Definitions

CHANNEL CALIBRATION (continued)	
	devices in the channel. The CHANNEL CALIBRATION may be performed by means of any series of sequential, overlapping, or total channel steps.
CHANNEL CHECK	A CHANNEL CHECK shall be the qualitative assessment, by observation, of channel behavior during operation. This determination shall include, where possible, comparison of the channel indication and status to other indications or status derived from independent instrument channels measuring the same parameter.
CHANNEL OPERATIONAL TEST (COT)	A COT shall be the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify the OPERABILITY of all devices in the channel required for channel OPERABILITY. The COT shall include adjustments, as necessary, of the required alarm, interlock, and trip setpoints required for channel OPERABILITY such that the setpoints are within the necessary range and accuracy. The COT may be performed by means of any series of sequential, overlapping, or total channel steps.
CORE ALTERATION	CORE ALTERATION shall be the movement of any fuel, sources, or reactivity control components, within the reactor vessel with the vessel head removed and fuel in the vessel. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.
CORE OPERATING LIMITS REPORT (COLR)	The COLR is the unit specific document that provides cycle specific parameter limits for the current reload cycle. These cycle specific parameter limits shall be determined for each reload cycle in accordance with Specification 5.6.5. Plant operation within these parameter limits is addressed in individual Specifications.
DOSE EQUIVALENT I-131	DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries/gram) that alone would produce the same committed effective dose equivalent as the quantity and isotopic mixture of I-130, I-131, I-132, I-133, I-134, and I-135 actually present. The dose conversion factors used for this calculation shall be those listed in Table 2.1 of EPA Federal Guidance Report No. 11, “Limiting Values of Radionuclide

1.1 Definitions

DOSE EQUIVALENT I-131 (continued)

Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion, and Ingestion," EPA-520/ 1-88-020, September 1988.

DOSE EQUIVALENT XE-133

DOSE EQUIVALENT XE-133 shall be that concentration of Xe-133 (microcuries per gram) that alone would produce the same effective dose equivalent as the quantity and isotopic mixture of noble gases (Kr-85m, Kr-85, Kr-87, Kr-88, Xe-131m, Xe-133m, Xe-133, Xe-135m, Xe-135, and Xe-138) actually present. The dose conversion factors used for this calculation shall be those listed in Table III.1 of EPA Federal Guidance Report No. 12, "External Exposure to Radionuclides in Air, Water, and Soil," EPA 402-R-93-081, September 1993.

ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME

The ESF RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions). The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

LEAKAGE

LEAKAGE shall be:

a. <u>Identified LEAKAGE</u>

1. LEAKAGE, such as that from seals or valve packing, that is captured and conducted to collection systems or a sump or collecting tank;

2. LEAKAGE into the containment atmosphere from sources that are both specifically located and known either not to interfere with the operation of leakage detection systems or not to be pressure boundary LEAKAGE;

1.1 Definitions

LEAKAGE (continued)

3. Reactor Coolant System (RCS) LEAKAGE through a steam generator (SG) to the Secondary System (primary to secondary LEAKAGE); or

4. RCS LEAKAGE through the passive residual heat removal heat exchanger (PRHR HX) to the In-containment Refueling Water Storage Tank (IRWST).

b. Unidentified LEAKAGE

All LEAKAGE that is not identified LEAKAGE.

c. Pressure Boundary LEAKAGE

LEAKAGE (except primary to secondary LEAKAGE and PRHR HX tube LEAKAGE) through a nonisolatable fault in a RCS component body, pipe wall, or vessel wall.

MODE

A MODE shall correspond to any one inclusive combination of core reactivity condition, power level, average reactor coolant temperature, and reactor vessel head closure bolt tensioning specified in Table 1.1-1 with fuel in the reactor vessel.

OPERABLE-OPERABILITY

A system, subsystem, train, component, or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified safety function(s) and when all necessary attendant instrumentation, controls, normal or emergency electrical power, cooling and seal water, lubrication, and other auxiliary equipment that are required for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s).

PHYSICS TESTS

PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation. These tests are:

a. Described in Chapter 14, Initial Test Program;

b. Authorized under the provisions of 10 CFR 50.59; or

c. Otherwise approved by the Nuclear Regulatory Commission.

1.1 Definitions

PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)	The PTLR is the unit specific document that provides the reactor vessel pressure and temperature limits, including heatup and cooldown rates, for the current reactor vessel fluence period. These pressure and temperature limits shall be determined for each fluence period in accordance with Specification 5.6.6. Plant operation within these operating limits is addressed in LCO 3.4.3, “RCS Pressure and Temperature (P/T) Limits” and LCO 3.4.14, “Low Temperature Overpressure Protection (LTOP) System.”
QUADRANT POWER TILT RATIO (QPTR)	QPTR shall be the ratio of the maximum upper excore detector calibrated output to the average of the upper excore detector calibrated outputs, or the ratio of maximum lower excore detector calibrated output to the average of the lower excore detector calibrated outputs, whichever is greater.
RATED THERMAL POWER (RTP)	RTP shall be a total reactor core heat transfer rate to the reactor coolant of 3400 MWt.
REACTOR TRIP CHANNEL OPERATIONAL TEST (RTCOT)	A RTCOT shall be the injection of a simulated or actual signal into the reactor trip channel as close to the sensor as practicable to verify OPERABILITY of the required interlock and/or trip functions. The RTCOT may be performed by means of a series of sequential, overlapping, or total channel steps so that the entire channel is tested from the signal conditioner through the trip logic.
REACTOR TRIP SYSTEM (RTS) RESPONSE TIME	The RTS RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its RTS trip setpoint at the channel sensor until loss of stationary gripper coil voltage. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.
SHUTDOWN MARGIN (SDM)	SDM shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming: a. All rod cluster control assemblies (RCCAs) are fully inserted except for the single assembly of highest reactivity worth, which is assumed to be fully withdrawn.

1.1 Definitions

SHUTDOWN MARGIN (continued)	However, with all RCCAs verified fully inserted by two independent means, it is not necessary to account for a stuck RCCA in the SDM calculation. With any RCCAs not capable of being fully inserted, the reactivity worth of these assemblies must be accounted for in the determination of SDM; and b. In MODES 1 and 2, the fuel and moderator temperatures are changed to the nominal zero power design level. c. In MODE 2 with k_{eff} < 1.0, and MODES 3, 4, and 5, the worth of fully inserted Gray Rod Cluster Assemblies (GRCAs) will be included in the SDM calculation.
STAGGERED TEST BASIS	A STAGGERED TEST BASIS shall consist of the testing of one of the systems, subsystems, channels, or other designated components during the interval specified by the Surveillance Frequency, so that all systems, subsystems, channels, or other designated components are tested during n Surveillance Frequency intervals, where n is the total number of systems, subsystems, channels, or other designated components in the associated function.
THERMAL POWER	THERMAL POWER shall be the total reactor core heat transfer rate to the reactor coolant.
TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT)	A TADOT shall consist of operating the trip actuating device and verifying the OPERABILITY of all devices in the channel required for trip actuating device OPERABILITY. The TADOT shall include adjustment, as necessary, of the trip actuating device so that it actuates at the required setpoint within the required accuracy. The TADOT may be performed by means of any series of sequential, overlapping, or total channel steps.

Table 1.1-1 (page 1 of 1)
MODES

MODES	TITLE	REACTIVITY CONDITION (k_{eff})	% RATED THERMAL POWER[(a)]	AVERAGE REACTOR COOLANT TEMPERATURE (°F)
1	Power Operation	≥ 0.99	> 5	NA
2	Startup	≥ 0.99	≤ 5	NA
3	Hot Standby	< 0.99	NA	> 420
4	Safe Shutdown[(b)]	< 0.99	NA	420 ≥ T_{avg} > 200
5	Cold Shutdown[(b)]	< 0.99	NA	≤ 200
6	Refueling[(c)]	NA	NA	NA

(a) Excluding decay heat.

(b) All reactor vessel head closure bolts fully tensioned.

(c) One or more reactor vessel head closure bolts less than fully tensioned.

1.0 USE AND APPLICATION

1.2 Logical Connectors

PURPOSE	The purpose of this section is to explain the meaning of logical connectors. Logical connectors are used in Technical Specifications to discriminate between, and yet connect, discrete Conditions, Required Actions, Completion Times, Surveillances, and Frequencies. The only logical connectors that appear in Technical Specifications are AND and OR. The physical arrangement of these connectors constitutes logical conventions with specific meaning.
BACKGROUND	Several levels of logic may be used to state Required Actions. These levels are identified by the placement (or nesting) of the logical connectors and the number assigned to each Required Action. The first level of logic is identified by the first digit of the number assigned to a Required Action and the placement of the logical connector in the first level of nesting (i.e., left justified with the number of the Required Action). The successive levels of logic are identified by additional digits of the Required Action number and by successive indentions of the logical connectors. When logical connectors are used to state a Condition, Completion Time, Surveillance, or Frequency, only the first level of logic is used, and the logical connector is left justified with the statement of the Condition, Completion Time, Surveillance, or Frequency.
EXAMPLES	The following examples illustrate the use of logical connectors.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Verify . . . AND A.2 Restore . . .	

In this example, the logical connector AND is used to indicate that when in Condition A, both Required Actions A.1 and A.2 must be completed.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Trip ... OR A.2.1 Verify ... AND A.2.2.1 Reduce ... OR A.2.2.2 Perform ... OR A.3 Align ...	

This example represents a more complicated use of logical connectors. Required Actions A.1, A.2, and A.3 are alternative choices, only one of which must be performed as indicated by the use of the logical connector OR and the left justified placement. Any one of these three Actions may be chosen. If A.2 is chosen, then both A.2.1 and A.2.2 must be performed as indicated by the logical connector AND. Required Action A.2.2 is met by performing A.2.2.1 or A.2.2.2. The indented position of the logical connector OR indicates that A.2.2.1 and A.2.2.2 are alternative choices, only one of which must be performed.

1.0 USE AND APPLICATION

1.3 Completion Times

PURPOSE

The purpose of this section is to establish the Completion Time convention and to provide guidance for its use.

BACKGROUND

Limiting Conditions for Operation (LCOs) specify minimum requirements for ensuring safe operation of the unit. The ACTIONS associated with an LCO state Conditions that typically describe the ways in which the requirements of the LCO can fail to be met. Specified with each stated Condition are Required Action(s) and Completion Time(s).

DESCRIPTION

The Completion Time is the amount of time allowed for completing a Required Action. It is referenced to the time of discovery of a situation (e.g., inoperable equipment or variable not within limits) that requires entering an ACTIONS Condition unless otherwise specified, providing the unit is in a MODE or specified condition stated in the Applicability of the LCO. Required Actions must be completed prior to the expiration of the specified Completion Time. An ACTIONS Condition remains in effect and the Required Actions apply until the Condition no longer exists or the unit is not within the LCO Applicability.

If situations are discovered that require entry into more than one Condition at a time within a single LCO (multiple Conditions), the Required Actions for each Condition must be performed within the associated Completion Time. When in multiple Conditions, separate Completion Times are tracked for each Condition starting from the time of discovery of the situation that required entry into the Condition.

Once a Condition has been entered, subsequent trains, subsystems, components, or variables expressed in the Condition, discovered to be inoperable or not within limits, will not result in separate entry into the Condition, unless specifically stated. The Required Actions of the Condition continue to apply to each additional failure, with Completion Times based on initial entry into the Condition.

However, when a subsequent train, subsystem, component, or variable, expressed in the Condition, is discovered to be inoperable or not within

1.3 Completion Times

DESCRIPTION (continued)

limits, the Completion Time(s) may be extended. To apply this Completion Time extension, two criteria must first be met. The subsequent inoperability:

a. Must exist concurrent with the first inoperability; and

b. Must remain inoperable or not within limits after the first inoperability is resolved.

The total Completion Time allowed for completing a Required Action to address the subsequent inoperability shall be limited to the more restrictive of either:

a. The stated Completion Time, as measured from the initial entry into the Condition, plus an additional 24 hours; or

b. The stated Completion Time as measured from discovery of the subsequent inoperability.

The above Completion Time extensions do not apply to those Specifications that have exceptions that allow completely separate re-entry into the Condition (for each train, subsystem, component, or variable expressed in the Condition) and separate tracking of Completion Times based on this re-entry. These exceptions are stated in individual Specifications.

The above Completion Time extension does not apply to a Completion Time with a modified “time zero.” This modified “time zero” may be expressed as a repetitive time (i.e., “once per 8 hours,” where the Completion Time is referenced from a previous completion of the Required Action versus the time of Condition entry) or as a time modified by the phrase “from discovery ....” Example 1.3-3 illustrates one use of this type of Completion Time. The 10 day Completion Time specified for Conditions A and B in example 1.3-3 may not be extended.

1.3 Completion Times

EXAMPLES The following examples illustrate the use of Completion Times with different types of Conditions and changing Conditions.

EXAMPLE 1.3-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

Condition B has two Required Actions. Each Required Action has its own separate Completion Time. Each Completion Time is referenced to the time that Condition B is entered.

The Required Actions of Condition B are to be in MODE 3 within 6 hours AND in MODE 5 in 36 hours. A total of 6 hours is allowed for reaching MODE 3 and a total of 36 hours (not 42 hours) is allowed for reaching MODE 5 from the time that Condition B was entered. If MODE 3 is reached within 3 hours, the time allowed for reaching MODE 5 is the next 33 hours because the total time allowed for reaching MODE 5 is 36 hours.

If Condition B is entered while in MODE 3, the time allowed for reaching MODE 5 is the next 36 hours.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One valve inoperable.	A.1 Restore valve to OPERABLE status.	7 days
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

When a valve is declared inoperable, Condition A is entered. If the valve is not restored to OPERABLE status within 7 days, Condition B is also entered and the Completion time clocks for Required Actions B.1 and B.2 start. If the inoperable valve is restored to OPERABLE status after Condition B is entered, Condition A and B are exited, and therefore, the Required Actions of Condition B may be terminated.

When a second valve is declared inoperable while the first valve is still inoperable, Condition A is not re-entered for the second valve. LCO 3.0.3 is entered, since the ACTIONS do not include a Condition for more than one inoperable valve. The Completion Time clock for Condition A does not stop after LCO 3.0.3 is entered, but continues to be tracked from the time Condition A was initially entered.

While in LCO 3.0.3, if one of the inoperable valves is restored to OPERABLE status and the Completion Time for Condition A has not expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition A.

While in LCO 3.0.3, if one of the inoperable valves is restored to OPERABLE status and the Completion Time for Condition A has expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition B. The Completion Time for Condition B is tracked from the time the Condition A Completion Time expired.

1.3 Completion Times

EXAMPLES (continued)

On restoring one of the valves to OPERABLE status the Condition A Completion Time is not reset, but continues from the time the first valve was declared inoperable. This Completion Time may be extended if the valve restored to OPERABLE status was the first inoperable valve. A 24 hour extension to the stated 7 days is allowed, provided this does not result in the second valve being inoperable for > 7 days.

EXAMPLE 1.3-3

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One Function X train inoperable.	A.1 Restore Function X train to OPERABLE status.	7 days AND 10 days from discovery of failure to meet the LCO
B. One Function Y train inoperable.	B.1 Restore Function Y train to OPERABLE status.	72 hours AND 10 days from discovery of failure to meet the LCO
C. One Function X train inoperable. AND One Function Y train inoperable.	C.1 Restore Function X train to OPERABLE status. OR C.2 Restore Function Y train to OPERABLE status.	72 hours 72 hours

When one Function X train and one Function Y train are inoperable, Condition A and Condition B are concurrently applicable. The Completion

1.3 Completion Times

EXAMPLES (continued)

Times for Condition A and Condition B are tracked separately for each train starting from the time each train was declared inoperable and the Condition was entered. A separate Completion Time is established for Condition C and tracked from the time the second train was declared inoperable (i.e., the time the situation described in Condition C was discovered).

If Required Action C.2 is completed within the specified Completion Time, Conditions B and C are exited. If the Completion Time for Required Action A.1 has not expired, operation may continue in accordance with Condition A. The remaining Completion Time in Condition A is measured from the time the affected train was declared inoperable (i.e., initial entry into Condition A).

The Completion Times of Conditions A and B are modified by a logical connector with a separate 10 day Completion Time measured from the time it was discovered the LCO was not met. In this example, without the separate Completion Time, it would be possible to alternate between Conditions A, B, and C in such a manner that operation could continue indefinitely without ever restoring systems to meet the LCO. The separate Completion Time modified by the phrase “from discovery of failure to meet the LCO” is designed to prevent indefinite continued operation while not meeting the LCO. This Completion Time allows for an exception to the normal “time zero” for beginning the Completion Time “clock.” In this instance, the Completion Time “time zero” is specified as commencing at the time the LCO was initially not met, instead of at the time the associated Condition was entered.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-4

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve(s) to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

A single Completion Time is used for any number of valves inoperable at the same time. The Completion Time associated with Condition A is based on the initial entry into Condition A and is not tracked on a per valve basis. Declaring subsequent valves inoperable, while Condition A is still in effect, does not trigger the tracking of separate Completion Times.

Once one of the valves has been restored to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first valve was declared inoperable. The Completion Time may be extended if the valve restored to OPERABLE status was the first inoperable valve. The Condition A Completion Time may be extended for up to 4 hours provided this does not result in any subsequent valve being inoperable for > 4 hours. If the Completion Time of 4 hours (including the extension) expires while one or more valves are still inoperable, Condition B is entered.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-5

ACTIONS

- NOTE -
Separate Condition entry is allowed for each inoperable valve.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4.	6 hours 12 hours

The Note above the ACTIONS Table is a method of modifying how the Completion Time is tracked. If this method of modifying how the Completion Time is tracked was only applicable to a specific Condition, the Note would appear in that Condition rather than at the top of the ACTIONS Table.

The Note allows Condition A to be entered separately for each inoperable valve, and Completion Times tracked on a per valve basis. When a valve is declared inoperable, Condition A is entered and its Completion Time starts. If subsequent valves are declared inoperable, Condition A is entered for each valve and separate Completion Times start and are tracked for each valve.

If the Completion Time associated with a valve in Condition A expires, Condition B is entered for that valve. If the Completion Times associated with subsequent valves in Condition A expire, Condition B is entered separately for each valve and separate Completion Times start and are tracked for each valve. If a valve which caused entry into Condition B is restored to OPERABLE status, Condition B is exited for that valve. Since the Note in this example allows multiple Condition entry and tracking of separate Completion Times, Completion Time extensions do not apply.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-6

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One channel inoperable.	A.1 Perform SR 3.x.x.x. OR A.2 Reduce THERMAL POWER to ≤ 50% RTP.	Once per 8 hours 8 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours

Entry into Condition A offers a choice between Required Action A.1 or A.2. Required Action A.1 has a “once per” Completion Time, which qualifies for the 25% extension, per SR 3.0.2, to each performance after the initial performance. The initial 8 hours interval of Required Action A.1 begins when Condition A is entered and the initial performance of Required Action A.1 must be complete within the first 8 hour interval. If Required Action A.1 is followed, and the Required Action is not met within the Completion Time (plus the extension allowed by SR 3.0.2), Condition B is entered. If Required Action A.2 is followed and the Completion Time of 8 hours is not met, Condition B is entered.

If after entry into Condition B, Required Action A.1 or A.2 is met, Condition B is exited and operation may then continue in Condition A.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-7

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Verify affected subsystem isolated.	1 hour AND Once per 8 hours thereafter
	AND	
	A.2 Restore subsystem to OPERABLE status.	72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	AND	
	B.2 Be in MODE 5.	36 hours

Required Action A.1 has two Completion Times. The 1 hour Completion Time begins at the time the Condition is entered and each “Once per 8 hours thereafter” interval begins upon performance of Required Action A.1.

If after Condition A is entered, Required Action A.1 is not met within either the initial 1 hour, or any subsequent 8 hour interval from the previous performance (plus the extension allowed by SR 3.0.2), Condition B is entered. The Completion Time clock for Condition A does not stop after Condition B is entered, but continues from the time Condition A was initially entered. If Required Action A.1 is met after Condition B is entered, Condition B is exited and operation may continue in accordance with Condition A, provided the Completion Time for Required Action A.2 has not expired.

1.3 Completion Times

IMMEDIATE COMPLETION TIME	When “Immediately” is used as a Completion Time, the Required Action should be pursued without delay and in a controlled manner.

1.0 USE AND APPLICATION

1.4 Frequency

PURPOSE

The purpose of this section is to define the proper use and application of Frequency requirements.

DESCRIPTION

Each Surveillance Requirement (SR) has a specified Frequency in which the surveillance must be met in order to meet the associated LCO. An understanding of the correct application of the specified Frequency is necessary for compliance with the SR.

The “specified Frequency” is referred to throughout this section and each of the Specifications of Section 3.0, Surveillance Requirement (SR) Applicability. The “specified Frequency” consists of the requirements of the Frequency column of each SR as well as certain Notes in the Surveillance column that modify performance requirements.

Sometimes special situations dictate when the requirements of a Surveillance are to be met. They are “otherwise stated” conditions allowed by SR 3.0.1. They may be stated as clarifying Notes in the Surveillance, as part of the Surveillances, or both.

Situations where a Surveillance could be required (i.e., its Frequency could expire), but where it is not possible or not desired that it be performed until sometime after the associated LCO is within its Applicability, represent potential SR 3.0.4 conflicts. To avoid these conflicts, the SR (i.e., the Surveillance or the Frequency) is stated such that it is only “required” when it can be and should be performed. With an SR satisfied, SR 3.0.4 imposes no restriction.

The use of “met” or “performed” in these instances conveys specific meanings. A Surveillance is “met” only when the acceptance criteria are satisfied. Known failure of the requirements of a Surveillance, even without a Surveillance specifically being "performed," constitutes a Surveillance not “met.” “Performance” refers only to the requirement to specifically determine the ability to meet the acceptance criteria.

Some Surveillances contain notes that modify the Frequency of performance or the conditions during which the acceptance criteria must be satisfied. For these Surveillances, the MODE-entry restrictions of SR 3.0.4 may not apply. Such a Surveillance is not required to be

1.4 Frequency

DESCRIPTION (continued)

performed prior to entering a MODE or other specified condition in the Applicability of the associated LCO if any of the following three conditions are satisfied:

a. The Surveillance is not required to be met in the MODE or other specified condition to be entered; or

b. The Surveillance is required to be met in the MODE or other specified condition to be entered, but has been performed within the specified Frequency (i.e., it is current) and is known not to be failed; or

c. The Surveillance is required to be met, but not performed, in the MODE or other specified condition to be entered, and is known not to be failed.

Examples 1.4-3, 1.4-4, 1.4-5, and 1.4-6 discusses these special situations.

EXAMPLES The following examples illustrate the various ways that Frequencies are specified. In these examples, the Applicability of the LCO (LCO not shown) is MODES 1, 2, and 3.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-1

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Perform CHANNEL CHECK.	12 hours

Example 1.4-1 contains the type of SR most often encountered in the Technical Specifications (TS). The Frequency specifies an interval (12 hours) during which the associated surveillance must be performed at least one time. Performance of the surveillance initiates the subsequent interval. Although the Frequency is stated as 12 hours, an extension of the time interval to 1.25 times the stated Frequency is allowed by SR 3.0.2 for operational flexibility. The measurement of this interval continues at all times, even when the SR is not required to be met per SR 3.0.1 (such as when the equipment is inoperable, a variable is outside the specified limits, or the Unit is outside the Applicability of the LCO). If the interval specified by SR 3.0.2 is exceeded while the unit is in a MODE or other specified condition in the Applicability of the LCO, and the performance of the Surveillance is not otherwise modified (refer to Example 1.4-3), then SR 3.0.3 becomes applicable.

If the interval specified by SR 3.0.2 is exceeded while the unit is not in a MODE or other specified condition in the Applicability of the LCO for which performance of the SR is required, then SR 3.0.4 becomes applicable. The Surveillance must be performed within the Frequency requirements of SR 3.0.2, as modified by SR 3.0.3, prior to entry into the MODE or other specified condition or the LCO is considered not met (in accordance with SR 3.0.1) and LCO 3.0.4 becomes applicable.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-2

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Verify flow is within limits.	Once within 12 hours after ≥ 25% RTP AND 24 hours thereafter

Example 1.4-2 has two Frequencies. The first is a one time performance Frequency, and the second is of the type shown in Example 1.4-1. The logical connector "AND" indicates that both Frequency requirements must be met. Each time the reactor power is increased from a power level < 25% RTP to ≥ 25% RTP, the surveillance must be performed within 12 hours.

The use of "Once" indicates a single performance will satisfy the specified Frequency (assuming no other Frequencies are connected by "AND"). This type of Frequency does not qualify for the 25% extension allowed by SR 3.0.2. "Thereafter" indicates future performances must be established per SR 3.0.2, but only after a specified condition is first met (i.e., the "once" performance in this example). If reactor power decreases to < 25% RTP, the measurement of both intervals stops. New intervals start upon reactor power reaching 25% RTP.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-3

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
---------- **- NOTE -** Not required to be performed until 12 hours after ≥ 25% RTP. ----------	
Perform channel adjustment.	7 days

The interval continues, whether or not the unit operation is < 25% RTP between performances.

As the Note modifies the required performance of the Surveillance, it is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is < 25% RTP, this Note allows 12 hours after power reaches ≥ 25% RTP to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency." Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was < 25% RTP, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not exceed 12 hours with power ≥ 25% RTP.

Once the unit reaches 25% RTP, 12 hours would be allowed for completing the Surveillance. If the Surveillance were not performed within this 12 hour interval, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-4

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
---------- **- NOTE -** Only required to be met in MODE 1. ----------	
Verify leakage rates are within limits.	24 hours

Example 1.4-4 specifies that the requirements of this Surveillance do not have to be met until the unit is in MODE 1. The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an “otherwise stated” exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), but the unit was not in MODE 1, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES, even with the 24 hour Frequency exceeded, provided the MODE change was not made into MODE 1. Prior to entering MODE 1 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-5

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
---------- **- NOTE -** Only required to be performed in MODE 1. ---------- Perform complete cycle of the valve.	7 days

The interval continues, whether or not the unit operation is in MODE 1, 2, or 3 (the assumed Applicability of the associated LCO) between performances.

As the Note modifies the required performance of the Surveillance, the Note is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is not in MODE 1, this Note allows entry into and operation in MODES 2 and 3 to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency" if completed prior to entering MODE 1. Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was not in MODE 1, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not result in entry into MODE 1.

Once the unit reaches MODE 1, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance had been performed. If the Surveillance were not performed prior to entering MODE 1, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-6

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
--- **- NOTE -** Not required to be met in MODE 3. ---	
Verify parameter is within limits.	24 hours

Example 1.4-6 specifies that the requirements of this Surveillance do not have to be met while the unit is in MODE 3 (the assumed Applicability of the associated LCO is MODES 1, 2, and 3). The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an “otherwise stated” exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), and the unit was in MODE 3, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES to enter MODE 3, even with the 24 hour Frequency exceeded, provided the MODE change does not result in entry into MODE 2. Prior to entering MODE 2 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

2.0 SAFETY LIMITS (SLs)

2.1 SLs

2.1.1 Reactor Core SLs

In MODES 1 and 2, the combination of THERMAL POWER, Reactor Coolant System (RCS) highest loop cold leg temperature, and pressurizer pressure shall not exceed the limits specified in the COLR; and the following SLs shall not be exceeded:

2.1.1.1 The departure from nucleate boiling ratio (DNBR) shall be maintained ≥ 1.14 for the WRB-2M DNB correlation.

2.1.1.2 The peak fuel centerline temperature shall be maintained < 5080°F, decreasing by 58°F per 10,000 MWD/MTU of burnup.

2.1.2 RCS Pressure SL

In MODES 1, 2, 3, 4, and 5 the RCS pressure shall be maintained ≤ 2733.5 psig.

2.2 SL Violations

2.2.1 If SL 2.1.1 is violated, restore compliance and be in MODE 3 within 1 hour.

2.2.2 If SL 2.1.2 is violated:

2.2.2.1 In MODE 1 or 2, restore compliance and be in MODE 3 within 1 hour.

2.2.2.2 In MODE 3, 4, or 5, restore compliance within 5 minutes.

3.0 LIMITING CONDITIONS FOR OPERATION (LCO) APPLICABILITY

LCO 3.0.1 LCOs shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2.

LCO 3.0.2 Upon discovery of a failure to meet an LCO, the Required Actions of the associated Conditions shall be met, except as provided in LCO 3.0.5 and 3.0.6.

If the LCO is met, or is no longer applicable prior to expiration of the specified Completion Time(s), completion of the Required Action(s) is not required, unless otherwise stated.

LCO 3.0.3 When an LCO is not met and the associated ACTIONS are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in:

a. MODE 3 within 7 hours; and

b. MODE 4 within 13 hours; and

c. MODE 5 within 37 hours.

Exceptions to this Specification are stated in the individual Specifications.

Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required.

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

LCO 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall not be made except when the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time. This Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or are part of a shutdown of the unit.

Exceptions to this Specification are stated in the individual Specifications.

LCO 3.0.4 is only applicable for entry into a MODE or other specified condition in the Applicability in MODES 1, 2, 3, and 4.

3.0 LCO Applicability

LCO 3.0.5 Equipment removed from service or declared inoperable to comply with ACTIONS may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the test required to demonstrate OPERABILITY.

LCO 3.0.6 When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, additional evaluations and limitations may be required in accordance with Specification 5.5.7, “Safety Function Determination Program (SFDP).” If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

When a support system’s Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

LCO 3.0.7 Test Exception LCO 3.1.8 allows specified Technical Specification (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with Test Exception LCOs is optional. When a Test Exception LCO is desired to be met but is not met, the ACTIONS of the Test Exception LCO shall be met. When a Test Exception LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall be made in accordance with the other applicable Specifications.

LCO 3.0.8 When an LCO is not met and the associated ACTIONS are not met or an associated ACTION is not provided, action shall be initiated within 1 hour to:

a. Restore inoperable equipment and

b. Monitor Safety System Shutdown Monitoring Trees parameters

Exceptions to this Specification are stated in the individual Specifications.

3.0 LCO Applicability

LCO 3.0.8 (continued)

Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.8 is not required.

LCO 3.0.8 is only applicable in MODES 5 and 6.

3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

SR 3.0.1

SRs shall be met during the MODES or other specified Conditions in the Applicability of individual LCOs, unless otherwise stated in the SR. Failure to meet a Surveillance, whether such failure is experienced during the performance of the surveillance or between performances of the Surveillance, shall be a failure to meet the LCO. Failure to perform a Surveillance within the specified Frequency shall be failure to meet the LCO except as provided in SR 3.0.3. Surveillances do not have to be performed on inoperable equipment or variables outside specified limits.

SR 3.0.2

The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met.

For Frequencies specified as “once”, the above interval extension does not apply.

If a Completion Time requires periodic performance on a “once per...” basis, the above Frequency extension applies to each performance after the initial performance.

Exceptions to this Specification are stated in the individual Specifications.

SR 3.0.3

If it is discovered that a Surveillance was not performed within its specified Frequency, then compliance with the requirement to declare the LCO not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified Frequency, which ever is greater. This delay period is permitted to allow performance of the Surveillance. A risk evaluation shall be performed for any Surveillance delayed greater than 24 hours and the risk impact shall be managed.

If the Surveillance is not performed within the delay period, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

When the Surveillance is performed within the delay period, and the Surveillance is not met, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

3.0 SR Applicability

SR 3.0.4	Entry into a MODE or other specified condition in the Applicability of a LCO shall not be made unless the LCO's Surveillances have been met within their specified Frequency. This provision shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit. SR 3.0.4 is only applicable for entry into a MODE or other specified condition in the Applicability in MODES 1, 2, 3, and 4.

3.1 REACTIVITY CONTROL SYSTEMS

3.1.1 SHUTDOWN MARGIN (SDM)

LCO 3.1.1 The SDM shall be within the limits specified in the COLR.

APPLICABILITY: MODE 2 with $k_{eff} < 1.0$.
MODES 3, 4, and 5.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. SDM not within limits.	A.1 Initiate boration to restore SDM to within limits.	15 minutes

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.1.1	Verify SDM to be within limits.	24 hours

3.1 REACTIVITY CONTROL SYSTEMS

3.1.2 Core Reactivity

LCO 3.1.2 The measured core reactivity shall be within ±1% Δk/k of the normalized predicted values.

APPLICABILITY: MODES 1 and 2.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. Measured core reactivity not within limit.	A.1	Re-evaluate core design and safety analysis, and determine that the reactor core is acceptable for continued operation.	7 days
	AND		
	A.2	Establish appropriate operating restrictions and SRs.	7 days
B. Required Action and associated Completion Time not met.	B.1	Be in MODE 3.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.2.1	---------- **- NOTE -** The predicted reactivity values may be adjusted (normalized) to correspond to the measured core reactivity prior to exceeding a fuel burnup of 60 effective full power days (EFPD) after each fuel loading. ---------- Verify measured core reactivity is within ±1% Δk/k of predicted values.	Prior to entering MODE 1 after each refueling AND ---------- **- NOTE -** Only required after 60 EFPD ---------- 31 EFPD thereafter

3.1 REACTIVITY CONTROL SYSTEMS

3.1.3 Moderator Temperature Coefficient (MTC)

LCO 3.1.3 The MTC shall be maintained within the limits specified in the COLR.

APPLICABILITY: MODE 1 for the upper MTC limit.
MODE 2 with $k_{eff} \geq 1.0$ for the upper MTC limit.
MODES 1, 2, and 3 for the lower MTC limit.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. MTC not within upper limit.	A.1 Establish administrative withdrawal limits for control banks to maintain MTC within limit.	24 hours
B. Required Action and associated Completion Time of Condition A not met.	B.1 Be in MODE 2 with $k_{eff} < 1.0$.	6 hours
C. MTC not within lower limit.	C.1 Be in MODE 4.	12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.3.1	Verify MTC within upper limit.	Prior to entering MODE 1 after each refueling

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.1.3.2	---------- **- NOTES -** 1. Not required to be performed until 7 effective full power days (EFPD) after reaching the equivalent of an equilibrium RTP all rods out (ARO) boron concentration of 300 ppm. 2. If the MTC is more negative than the 300 ppm Surveillance limit (not LCO limit) specified in the COLR, SR 3.1.3.2 shall be repeated once per 14 EFPD during the remainder of the fuel cycle. 3. SR 3.1.3.2 need not be repeated if the MTC measured at the equivalent of equilibrium RTP-ARO boron concentration of ≤ 60 ppm is less negative than the 60 ppm Surveillance limit specified in the COLR. ---------- Verify MTC is within lower limit.	Once each cycle

3.1 REACTIVITY CONTROL SYSTEMS

3.1.4 Rod Group Alignment Limits

LCO 3.1.4 All shutdown and control rods shall be OPERABLE.

AND

Individual indicated rod positions shall be within 12 steps of their group step counter demand position.

- NOTE -

Not applicable to Gray Rod Cluster Assemblies (GRCAs) during GRCA bank sequence exchange with the On-Line Power Distribution Monitoring System (OPDMS) OPERABLE.

APPLICABILITY: MODES 1 and 2.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or more rod(s) inoperable.	A.1.1	Verify SDM to be within the limits specified in the COLR.	1 hour
	OR		
	A.1.2	Initiate boration to restore SDM within limit.	1 hour
	AND		
	A.2	Be in MODE 3.	6 hours
B. One rod not within alignment limits.	B.1	Restore rod, to within alignment limits.	8 hours with the OPDMS OPERABLE OR 1 hour with the OPDMS inoperable
	OR		

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	B.2.1.1 Verify SDM to be within the limits specified in the COLR. OR	1 hour
	B.2.1.2 Initiate boration to restore SDM within limit. AND	1 hour
	B.2.2 Reduce THERMAL POWER to ≤ 75% RTP. AND	2 hours
	B.2.3 Verify SDM is within the limits specified in the COLR. AND	Once per 12 hours
	B.2.4 ---------- **- NOTE -** Only required to be performed when OPDMS is inoperable. ---------- Perform SR 3.2.1.1 and SR 3.2.1.2. AND	72 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	B.2.5	---------- **- NOTE -** Only required to be performed when OPDMS is inoperable. ---------- Perform SR 3.2.2.1.	72 hours
		AND	
	B.2.6	Re-evaluate safety analyses and confirm results remain valid for duration of operation under these conditions.	5 days
C. Required Action and associated Completion Time of Condition B not met.	C.1	Be in MODE 3.	6 hours
D. More than one rod not within alignment limit.	D.1.1	Verify SDM is within the limits specified in the COLR.	1 hour
		OR	
	D.1.2	Initiate boration to restore required SDM to within limit.	1 hour
		AND	
	D.2	Be in MODE 3.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.4.1	Verify individual rod positions within alignment limit.	12 hours
SR 3.1.4.2	---------- **- NOTE -** Not applicable to GRCAs. ---------- Verify rod freedom of movement (trippability) by moving each rod not fully inserted in the core ≥ 10 steps in either direction.	92 days
SR 3.1.4.3	---------- **- NOTE -** Not applicable to GRCAs. ---------- Verify rod drop time of each rod, from the fully withdrawn position, is ≤ 2.47 seconds from the beginning of decay of stationary gripper coil voltage to dashpot entry, with: a. T_{avg} ≥ 500°F, and b. All reactor coolant pumps operating.	Prior to reactor criticality after each removal of the reactor head, and after each earthquake requiring plant shutdown

3.1 REACTIVITY CONTROL SYSTEMS

3.1.5 Shutdown Bank Insertion Limits

LCO 3.1.5 Each Shutdown Bank shall be within insertion limits specified in the COLR.

APPLICABILITY: MODES 1 and 2.

- NOTE -

This LCO is not applicable while performing SR 3.1.4.2.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or more shutdown banks not within limits.	A.1.1	Verify SDM is within the limits specified in the COLR.	1 hour
	OR		
	A.1.2	Initiate boration to restore SDM to within limit.	1 hour
	AND		
	A.2	Restore shutdown banks to within limits.	2 hours
B. Required Action and associated Completion Time not met.	B.1	Be in MODE 3.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.5.1	Verify each shutdown bank is within the insertion limits specified in the COLR.	12 hours

3.1 REACTIVITY CONTROL SYSTEMS

3.1.6 Control Bank Insertion Limits

LCO 3.1.6 Control banks shall be within the insertion, sequence, and overlap limits specified in the COLR.

APPLICABILITY: MODE 1.
MODE 2 with $k_{eff} \geq 1.0$.

- NOTES -

1. This LCO is not applicable while performing SR 3.1.4.2.

2. This LCO is not applicable to Gray Rod Cluster Assembly (GRCA) banks during GRCA bank sequence exchange with OPDMS OPERABLE.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Control Bank insertion limits not met.	A.1.1 Verify SDM is within the limits specified in the COLR. OR A.1.2 Initiate boration to restore SDM to within limit. AND A.2 Restore control bank(s) to within limits.	1 hour 1 hour 2 hours
B. Control bank sequence or overlap limits not met.	B.1.1 Verify SDM is within the limits specified in the COLR. OR	1 hour

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	B.1.2 Initiate boration to restore SDM to within limit. AND	1 hour
	B.2 Restore control bank sequence and overlap to within limits.	2 hours
C. Required Action and associated Completion Time not met.	C.1 Be in MODE 2 with $k_{eff} < 1.0$.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.6.1	Verify the estimated critical control bank position is within limits specified in the COLR.	Within 4 hours prior to achieving criticality
SR 3.1.6.2	Verify each control bank insertion is within the limits specified in the COLR.	12 hours
SR 3.1.6.3	Verify sequence and overlap limits, specified in the COLR, are met for control banks not fully withdrawn from the core.	12 hours

3.1 REACTIVITY CONTROL SYSTEMS

3.1.7 Rod Position Indication

LCO 3.1.7 The Digital Rod Position Indication (DRPI) System and the Bank Demand Position Indication System shall be OPERABLE.

APPLICABILITY: MODES 1 and 2.

ACTIONS

- NOTE -

Separate Condition entry is allowed for each inoperable rod position indicator and each demand position indicator.

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One DRPI per group inoperable for one or more groups.	A.1	Verify the position of the rods with inoperable position indicators by using the On-line Power Distribution Monitoring System (OPDMS).	Once per 8 hours
	OR		
	A.2	Reduce THERMAL POWER to ≤ 50% RTP.	8 hours
B. More than one DRPI per group inoperable.	B.1	Place the control rods under manual control.	Immediately
	AND		
	B.2	Monitor and record Reactor Coolant System (RCS) T_{avg}.	Once per 1 hour
	AND		

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	B.3 Verify the position of the rods with inoperable position indicators indirectly by using the incore detectors. AND	Once per 8 hours
	B.4 Restore inoperable position indicators to OPERABLE status such that a maximum of one DRPI per group is inoperable.	24 hours
C. One or more rods with inoperable position indicators have been moved in excess of 24 steps in one direction since the last determination of the rod's position.	C.1 Verify the position of the rods with inoperable position indicators by using the OPDMS. OR	4 hours
	C.2 Reduce THERMAL POWER to ≤ 50% RTP.	8 hours
D. One demand position indicator per bank inoperable for one or more banks.	D.1.1 Verify by administrative means all DRPIs for the affected banks are OPERABLE. AND	Once per 8 hours
	D.1.2 Verify the most withdrawn rod and the least withdrawn rod of the affected banks are ≤ 12 steps apart. OR	Once per 8 hours
	D.2 Reduce THERMAL POWER to ≤ 50% RTP.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Required Action and associated Completion Time not met.	E.1 Be in MODE 3.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.7.1	Verify each DRPI agrees within 12 steps of the group demand position for the full indicated range of rod travel.	Prior to criticality after each removal of the reactor head

3.1 REACTIVITY CONTROL SYSTEMS

3.1.8 PHYSICS TESTS Exceptions – MODE 2

LCO 3.1.8 During the performance of PHYSICS TESTS, the requirements of:

LCO 3.1.3 "Moderator Temperature Coefficient (MTC),"
LCO 3.1.4 "Rod Group Alignment Limits,"
LCO 3.1.5 "Shutdown Bank Insertion Limits,"
LCO 3.1.6 "Control Bank Insertion Limits," and
LCO 3.4.2 "RCS Minimum Temperature for Criticality"

may be suspended, and the number of required channels for LCO 3.3.1, "RTS Instrumentation," Functions 2, 3, 6, and 16.b, may be reduced to 3 provided:

a. Reactor Coolant System (RCS) lowest loop average temperature is ≥ 541°F,

b. SDM is within the limits specified in the COLR, and

c. THERMAL POWER is ≤ 5% RTP.

APPLICABILITY: During PHYSICS TESTS initiated in MODE 2.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. SDM not within limit.	A.1	Initiate boration to restore SDM to within limit.	15 minutes
	AND		
	A.2	Suspend PHYSICS TESTS exceptions.	1 hour
B. THERMAL POWER not within limit.	B.1	Open reactor trip breakers.	Immediately
C. RCS lowest loop average temperature not within limit.	C.1	Restore RCS lowest loop average temperature to within limit.	15 minutes

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
D. Required Action and Associated Completion Time of Condition C not met.	D.1 Be in MODE 3.	15 minutes

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.8.1	Perform a REACTOR TRIP CHANNEL OPERATIONAL TEST on power range and intermediate range channels per SR 3.3.1.8 and SR 3.3.1.9.	Prior to initiation of PHYSICS TESTS
SR 3.1.8.2	Verify the RCS lowest loop average temperature is ≥ 541°F.	30 minutes
SR 3.1.8.3	Verify THERMAL POWER is ≤ 5% RTP.	30 minutes
SR 3.1.8.4	Verify SDM is within the limits specified in the COLR.	24 hours

3.1 REACTIVITY CONTROL SYSTEMS

3.1.9 Chemical and Volume Control System (CVS) Demineralized Water Isolation Valves and Makeup Line Isolation Valves

LCO 3.1.9 Two CVS Demineralized Water Isolation Valves and two Makeup Line Isolation Valves shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, 4, and 5.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One CVS demineralized water isolation valve inoperable. OR One makeup line isolation valve inoperable. OR One CVS demineralized water isolation valve and one makeup line isolation valve inoperable.	A.1 Restore two CVS demineralized water isolation valves and two makeup line isolation valves to OPERABLE status.	72 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time of Condition not met. OR Two CVS demineralized water isolation valves inoperable. OR Two makeup line isolation valves inoperable.	B.1 ---------- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---------- Isolate the flow path from the demineralized water storage tank to the Reactor Coolant System by use of at least one closed manual or one closed and de-activated automatic valve.	1 hour

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.1.9.1	Verify two CVS demineralized water isolation valves and two makeup line isolation valves are OPERABLE by stroking the valve closed.	In accordance with the Inservice Testing Program

3.2 POWER DISTRIBUTION LIMITS

3.2.1 Heat Flux Hot Channel Factor ($F_Q(Z)$) (F_Q Methodology)

LCO 3.2.1 $F_Q(Z)$, as approximated by $F_Q^C(Z)$ and $F_Q^W(Z)$, shall be within the limits specified in the COLR.

APPLICABILITY: MODE 1 with On-line Power Distribution Monitoring System (OPDMS) inoperable.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. ---------- **- NOTE -** Required Action A.4 shall be completed whenever this Condition is entered. ---------- $F_Q^C(Z)$ not within limit.	A.1 Reduce THERMAL POWER ≥ 1% RTP for each 1% $F_Q^C(Z)$ exceeds limit.	15 minutes after each $F_Q^C(Z)$ determination
	AND	
	A.2 Reduce Power Range Neutron Flux – High trip setpoints ≥ 1% for each 1% $F_Q^C(Z)$ exceeds limit.	72 hours after each $F_Q^C(Z)$ determination
	AND	
	A.3 Reduce Overpower ΔT trip setpoints ≥ 1% for each 1% $F_Q^C(Z)$ exceeds limit.	72 hours after each $F_Q^C(Z)$ determination
	AND	
	A.4 Perform SR 3.2.1.1 and SR 3.2.1.2.	Prior to increasing THERMAL POWER above the limit of Required Action A.1

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
B. ---------- **- NOTE -** Required Action B.4 shall be completed whenever this Condition is entered. ---------- $F_Q^W(Z)$ not within limits.	B.1	Reduce AFD limits ≥ 1% for each 1% $F_Q^W(Z)$ exceeds limit.	4 hours
	AND		
	B.2	Reduce Power Range Neutron Flux – High trip setpoints ≥ 1% for each 1% that the maximum allowable power of the AFD limits is reduced.	72 hours
	AND		
	B.3	Reduce Overpower ΔT trip setpoints ≥ 1% for each 1% that the maximum allowable power of the AFD limits is reduced.	72 hours
	AND		
	B.4	Perform SR 3.2.1.1 and SR 3.2.1.2.	Prior to increasing THERMAL POWER above the maximum allowable power of the AFD limits
C. Required Action and associated Completion Time not met.	C.1	Be in MODE 2.	6 hours

SURVEILLANCE REQUIREMENTS

- NOTES -

1. During power escalation at the beginning of each cycle, THERMAL POWER may be increased until a power level for extended operation has been achieved at which a power distribution map is obtained.
2. If the OPDMS becomes inoperable while in MODE 1 these surveillances must be performed within 31 days of the last verification of OPDMS parameters.

SURVEILLANCE		FREQUENCY
SR 3.2.1.1	Verify $F_Q^C(Z)$ within limit.	Once after each refueling prior to THERMAL POWER exceeding 75% RTP AND Once within 12 hours after achieving equilibrium conditions after exceeding, by ≥ 10% RTP, the THERMAL POWER at which $F_Q^C(Z)$ was last verified AND 31 effective full power days (EFPD) thereafter

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.2.1.2	--- **- NOTE -** If $F_Q^W(Z)$ measurements indicate maximum over z $F_Q^C(Z)$ has increased since the previous evaluation of $F_Q^C(Z)$: a. Increase $F_Q^W(Z)$ by the greater of a factor of 1.02 or by an appropriate factor specified in the COLR and reverify $F_Q^W(Z)$ is within limits; or b. Repeat SR 3.2.1.2 once per 7 EFPD until two successive flux maps indicate maximum over z $F_Q^C(Z)$ has not increased. --- Verify $F_Q^W(Z)$ within limits.	Once after each refueling prior to THERMAL POWER exceeding 75% RTP AND Once within 12 hours after achieving equilibrium conditions after exceeding, by ≥ 10% RTP, the THERMAL POWER at which $F_Q^W(Z)$ was last verified AND 31 EFPD thereafter

3.2 POWER DISTRIBUTION LIMITS

3.2.2 Nuclear Enthalpy Rise Hot Channel Factor ($F^N_{\Delta H}$)

LCO 3.2.2 $F^N_{\Delta H}$ shall be within the limits specified in the COLR.

APPLICABILITY: MODE 1 with On-line Power Distribution Monitoring System (OPDMS) inoperable.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. ---------- **- NOTE –** Required Actions A.2 and A.3 must be completed whenever Condition A is entered. ---------- $F^N_{\Delta H}$ not within limits.	A.1.1	Restore $F^N_{\Delta H}$ to within limit.	4 hours
	OR		
	A.1.2.1	Reduce THERMAL POWER to < 50% RTP.	4 hours
	AND		
	A.1.2.2	Reduce Power Range Neutron Flux – High trip setpoints to ≤ 55% RTP.	72 hours
	AND		
	A.2	Perform SR 3.2.2.1.	24 hours
	AND		

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.3 ---------- **- NOTE -** THERMAL POWER does not have to be reduced to comply with this Required Action. ---------- Perform SR 3.2.2.1.	Prior to THERMAL POWER exceeding 50% RTP AND Prior to THERMAL POWER exceeding 75% RTP AND 24 hours after THERMAL POWER reaching ≥ 95% RTP
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 2.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.2.2.1	--- **- NOTE -** If the OPDMS becomes inoperable while in MODE 1 these Surveillances must be performed within 31 days of the last verification of OPDMS parameters. --- Verify $F^N_{\Delta H}$ within limits specified in the COLR.	Once after each refueling prior to THERMAL POWER exceeding 75% RTP AND 31 effective full power days (EFPD) thereafter

3.2 POWER DISTRIBUTION LIMITS

3.2.3 AXIAL FLUX DIFFERENCE (AFD) (Relaxed Axial Offset Control (RAOC) Methodology)

LCO 3.2.3 The AFD in %-flux-difference units shall be maintained within the limits specified in the COLR.

- NOTE -

The AFD shall be considered outside limits when two or more OPERABLE excore channels indicate AFD to be outside limits.

APPLICABILITY: MODE 1 with THERMAL POWER ≥ 50% RTP and with the On-Line Power Distribution Monitoring System (OPDMS) inoperable.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. AFD not within limits.	A.1 Reduce THERMAL POWER to < 50% RTP.	30 minutes

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.2.3.1	Verify AFD within limits for each OPERABLE excore channel.	7 days

3.2 POWER DISTRIBUTION LIMITS

3.2.4 QUADRANT POWER TILT RATIO (QPTR)

LCO 3.2.4 The QPTR shall be ≤ 1.02.

APPLICABILITY: MODE 1 with THERMAL POWER > 50% RTP and with the On-Line Power Distribution Monitoring System (OPDMS) inoperable.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. QPTR not within limit.	A.1	Reduce THERMAL POWER ≥ 3% from RTP for each 1% of QPTR > 1.00.	2 hours after each QPTR determination
	AND		
	A.2	Perform SR 3.2.4.1.	Once per 12 hours
	AND		
	A.3	Perform SR 3.2.1.1 and SR 3.2.2.1.	24 hours after achieving equilibrium conditions from a THERMAL POWER reduction per Required Action A.1 AND Once per 7 days thereafter
	AND		
	A.4	Reevaluate safety analyses and confirm results remain valid for duration of operation under this condition.	Prior to increasing THERMAL POWER above the limit of Required Action A.1
	AND		

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.5 ---------- **- NOTES -** 1. Perform Required Action A.5 only after Required Action A.4 is completed. 2. Required Action A.6 shall be completed whenever Required Action A.5 is performed. ---------- Normalize excore detectors to restore QPTR to within limit. <u>AND</u> A.6 ---------- **- NOTE -** Perform Required Action A.6 only after Required Action A.5 is completed. ---------- Perform SR 3.2.1.1, SR 3.2.1.2, and SR 3.2.2.1.	Prior to increasing THERMAL POWER above the limit of Required Action A.1 Within 24 hours after achieving equilibrium conditions at RTP not to exceed 48 hours after increasing THERMAL POWER above the limit of Required Action A.1
B. Required Action and associated Completion Time not met.	B.1 Reduce THERMAL POWER to ≤ 50% RTP.	4 hours

SURVEILLANCE REQUIREMENTS

	SURVEILLANCE	FREQUENCY
SR 3.2.4.1	---------- **- NOTES -** 1. With one power range channel inoperable and THERMAL POWER < 75% RTP, the remaining three power range channels can be used for calculating QPTR. 2. SR 3.2.4.2 may be performed in lieu of this Surveillance. ---------- Verify QPTR within limit by calculation.	7 days
SR 3.2.4.2	---------- **- NOTE -** Not required to be performed until 12 hours after input from one or more Power Range Neutron Flux channels are inoperable with THERMAL POWER ≥ 75% RTP. ---------- Verify QPTR is within limit using a minimum of 4 symmetric pairs of fixed incore detectors.	12 hours

3.2 POWER DISTRIBUTION LIMITS

3.2.5 On-Line Power Distribution Monitoring System (OPDMS)-Monitored Parameters

LCO 3.2.5 The following parameters shall not exceed their operating limits as specified in the COLR:

a. Peak kw/ft(Z)
b. $F^N_{\Delta H}$
c. DNBR
d. SDM.

APPLICABILITY: MODE 1 with THERMAL POWER > 50% RTP with OPDMS OPERABLE for parameters a, b, and c.
MODE 1 with OPDMS OPERABLE for parameter d.
2 with $k_{eff} \geq 1.0$ and OPDMS OPERABLE for parameter d.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more of the parameters a. through c. above not within limits.	A.1 Restore all parameters to within limits.	1 hour
B. Required Action and associated Completion Time of Condition A not met.	B.1 ---------- **- NOTE -** If the power distribution parameters are restored to within their limits while power is being reduced, operation may continue at the power level where this occurs. ---------- Reduce THERMAL POWER to ≤ 50% RTP.	4 hours
C. Parameter d above not within limits.	C.1 Initiate boration to restore SDM to within limits.	15 minutes

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.2.5.1	Verify the parameters a. through d. to be within their limits.	24 hours with OPDMS alarms OPERABLE OR 12 hours with OPDMS alarms inoperable

3.3 INSTRUMENTATION

3.3.1 Reactor Trip System (RTS) Instrumentation

LCO 3.3.1 The RTS instrumentation for each Function in Table 3.3.1-1 shall be OPERABLE.

APPLICABILITY: According to Table 3.3.1-1.

ACTIONS

- NOTE -

Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one or more required channels inoperable.	A.1 Enter the Condition referenced in Table 3.3.1-1 for the channel(s).	Immediately
B. One manual initiation device inoperable.	B.1 Restore manual initiation device to OPERABLE status. OR B.2.1 Be in MODE 3. AND B.2.2 Open reactor trip breakers (RTBs).	48 hours 54 hours 55 hours
C. One manual initiation device inoperable.	C.1 Restore manual initiation device to OPERABLE status. OR C.2 Open RTBs.	48 hours 49 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
D. One or two Power Range Neutron Flux – High channels inoperable.	D.1.1 Reduce THERMAL POWER to ≤ 75% RTP.	12 hours
	AND	
	D.1.2 Place one inoperable channel in bypass or trip.	6 hours
	AND	
	D.1.3 With two inoperable channels, place one channel in bypass and one channel in trip.	6 hours
	OR	
	D.2.1 Place inoperable channel(s) in bypass.	6 hours
	AND	
	D.2.2 ---------- **- NOTE -** Only required to be performed when OPDMS is inoperable and the Power Range Neutron Flux input to QPTR is inoperable. ---------- Perform SR 3.2.4.2.	Once per 12 hours
	OR	
	D.3 Be in MODE 3.	12 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. One or two channels inoperable.	E.1.1 Place one inoperable channel in bypass or trip. AND	6 hours
	E.1.2 With two channels inoperable, place one channel in bypass and one channel in trip. OR E.2 Be in MODE 3.	6 hours 12 hours
F. THERMAL POWER between P-6 and P-10, one or two Intermediate Range Neutron Flux channels inoperable.	F.1.1 Place one inoperable channel in bypass or trip. AND F.1.2 With two channels inoperable, place one channel in bypass and one channel in trip. OR F.2 Reduce THERMAL POWER to < P-6. OR F.3 Increase THERMAL POWER to > P-10.	2 hours 2 hours 2 hours 2 hours
G. THERMAL POWER between P-6 and P-10, three Intermediate Range Neutron Flux channels inoperable.	G.1 Suspend operations involving positive reactivity additions. AND G.2 Reduce THERMAL POWER to < P-6.	Immediately 2 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
H. THERMAL POWER < P-6, one or two Intermediate Range Neutron Flux channels inoperable.	H.1 Restore three of four channels to OPERABLE status.	Prior to increasing THERMAL POWER to > P-6
I. One or two Source Range Neutron Flux channels inoperable.	I.1 Suspend operations involving positive reactivity additions.	Immediately
J. Three Source Range Neutron Flux channels inoperable.	J.1 Open RTBs.	Immediately
K. One or two channels inoperable.	K.1.1 Place one inoperable channel in bypass or trip. AND K.1.2 With two channels inoperable, place one channel in bypass and one channel in trip. OR K.2 Reduce THERMAL POWER to < P-10.	6 hours 6 hours 12 hours
L. One or two channels/ divisions inoperable.	L.1 Restore three of four channels/divisions to OPERABLE status. OR L.2 Be in MODE 3.	6 hours 12 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
M. One or two interlock channels inoperable.	M.1 Verify the interlocks are in required state for existing plant conditions.	1 hour
	OR	
	M.2.1 Place the Functions associated with one inoperable interlock channel in bypass or trip.	7 hours
	AND	
	M.2.2 With two interlock channels inoperable, place the Functions associated with one inoperable interlock channel in bypass and with one inoperable interlock channel in trip.	7 hours
	OR	
	M.3 Be in MODE 3.	13 hours
N. One division inoperable.	N.1 Open RTBs in inoperable division.	8 hours
	OR	
	N.2.1 Be in MODE 3, 4, or 5.	14 hours
	AND	
	N.2.2 Open RTBs.	14 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
O. Two divisions inoperable.	O.1	Restore three of four divisions to OPERABLE status.	1 hour
	OR		
	O.2.1	Be in MODE 3, 4, or 5.	7 hours
	AND		
	O.2.2	Open RTBs.	7 hours
P. One or two channels/ divisions inoperable.	P.1	Restore three of four channels/divisions to OPERABLE status.	48 hours
	OR		
	P.2	Open RTBs.	49 hours
Q. One or two Source Range Neutron Flux channel inoperable.	Q.1	Restore three of four channels to OPERABLE status.	48 hours
	OR		
	Q.2	Open RTBs.	49 hours
R. Required Source Range Neutron Flux channel inoperable.	R.1	Suspend operations involving positive reactivity additions.	Immediately
	AND		
	R.2	Close unborated water source isolation valves.	1 hour
	AND		
	R.3	Perform SR 3.1.1.1.	1 hour AND Once per 12 hours thereafter

SURVEILLANCE REQUIREMENTS

- NOTE -

Refer to Table 3.3.1-1 to determine which SRs apply for each RTS Function.

SURVEILLANCE		FREQUENCY
SR 3.3.1.1	Perform CHANNEL CHECK.	12 hours
SR 3.3.1.2	--- **- NOTES -** 1. Adjust nuclear instrument channel in the Protection and Safety Monitoring System (PMS) if absolute difference is > 1% RTP. 2. Required to be met within 12 hours after reaching 15% RTP. 3. If the calorimetric heat balance is < 70% RTP, and if the nuclear instrumentation channel indicated power is: a. lower than the calorimetric measurement by > 1%, then adjust the nuclear instrumentation channel upward to match the calorimetric measurement. b. higher than the calorimetric measurement, then no adjustment is required. --- Compare results of calorimetric heat balance to nuclear instrument channel output.	24 hours

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.3.1.3	--- **- NOTES -** 1. Adjust the conversion factor, ΔT°, in the ΔT power calculation ($q_{\Delta T}$) if absolute difference between $q_{\Delta T}$ and the calorimetric measurement is > 1% RTP. 2. Required to be met within 12 hours after reaching 50% RTP. 3. If the calorimetric heat balance is < 70% RTP, and if $q_{\Delta T}$ is: a. lower than the calorimetric measurement by > 5%, then adjust ΔT° to match the calorimetric measurement. b. higher than the calorimetric measurement, then no adjustment is required. --- Compare results of calorimetric heat balance to the ΔT power calculation ($q_{\Delta T}$) output.	24 hours
SR 3.3.1.4	--- **- NOTES -** 1. Adjust nuclear instrument channel in PMS if absolute difference is ≥ 3% AFD. 2. Required to be met within 24 hours after reaching 20% RTP. --- Compare results of the incore detector measurements to nuclear instrument channel AXIAL FLUX DIFFERENCE.	31 effective full power days (EFPD)

SURVEILLANCE REQUIREMENTS (continued)

	SURVEILLANCE	FREQUENCY
SR 3.3.1.5	---------- **- NOTE -** Required to be met within 24 hours after reaching 50% RTP. ---------- Calibrate excore channels to agree with incore detector measurements.	92 EFPD
SR 3.3.1.6	---------- **- NOTE -** This Surveillance must be performed on both reactor trip breakers associated with a single division. ---------- Perform TADOT.	92 days on a STAGGERED TEST BASIS
SR 3.3.1.7	Perform RTCOT.	92 days
SR 3.3.1.8	---------- **- NOTE -** Not required to be performed for source range instrumentation prior to entering MODE 3 from MODE 2 until 4 hours after entry into MODE 3. ---------- Perform RTCOT in accordance with Setpoint Program.	92 days

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.3.1.9	---------- **- NOTE -** This Surveillance shall include verification that interlocks P-6 and P-10 are in their required state for existing unit conditions. ---------- Perform RTCOT in accordance with Setpoint Program.	---------- **- NOTE -** Only required when not performed within previous 92 days ---------- Prior to reactor startup AND Four hours after reducing power below P-10 for power and intermediate instrumentation AND Four hours after reducing power below P-6 for source range instrumentation AND Every 92 days thereafter
SR 3.3.1.10	---------- **- NOTE -** This Surveillance shall include verification that the time constants are adjusted to the prescribed values. ---------- Perform CHANNEL CALIBRATION in accordance with Setpoint Program.	24 months

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.3.1.11	--- **- NOTE -** Neutron detectors are excluded from CHANNEL CALIBRATION. --- Perform CHANNEL CALIBRATION in accordance with Setpoint Program.	24 months
SR 3.3.1.12	--- **- NOTE -** Verification of setpoint is not required. --- Perform TADOT.	24 months
SR 3.3.1.13	--- **- NOTE -** Neutron detectors are excluded from response time testing. --- Verify RTS RESPONSE TIME is within limits.	24 months on a STAGGERED TEST BASIS

3.3 INSTRUMENTATION

3.3.2 Engineered Safety Feature Actuation System (ESFAS) Instrumentation

LCO 3.3.2 The ESFAS instrumentation for each function in Table 3.3.2-1 shall be OPERABLE.

APPLICABILITY: According to Table 3.3.2-1.

ACTIONS

- NOTES -

1. Separate condition entry is allowed for each Function.

2. The Conditions for each Function are given in Table 3.3.2-1. If the Required Actions and associated Completion Times of the first Condition are not met, refer to the second Condition.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one or more required channels or divisions inoperable.	A.1 Enter the Condition referenced in Table 3.3.2-1 for the channel(s) or division(s).	Immediately
B. One or two channels or divisions inoperable.	B.1 Place one inoperable channel or division in bypass or trip. AND B.2 With two inoperable channels or divisions, place one inoperable channel or division in bypass and one inoperable channel or division in trip.	6 hours 6 hours
C. One channel inoperable.	C.1 Place inoperable channel in bypass.	6 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
D. One required division inoperable.	D.1	Restore required division to OPERABLE status.	6 hours
E. One switch or switch set inoperable.	E.1	Restore switch and switch set to OPERABLE status.	48 hours
F. One channel inoperable.	F.1	Restore channel to OPERABLE status.	72 hours
	OR		
	F.2.1	Verify alternate radiation monitors are OPERABLE.	72 hours
	AND		
	F.2.2	Verify control room isolation and air supply initiation manual controls are OPERABLE.	72 hours
G. One switch, switch set, channel, or division inoperable.	G.1	Restore switch, switch set, channel, and division to OPERABLE status.	72 hours
H. One channel inoperable.	H.1	Place channel in trip.	6 hours
I. One or two channels inoperable.	I.1	Place one inoperable channel in bypass or trip.	6 hours
	AND		
	I.2	With two inoperable channels, place one channel in bypass and one channel in trip.	6 hours
J. One or two interlock channels inoperable.	J.1	Verify the interlocks are in the required state for the existing plant conditions.	1 hour
	OR		

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	J.2.1	Place the Functions associated with one inoperable interlock channel in bypass or trip.	7 hours
	AND		
	J.2.2	With two interlock channels inoperable, place the Functions associated with one inoperable interlock channel in bypass and with one inoperable interlock channel in trip.	7 hours
K. Required Action and associated Completion Time not met.	K.1	---------- **- NOTE -** LCO 3.0.8 is not applicable. ---------- Suspend movement of irradiated fuel assemblies.	Immediately
L. Required Action and associated Completion Time not met.	L.1	Be in MODE 3.	6 hours
M. Required Action and associated Completion Time not met.	M.1	Be in MODE 3.	6 hours
	AND		
	M.2	Be in MODE 4.	12 hours
N. Required Action and associated Completion Time not met.	N.1	Be in MODE 3.	6 hours
	AND		
	N.2	Be in MODE 4 with the Reactor Coolant System (RCS) cooling provided by the Normal Residual Heat Removal System (RNS).	24 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
O. Required Action and associated Completion Time not met.	O.1 Be in MODE 3. AND O.2 Be in MODE 5.	6 hours 36 hours
P. Required Action and associated Completion Time not met.	---------- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---------- P.1 Isolate the affected flow path(s). AND P.2.1 Isolate the affected flow path(s) by use of at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured. OR P.2.2 Verify the affected flow path is isolated.	 24 hours 7 days Once per 7 days
Q. Required Action and associated Completion Time not met.	Q.1 ---------- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ----------	

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	Isolate the affected flow path(s) by use of at least one closed manual or closed and de-activated automatic valve.	6 hours
	OR	
	Q.2.1 Be in MODE 3.	12 hours
	AND	
	Q.2.2 Be in MODE 4.	18 hours
R. Required Action and associated Completion Time not met.	R.1 Be in MODE 3.	6 hours
	AND	
	--- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---	
	R.2.1.1 Isolate the affected flow path(s).	12 hours
	AND	
	R.2.1.2 Verify the affected flow path is isolated.	Once per 7 days
	OR	
	R.2.2 Be in MODE 4 with the RCS cooling provided by the RNS.	30 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
S. Required Action and associated Completion Time not met.	S.1 Be in MODE 3. AND	6 hours
	S.2.1.1 Be in MODE 4 with the RCS cooling provided by the RNS. AND --- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---	24 hours
	S.2.1.2 Isolate the affected flow path(s). AND	30 hours
	S.2.1.3 Verify the affected flow path is isolated. OR	Once per 7 days
	S.2.2 Be in MODE 5.	42 hours
T. Required Action and associated Completion Time not met.	--- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. --- T.1.1 Isolate the affected flow path(s). AND	6 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	T.1.2.1 Isolate the affected flow path(s) by use of at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured.	7 days
	OR	
	T.1.2.2 Verify the affected flow path is isolated.	Once per 7 days
	OR	
	T.2.1 Be in MODE 3.	12 hours
	AND	
	T.2.2 Be in MODE 5.	42 hours
U. Required Action and associated Completion Time not met.	U.1 Be in MODE 5.	12 hours
	AND	
	U.2 Initiate action to open the RCS pressure boundary and establish a pressurizer level ≥ 20%.	12 hours
V. Required Action and associated Completion Time not met.	V.1 Restore the inoperable channel(s).	168 hours
	OR	
	V.2.1 Be in MODE 5.	180 hours
	AND	
	V.2.2 Initiate action to open the RCS pressure boundary and establish a pressurizer level ≥ 20%.	180 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
W. Required Action and associated Completion Time not met.	W.1	If in MODE 5 with the RCS open and < 20% pressurizer level, initiate action to be MODE 5 with the RCS pressure boundary open and ≥ 20% pressurizer level.	Immediately
	AND		
	W.2	If in MODE 5, isolate the flow path from the demineralized water storage tank to the RCS by use of at least one closed and de-activated automatic valve or closed manual valve.	Immediately
	AND		
	W.3	If in MODE 6, initiate action to be in MODE 6 with the water level ≥ 23 feet above the top of the reactor vessel flange.	Immediately
	AND		
	W.4	Suspend positive reactivity additions.	Immediately
X. Required Action and associated Completion Time not met.	X.1	If in MODE 5 with RCS open and < 20% pressurizer level, initiate action to be in MODE 5 with RCS open and ≥ 20% pressurizer level.	Immediately
	AND		

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	X.2	If in MODE 6 with upper internals in place, initiate action to be in MODE 6 with the upper internals removed.	Immediately
	AND		
	X.3	Suspend positive reactivity additions.	Immediately
Y. Required Action and associated Completion Time not met.	Y.1	Suspend positive reactivity additions.	Immediately
	AND		
	Y.2	If in MODE 4, be in MODE 5.	12 hours
	AND		
	Y.3	If in MODE 4 or 5, initiate action to establish a pressurizer level $\geq$ 20% with the RCS pressure boundary intact.	12 hours
	AND		
	Y.4	If in MODE 6, initiate action to be in MODE 6 with the water level $\geq$ 23 feet above the top of the reactor vessel flange.	Immediately
Z. Required Action and associated Completion Time not met.	Z.1	---------- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ----------	

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	Isolate the affected flow path(s) by use of at least one closed manual or closed and deactivated automatic valve.	6 hours
	OR	
	Z.2.1 Be in MODE 3.	12 hours
	AND	
	Z.2.2 Be in MODE 4 with the RCS cooling provided by the RNS.	30 hours
AA. Required Action and associated Completion Time not met.	--- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---	
	AA.1.1 Isolate the affected flow path(s).	24 hours
	AND	
	AA.1.2.1 Isolate the affected flow path(s) by use of at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured.	7 days
	OR	

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	AA.1.2.2 Verify the affected flow path is isolated. OR AA.2.1 If in MODE 4, be in MODE 5. AND AA.2.2 If in MODE 4 or 5, initiate action to establish a pressurizer level ≥ 20%. AND AA.2.3 If in MODE 6, initiate action to be in MODE 6 with the water level ≥ 23 feet above the top of the reactor vessel flange.	Once per 7 days 12 hours 12 hours Immediately
BB. One channel inoperable.	BB.1 Place channel in bypass. AND BB.2 Continuously monitor hot leg level.	6 hours 6 hours
CC. Required Action and associated Completion Time not met.	CC.1 Be in MODE 3. AND CC.2 Be in MODE 5 or 6. AND CC.3 Open a containment air flow path ≥ 6 inches in diameter.	6 hours 36 hours 44 hours

SURVEILLANCE REQUIREMENTS

- NOTE -

Refer to Table 3.3.2-1 to determine which SRs apply for each Engineered Safety Features (ESF) Function.

	SURVEILLANCE	FREQUENCY
SR 3.3.2.1	Perform CHANNEL CHECK.	12 hours
SR 3.3.2.2	Perform ACTUATION LOGIC TEST.	92 days on a STAGGERED TEST BASIS
SR 3.3.2.3	--- **- NOTE -** Verification of setpoint not required for manual initiation functions. --- Perform TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT).	24 months
SR 3.3.2.4	--- **- NOTE -** This surveillance shall include verification that the time constants are adjusted to the prescribed values. --- Perform CHANNEL CALIBRATION in accordance with Setpoint Program.	24 months
SR 3.3.2.5	Perform CHANNEL OPERATIONAL TEST (COT) in accordance with Setpoint Program.	92 days
SR 3.3.2.6	Verify ESFAS RESPONSE TIMES are within limit.	24 months on a STAGGERED TEST BASIS
SR 3.3.2.7	--- **- NOTE -** This Surveillance is not required to be performed for actuated equipment which is included in the Inservice Test (IST) Program. --- Perform ACTUATION DEVICE TEST.	24 months

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.3.2.8	Perform ACTUATION DEVICE TEST for squib valves.	24 months
SR 3.3.2.9	Perform ACTUATION DEVICE TEST for pressurizer heater circuit breakers.	24 months

3.3 INSTRUMENTATION

3.3.3 Post Accident Monitoring (PAM) Instrumentation

LCO 3.3.3 The PAM instrumentation for each Function in Table 3.3.3-1 shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.

ACTIONS

- NOTES -

1. LCO 3.0.4 not applicable.

2. Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one required channel inoperable.	A.1 Restore required channel to OPERABLE status.	30 days
B. Required Action and associated Completion Time of Condition A not met.	B.1 Initiate action in accordance with Specification 5.6.7.	Immediately
C. One or more Functions with two required channels inoperable.	C.1 Restore one channel to OPERABLE status.	7 days
D. Required Action and associated Completion Time of Condition C not met.	D.1 Enter the Condition referenced in Table 3.3.3-1 for the channel.	Immediately
E. As required by Required Action D.1 and referenced in Table 3.3.3-1.	E.1 Be in MODE 3. AND E.2 Be in MODE 4.	6 hours 12 hours

SURVEILLANCE REQUIREMENTS

- NOTE -

SR 3.3.3.1 and SR 3.3.3.2 apply to each PAM instrumentation Function in Table 3.3.3-1.

	SURVEILLANCE	FREQUENCY
SR 3.3.3.1	Perform CHANNEL CHECK for each required instrumentation channel that is normally energized.	31 days
SR 3.3.3.2	--- **- NOTE -** Neutron detectors are excluded from CHANNEL CALIBRATION. --- Perform CHANNEL CALIBRATION.	24 months

Table 3.3.3-1 (page 1 of 1)
Post-Accident Monitoring Instrumentation

	FUNCTION	REQUIRED CHANNELS/ DIVISIONS	CONDITION REFERENCED FROM REQUIRED ACTION D.1
1.	Neutron Flux (Intermediate Range)	2	E
2.	Reactor Coolant System (RCS) Hot Leg Temperature (Wide Range)	2	E
3.	RCS Cold Leg Temperature (Wide Range)	2	E
4.	RCS Pressure (Wide Range)	2	E
5.	Pressurizer Pressure and RCS Subcooling Monitor[(a)]	2	E
6.	Containment Water Level	2	E
7.	Containment Pressure	2	E
8.	Containment Pressure (Extended Range)	2	E
9.	Containment Area Radiation (High Range)	2	E
10.	Pressurizer Level and Associated Reference Leg Temperature	2	E
11.	In-Containment Refueling Water Storage Tank (IRWST) Water Level	2	E
12.	Passive Residual Heat Removal (PRHR) Flow and PRHR Outlet Temperature	2 flow & 1 temperature	E
13.	Core Exit Temperature -- Quadrant 1	2[(b)]	E
14.	Core Exit Temperature -- Quadrant 2	2[(b)]	E
15.	Core Exit Temperature -- Quadrant 3	2[(b)]	E
16.	Core Exit Temperature -- Quadrant 4	2[(b)]	E
17.	Passive Containment Cooling System (PCS) Storage Tank Level and PCS Flow	2 level & 1 flow	E
18.	Remotely Operated Containment Isolation Valve Position	1/valve[(c)]	E
19.	IRWST to Normal Residual Heat Removal System (RNS) Suction Valve Status	2	E

(a) RCS Subcooling calculated from pressurizer pressure and RCS hot leg temperature.

(b) A channel consists of two thermocouples within a single division. Each quadrant contains two divisions. The minimum requirement is two OPERABLE thermocouples in each of the two divisions.

(c) Not required for isolation valves whose associated penetration is isolated by at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured.

3.3 INSTRUMENTATION

3.3.4 Remote Shutdown Workstation (RSW)

LCO 3.3.4 The RSW shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with Reactor Coolant System (RCS) average temperature (T_{avg}) ≥ 350°F.

ACTIONS

- NOTE -

LCO 3.0.4 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. RSW inoperable.	A.1 Restore to OPERABLE status.	30 days
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4 with T_{avg} < 350°F.	6 hours 12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.3.4.1	Verify each required transfer switch is capable of performing the required function.	24 months
SR 3.3.4.2	Verify that the RSW communicates indication and controls with Division A, B, C and D of the Protection and Safety Monitoring System (PMS).	24 months
SR 3.3.4.3	Verify the OPERABILITY of the RSW hardware and software.	24 months

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.3.4.4	Perform TADOT of the reactor trip breaker open/closed indication.	24 months

3.3 INSTRUMENTATION

3.3.5 Diverse Actuation System (DAS) Manual Controls

LCO 3.3.5 The DAS manual controls for each function in Table 3.3.5-1 shall be OPERABLE.

APPLICABILITY: According to Table 3.3.5-1.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or more manual DAS controls inoperable.	A.1	Restore DAS manual controls to OPERABLE status.	30 days
B. Required Action and associated Completion Time of Condition A not met for inoperable DAS manual reactor trip control.	B.1 AND B.2	Perform SR 3.3.1.6. Restore all controls to OPERABLE status.	Once per 31 days on a STAGGERED TEST BASIS Prior to entering MODE 2 following next MODE 5 entry
C. Required Action and associated Completion Time of Condition A not met for inoperable DAS manual actuation control other than reactor trip.	C.1 AND C.2	Perform SR 3.3.2.2. Restore all controls to OPERABLE status.	Once per 31 days on a STAGGERED TEST BASIS Prior to entering MODE 2 following next MODE 5 entry
D. Required Action and associated Completion Time of Condition B not met. OR Required Action and associated Completion Time of Condition C not met.	D.1 AND D.2	Be in MODE 3. Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.3.5.1	---------- **- NOTE -** Verification of setpoint not required. ---------- Perform TRIP ACTUATION DEVICE OPERATIONAL TEST (TADOT).	24 months

Table 3.3.5-1 (page 1 of 1)
DAS Manual Controls

	FUNCTION	APPLICABLE MODES OR OTHER SPECIFIED CONDITIONS	REQUIRED CONTROLS
1.	Reactor trip manual controls	1,2	2 switches
2.	Passive Residual Heat Removal Heat Exchanger (PRHR HX) control and In-Containment Refueling Water Storage Tank (IRWST) gutter control valves	1,2,3,4,5(a)	2 switches
3.	Core Makeup Tank (CMT) isolation valves	1,2,3,4,5(a)	2 switches
4.	Automatic Depressurization System (ADS) stage 1 valves	1,2,3,4,5(a)	2 switches
5.	ADS stage 2 valves	1,2,3,4,5(a)	2 switches
6.	ADS stage 3 valves	1,2,3,4,5(a)	2 switches
7.	ADS stage 4 valves	1,2,3,4,5,6(c)	2 switches
8.	IRWST injection squib valves	1,2,3,4,5,6	2 switches
9.	Containment recirculation valves	1,2,3,4,5,6	2 switches
10.	Passive containment cooling drain valves	1,2,3,4,5(b),6(b)	2 switches
11.	Selected containment isolation valves	1,2,3,4,5,6	2 switches

(a) With Reactor Coolant System (RCS) pressure boundary intact.

(b) With the calculated reactor decay heat > 6.0 MWt.

(c) In MODE 6 with reactor internals in place.

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.1 RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits

LCO 3.4.1 RCS DNB parameters for pressurizer pressure, RCS average temperature, and RCS total flow rate shall be within the limits specified below:

a. Pressurizer Pressure is greater than or equal to the limit specified in the COLR

b. RCS Average Temperature is less than or equal to the limit specified in the COLR, and

c. RCS total flow rate ≥ 301,670 gpm and greater than or equal to the limit specified in the COLR.

APPLICABILITY: MODE 1.

- NOTE -

Pressurizer pressure limit does not apply during:

a. THERMAL POWER ramp > 5% RTP per minute, or

b. THERMAL POWER step > 10% RTP.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more RCS DNB parameters not within limits.	A.1 Restore RCS DNB parameter(s) to within limit.	2 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 2.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.1.1	Verify pressurizer pressure is greater than or equal to the limit specified in the COLR.	12 hours
SR 3.4.1.2	Verify RCS average temperature is less than or equal to the limit specified in the COLR.	12 hours
SR 3.4.1.3	Verify RCS total flow rate is ≥ 301,670 gpm and greater than or equal to the limit specified in the COLR.	12 hours
SR 3.4.1.4	Perform a CHANNEL CALIBRATION of RCS total flow rate indication (differential pressure) channels.	24 months
SR 3.4.1.5	---------- **- NOTE -** Not required to be performed until 24 hours after ≥ 90% RTP. ---------- Verify that RCS total flow rate is ≥ 301,670 gpm and greater than or equal to the limit specified in the COLR as determined by precision heat balance or RCS total flow rate indication (differential pressure) measurements.	24 months

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.2 RCS Minimum Temperature for Criticality

LCO 3.4.2 Each RCS loop average temperature (T_{avg}) shall be ≥ 551°F.

APPLICABILITY: MODE 1,
MODE 2 with k_{eff} ≥ 1.0.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. T_{avg} in one or more RCS loops not within limit.	A.1 Be in MODE 2 with k_{eff} < 1.0.	30 minutes

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.2.1	Verify RCS T_{avg} in each loop ≥ 551°F.	12 hours

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.3 RCS Pressure and Temperature (P/T) Limits

LCO 3.4.3 RCS pressure, RCS temperature, and RCS heatup and cooldown rates shall be maintained within the limits specified in the PTLR.

APPLICABILITY: At all times.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. ---------- **- NOTE -** Required Action A.2 shall be completed whenever this Condition is entered. ---------- Requirements of LCO not met in MODE 1, 2, 3, or 4.	A.1 Restore parameters to within limits. AND A.2 Determine RCS is acceptable for continued operation.	30 minutes 72 hours
B. Required Action and associated Completion Time of Condition A not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4 with RCS pressure < 500 psig.	6 hours 24 hours
C. ---------- **- NOTE -** Required Action C.2 shall be completed whenever this Condition is entered. ---------- Requirements of LCO not met any time in other than MODE 1, 2, 3, or 4.	C.1 Initiate action to restore parameter(s) to within limits. AND C.2 Determine RCS is acceptable for continued operation.	Immediately Prior to entering MODE 4

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.3.1	---------- **- NOTE -** Only required to be performed during RCS heatup and cooldown operations and inservice leak and hydrostatic testing. ---------- Verify RCS pressure, RCS temperature, and RCS heatup and cooldown rates within limits specified in the PTLR.	30 minutes

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.4 RCS Loops

LCO 3.4.4 Two RCS loops shall be OPERABLE with four Reactor Coolant Pumps (RCPs) in operation with variable speed control bypassed.

- NOTES -

1. No RCP shall be started when the reactor trip breakers are closed.
2. No RCP shall be started when the RCS temperature is ≥ 350°F unless pressurizer level is < 92%.
3. No RCP shall be started with any RCS cold leg temperature ≤ 350°F unless the secondary side water temperature of each steam generator (SG) is ≤ 50°F above each of the RCS cold leg temperatures and the RCP is started at ≤ 25% of RCP speed.
4. All RCPs may be de-energized in MODE 3, 4, or 5 for ≤ 1 hour per 8 hour period provided:
   a. No operations are permitted that would cause introduction into the RCS, coolant with boron concentration less than required to meet the SDM of LCO 3.1.1; and
   b. Core outlet temperature is maintained at least 10°F below saturation temperature.

APPLICABILITY: MODES 1 and 2,
MODES 3, 4, and 5, whenever the reactor trip breakers are closed.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. ---------- **- NOTE -** Required Action A.1 must be completed whenever Condition A is entered. ---------- Requirements of LCO not met in MODE 1 or 2.	A.1 Be in MODE 3 with the reactor trip breakers open.	6 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. ---------- **- NOTE -** Required Action B.1 must be completed whenever Condition B is entered. ---------- Requirements of LCO not met in MODE 3, 4, or 5.	B.1 Open reactor trip breakers.	1 hour

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.4.1	Verify each RCS loop is in operation with variable speed control bypassed.	12 hours

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.5 Pressurizer

LCO 3.4.5 The pressurizer water level shall be ≤ 92% of span.

APPLICABILITY: MODES 1, 2, and 3.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Pressurizer water level not within limit.	A.1 Restore pressurizer water level within limit.	6 hours
	OR	
	A.2.1 Be in MODE 3 with reactor trip breakers open.	6 hours
	AND	
	A.2.2 Be in MODE 4.	12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.5.1	Verify pressurizer water level ≤ 92% of span.	12 hours

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.6 Pressurizer Safety Valves

LCO 3.4.6 Two pressurizer safety valves shall be OPERABLE with lift settings ≥ 2460 psig and ≤ 2510 psig.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with Normal Residual Heat Removal System (RNS) isolated or RCS temperature ≥ 275°F.

- NOTE -

The lift settings are not required to be within the LCO limits during MODES 3 and 4 for the purpose of setting the pressurizer safety valves under ambient (hot) conditions.

This exception is allowed for 36 hours following entry into MODE 3, provided a preliminary cold setting was made prior to heatup.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One pressurizer safety valve inoperable.	A.1 Restore valve to OPERABLE status.	15 minutes
B. Required Action and associated Completion Time not met. OR Two pressurizer safety valves inoperable.	B.1 Be in MODE 3. AND B.2 Be in MODE 4 with RNS aligned to the RCS and RCS temperature < 275°F.	6 hours 24 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.6.1	Verify each pressurizer safety valve OPERABLE in accordance with the Inservice Testing Program. Following testing, lift settings shall be within ±1%.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.7 RCS Operational LEAKAGE

LCO 3.4.7 RCS operational LEAKAGE shall be limited to:

a. No pressure boundary LEAKAGE,

b. 0.5 gpm unidentified LEAKAGE,

c. 10 gpm identified LEAKAGE from the RCS,

d. 150 gallons per day primary to secondary LEAKAGE through any one Steam Generator (SG), and

e. 500 gallons per day primary to In-Containment Refueling Water Storage Tank (IRWST) LEAKAGE through the passive residual heat removal heat exchanger (PRHR HX).

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. RCS operational LEAKAGE not within limits for reasons other than pressure boundary LEAKAGE or primary to secondary LEAKAGE.	A.1 Reduce LEAKAGE to within limits.	4 hours
B. Required Action and associated Completion Time not met. OR Pressure boundary LEAKAGE exists. OR Primary to secondary LEAKAGE not within limit.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.7.1	---------- **- NOTES -** 1. Not required to be performed until 12 hours after establishment of steady state operation. 2. Not applicable to primary to secondary LEAKAGE. ---------- Verify RCS operational LEAKAGE is within limits by performance of RCS water inventory balance.	72 hours
SR 3.4.7.2	---------- **- NOTE -** Not required to be performed until 12 hours after establishment of steady state operation. ---------- Verify primary to secondary LEAKAGE is ≤ 150 gallons per day through any one SG.	72 hours

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.8 Minimum RCS Flow

LCO 3.4.8 At least one Reactor Coolant Pump (RCP) shall be in operation with a total flow through the core of at least 3,000 gpm.

- NOTES -

1. All RCPs may be de-energized for ≤ 1 hour per 8 hour period provided:

   a. No operations are permitted that would cause introduction into the RCS, coolant with boron concentration less than required to meet the SDM of LCO 3.1.1; and

   b. Core outlet temperature is maintained at least 10°F below saturation temperature.

2. No RCP shall be started when the RCS temperature is ≥ 350°F unless pressurizer level is < 92%.

3. No RCP shall be started with any RCS cold leg temperature ≤ 350°F unless the secondary side water temperature of each steam generator (SG) is ≤ 50°F above each of the RCS cold leg temperatures and the RCP is started at ≤ 25% of RCP speed.

APPLICABILITY: MODES 3, 4, and 5, whenever the reactor trip breakers are open and with unborated water sources not isolated from the RCS.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. No RCP in operation.	A.1 Isolate all sources of unborated water. AND A.2 Perform SR 3.1.1.1.	1 hour 1 hour

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.8.1	Verify that at least one RCP is in operation at ≥ 10% rated speed or equivalent.	12 hours

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.9 RCS Leakage Detection Instrumentation

LCO 3.4.9 The following RCS leakage detection instrumentation shall be OPERABLE:

a. Two containment sump level channels;

b. One containment atmosphere radioactivity monitor (F18 particulate).

APPLICABILITY: MODES 1, 2, 3, and 4.

- NOTES -

1. The F18 particulate containment atmosphere radioactivity monitor is only required to be OPERABLE in MODE 1 with RTP > 20%.

2. Containment sump level measurements cannot be used for leak detection if leakage is prevented from draining to the sump such as by redirection to the In-Containment Refueling Water Storage Tank (IRWST) by the containment shell gutter drains.

ACTIONS

- NOTE

LCO 3.0.4 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One required containment sump channel inoperable.	A.1 Verify that the volume input per day to the containment sump does not change (+ or -) more than 10 gallons or 33% of the volume input (whichever is greater). The volume used for comparison will be the value taken during the first day following the entrance into this CONDITION. AND	Once per 24 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	A.2	Restore two containment sump channels to OPERABLE status.	14 days
B. Two required containment sump channels inoperable.	B.1	---------- **- NOTE -** Not required until 12 hours after establishment of steady state operation. ---------- Perform SR 3.4.7.1.	Once per 24 hours
	AND		
	B.2	Restore one containment sump channel to OPERABLE status.	72 hours
C. Required containment atmosphere radioactivity monitor inoperable.	C.1.1	Analyze grab samples of containment atmosphere.	Once per 24 hours
	OR		
	C.1.2	---------- **- NOTE -** Not required until 12 hours after establishment of steady state operation. ---------- Perform SR 3.4.7.1.	Once per 24 hours
	AND		
	C.2	Restore containment atmosphere radioactivity monitor to OPERABLE status.	30 days
D. Required Action and associated Completion Time not met.	D.1	Be in MODE 3.	6 hours
	AND		
	D.2	Be in MODE 5.	36 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. All required monitors inoperable.	E.1 Enter LCO 3.0.3.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.9.1	Perform a CHANNEL CHECK of required containment atmosphere radioactivity monitor.	12 hours
SR 3.4.9.2	Perform a COT of required containment atmosphere radioactivity monitor.	92 days
SR 3.4.9.3	Perform a CHANNEL CALIBRATION of required containment sump monitor.	24 months
SR 3.4.9.4	Perform a CHANNEL CALIBRATION of required containment atmosphere radioactivity monitor.	24 months

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.10 RCS Specific Activity

LCO 3.4.10 The specific activity of the reactor coolant shall be within limits.

APPLICABILITY: MODES 1 and 2.
MODE 3 with RCS average temperature (T_{avg}) ≥ 500°F.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. DOSE EQUIVALENT I-131 > 1.0 µCi/gm.	--- **- NOTE -** LCO 3.0.4 is not applicable. --- A.1 Verify DOSE EQUIVALENT I-131 to be ≤ 60 µCi/gm. AND A.2 Restore DOSE EQUIVALENT I-131 to within limit.	 Once per 4 hours 48 hours
B. DOSE EQUIVALENT XE-133 > 280 µCi/gm.	B.1 Perform SR 3.4.10.2. AND B.2 Be in MODE 3 with T_{avg} < 500°F.	4 hours 6 hours
C. Required Action and associated Completion Time of Condition A not met. OR DOSE EQUIVALENT I-131 > 60 µCi/gm.	C.1 Be in MODE 3 with T_{avg} < 500°F.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.10.1	Verify reactor coolant DOSE EQUIVALENT XE-133 specific activity $\leq$ 280 µCi/gm.	7 days
SR 3.4.10.2	---------- **- NOTE -** Only required to be performed in MODE 1. ---------- Verify reactor coolant DOSE EQUIVALENT I-131 specific activity ≤ 1.0 µCi/gm.	14 days AND Between 2 to 6 hours after a THERMAL POWER change of ≥ 15% of RTP within a 1 hour period

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.11 Automatic Depressurization System (ADS) – Operating

LCO 3.4.11 The ADS, including 10 flow paths, shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One stage 1, 2, or 3 ADS flow path inoperable.	A.1 Restore flow path to OPERABLE status.	7 days
B. One stage 4 ADS flow path inoperable.	B.1 Restore flow path to OPERABLE status.	72 hours
C. Two or three ADS flow paths inoperable with a combined inoperable flow capacity less than or equal to that of a division with the largest ADS flow capacity.	C.1 Restore flow paths to OPERABLE status.	72 hours
D. Required Action and associated Completion Time not met. OR Requirements of LCO not met for reasons other than Condition A, B, or C.	D.1 Be in MODE 3. AND D.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.11.1	Verify that the motor operated valve in series with each 4th stage ADS valve is fully open.	12 hours
SR 3.4.11.2	Verify that each stage 1, 2, and 3 ADS valve is OPERABLE by stroking them open.	In accordance with the Inservice Testing Program
SR 3.4.11.3	Verify that each stage 4 ADS valve is OPERABLE in accordance with the Inservice Testing Program.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.12 Automatic Depressurization System (ADS) – Shutdown, RCS Intact

LCO 3.4.12 The ADS, including 9 flow paths, shall be OPERABLE.

APPLICABILITY: MODE 5 with RCS pressure boundary intact.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One required stage 1, 2, or 3 ADS flow path inoperable.	A.1 Restore flow path to OPERABLE status.	7 days
B. One required stage 4 ADS flow path inoperable.	B.1 Restore flow path to OPERABLE status.	72 hours
C. Two or three required ADS flow paths inoperable with a combined inoperable flow capacity less than or equal to that of a division with the largest ADS flow capacity.	C.1 Restore flow paths to OPERABLE status.	72 hours
D. Required Action and associated Completion Time not met. <u>OR</u> Requirements of LCO not met for reasons other than Condition A, B, or C.	D.1 Initiate action to be in MODE 5, with RCS open and ≥ 20% pressurizer level.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.12.1	For flow paths required to be OPERABLE, the SRs of LCO 3.4.11, “Automatic Depressurization System (ADS) – Operating” are applicable.	In accordance with applicable SRs

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.13 Automatic Depressurization System (ADS) – Shutdown, RCS Open

LCO 3.4.13 ADS stage 1, 2, and 3, flow paths shall be open.
ADS stage 4 with 2 flow paths shall be OPERABLE.

- NOTE -

In MODE 5, the ADS valves may be closed to facilitate RCS vacuum fill operations to establish a pressurizer level ≥ 20%, provided ADS valve OPERABILITY meets LCO 3.4.12, ADS – Shutdown, RCS Intact.

APPLICABILITY: MODE 5 with RCS pressure boundary open or pressurizer level < 20%;
MODE 6 with upper internals in place.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One required ADS stage 1, 2, or 3 flow path not open.	A.1	Open the affected flow path.	72 hours
	OR		
	A.2	Open an alternative flow path with an equivalent area.	72 hours
B. One required ADS stage 4 flow path closed and inoperable.	B.1	Open an alternative flow path with an equivalent area.	36 hours
	OR		
	B.2	Restore two ADS stage 4 flow paths to OPERABLE status.	36 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. Required Action and associated Completion Time not met while in MODE 5. OR Requirements of LCO not met for reasons other than Conditions A or B while in MODE 5.	C.1 Initiate action to fill the RCS to establish ≥ 20% pressurizer level. AND C.2 Suspend positive reactivity additions.	Immediately Immediately
D. Required Action and associated Completion Time not met while in MODE 6. OR Requirements of LCO not met for reasons other than Conditions A or B while in MODE 6.	D.1 Initiate action to remove the upper internals. AND D.2 Suspend positive reactivity additions.	Immediately Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.13.1	Verify that each ADS stage 1, 2, and 3 valve is in the fully open position.	12 hours
SR 3.4.13.2	For each ADS stage 4 flow path required to be OPERABLE, the following SRs of LCO 3.4.11, “Automatic Depressurization System (ADS) – Operating” are applicable: SR 3.4.11.1 SR 3.4.11.3	In accordance with applicable SRs

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.14 Low Temperature Overpressure Protection (LTOP) System

LCO 3.4.14 At least one of the following Overpressure Protection Systems shall be OPERABLE, with the accumulators isolated:

a. The Normal Residual Heat Removal System (RNS) suction relief valve with lift setting within the limit specified in the PTLR, or

b. The RCS depressurized and an RCS vent of ≥ 4.15 square inches.

- NOTE -

1. No reactor coolant pump (RCP) shall be started when the RCS temperature is ≥ 350°F unless pressurizer level is < 92%.

2. No RCP shall be started with any RCS cold leg temperature ≤ 350°F unless the secondary side water temperature of each steam generator (SG) is ≤ 50°F above each of the RCS cold leg temperatures and the RCP is started at ≤ 25% of RCP speed.

APPLICABILITY: MODE 4 when any cold leg temperature is ≤ 275°F,
MODE 5,
MODE 6 when the reactor vessel head is on.

- NOTE -

Accumulator isolation is only required when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in the PTLR.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. An accumulator not isolated when the accumulator pressure is ≥ to the maximum RCS pressure for existing cold leg temperature allowed in the PTLR.	A.1 Isolate affected accumulator.	1 hour
B. Required Action and associated Completion Time of Condition A not met.	B.1 Increase RCS cold leg temperature to a level acceptable for the existing accumulator pressure allowed in the PTLR. OR B.2 Depressurize affected accumulator to less than the maximum RCS pressure for existing cold leg temperature allowed in the PTLR.	12 hours 12 hours
C. The RNS suction relief valve inoperable.	C.1 Restore the RNS suction relief valve to OPERABLE status. OR C.2 Depressurize RCS and establish RCS vent of ≥ 4.15 square inches.	12 hours 12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.14.1	Verify each accumulator is isolated.	12 hours
SR 3.4.14.2	Verify both RNS suction isolation valves in one RNS suction flow path are open.	12 hours
SR 3.4.14.3	--- **- NOTE -** Only required to be performed when complying with LCO 3.4.14.b. --- Verify RCS vent ≥ 4.15 square inches is open.	12 hours for unlocked-open vent AND 31 days for locked-open vent
SR 3.4.14.4	Verify the lift setting of the RNS suction relief valve.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.15 RCS Pressure Isolation Valve (PIV) Integrity

LCO 3.4.15 Leakage from each RCS PIV shall be within limit.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4, with the RCS not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

- NOTES -

1. Separate Condition entry is allowed for each flow path.

2. Enter applicable Conditions and Required Actions for systems made inoperable by an inoperable PIV.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Leakage from one or more RCS PIVs not within limit.	--- **NOTE -** Each valve used to satisfy Required Action A.1 and Required Action A.2 must have been verified to meet SR 3.4.15.1 and be in the reactor coolant pressure boundary or the high pressure portion of the system. --- A.1 Isolate the high pressure portion of the affected system from the low pressure portion by use of one closed manual, deactivated automatic, or check valve. AND	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	A.2	Verify a second OPERABLE PIV can meet the leakage limits. This valve is required to be a check valve, or a closed valve, if it isolates a line that penetrates containment.	72 hours
B. Required Action and associated Completion Time not met.	B.1	Be in MODE 3.	6 hours
	AND		
	B.2	Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.15.1	Verify leakage of each RCS PIV is equivalent to ≤ 0.5 gpm per nominal inch valve size up to a maximum of 5 gpm at an RCS pressure ≥ 2215 and ≤ 2255 psig.	24 months

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.16 Reactor Vessel Head Vent (RVHV)

LCO 3.4.16 The Reactor Vessel Head Vent shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with the RCS not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One flow path inoperable.	A.1 Restore flow path to OPERABLE status.	72 hours
B. Two flow paths inoperable.	B.1 Restore at least one flow path to OPERABLE status.	6 hours
C. Required Action and associated Completion Time not met. OR Requirements of LCO not met for reasons other than Conditions A or B.	C.1 Be in MODE 3. AND C.2 Be in MODE 4, with the RCS cooling provided by the RNS.	6 hours 12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.16.1	Verify that each RVHV valve is OPERABLE by stroking it open.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.17 Chemical and Volume Control System (CVS) Makeup Isolation Valves

LCO 3.4.17 Two CVS Makeup Isolation Valves shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One CVS makeup isolation valve inoperable.	A.1 Restore two CVS makeup isolation valves to OPERABLE status.	72 hours
B. Required Action and associated Completion Time not met. <u>OR</u> Two CVS makeup isolation valves inoperable.	B.1 ---------- **- NOTE -** Flow path(s) may be unisolated intermittently under administrative controls. ---------- Isolate the flow path from the CVS makeup pumps to the Reactor Coolant System by use of at least one closed manual or one closed and de-activated automatic valve.	1 hour

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.17.1	Verify two CVS makeup isolation valves are OPERABLE by stroking the valves closed.	In accordance with the Inservice Testing Program
SR 3.4.17.2	Verify closure time of each CVS makeup isolation valve is ≤ 30 seconds on an actual or simulated actuation signal.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.18 Steam Generator (SG) Tube Integrity

LCO 3.4.18 SG tube integrity shall be maintained.

AND

All SG tubes satisfying the tube repair criteria shall be plugged in accordance with the Steam Generator Program.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

- NOTE -
Separate Condition entry is allowed for each SG tube.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more SG tubes satisfying the tube repair criteria and not plugged in accordance with the Steam Generator Program.	A.1 Verify tube integrity of the affected tube(s) is maintained until the next refueling outage or SG tube inspection. AND A.2 Plug the affected tube(s) in accordance with the Steam Generator Program.	7 days Prior to entering MODE 4 following the next refueling outage or SG tube inspection
B. Required Action and associated Completion Time of Condition A not met. OR SG tube integrity not maintained.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.18.1	Verify SG tube integrity in accordance with the Steam Generator Program.	In accordance with the Steam Generator Program
SR 3.4.18.2	Verify that each inspected SG tube that satisfies the tube repair criteria is plugged in accordance with the Steam Generator Program.	Prior to entering MODE 4 following a SG tube inspection

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.1 Accumulators

LCO 3.5.1 Both accumulators shall be OPERABLE.

APPLICABILITY: MODES 1 and 2.
MODES 3 and 4 with Reactor Coolant System (RCS) pressure > 1000 psig.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One accumulator inoperable due to boron concentration outside limits.	A.1 Restore boron concentration to within limits.	72 hours
B. One accumulator inoperable for reasons other than Condition A.	B.1 Restore accumulator to OPERABLE status.	8 hours if Condition C or E of LCO 3.5.2 has not been entered OR 1 hour if Condition C or E of LCO 3.5.2 has been entered
C. Required Action and associated Completion Time of Condition A or B not met.	C.1 Be in MODE 3. AND C.2 Reduce RCS pressure to ≤ 1000 psig.	6 hours 12 hours
D. Two accumulators inoperable.	D.1 Enter LCO 3.0.3.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.1.1	Verify each accumulator isolation valve is fully open.	12 hours
SR 3.5.1.2	Verify the borated water volume in each accumulator is ≥ 1667 cu. ft., and ≤ 1732 cu. ft.	12 hours
SR 3.5.1.3	Verify the nitrogen cover gas pressure in each accumulator is ≥ 637 psig and ≤ 769 psig.	12 hours
SR 3.5.1.4	Verify the boron concentration in each accumulator is ≥ 2600 ppm and ≤ 2900 ppm.	31 days AND ---------- **- NOTE -** Only required for affected accumulators. ---------- Once within 6 hours after each solution volume increase of ≥ 51 cu. ft., 3.0% that is not the result of addition from the in-containment refueling water storage tank
SR 3.5.1.5	Verify power is removed from each accumulator isolation valve operator when pressurizer pressure is ≥ 2000 psig.	31 days
SR 3.5.1.6	Verify system flow performance of each accumulator in accordance with the System Level OPERABILITY Testing Program.	10 years

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.2 Core Makeup Tanks (CMTs) – Operating

LCO 3.5.2 Both CMTs shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with the Reactor Coolant System (RCS) not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One CMT inoperable due to one CMT outlet isolation valve inoperable.	A.1 Restore outlet isolation valve to OPERABLE status.	72 hours
B. One CMT inoperable due to one or more parameters (water temperature, boron concentration) not within limits.	B.1 Restore water temperature or boron concentration to within limits.	72 hours
C. Two CMTs inoperable due to water temperature or boron concentration not within limits.	C.1 Restore water temperature or boron concentration to within limits for one CMT.	8 hours if Condition B of LCO 3.5.1 has not been entered OR 1 hour if Condition B of LCO 3.5.1 has been entered
D. One CMT inoperable due to presence of non-condensible gases in one high point vent.	D.1 Vent noncondensible gases.	24 hours
E. One CMT inoperable for reasons other than Condition A, B, C, or D.	E.1 Restore CMT to OPERABLE status.	8 hours if Condition B of LCO 3.5.1 has not been entered OR 1 hour if Condition B of LCO 3.5.1 has been entered

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
F. Required Action and associated Completion Time not met. OR LCO not met for reasons other than A, B, C, D, or E.	F.1 Be in MODE 3. AND F.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.2.1	Verify the temperature of the borated water in each CMT is < 120°F.	24 hours
SR 3.5.2.2	Verify the borated water volume in each CMT is ≥ 2500 cu. ft.	7 days
SR 3.5.2.3	Verify each CMT inlet isolation valve is fully open.	12 hours
SR 3.5.2.4	Verify the volume of noncondensible gases in each CMT inlet line has not caused the high-point water level to drop below the sensor.	24 hours
SR 3.5.2.5	Verify the boron concentration in each CMT is ≥ 3400 ppm, and ≤ 3700 ppm.	7 days
SR 3.5.2.6	Verify each CMT outlet isolation valve is OPERABLE by stroking it open.	In accordance with the Inservice Testing Program
SR 3.5.2.7	Verify system flow performance of each CMT in accordance with the System Level OPERABILITY Testing Program.	10 years

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.3 Core Makeup Tanks (CMTs) – Shutdown, Reactor Coolant System (RCS) Intact

LCO 3.5.3 One CMT shall be OPERABLE.

APPLICABILITY: MODE 4 with the RCS cooling provided by the Normal Residual Heat Removal System (RNS).
MODE 5 with the RCS pressure boundary intact.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Required CMT inoperable due to one outlet isolation valve inoperable.	A.1 Restore required isolation valve to OPERABLE status.	72 hours
B. Required CMT inoperable due to one or more parameters (water temperature, boron concentration) not within limits.	B.1 Restore water temperature or boron concentration to within limits.	72 hours
C. Required CMT inoperable for reasons other than A or B.	C.1 Restore required CMT to OPERABLE status.	8 hours
D. Required Action and associated Completion Time not met. <u>OR</u> LCO not met for reasons other than A, B, or C.	D.1 Initiate action to be in MODE 5 with RCS pressure boundary open and ≥ 20% pressurizer level.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.3.1	For the CMT required to be OPERABLE, the SRs of Specification 3.5.2, “Core Makeup Tanks (CMTs) – Operating” are applicable.	In accordance with applicable SRs

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.4 Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Operating

LCO 3.5.4 The PRHR HX shall be OPERABLE.

- NOTE -

When any reactor coolant pumps (RCPs) are operating, at least one RCP must be operating in the loop with the PRHR HX, Loop 1.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with the Reactor Coolant System (RCS) not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One air operated outlet isolation valve inoperable.	A.1 Restore air operated outlet isolation valve to OPERABLE status.	72 hours
B. One air operated In-Containment Refueling Water Storage Tank (IRWST) gutter isolation valve inoperable.	B.1 Restore air operated IRWST gutter isolation valve to OPERABLE status.	72 hours
C. Presence of non-condensible gases in the high point vent.	C.1 Vent noncondensible gases.	24 hours
D. Required Action and associated Completion Time of Condition A, B, or C not met.	D.1 Be in MODE 3. AND D.2 Be in MODE 4 with the RCS cooling provided by the RNS.	6 hours 24 hours
E. LCO not met for reasons other than Condition A, B, or C.	E.1 Restore PRHR HX to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
F. Required Action and associated Completion Time of Condition E not met.	F.1 ---------- **- NOTE -** Prior to initiating actions to change to a lower MODE, verify that redundant means of providing Steam Generator (SG) feedwater are OPERABLE. If redundant means are not OPERABLE, suspend LCO 3.0.3 and all other LCO Required Actions requiring MODE changes until redundant means are restored to OPERABLE status. ---------- Be in MODE 3.	6 hours
	AND	
	F.2 ---------- **- NOTE -** Prior to stopping the SG feedwater, verify that redundant means of cooling the RCS to cold shutdown conditions are OPERABLE. If redundant means are not OPERABLE, suspend LCO 3.0.3 and all other LCO Required Actions requiring MODE changes until redundant means are restored to OPERABLE status. ---------- Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.4.1	Verify the outlet manual isolation valve is fully open.	12 hours
SR 3.5.4.2	Verify the inlet motor operated isolation valve is open.	12 hours
SR 3.5.4.3	Verify the volume of noncondensible gases in the PRHR HX inlet line has not caused the high-point water level to drop below the sensor.	24 hours
SR 3.5.4.4	Verify that power is removed from the inlet motor operated isolation valve.	31 days
SR 3.5.4.5	Verify both PRHR air operated outlet isolation valves and both IRWST gutter isolation valves are OPERABLE by stroking open the valves.	In accordance with the Inservice Testing Program
SR 3.5.4.6	Verify PRHR HX heat transfer performance in accordance with the System Level OPERABILITY Testing Program.	10 years
SR 3.5.4.7	Verify by visual inspection that the IRWST gutters are not restricted by debris.	24 months

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.5 Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Shutdown, Reactor Coolant System (RCS) Intact

LCO 3.5.5 The PRHR HX shall be OPERABLE.

- NOTE -

When any reactor coolant pumps (RCPs) are operating, at least one RCP must be operating in the loop with the PRHR HX, Loop 1.

APPLICABILITY: MODE 4 with the RCS cooling provided by the Normal Residual Heat Removal System (RNS).
MODE 5 with the RCS pressure boundary intact and pressurizer level ≥ 20%.

ACTIONS

CONDITION		REQUIRED ACTION		COMPLETION TIME
A.	One air operated outlet isolation valve inoperable.	A.1	Restore air operated outlet valve to OPERABLE status.	72 hours
B.	One air operated In-Containment Refueling Water Storage Tank (IRWST) gutter isolation valve inoperable.	B.1	Restore air operated IRWST gutter isolation valve to OPERABLE status.	72 hours
C.	Presence of non-condensible gases in the high point vent.	C.1	Vent noncondensible gases.	24 hours
D.	PRHR HX inoperable for reasons other than Condition A, B, or C.	D.1	Restore PRHR HX to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Required Action and associated Completion Time not met. OR LCO not met for reasons other than A, B, C, or D.	E.1 Initiate action to be in MODE 5 with the RCS pressure boundary open and > 20% pressurizer level.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.5.1	The SRs of Specification 3.5.4, “Passive Residual Heat Removal Heat Exchanger (PRHR HX) – Operating” – are applicable.	In accordance with applicable SRs

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.6 In-containment Refueling Water Storage Tank (IRWST) – Operating

LCO 3.5.6 The IRWST, with two injection flow paths and two containment recirculation flow paths, shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One IRWST injection line actuation valve flow path inoperable. OR One containment recirculation line actuation valve flow path inoperable.	A.1 Restore the inoperable actuation valve flow path to OPERABLE status.	72 hours
B. One IRWST injection line inoperable due to presence of noncondensible gases in one high point vent.	B.1 Vent noncondensible gases.	72 hours
C. One IRWST injection line inoperable due to presence of noncondensible gases in both high point vents.	C.1 Vent noncondensible gases from one high point vent.	8 hours
D. IRWST boron concentration not within limits. OR IRWST borated water temperature not within limits. OR	D.1 Restore IRWST to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
IRWST borated water volume < 100% and > 97% of limit.		
E. One motor operated IRWST isolation valve not fully open. OR Power is not removed from one or more motor operated IRWST isolation valves.	E.1 Restore motor operated IRWST isolation valve to fully open condition with power removed from both valves.	1 hour
F. Required Action and associated Completion Time not met. OR LCO not met for reasons other than Condition A, B, C, D, or E.	F.1 Be in MODE 3. AND F.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.6.1	Verify the IRWST water temperature is < 120°F.	24 hours
SR 3.5.6.2	Verify the IRWST borated water volume is > 73,100 cu. ft.	24 hours
SR 3.5.6.3	Verify the volume of noncondensible gases in each of the four IRWST injection squib valve outlet line pipe stubs has not caused the high-point water level to drop below the sensor.	24 hours

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.5.6.4	Verify the IRWST boron concentration is ≥ 2600 ppm and ≤ 2900 ppm.	31 days AND Once within 6 hours after each solution volume increase of 15,000 gal
SR 3.5.6.5	Verify each motor operated IRWST isolation valve is fully open.	12 hours
SR 3.5.6.6	Verify power is removed from each motor operated IRWST isolation valve.	31 days
SR 3.5.6.7	Verify each motor operated containment recirculation isolation valve is fully open.	31 days
SR 3.5.6.8	Verify each IRWST injection and containment recirculation squib valve is OPERABLE in accordance with the Inservice Testing Program.	In accordance with the Inservice Testing Program
SR 3.5.6.9	Verify by visual inspection that the IRWST screens and the containment recirculation screens are not restricted by debris.	24 months
SR 3.5.6.10	Verify IRWST injection and recirculation system flow performance in accordance with the System Level OPERABILITY Testing Program.	10 years

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.7 In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 5

LCO 3.5.7 The IRWST, with one injection flow path and one containment recirculation flow path, shall be OPERABLE.

APPLICABILITY: MODE 5.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Required motor operated containment recirculation isolation valve not fully open.	A.1 Open required motor operated containment recirculation isolation valve.	72 hours
B. Required IRWST injection line inoperable due to presence of noncondensible gases in one high point vent.	B.1 Vent noncondensible gases.	72 hours
C. Required IRWST injection line inoperable due to presence of noncondensible gases in both high point vents.	C.1 Vent noncondensible gases from one high point vent.	8 hours
D. IRWST boron concentration not within limits. OR IRWST borated water temperature not within limits. OR IRWST borated water volume < 100% and > 97% of limit.	D.1 Restore IRWST to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Required motor operated IRWST isolation valve not fully open. OR Power is not removed from required motor operated IRWST isolation valve.	E.1 Restore required motor operated IRWST isolation valve to fully open condition with power removed.	1 hour
F. Required Action and associated Completion Time not met. OR LCO not met for reasons other than Condition A, B, C, D, or E.	F.1 Initiate action to be in MODE 5 with the Reactor Coolant System (RCS) pressure boundary intact and ≥ 20% pressurizer level. AND F.2 Suspend positive reactivity additions.	Immediately Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.7.1	For the IRWST and flow paths required to be OPERABLE, the SRs of Specification 3.5.6, “In-containment Refueling Water Storage Tank (IRWST) – Operating,” are applicable.	In accordance with applicable SRs

3.5 PASSIVE CORE COOLING SYSTEM (PXS)

3.5.8 In-containment Refueling Water Storage Tank (IRWST) – Shutdown, MODE 6

LCO 3.5.8 The IRWST, with one injection flow path and one containment recirculation flow path, shall be OPERABLE.

APPLICABILITY: MODE 6.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Required motor operated containment recirculation isolation valve not fully open.	A.1 Open required motor operated containment recirculation isolation valve.	72 hours
B. Required IRWST injection line inoperable due to presence of noncondensible gases in one high point vent.	B.1 Vent noncondensible gases.	72 hours
C. Required IRWST injection line inoperable due to presence of noncondensible gases in both high point vents.	C.1 Vent noncondensible gases from one high point vent.	8 hours
D. IRWST and refueling cavity boron concentration not within limits. OR IRWST and refueling cavity borated water temperature not within limits. OR IRWST and refueling cavity borated water volume < 100% and > 97% of limit.	D.1 Restore IRWST to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Required motor operated IRWST isolation valve not fully open. OR Power is not removed from required motor operated IRWST isolation valve.	E.1 Restore required motor operated IRWST isolation valve to fully open condition with power removed.	1 hour
F. Required Action and associated Completion Time not met. OR LCO not met for reasons other than Condition A, B, C, D, or E.	F.1 Initiate action to be in MODE 6 with the water level ≥ 23 feet above the top of the reactor vessel flange. AND F.2 Suspend positive reactivity additions.	Immediately Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.5.8.1	Verify the IRWST and refueling cavity water temperature is < 120°F.	24 hours
SR 3.5.8.2	Verify the IRWST and refueling cavity water total borated water volume is > 73,100 cu. ft.	24 hours
SR 3.5.8.3	Verify the IRWST and refueling cavity boron concentration is ≥ 2600 ppm and ≤ 2900 ppm.	31 days AND Once within 6 hours after each solution volume increase of 15,000 gal

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.5.8.4	For the IRWST and flow paths required to be OPERABLE, the following SRs of Specification 3.5.6, "In-containment Refueling Water Storage Tank (IRWST) – Operating" are applicable: SR 3.5.6.3 SR 3.5.6.6 SR 3.5.6.8 SR 3.5.6.10 SR 3.5.6.5 SR 3.5.6.7 SR 3.5.6.9	In accordance with applicable SRs

3.6 CONTAINMENT SYSTEMS

3.6.1 Containment

LCO 3.6.1 Containment shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Containment inoperable.	A.1 Restore containment to OPERABLE status.	1 hour
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.1.1	Perform required visual examinations and leakage-rate testing except for containment air-lock testing, in accordance with the Containment Leakage Rate Testing Program.	In accordance with the Containment Leakage Rate Testing Program

3.6 CONTAINMENT SYSTEMS

3.6.2 Containment Air Locks

LCO 3.6.2 Two containment air locks shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

- NOTES -

1. Entry and exit is permissible to perform repairs on the affected air lock components.
2. Separate Condition entry is allowed for each air lock.
3. Enter applicable Conditions and Required Actions of LCO 3.6.1, “Containment,” when air lock leakage results in exceeding the overall containment leakage rate acceptance criteria.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more containment air locks with one containment air lock door inoperable.	--- **- NOTES -** 1. Required Actions A.1, A.2, and A.3 are not applicable if both doors in the same air lock are inoperable and Condition C is entered. 2. Entry and exit is permissible for 7 days under administrative controls if both air locks are inoperable. --- A.1 Verify the OPERABLE door is closed in the affected air lock. <u>AND</u>	1 hour

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.2 Lock the OPERABLE door closed in the affected air lock. AND A.3 ---------- **- NOTE -** Air lock doors in high radiation areas may be verified locked closed by administrative means. ---------- Verify the OPERABLE door is locked closed in the affected air lock.	24 hours Once per 31 days
B. One or more containment air locks with containment air lock interlock mechanism inoperable.	---------- **- NOTES -** 1. Required Actions B.1, B.2, and B.3 are not applicable if both doors in the same air lock are inoperable and Condition C is entered. 2. Entry and exit of containment is permissible under the control of a dedicated individual. ---------- B.1 Verify an OPERABLE door is closed in the affected air lock. AND	 1 hour

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
	B.2	Lock an OPERABLE door closed in the affected air lock. AND	24 hours
	B.3	---------- **- NOTE -** Air lock doors in high radiation areas may be verified locked closed by administrative means. ---------- Verify an OPERABLE door is locked closed in the affected air lock.	Once per 31 days
C. One or more containment air locks inoperable for reasons other than Condition A or B.	C.1	Initiate action to evaluate overall containment leakage rate per LCO 3.6.1. AND	Immediately
	C.2	Verify a door is closed in the affected air lock. AND	1 hour
	C.3	Restore air lock to OPERABLE status.	24 hours
D. Required Action and associated Completion Time not met.	D.1	Be in MODE 3. AND	6 hours
	D.2	Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.2.1	---------- **- NOTES -** 1. An inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test. 2. Results shall be evaluated against acceptance criteria applicable to SR 3.6.1.1. ---------- Perform required air lock leakage rate testing in accordance with the Containment Leakage Rate Testing Program.	In accordance with the Containment Leakage Rate Testing Program
SR 3.6.2.2	Verify only one door in the air lock can be opened at a time.	24 months

3.6 CONTAINMENT SYSTEMS

3.6.3 Containment Isolation Valves

LCO 3.6.3 Each containment isolation valve shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

- NOTES -

1. Penetration flow path(s) may be unisolated intermittently under administrative controls.
2. Separate Condition entry is allowed for each penetration flow path.
3. Enter applicable Conditions and Required Actions for systems made inoperable by containment isolation valves.
4. Enter applicable Conditions and Required Actions of LCO 3.6.1, “Containment,” when isolation valve leakage results in exceeding the overall containment leakage rate acceptance criteria.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. --- **- NOTE -** Only applicable to penetration flow paths with two containment isolation valves. --- One or more penetration flow paths with one containment isolation valve inoperable.	A.1 Isolate the affected penetration flow path by use of at least one closed and de-activated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured. <u>AND</u>	4 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.2 ---------- **- NOTES -** 1. Isolation devices in high radiation areas may be verified by use of administrative means. 2. Isolation devices that are locked, sealed, or otherwise secured may be verified by administrative means. ---------- Verify the affected penetration flow path is isolated.	Once per 31 days for isolation devices outside containment <u>AND</u> Prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days for isolation devices inside containment
B. ---------- **- NOTE -** Only applicable to penetration flow paths with two containment isolation valves. ---------- One or more penetration flow paths with two containment isolation valves inoperable.	B.1 Isolate the affected penetration flow path by use of at least one closed and de-activated automatic valve, closed manual valve, or blind flange.	1 hour

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. ---------- **- NOTE -** Only applicable to penetration flow paths with only one containment isolation valve and a closed system. ---------- One or more penetration flow paths with one containment isolation valve inoperable.	C.1 Isolate the affected penetration flow path by use of at least one closed and de-activated automatic valve, closed manual valve, or blind flange. AND C.2 ---------- **- NOTES -** 1. Isolation devices in high radiation areas may be verified by use of administrative means. 2. Isolation devices that are locked, sealed, or otherwise secured may be verified by administrative means. ---------- Verify that the affected penetration flow path is isolated.	72 hours Once per 31 days
D. Required Action and associated Completion Time not met.	D.1 Be in MODE 3. AND D.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

	SURVEILLANCE	FREQUENCY
SR 3.6.3.1	Verify each 16 inch containment purge valve is closed, except when the 16 inch containment purge valves are open for pressure control, ALARA or air quality considerations for personnel containment entry, or for Surveillances which require the valves to be open.	31 days
SR 3.6.3.2	--- **- NOTE -** Valves and blind flanges in high radiation areas may be verified by use of administrative controls. --- Verify each containment isolation manual valve and blind flange that is located outside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed, except for containment isolation valves that are open under administrative controls.	31 days
SR 3.6.3.3	--- **- NOTE -** Valves and blind flanges in high radiation areas may be verified by use of administrative controls. --- Verify each containment isolation manual valve and blind flange that is located inside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed, except for containment isolation valves that are open under administrative controls.	Prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days
SR 3.6.3.4	Verify the isolation time of each automatic power operated containment isolation valve is within limits.	In accordance with the Inservice Testing Program
SR 3.6.3.5	Verify each automatic containment isolation valve that is not locked, sealed or otherwise secured in position, actuates to the isolation position on an actual or simulated actuation signal.	24 months

3.6 CONTAINMENT SYSTEMS

3.6.4 Containment Pressure

LCO 3.6.4 Containment pressure shall be ≥ -0.2 psig and ≤ +1.0 psig.

APPLICABILITY: MODES 1, 2, 3, and 4.
MODES 5 and 6 without an open containment air flow path ≥ 6 inches in diameter.

- NOTE -

The high pressure LCO limit is not applicable in MODES 5 or 6.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. Containment pressure not within limits.	A.1	Restore containment pressure to within limits.	1 hour
B. Required Action and associated Completion Time not met.	B.1	Be in MODE 3.	6 hours
	AND		
	B.2	Be in MODE 5.	36 hours
	AND		
	B.3	Open a containment air flow path ≥ 6 inches in diameter.	44 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.4.1	Verify containment pressure is within limits.	12 hours

3.6 CONTAINMENT SYSTEMS

3.6.5 Containment Air Temperature

LCO 3.6.5 Containment average air temperature shall be ≤ 120°F.

APPLICABILITY: MODES 1, 2, 3, and 4,
MODES 5 and 6 with both containment equipment hatches and both containment airlocks closed.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Containment average air temperature not within limit.	A.1 Restore containment average air temperature to within limit.	8 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. <u>AND</u> B.2 Be in MODE 5 or 6. <u>AND</u> <u>B.3</u> Open containment equipment hatch or containment airlock.	6 hours 36 hours 44 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.5.1	Verify containment average air temperature is within limit.	24 hours

3.6 CONTAINMENT SYSTEMS

3.6.6 Passive Containment Cooling System (PCS) – Operating

LCO 3.6.6 The passive containment cooling system shall be OPERABLE, with all three water flow paths OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One passive containment cooling water flow path inoperable.	A.1 Restore flow path to OPERABLE status.	7 days
B. Two passive containment cooling water flow paths inoperable.	B.1 Restore flow paths to OPERABLE status.	72 hours
C. One or more water storage tank parameters (temperature and volume) not within limits.	C.1 Restore water storage tank to OPERABLE status.	8 hours
D. Required Action and associated Completion Time not met. OR LCO not met for reasons other than A, B, or C.	D.1 Be in MODE 3. AND D.2 Be in MODE 5.	6 hours 84 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.6.1	Verify the water storage tank temperature ≥ 40°F and ≤ 120°F.	7 days AND 24 hours when water storage tank temperature is verified ≤ 50°F or ≥ 100°F
SR 3.6.6.2	Verify the water storage tank volume ≥ 756,700 gallons.	7 days
SR 3.6.6.3	Verify each passive containment cooling system, power operated, and automatic valve in each flow path that is not locked, sealed, or otherwise secured in position, is in the correct position.	31 days
SR 3.6.6.4	Verify each passive containment cooling system automatic valve in each flow path that is not locked, sealed, or otherwise secured in position, actuates to the correct position on an actual or simulated actuation signal.	24 months
SR 3.6.6.5	Verify the air flow path from the shield building annulus inlet to the exit is unobstructed and, that all air baffle sections are in place.	24 months
SR 3.6.6.6	Verify passive containment cooling system flow and water coverage performance in accordance with the System Level OPERABILITY Testing Program.	At first refueling AND 10 years

3.6 CONTAINMENT SYSTEMS

3.6.7 Passive Containment Cooling System (PCS) – Shutdown

LCO 3.6.7 The passive containment cooling system shall be OPERABLE with all three water flow paths OPERABLE.

APPLICABILITY: MODE 5 with the calculated reactor decay heat > 6.0 MWt,
MODE 6 with the calculated reactor decay heat > 6.0 MWt.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One passive containment cooling water flow path inoperable.	A.1 Restore flow path to OPERABLE status.	7 days
B. Two passive containment cooling water flow paths inoperable.	B.1 Restore flow paths to OPERABLE status.	72 hours
C. One or more water storage tank parameters (temperature and volume) not within limits.	C.1 Restore water storage tank to OPERABLE status.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
D. Required Action and associated Completion Time not met. OR LCO not met for reasons other than Condition A, B, or C.	D.1.1	If in MODE 5, initiate action to be in MODE 5 with the Reactor Coolant System (RCS) pressure boundary intact and ≥ 20% pressurizer level.	Immediately
	OR		
	D.1.2	If in MODE 6, initiate action to be in MODE 6 with the water level ≥ 23 feet above the top of the reactor vessel flange.	Immediately
	AND		
	D.2	Suspend positive reactivity additions.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.7.1	The SRs of Specification 3.6.6, “Passive Containment Cooling System – Operating,” are applicable.	In accordance with applicable SRs

3.6 CONTAINMENT SYSTEMS

3.6.8 Containment Penetrations

LCO 3.6.8 The containment penetrations shall be in the following status:

a. The equipment hatches closed and held in place by four bolts or, if open, clear of obstructions such that the hatches can be closed prior to steaming into the containment.

b. One door in each air lock closed or, if open, the containment air locks shall be clear of obstructions such that they can be closed prior to steaming into the containment.

c. The containment spare penetrations, if open, shall be clear of obstructions such that the penetrations can be closed prior to steaming into the containment.

d. Each penetration providing direct access from the containment atmosphere to the outside atmosphere either:

1. closed by a manual or automatic isolation valve, blind flange, or equivalent, or

2. capable of being closed by an OPERABLE Containment Isolation signal.

APPLICABILITY: MODES 5 and 6.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more containment penetrations not in required status.	A.1 Restore containment penetrations to required status.	1 hour

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
B. Required Action and associated Completion Time not met. OR LCO not met for reasons other than Condition A.	B.1.1	If in MODE 5, initiate action to be in MODE 5 with the Reactor Coolant System (RCS) pressure boundary intact and ≥ 20% pressurizer level.	Immediately
	OR		
	B.1.2	If in MODE 6, initiate action to be in MODE 6 with the water level ≥ 23 feet above the top of the reactor vessel flange.	Immediately
	AND		
	B.2	Suspend positive reactivity additions.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.8.1	Verify each required containment penetration is in the required status.	7 days
SR 3.6.8.2	--- **- NOTE -** Only required to be met for an open equipment hatch. --- Verify that the hardware, tools, equipment and power source necessary to install the equipment hatch are available.	Prior to hatch removal AND 7 days

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.6.8.3	---------- **- NOTE -** Not required to be met for automatic isolation valve(s) in penetrations closed to comply with LCO 3.6.8.d.1. ---------- Verify one automatic isolation valve in each open penetration providing direct access from the containment atmosphere to the outside atmosphere actuates to the isolation position on an actual or simulated actuation signal.	24 months

3.6 CONTAINMENT SYSTEMS

3.6.9 pH Adjustment

LCO 3.6.9 The pH adjustment baskets shall contain ≥ 560 ft^3 of trisodium phosphate (TSP).

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. The volume of trisodium phosphate not within limit.	A.1 Restore volume of trisodium phosphate to within limit.	72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 84 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.9.1	Verify that the pH adjustment baskets contain at least 560 ft^3 of TSP (Na_3PO_4-12 H_2O).	24 months
SR 3.6.9.2	Verify that a sample from the pH adjustment baskets provides adequate pH adjustment of the post-accident water.	24 months

3.6 CONTAINMENT SYSTEMS

3.6.10 Vacuum Relief Valves

LCO 3.6.10 Two vacuum relief flow paths shall be OPERABLE.

AND

Containment inside to outside differential air temperature shall be ≤ 90°F.

APPLICABILITY: MODES 1, 2, 3, and 4.
MODES 5 and 6 without an open containment air flow path ≥ 6 inches in diameter.

ACTIONS

CONDITION		REQUIRED ACTION		COMPLETION TIME
A.	One vacuum relief flow path inoperable.	A.1	Restore vacuum relief flow path to OPERABLE status.	72 hours
B.	Containment inside to outside differential air temperature > 90°F.	B.1	Restore containment inside to outside differential air temperature to within limit.	8 hours
		OR		
		B.2	Reduce containment average temperature ≤ 80°F.	8 hours
C.	Required Action and associated Completion Time of Conditions A or B not met.	C.1	Be in MODE 3.	6 hours
		AND		
		C.2	Be in MODE 5.	36 hours
	OR	AND		
	Both vacuum relief flow paths inoperable.	C.3	Open a containment air flow path ≥ 6 inches in diameter.	44 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.6.10.1	Verify containment inside to outside differential air temperature is ≤ 90°F.	12 hours
SR 3.6.10.2	Verify each vacuum relief flow path is OPERABLE in accordance with the Inservice Testing Program.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.1 Main Steam Safety Valves (MSSVs)

LCO 3.7.1 The MSSVs shall be OPERABLE as specified in Table 3.7.1-1 and Table 3.7.1-2.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with the Reactor Coolant System (RCS) not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

- NOTE -
Separate Condition entry is allowed for each MSSV.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required MSSVs inoperable.	A.1 Reduce THERMAL POWER to less than or equal to the Maximum Allowable % RTP specified in Table 3.7.1-1 for the number of OPERABLE MSSVs. AND	4 hours
	A.2 ---------- **- NOTE -** Only required in MODE 1. ---------- Reduce the Power Range Neutron Flux – High reactor trip setpoint to less than or equal to the Maximum Allowable % RTP specified in Table 3.7.1-1 for the number of OPERABLE MSSVs.	36 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met. OR One or more steam generators with ≥ 5 MSSVs inoperable.	B.1 Be in MODE 3. AND B.2 Be in MODE 4 with the RCS cooling provided by the RNS.	6 hours 24 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.1.1	---------- **- NOTE -** Only required to be performed in MODES 1 and 2. ---------- Verify each required MSSV lift setpoint per Table 3.7.1-2 in accordance with the Inservice Testing Program. Following testing, lift settings shall be within ±1%.	In accordance with the Inservice Testing Program

Table 3.7.1-1 (page 1 of 1)
OPERABLE MSSVs versus Maximum Allowable Power

NUMBER OF OPERABLE MSSVs PER STEAM GENERATOR	MAXIMUM ALLOWABLE POWER (% RTP)
5	60
4	46
3	32
2	18

Table 3.7.1-2 (page 1 of 1)
Main Steam Safety Valve Lift Settings

VALVE NUMBER		LIFT SETTING (psig ± 1%)
STEAM GENERATOR		
#1	#2	
V030A	V030B	1185
V031A	V031B	1197
V032A	V032B	1209
V033A	V033B	1221
V034A	V034B	1232
V035A	V035B	1232

3.7 PLANT SYSTEMS

3.7.2 Main Steam Isolation Valves (MSIVs)

LCO 3.7.2 The minimum combination of valves required for steam flow isolation shall be OPERABLE.

APPLICABILITY: MODE 1,
MODES 2, 3, and 4 except when steam flow is isolated.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One MSIV inoperable in MODE 1.	A. Restore valve to OPERABLE status.	8 hours
B. One or more of the turbine stop valves and its associated turbine control valve, turbine bypass valves, or moisture separator reheater 2nd stage steam isolation valves inoperable in MODE 1.	B. Restore valve to OPERABLE status.	72 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. Two MSIVs inoperable in MODE 1. OR One MSIV inoperable and one or more of the turbine stop valves and its associated turbine control valve, all turbine bypass valves, or moisture separator reheater 2nd stage steam isolation valves inoperable in MODE 1. OR Required Action and associated Completion Time of Condition A or B not met.	C.1 Be in MODE 2.	6 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
D. ---------- **- NOTE -** Separate Condition entry is allowed for each MSIV. ---------- One or two MSIVs inoperable in MODE 2, 3, or 4. OR One or more of the turbine stop valves and its associated turbine control valve, all turbine bypass valves, or moisture separator reheater 2nd stage steam isolation valves inoperable in MODE 2, 3, or 4.	D.1	Isolate associated steam flow path. AND	8 hours
	D.2	Verify flow path remains closed.	Once per 7 days
E. Required Action and associated Completion Time of Condition D not met.	E.1	Be in MODE 3. AND	6 hours
	E.2	Be in MODE 4 with the Reactor Coolant System (RCS) cooling provided by the Normal Residual Heat Removal System (RNS).	24 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.2.1	---------- **- NOTE -** Only required to be performed prior to entry into MODE 2. ---------- Verify MSIV closure time ≤ 5 seconds on an actual or simulated actuation signal.	In accordance with the Inservice Testing Program
SR 3.7.2.2	---------- **- NOTE -** Only required to be performed prior to entry into MODE 2. ---------- Verify turbine stop, turbine control, turbine bypass, and moisture separator reheater 2nd stage steam isolation valves' closure time ≤ 5 seconds on an actual or simulated actuation signal.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.3 Main Feedwater Isolation and Control Valves (MFIVs and MFCVs)

LCO 3.7.3 The MFIV and the MFCV for each Steam Generator shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4 except when the MFIVs or associated MFCV are closed and deactivated.

ACTIONS

- NOTE -

Separate Condition entry is allowed for each valve.

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or two MFIVs inoperable.	A.1	Close or isolate the MFIV flow path.	72 hours
	AND		
	A.2	Verify MFIV is closed or isolated.	Once per 7 days
B. One or two MFCVs inoperable.	B.1	Close or isolate the MFCV the flow path.	72 hours
	AND		
	B.2	Verify MFCV is closed or isolated.	Once per 7 days
C. Two valves in the same flow path inoperable.	C.1	Isolate affected flow path.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
D. Required Action and associated Completion Time not met.	D.1	Be in MODE 3.	6 hours
	AND		
	D.2	Be in MODE 4 with the Reactor Coolant System (RCS) cooling provided by the Normal Residual Heat Removal System (RNS).	24 hours
	AND		
	D.3.1	Isolate the affected flow path(s).	36 hours
	OR		
	D.3.2	Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.3.1	--- **- NOTE -** Only required to be performed prior to entry into MODE 2. ---	
	Verify the closure time of each MFIV and MFCV is ≤ 5 seconds on an actual or simulated actuation signal.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.4 Secondary Specific Activity

LCO 3.7.4 The specific activity of the secondary coolant shall be ≤ 0.1 µCi/gm DOSE EQUIVALENT I-131.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Specific activity not within limit.	A.1 Be in MODE 3. AND A.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.4.1	Verify the specific activity of the secondary coolant ≤ 0.1 µCi/gm DOSE EQUIVALENT I-131.	31 days

3.7 PLANT SYSTEMS

3.7.5 Spent Fuel Pool Water Level

LCO 3.7.5 The spent fuel pool water level shall be ≥ 23 ft above the top of irradiated fuel assemblies seated in the storage racks.

APPLICABILITY: At all times.

ACTIONS

- NOTE -

LCOs 3.0.3 and 3.0.8 are not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Spent fuel pool water level < 23 ft.	A.1 Suspend movement of irradiated fuel assemblies in the spent fuel pool. AND	Immediately
	A.2 Initiate action to restore water level to ≥ 23 ft.	1 hour

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.5.1	Verify the spent fuel pool water level is ≥ 23 ft above the top of the irradiated fuel assemblies seated in the storage racks.	7 days

3.7 PLANT SYSTEMS

3.7.6 Main Control Room Emergency Habitability System (VES)

LCO 3.7.6 The VES shall be OPERABLE.

- NOTE -

The main control room envelope (MCRE) boundary may be opened intermittently under administrative control.

APPLICABILITY: MODES 1, 2, 3, and 4,
During movement of irradiated fuel assemblies.

ACTIONS

- NOTE -

LCO 3.0.8 is not applicable.

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One valve or damper inoperable.	A.1	Restore valve or damper to OPERABLE status.	7 days
B. MCRE air temperature not within limit.	B.1	Restore MCRE air temperature to within limit.	24 hours
C. VES inoperable due to inoperable MCRE boundary in MODE 1, 2, 3, or 4.	C.1 AND	Initiate action to implement mitigating actions.	Immediately
	C.2 AND	Verify mitigating actions ensure MCRE occupant exposures to radiological, chemical, and smoke hazards will not exceed limits.	24 hours
	C.3	Restore MCRE boundary to OPERABLE status.	90 days

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
D. One bank of VES air tanks (8 tanks) inoperable.	D.1	Verify that the OPERABLE tanks contain greater than 245,680 scf of compressed air.	2 hours AND Once per 12 hours thereafter
	AND		
	D.2	Verify VBS MCRE ancillary fans and supporting equipment are available.	24 hours
	AND		
	D.3	Restore VES to OPERABLE status.	7 days
E. Required Action and associated Completion Time of Conditions A, B, C, or D not met in MODE 1, 2, 3, or 4. OR VES inoperable for reasons other than Conditions A, B, C, or D in MODE 1, 2, 3, or 4.	E.1	Be in MODE 3.	6 hours
	AND		
	E.2	Be in MODE 5.	36 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
F. Required Action and associated Completion Time of Conditions A, B, C, or D not met during movement of irradiated fuel. OR VES inoperable for reasons other than Conditions A, B, C, or D during movement of irradiated fuel. OR VES inoperable due to inoperable MCRE boundary during movement of irradiated fuel.	F.1 Suspend movement of irradiated fuel assemblies.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.6.1	Verify MCRE air temperature is ≤ 75°F.	24 hours
SR 3.7.6.2	Verify that the compressed air storage tanks contain greater than 327,574 scf of compressed air.	24 hours
SR 3.7.6.3	Verify that each VES air delivery isolation valve is OPERABLE.	In accordance with the Inservice Testing Program
SR 3.7.6.4	Operate VES for ≥ 15 minutes.	31 days
SR 3.7.6.5	Verify that each VES air header manual isolation valve is in an open position.	31 days

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.6.6	Verify that the air quality of the air storage tanks meets the requirements of Appendix C, Table C-1 of ASHRAE Standard 62.	92 days
SR 3.7.6.7	Verify that all MCRE isolation valves are OPERABLE and will close upon receipt of an actual or simulated actuation signal.	24 months
SR 3.7.6.8	Verify that each VES pressure relief isolation valve within the MCRE pressure boundary is OPERABLE.	In accordance with the Inservice Testing Program
SR 3.7.6.9	Verify that each VES pressure relief damper is OPERABLE.	24 months
SR 3.7.6.10	Verify that the self-contained pressure regulating valve in each VES air delivery flow path is OPERABLE.	In accordance with the Inservice Testing Program
SR 3.7.6.11	Perform required MCRE unfiltered air inleakage testing in accordance with the Main Control Room Envelope Habitability Program.	In accordance with the Main Control Room Envelope Habitability Program
SR 3.7.6.12	Perform required VES Passive Filtration system filter testing in accordance with the Ventilation Filter Testing Program (VFTP).	In accordance with the VFTP

3.7 PLANT SYSTEMS

3.7.7 Startup Feedwater Isolation and Control Valves

LCO 3.7.7 Both Startup Feedwater Isolation Valves and Control Valves shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4 except when the startup feedwater flow paths are isolated.

ACTIONS

- NOTES -

1. Flow paths may be unisolated intermittently under administrative controls.
2. Separate Condition entry is allowed for each flow path.

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or more flow paths with one inoperable valve.	A.1	Isolate the affected flow path(s).	72 hours
	AND		
	A.2	Verify affected flow path(s) is isolated.	Once per 7 days
B. One flow path with two inoperable valves.	B.1	Isolate the affected flow path.	8 hours
C. Required Action and associated Completion Time not met.	C.1	Be in MODE 3.	6 hours
	AND		
	C.2	Be in MODE 4 with the Reactor Coolant System (RCS) cooling provided by the Normal Residual Heat Removal System (RNS).	24 hours
	AND		
	C.3	Isolate the affected flow path(s).	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.7.1	Verify both startup feedwater isolation and control valves are OPERABLE.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.8 Main Steam Line Leakage

LCO 3.7.8 Main Steam Line leakage through the pipe walls inside containment shall be limited to 0.5 gpm.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Main Steam Line leakage exceeds operational limit.	A.1 Be in MODE 3. AND A.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.8.1	Verify main steam line leakage into the containment sump ≤ 0.5 gpm.	Per SR 3.4.7.1

3.7 PLANT SYSTEMS

3.7.9 Fuel Storage Pool Makeup Water Sources

LCO 3.7.9 Fuel storage pool makeup water sources shall be OPERABLE.

- NOTES -

1. OPERABILITY of the cask washdown pit is required when the calculated spent fuel storage pool decay heat > 4.7 MWt and ≤ 7.2 MWt.

2. OPERABILITY of the cask loading pit is required when the calculated spent fuel storage pool decay heat > 5.6 MWt and ≤ 7.2 MWt.

3. OPERABILITY of the Passive Containment Cooling Water Storage Tank (PCCWST) is required as a spent fuel storage pool makeup water source when the calculated spent fuel storage pool decay heat > 7.2 MWt. If the reactor decay heat is > 6.0 MWt, the PCCWST must be exclusively available for containment cooling in accordance with LCO 3.6.7.

APPLICABILITY: During storage of fuel in the spent fuel storage pool with a calculated decay heat > 4.7 MWt.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required spent fuel storage pool makeup water sources inoperable.	A.1 --- **- NOTE -** LCOs 3.0.3 and 3.0.8 are not applicable. --- Initiate action to restore the required makeup water source(s) to OPERABLE status.	Immediately

SURVEILLANCE REQUIREMENTS

	SURVEILLANCE	FREQUENCY
SR 3.7.9.1	---------- **- NOTE -** Only required to be performed when spent fuel storage pool calculated decay heat is > 7.2 MWt. ---------- Verify one passive containment cooling system, motor-operated valve in each flow path is closed and locked, sealed, or otherwise secured in position.	7 days
SR 3.7.9.2	---------- **- NOTE -** Only required to be performed when spent fuel storage pool calculated decay heat is > 7.2 MWt. ---------- Verify the PCCWST volume is ≥ 756,700 gallons.	7 days
SR 3.7.9.3	---------- **- NOTE -** Only required to be performed when spent fuel storage pool calculated decay heat is ≤ 7.2 MWt. ---------- Verify the water level in the cask washdown pit is ≥ 13.75 ft.	31 days
SR 3.7.9.4	---------- **- NOTE -** Only required to be performed when spent fuel storage pool calculated decay heat is > 5.6 MWt and ≤ 7.2 MWt. ---------- Verify the water level in the cask loading pit is ≥ 43.9 ft. and in communication with the spent fuel storage pool.	31 days

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.9.5	Verify the spent fuel storage pool makeup isolation valves PCS-PL-V009, PCS-PL-V045, PCS-PL-V051, SFS-PL-V042, SFS-PL-V045, SFS-PL-V049, SFS-PL-V066, and SFS-PL-V068 are OPERABLE in accordance with the Inservice Testing Program.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.10 Steam Generator (SG) Isolation Valves

LCO 3.7.10 The steam generator isolation valves shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with the Reactor Coolant System (RCS) not being cooled by the Normal Residual Heat Removal System (RNS).

ACTIONS

- NOTES -

1. Steam generator blowdown flow path(s) may be unisolated intermittently under administrative controls.

2. Separate Condition entry is allowed for each flow path.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more PORV flow paths with one SG isolation valve inoperable.	A.1 Isolate the flow path by use of at least one closed and deactivated automatic valve.	72 hours
B. One or more blowdown flow paths with one SG isolation valve inoperable.	B.1 Isolate the flow path by one closed valve. AND B.2 Verify that the affected SG blowdown flow path is isolated.	72 hours Once per 7 days
C. One or more PORV flow paths with two SG isolation valves inoperable.	C.1 Isolate the affected flow path by use of at least one closed and deactivated automatic valve.	8 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
D. One or more blowdown flow paths with two SG isolation valves inoperable.	D.1 Isolate the flow path by one closed valve. AND	8 hours
	D.2 Verify that the affected SG blowdown flow path is isolated.	Once per 7 days
E. Required Action and associated Completion Time not met.	E.1 Be in MODE 3. AND	6 hours
	E.2 Be in MODE 4 with the RCS cooling provided by the RNS.	24 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.10.1	Verify each steam generator isolation valve (PORV block valves (SGS-PL-V027A & B), PORVs (SGS-PL-V233A & B), and blowdown isolation valves (SGS-PL-V074A & B and SGS-PL-V075A & B)) is OPERABLE by stroking the valve closed.	In accordance with the Inservice Testing Program

3.7 PLANT SYSTEMS

3.7.11 Fuel Storage Pool Boron Concentration

LCO 3.7.11 The fuel storage pool boron concentration shall be ≥ 2300 ppm.

APPLICABILITY: When fuel assemblies are stored in the fuel storage pool and a fuel storage pool verification has not been performed since the last movement of fuel assemblies in the fuel storage pool.

ACTIONS

- NOTE -

LCOs 3.0.3 and 3.0.8 are not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Fuel storage pool boron concentration not within limit.	A.1 Suspend movement of fuel assemblies in the fuel storage pool. AND A.2.1 Initiate action to restore fuel storage pool boron concentration to within limit. OR A.2.2 Initiate action to perform a fuel storage pool verification.	Immediately Immediately Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.11.1	Verify the fuel storage pool boron concentration is within limit.	7 days

3.7 PLANT SYSTEMS

3.7.12 Spent Fuel Pool Storage

LCO 3.7.12 The combination of initial enrichment and burnup of each fuel assembly stored in Region 2 shall be within the limits specified in Figure 3.7.12-1.

APPLICABILITY: Whenever any fuel assembly is stored in Region 2 of the spent fuel storage pool.

ACTIONS

- NOTE -

LCOs 3.0.3 and 3.0.8 are not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Requirements of the LCO not met.	A.1 Initiate action to move the noncomplying fuel assembly to an acceptable storage location.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.12.1	Verify by administrative means the initial enrichment and burnup of the fuel assembly is in accordance with Figure 3.7.12-1.	Prior to storing the fuel assembly in Region 2

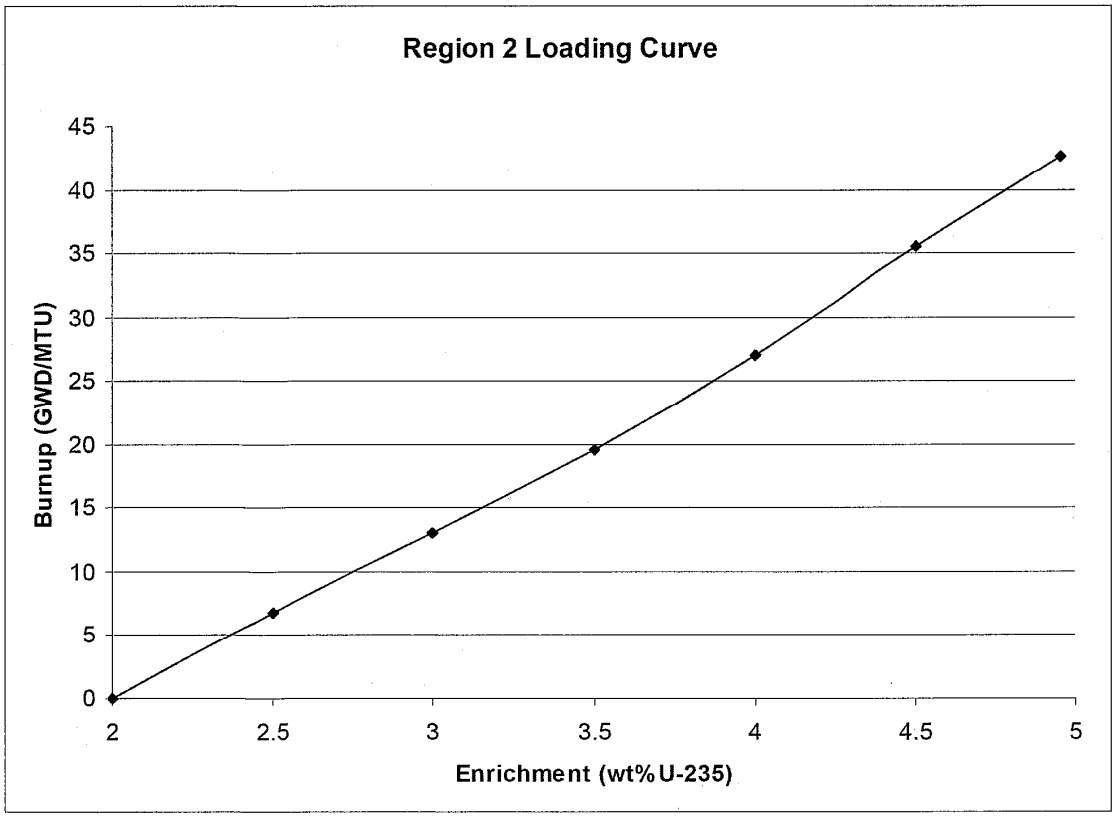

Figure 3.7.12-1

Minimum Fuel Assembly Burnup Versus Initial Enrichment for Region 2 Spent Fuel Cells

3.8 ELECTRICAL POWER SYSTEMS

3.8.1 DC Sources – Operating

LCO 3.8.1 The Division A, B, C, and D Class 1E DC power subsystems shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One or more battery chargers in one division inoperable.	A.1	Restore battery terminal voltage to greater than or equal to the minimum established float voltage.	6 hours
	AND		
	A.2	Verify battery float current ≤ 2 amps.	Once per 24 hours
	AND		
	A.3	Restore battery charger(s) to OPERABLE status.	7 days
B. One or more battery chargers in two divisions inoperable.	B.1	Restore battery terminal voltage to greater than or equal to the minimum established float voltage.	2 hours
	AND		
	B.2	Verify battery float current ≤ 2 amps.	Once per 24 hours
	AND		
	B.3	Restore battery charger(s) to OPERABLE status.	7 days

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. One or more batteries in one division inoperable.	C.1 Restore batteries to OPERABLE status.	6 hours
D. One or more batteries in two divisions inoperable.	D.1 Restore batteries to OPERABLE status.	2 hours
E. One DC electrical power subsystem inoperable for reasons other than Condition A or C.	E.1 Restore DC electrical power subsystem to OPERABLE status.	6 hours
F. Two DC electrical power subsystems inoperable for reasons other than B or D.	F.1 Restore DC electrical power subsystem to OPERABLE status.	2 hours
G. Required Action and associated Completion Time not met.	G.1 Be in MODE 3. AND G.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.1.1	Verify battery terminal voltage is greater than or equal to the minimum established float voltage.	7 days

SURVEILLANCE REQUIREMENTS (continued)

	SURVEILLANCE	FREQUENCY
SR 3.8.1.2	Verify each battery charger supplies ≥ 200 amps at greater than or equal to the minimum established float voltage for ≥ 8 hours. OR Verify each battery charger can recharge the battery to the fully charged state within 24 hours while supplying the largest combined demands of the various continuous steady state loads, after a battery discharge to the bounding design basis event discharge state.	24 months
SR 3.8.1.3	---------- **- NOTES -** 1. The modified performance discharge test in SR 3.8.7.6 may be performed in lieu of SR 3.8.1.3. 2. This Surveillance shall not normally be performed in MODE 1, 2, 3, or 4 unless the spare battery is connected to replace the battery being tested. However, portions of the Surveillance may be performed to reestablish OPERABILITY provided an assessment determines the safety of the plant is maintained or enhanced. ---------- Verify battery capacity is adequate to supply, and maintain in OPERABLE status, the required emergency loads for the design duty cycle when subjected to a battery service test.	24 months

3.8 ELECTRICAL POWER SYSTEMS

3.8.2 DC Sources – Shutdown

LCO 3.8.2 DC electrical power subsystems shall be OPERABLE to support the DC electrical power distribution subsystem(s) required by LCO 3.8.6, "Distribution Systems – Shutdown."

APPLICABILITY: MODES 5 and 6,
During movement of irradiated fuel assemblies.

ACTIONS

- NOTE -

LCO 3.0.3 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required DC electrical power subsystems inoperable.	A.1 Declare affected required features inoperable.	Immediately
	OR	
	A.2.1 Suspend CORE ALTERATIONS.	Immediately
	AND	
	A.2.2 Suspend movement of irradiated fuel assemblies.	Immediately
	AND	
	A.2.3 Suspend operations with a potential for draining the reactor vessel.	Immediately
	AND	

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.2.4 Suspend operations involving positive reactivity additions that could result in loss of required SDM or boron concentration. AND	Immediately
	A.2.5 Initiate action to restore required DC electrical power subsystems to OPERABLE status.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.2.1	---------- **- NOTE -** The following SRs are not required to be performed: SR 3.8.1.2 and SR 3.8.1.3. ----------	
	For DC sources required to be OPERABLE, the following SRs are applicable: SR 3.8.1.1 SR 3.8.1.2 SR 3.8.1.3	In accordance with applicable SRs

3.8 ELECTRICAL POWER SYSTEMS

3.8.3 Inverters – Operating

LCO 3.8.3 The Division A, B, C, and D inverters (Divisions A and D, one each and Divisions B and C two each; six total) shall be OPERABLE.

- NOTES -

One inverter may be disconnected from its associated DC bus for ≤ 72 hours to perform an equalizing charge on its associated battery, providing:

1. The associated instrument and control bus is energized from its Class 1E constant voltage source transformer; and

2. All other AC instrument and control buses are energized from their associated OPERABLE inverters.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One inverter inoperable.	A.1	--- **- NOTE -** Enter applicable Conditions and Required Actions of LCO 3.8.5 “Distribution Systems – Operating” with any instrument and control bus de-energized. --- Restore inverter to OPERABLE status.	24 hours
B. Required Action and associated Completion Time not met.	B.1 <u>AND</u> B.2	Be in MODE 3. Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.3.1	Verify correct inverter voltage, frequency, and alignment to required AC instrument and control buses.	7 days

3.8 ELECTRICAL POWER SYSTEMS

3.8.4 Inverters – Shutdown

LCO 3.8.4 Inverters shall be OPERABLE to support the onsite Class 1E power distribution subsystems required by LCO 3.8.6, “Distribution Systems – Shutdown.”

APPLICABILITY: MODES 5 and 6,
During movement of irradiated fuel assemblies.

ACTIONS

- NOTE -

LCO 3.0.3 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required inverters inoperable.	A.1 Declare affected required features inoperable.	Immediately
	OR	
	A.2.1 Suspend CORE ALTERATIONS.	Immediately
	AND	
	A.2.2 Suspend movement of irradiated fuel assemblies.	Immediately
	AND	
	A.2.3 Suspend operations with a potential for draining the reactor vessel.	Immediately
	AND	

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.2.4 Suspend operations involving positive reactivity additions that could result in loss of required SDM or boron concentration. AND	Immediately
	A.2.5 Initiate action to restore required inverters to OPERABLE status.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.4.1	Verify correct inverter voltage, frequency, and alignments to required AC instrument and control buses.	7 days

3.8 ELECTRICAL POWER SYSTEMS

3.8.5 Distribution Systems – Operating

LCO 3.8.5 The Division A, B, C, and D AC instrument and control bus and DC electrical power distribution subsystems shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One Division AC instrument and control bus inoperable.	A.1 Restore AC instrument and control bus to OPERABLE status.	6 hours AND 12 hours from discovery of failure to meet the LCO
B. One Division DC electrical power distribution subsystem inoperable.	B.1 Restore DC electrical power distribution subsystem to OPERABLE status.	6 hours AND 12 hours from discovery of failure to meet the LCO
C. Two Divisions AC instrument and control bus inoperable.	C.1 Restore AC instrument and control bus to OPERABLE status.	2 hours AND 16 hours from discovery of failure to meet the LCO.
D. Two Divisions DC electrical power distribution subsystem inoperable.	D.1 Restore DC electrical power distribution subsystem to OPERABLE status.	2 hours AND 16 hours from discovery of failure to meet the LCO.

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Required Action and associated Completion Time not met.	E.1 Be in MODE 3. AND E.2 Be in MODE 5.	6 hours 36 hours
F. Two Divisions with inoperable distribution subsystems that result in a loss of safety function.	F.1 Enter LCO 3.0.3.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.5.1	Verify correct breaker and switch alignments and voltage to required DC and AC instrument and control bus electrical power distribution subsystems.	7 days

3.8 ELECTRICAL POWER SYSTEMS

3.8.6 Distribution Systems – Shutdown

LCO 3.8.6 The necessary portions of DC and AC instrument and control bus electrical power distribution subsystems shall be OPERABLE to support equipment required to be OPERABLE.

APPLICABILITY: MODES 5 and 6,
During movement of irradiated fuel assemblies.

ACTIONS

- NOTE -

LCO 3.0.3 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required DC or AC instrument and control bus electrical power distribution subsystems inoperable.	A.1 Declare associated supported required features inoperable. OR A.2.1 Suspend CORE ALTERATIONS. AND A.2.2 Suspend movement of irradiated fuel assemblies. AND A.2.3 Initiate action to suspend operations with a potential for draining the reactor vessel. AND	Immediately Immediately Immediately Immediately

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
	A.2.4 Suspend operations involving positive reactivity additions that could result in loss of required SDM or boron concentration. AND	Immediately
	A.2.5 Initiate actions to restore required DC and AC instrument and control bus electrical power distribution subsystems to OPERABLE status.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.6.1	Verify correct breaker and switch alignments and voltage to required DC and AC instrument and control bus electrical power distribution subsystems.	7 days

3.8 ELECTRICAL POWER SYSTEMS

3.8.7 Battery Parameters

LCO 3.8.7 Battery Parameters for Division A, B, C, and D batteries shall be within limits.

APPLICABILITY: When associated DC electrical power sources are required to be OPERABLE.

ACTIONS

- NOTE -
Separate Condition entry is allowed for each battery.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more batteries in one division with one or more battery cells float voltage < 2.07 V.	A.1 Perform SR 3.8.1.1. AND A.2 Perform SR 3.8.7.1. AND A.3 Restore affected cell voltage ≥ 2.07 V.	2 hours 2 hours 24 hours
B. One or more batteries in one division with float current > 2 amps.	B.1 Perform SR 3.8.1.1. AND B.2 Restore battery float current to ≤ 2 amps.	2 hours 24 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION		COMPLETION TIME
---------- **- NOTE -** Required Action C.2 shall be completed if electrolyte level was below the top of plates. ----------	---------- **- NOTE -** Required Actions C.1 and C.2 are only applicable if electrolyte level was below the top of plates. ----------[----------		
C. One or more batteries in one division with one or more cells electrolyte level less than minimum established design limits.	C.1	Restore electrolyte level to above top of plates.	8 hours
	AND		
	C.2	Verify no evidence of leakage.	12 hours
	AND		
	C.3	Restore electrolyte level to greater than or equal to minimum established design limits.	31 days
D. One or more batteries in one division with pilot cell electrolyte temperature less than minimum established design limits.	D.1	Restore battery pilot cell temperature to greater than or equal to minimum established design limits.	12 hours
E. One or more batteries in two or more divisions with battery parameters not within limits.	E.1	Restore battery parameters for batteries in three divisions to within limits.	2 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
F. Required Action and associated Completion Time not met. OR One or more batteries in one division with one or more battery cells float voltage < 2.07 V and float current > 2 amps.	F.1 Declare associated battery inoperable.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.8.7.1	---------- **- NOTE -** Not required to be met when battery terminal voltage is less than the minimum established float voltage of SR 3.8.1.1. ---------- Verify each battery float current is ≤ 2 amps.	7 days
SR 3.8.7.2	Verify each battery pilot cell voltage is ≥ 2.07 V.	31 days
SR 3.8.7.3	Verify each battery connected cell electrolyte level is greater than or equal to minimum established design limits.	31 days
SR 3.8.7.4	Verify each battery pilot cell temperature is greater than or equal to minimum established design limits.	31 days
SR 3.8.7.5	Verify each battery connected cell voltage is ≥ 2.07 V.	92 days

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE		FREQUENCY
SR 3.8.7.6	--- **- NOTE-** This Surveillance shall not be performed in MODE 1, 2, 3, or 4. However, credit may be taken for unplanned events that satisfy this SR. ---	
	Verify battery capacity is ≥ 80% of the manufacturer's rating when subjected to a performance discharge test or a modified performance discharge test.	60 months AND 12 months when battery shows degradation, or has reached 85% of the expected life with capacity < 100% of manufacturer's rating AND 24 months when battery has reached 85% of the expected life with capacity ≥ 100% of manufacturer's rating

3.9 REFUELING OPERATIONS

3.9.1 Boron Concentration

LCO 3.9.1 Boron concentration of the Reactor Coolant System (RCS), the fuel transfer canal, and the refueling cavity shall be maintained within the limit specified in COLR.

APPLICABILITY: MODE 6.

- NOTE -

Only applicable to the fuel transfer canal and the refueling cavity when connected to the RCS.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Boron concentration not within limit.	A.1 Suspend CORE ALTERATIONS.	Immediately
	AND	
	A.2 Suspend positive reactivity additions.	Immediately
	AND	
	A.3 Initiate actions to restore boron concentration to within limits.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.1.1	Verify boron concentration is within the limit specified in the COLR.	72 hours

3.9 REFUELING OPERATIONS

3.9.2 Unborated Water Source Flow Paths

LCO 3.9.2 Each unborated water source flow path shall be isolated.

APPLICABILITY: MODE 6.

ACTIONS

- NOTE -
Separate condition entry is allowed for each unborated water source flow path.

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. --- **- NOTE -** Required Action A.3 must be completed whenever Condition A is entered. --- One or more flow paths not isolated.	A.1	Suspend CORE ALTERATIONS.	Immediately
	AND		
	A.2	Initiate actions to isolate flow paths.	Immediately
	AND		
	A.3	Perform SR 3.9.1.1.	4 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.2.1	Verify each unborated water source flow path is isolated by at least one valve secured in the closed position.	31 days

3.9 REFUELING OPERATIONS

3.9.3 Nuclear Instrumentation

LCO 3.9.3 Two source range neutron flux monitors shall be OPERABLE.

APPLICABILITY: MODE 6.

ACTIONS

CONDITION	REQUIRED ACTION		COMPLETION TIME
A. One required source range neutron flux monitor inoperable.	A.1	Suspend CORE ALTERATIONS.	Immediately
	AND		
	A.2	Suspend operations that would cause introduction into the Reactor Coolant System (RCS), coolant with boron concentration less than required to meet the boron concentration of LCO 3.9.1.	Immediately
B. Two required source range neutron flux monitors inoperable.	B.1	Initiate action to restore one source range neutron flux monitor to OPERABLE status.	Immediately
	AND		
	B.2	Perform SR 3.9.1.1.	Once per 12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.3.1	Perform a CHANNEL CHECK.	12 hours
SR 3.9.3.2	---------- **- NOTE-** Neutron detectors are excluded from CHANNEL CALIBRATION. ---------- Perform CHANNEL CALIBRATION.	24 months

3.9 REFUELING OPERATIONS

3.9.4 Refueling Cavity Water Level

LCO 3.9.4 Refueling Cavity Water Level shall be maintained ≥ 23 ft above the top of the reactor vessel flange.

APPLICABILITY: During movement of irradiated fuel assemblies within containment.

ACTIONS

- NOTE -

LCO 3.0.8 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Refueling cavity water level not within limit.	A.1 Suspend movement of irradiated fuel assemblies within containment.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.4.1	Verify that refueling cavity water level is ≥ 23 ft above the top of reactor vessel flange.	24 hours

3.9 REFUELING OPERATIONS

3.9.5 Containment Penetrations

LCO 3.9.5 The containment penetrations shall be in the following status:

a. The equipment hatches closed and held in place by four bolts or, if open, the containment air filtration system (VFS) shall be OPERABLE and operating;

b. One door in each air lock closed or, if open, the VFS shall be OPERABLE and operating;

c. The containment spare penetrations closed or, if open, the VFS shall be OPERABLE and operating;

d. Each penetration providing direct access from the containment atmosphere to the outside atmosphere either:

1. Closed by a manual or automatic isolation valve, blind flange, or equivalent, or

2. Capable of being closed by an OPERABLE Containment Isolation signal.

- NOTE -

Penetration flow path(s) providing direct access from the containment atmosphere to the outside atmosphere may be unisolated under administrative controls.

APPLICABILITY: During movement of irradiated fuel assemblies within containment.

ACTIONS

- NOTE -

LCO 3.0.8 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Suspend movement of irradiated fuel assemblies within containment.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.5.1	Verify each required containment penetration is in the required status.	7 days
SR 3.9.5.2	---------- **- NOTE-** Not required to be met for containment purge and exhaust valve(s) in penetrations closed to comply with LCO 3.9.5.d.1. ---------- Verify each required containment purge and exhaust valve actuates to the isolation position on a manual actuation signal.	In accordance with the Inservice Test Program
SR 3.9.5.3	Verify the VFS can maintain a negative pressure (≤ -0.125 inches water gauge relative to outside atmospheric pressure) in the area enclosed by the containment and alternate barrier.	24 months
SR 3.9.5.4	Operate each VFS train for ≥ 10 continuous hours with the heaters operating.	Within 31 days prior to fuel movement or CORE ALTERATIONS

3.9 REFUELING OPERATIONS

3.9.6 Containment Air Filtration System (VFS)

LCO 3.9.6 One VFS exhaust subsystem shall be OPERABLE.

APPLICABILITY: During movement of irradiated fuel assemblies in the fuel building.

ACTIONS

- NOTE -

LCOs 3.0.3 and 3.0.8 are not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Required VFS exhaust subsystem inoperable.	A.1 Suspend movement of irradiated fuel assemblies in the fuel building.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.6.1	Operate each VFS exhaust subsystem for $\geq$ 10 continuous hours with the heaters operating.	Within 31 days prior to fuel movement
SR 3.9.6.2	Verify the VAS fuel handling area subsystem aligns to the VFS exhaust subsystem on an actual or simulated actuation signal.	24 months
SR 3.9.6.3	Verify one VFS exhaust subsystem can maintain a negative pressure ($\leq$ -0.125 inches water gauge relative to outside atmospheric pressure) in the fuel handling area.	24 months

3.9 REFUELING OPERATIONS

3.9.7 Decay Time

LCO 3.9.7 The reactor shall be subcritical for ≥ 48 hours.

APPLICABILITY: During movement of irradiated fuel in the reactor pressure vessel.

ACTIONS

- NOTE -

LCO 3.0.8 is not applicable.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Reactor subcritical < 48 hours.	A.1 Suspend all operations involving movement of irradiated fuel in the reactor pressure vessel.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.9.7.1	Verify that the reactor has been subcritical for ≥ 48 hours by verification of the date and time of subcriticality.	Prior to movement of irradiated fuel in the reactor vessel

4.0 DESIGN FEATURES

4.1 Site

The site is approximately 25 miles south of Miami, 8 miles east of Florida City, and 9 miles southeast of Homestead, Florida.

4.1.1 Site and Exclusion Boundaries

The Site Boundary is shown in Figure 4.1-1.

The Exclusion Area Boundary is shown in Figure 4.1-2.

4.1.2 Low Population Zone (LPZ)

The LPZ is defined by the 5 mile radius from the site center point as shown in Figure 4.1-1.

4.2 Reactor Core

4.2.1 Fuel Assemblies

The reactor shall contain 157 fuel assemblies. Each assembly shall consist of a matrix of fuel rods clad with a zirconium based alloy and containing an initial composition of natural or slightly enriched uranium dioxide (UO_2) as fuel material. Limited substitutions of zirconium based alloy or stainless steel filler rods for fuel rods, in accordance with approved applications of fuel rod configurations, may be used. Fuel assemblies shall be limited to those fuel designs that have been analyzed with applicable NRC staff approved codes and methods and shown by tests or analyses to comply with fuel safety design bases. A limited number of lead test assemblies that have not completed representative testing may be placed in nonlimiting core regions.

4.2.2 Control Rod and Gray Rod Assemblies

The reactor core shall contain 53 Rod Cluster Control Assemblies (RCCAs), each with 24 rodlets/RCCA. The RCCA absorber material shall be silver indium cadmium as approved by the NRC.

Additionally, there are 16 low worth Gray Rod Cluster Assemblies (GRCAs), with 24 rodlets/GRCA, which, in conjunction with the RCCAs, are used to augment MSHIM load follow operation.

4.0 DESIGN FEATURES

4.3 Fuel Storage

4.3.1 Criticality

4.3.1.1 The spent fuel storage racks are designed and shall be maintained with:

a. Fuel assemblies having a maximum U-235 enrichment of 4.95 weight percent;

b. $k_{eff} \leq 0.95$ if flooded with unborated water which includes an allowance for uncertainties (Region 1 racks);

c. A nominal 10.93 inch center-to-center distance between fuel assemblies placed in Region 1, a nominal 9.04 inch center-to-center distance between fuel assemblies placed in Region 2 of the spent fuel storage racks, and a nominal 11.65 inch center-to-center distance between fuel assemblies placed in the Defective Fuel Cells;

d. New or partially spent fuel assemblies with any discharge burnup may be allowed unrestricted storage in Region 1 and the Defective Fuel Cells of Figure 4.3-1;

e. Partially spent fuel assemblies meeting the initial enrichment and burnup requirements of LCO 3.7.12, “Spent Fuel Pool Storage,” may be stored in Region 2 of Figure 4.3-1; and

f. $k_{eff} < 1.0$ if flooded with unborated water and $k_{eff} \leq 0.95$ if flooded with borated water at a minimum soluble boron concentration described in the Bases for LCO 3.7.12 for normal and design basis criticality-related accident conditions, which includes an allowance for uncertainties (Region 2 racks).

4.3.1.2 The new fuel storage racks are designed and shall be maintained with:

a. Fuel assemblies having a maximum U-235 enrichment of 5.0 weight percent;

b. The maximum k_{eff} value, including all biases and uncertainties, shall be less than or equal to 0.95 with full density unborated water;

c. The maximum k_{eff} value, including all biases and uncertainties, shall be less than or equal to 0.98 with optimum moderation and full reflection conditions; and

d. A nominal 10.90 inch center-to-center distance between fuel assemblies placed in the new fuel storage racks.

4.0 DESIGN FEATURES

4.3.2 Drainage

The spent fuel pool is designed and shall be maintained to prevent inadvertent draining of the pool below a minimum water depth of ≥ 23 ft above the surface of the fuel storage racks.

4.3.3 Capacity

The spent fuel pool is designed and shall be maintained with a storage capacity limited to no more than 889 fuel assemblies.

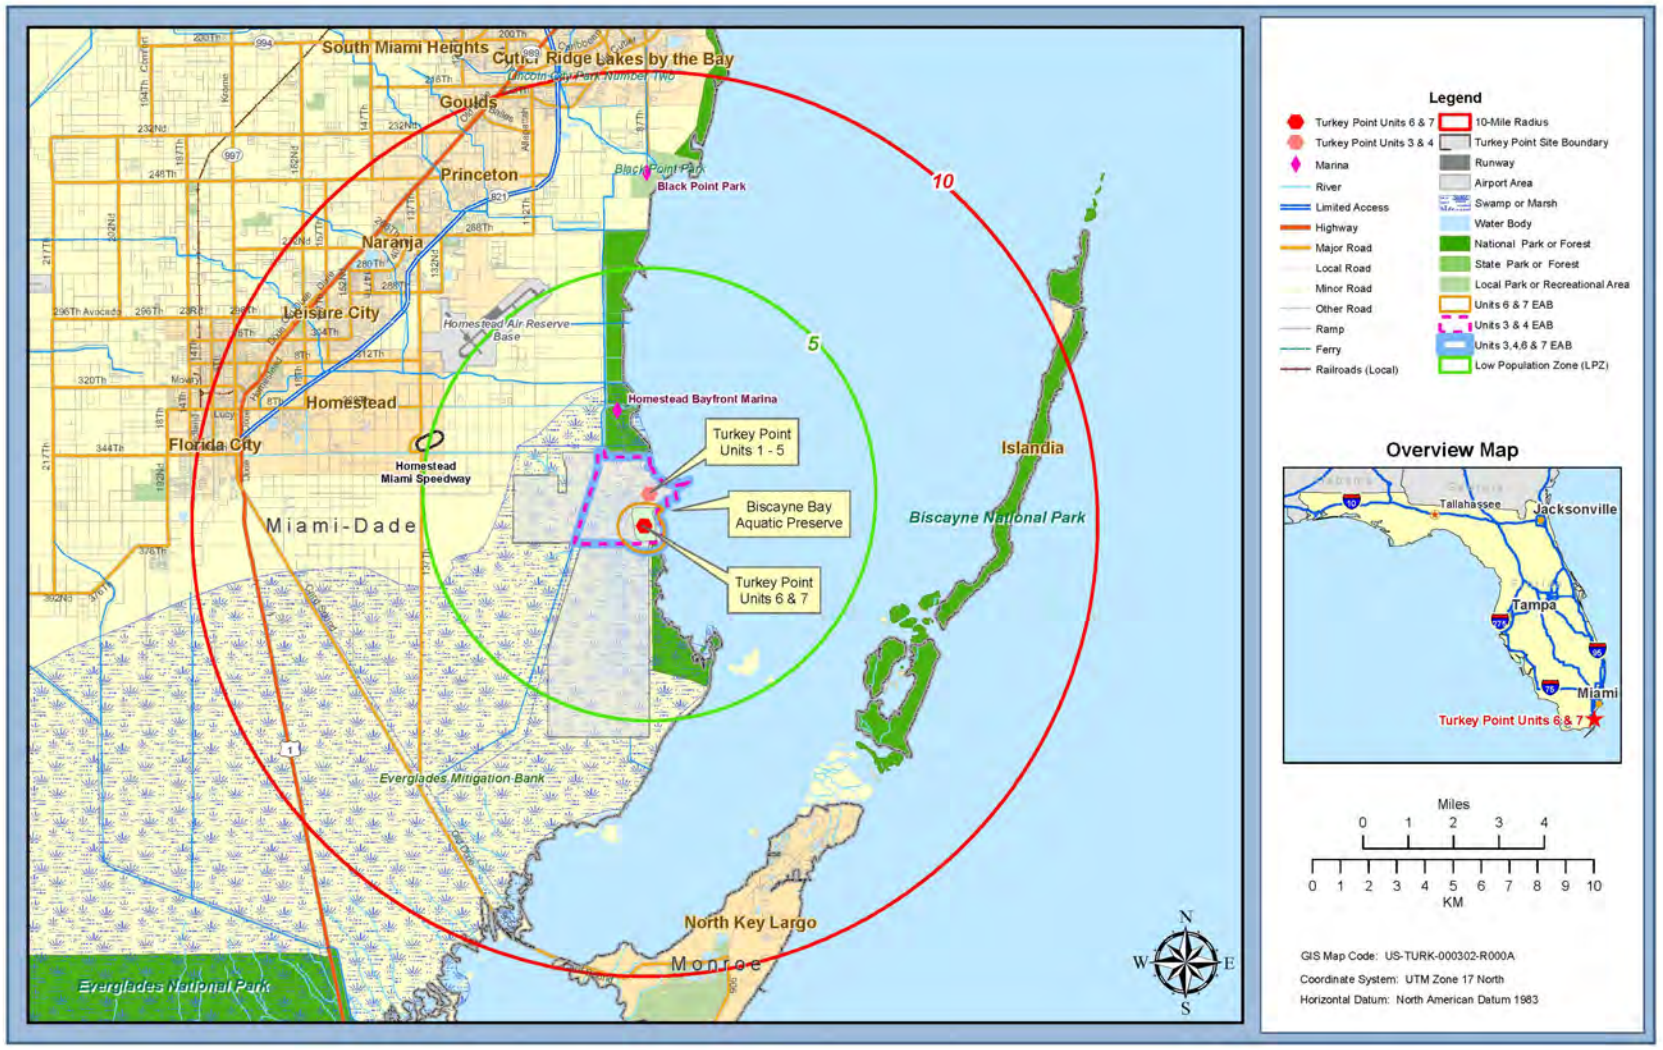

FIGURE 4.1-1 Low Population Zone and Site Boundary Map

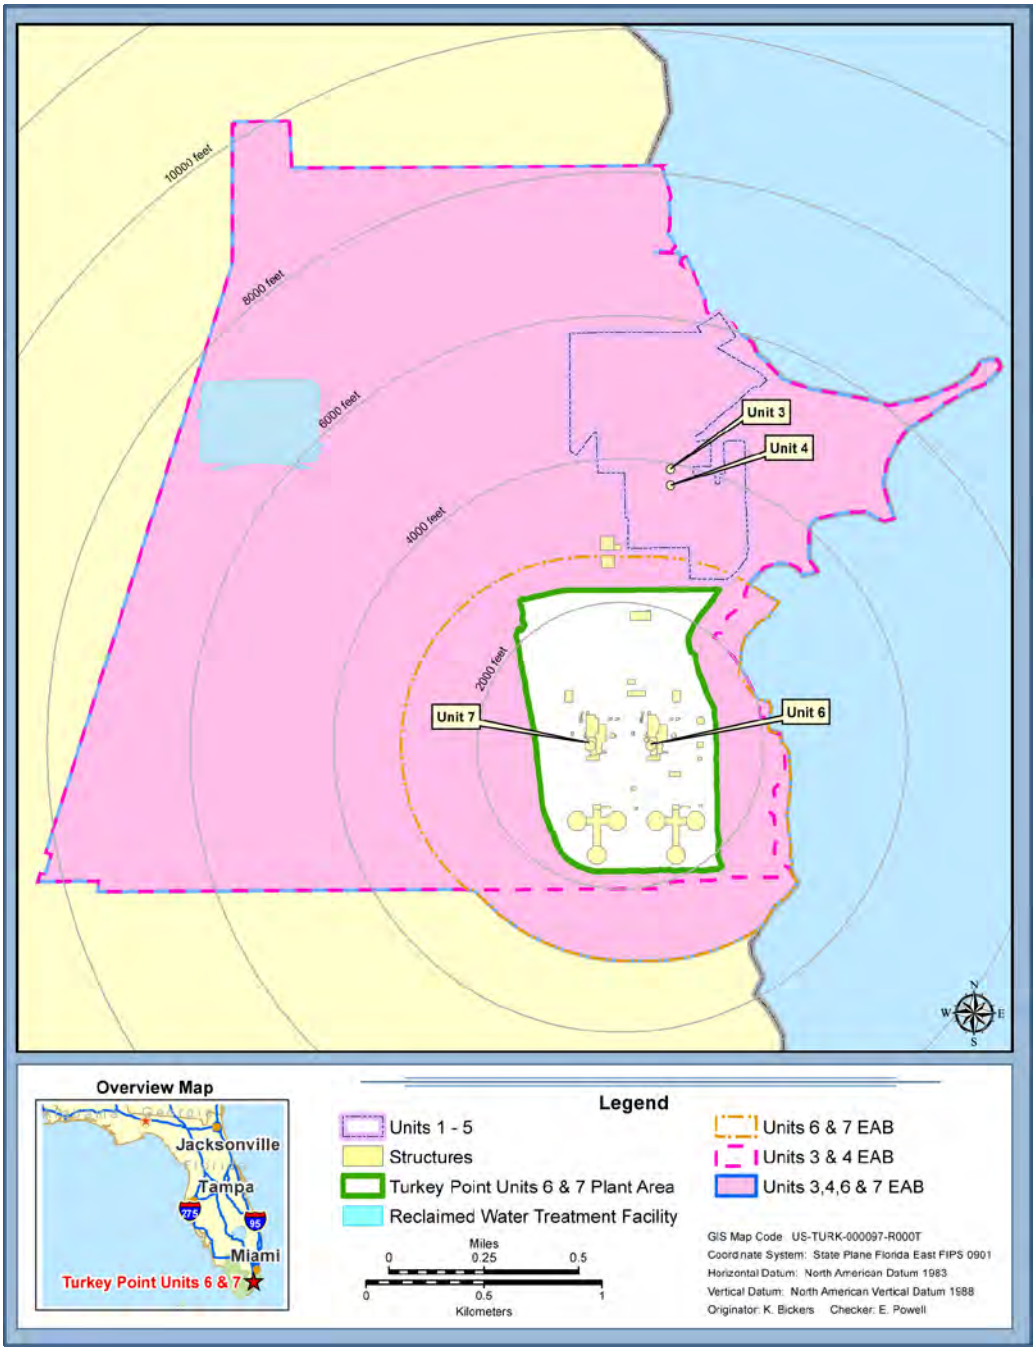

FIGURE 4.1-2 Exclusion Area Boundary

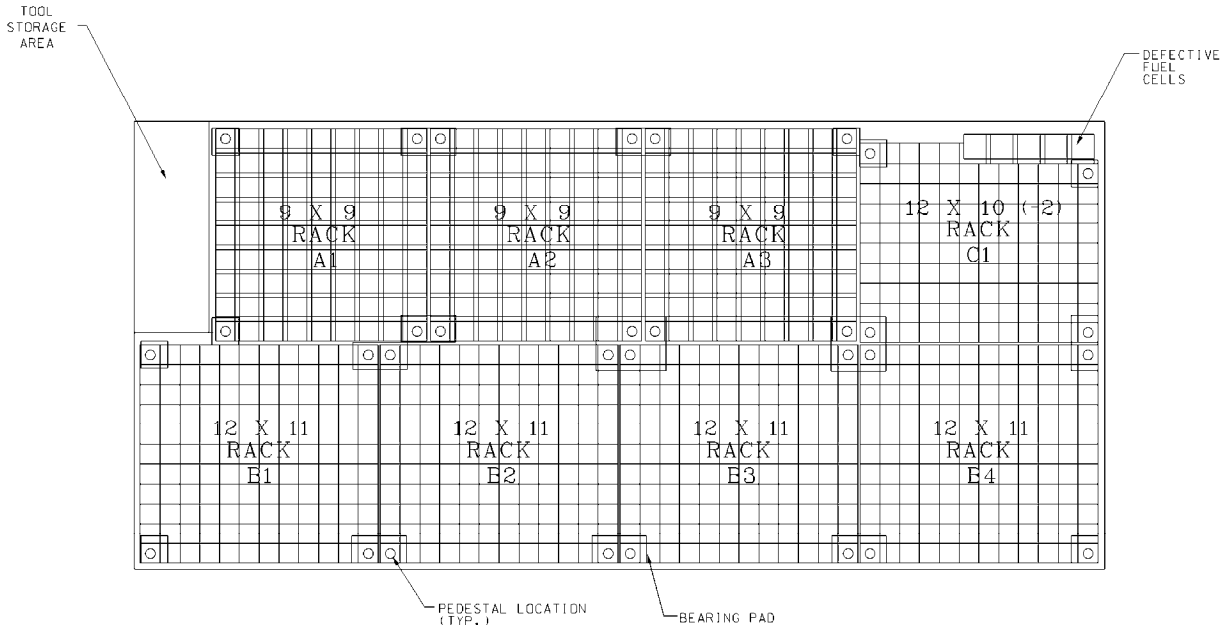

Region 1 (A1, A2, A3) – 243 locations

Region 2 (B1, B2, B3, B4, C1) – 641 locations

Defective Fuel Cells (DFCs) – 5 locations

Total Storage Locations – 889

Figure 4.3-1
Discrete Two Region Spent Fuel Pool Rack Layout

5.0 ADMINISTRATIVE CONTROLS

5.1 Responsibility

5.1.1 The plant manager shall be responsible for overall unit operations and shall delegate in writing the succession to this responsibility during his absence.

The plant manager or his designee shall approve, prior to implementation, each proposed test, experiment or modification to systems or equipment that affect nuclear safety.

5.1.2 The shift manager (SM) shall be responsible for the control room command function. During any absence of the SM from the control room while the unit is in MODE 1, 2, 3, or 4, an individual with an active Senior Reactor Operator (SRO) license shall be designated to assume the control room command function. During any absence of the SM from the control room while the unit is in MODE 5 or 6, an individual with an active SRO license or Reactor Operator license shall be designated to assume the control room command function.

5.0 ADMINISTRATIVE CONTROLS

5.2 Organization

5.2.1 Onsite and Offsite Organizations

Onsite and offsite organizations shall be established for unit operation and corporate management, respectively. The onsite and offsite organizations shall include the positions for activities affecting safety of the nuclear power plant.

a. Lines of authority, responsibility, and communication shall be defined and established throughout highest management levels, intermediate levels, and all operating organization positions. These relationships shall be documented and updated, as appropriate, in organization charts, functional descriptions of departmental responsibilities and relationships, and job descriptions for key personnel positions, or in equivalent forms of documentation. These requirements including the plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the FSAR;

b. The plant manager shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant;

c. A specified corporate officer shall have corporate responsibility for overall plant nuclear safety and shall take any measures needed to ensure acceptable performance of the staff in operating, maintaining, and providing technical support to the plant to ensure nuclear safety; and

d. The individuals who train the operating staff, carry out radiation protection, or perform quality assurance functions may report to the appropriate onsite manager; however, these individuals shall have sufficient organizational freedom to ensure their independence from operation pressures.

5.2.2 Unit Staff

The unit staff organization shall include the following:

a. A non-licensed operator shall be assigned to each reactor containing fuel and an additional non-licensed operator shall be assigned for each control room from which a reactor is operating in MODE 1, 2, 3, or 4.

b. Shift crew composition may be less than the minimum requirement of 10 CFR 50.54(m)(2)(i) and 5.2.2.a and 5.2.2.e for a period of time not to exceed 2 hours in order to accommodate unexpected absence of on-duty shift crew members provided immediate action is taken to restore the shift crew composition to within the minimum requirements.

5.2 Organization

5.2.2 Unit Staff (continued)

c. A radiation protection technician shall be on site when fuel is in the reactor. The position may be vacant for not more than 2 hours, in order to provide for unexpected absence, provided immediate action is taken to fill the required position.

d. The operations manager or assistant operations manager shall hold an SRO license.

e. An individual shall provide advisory technical support to the unit operations shift crew in the areas of thermal hydraulics, reactor engineering, and plant analysis with regard to the safe operation of the unit. This individual shall meet the qualifications specified by the Commission Policy Statement on Engineering Expertise on Shift.

5.0 ADMINISTRATIVE CONTROLS

5.3 Unit Staff Qualifications

5.3.1 Each member of the unit staff shall meet or exceed the minimum qualifications of Regulatory Guide 1.8, Revision 3, 2000, with the following exception:

a. During cold license operator training through the first refueling outage, the Regulatory Position C.1.b of Regulatory Guide 1.8, Revision 2, 1987, applies: cold license operator candidates meet the training elements defined in ANSI/ANS 3.1-1993 but are exempt from the experience requirements defined in ANSI/ANS 3.1-1993.

5.3.2 For the purpose of 10 CFR 55.4, a licensed Senior Reactor Operator (SRO) and a licensed reactor operator (RO) are those individuals who, in addition to meeting the requirements of TS 5.3.1, perform the functions described in 10 CFR 50.54(m).

5.0 ADMINISTRATIVE CONTROLS

5.4 Procedures

5.4.1 Written procedures shall be established, implemented, and maintained covering the following activities:

a. The applicable procedures recommended in Regulatory Guide 1.33, Revision 2, Appendix A, February 1978;

b. The emergency operating procedures required to implement the requirements of NUREG-0737 and NUREG-0737, Supplement 1, as stated in Generic Letter 82-33;

c. Quality assurance for effluent and environmental monitoring;

d. Fire Protection Program implementation; and

e. All programs specified in Specification 5.5.

5.0 ADMINISTRATIVE CONTROLS

5.5 Programs and Manuals

The following programs shall be established, implemented, and maintained.

5.5.1 Offsite Dose Calculation Manual (ODCM)

a. The ODCM shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring alarm and trip setpoints, and in the conduct of the radiological environmental monitoring program; and

b. The ODCM shall also contain the radioactive effluent controls and radiological environmental monitoring activities, and descriptions of the information that should be included in the Annual Radiological Environmental Operating, and Radioactive Effluent Release Reports required by Specification 5.6.2 and Specification 5.6.3.

Licensee initiated changes to the ODCM:

a. Shall be documented and records of reviews performed shall be retained. This documentation shall contain:

1. Sufficient information to support the change(s) together with the appropriate analyses or evaluations justifying the change(s), and

2. A determination that the change(s) maintain the levels of radioactive effluent control required by 10 CFR 20.1302, 40 CFR 190, 10 CFR 50.36a, and 10 CFR 50, Appendix I, and not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations;

b. Shall become effective after the approval of the plant manager; and

c. Shall be submitted to the NRC in the form of a complete, legible copy of the changed portion of the ODCM as a part of or concurrent with the Radioactive Effluent Release Report for the period of the report in which any change in the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (i.e., month and year) the change was implemented.

5.5 Programs and Manuals

5.5.2 Radioactive Effluent Control Program

This program conforms to 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to members of the public from radioactive effluents as low as reasonably achievable. The program shall be contained in the ODCM, shall be implemented by procedures, and shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

a. Limitations on the functional capability of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoints determination in accordance with the methodology in the ODCM;

b. Limitations on the concentrations of radioactive material released in liquid effluents to unrestricted areas, conforming to ten times the concentration values in Appendix B, Table 2, Column 2 to 10 CFR 20;

c. Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM;

d. Limitations on the annual and quarterly doses or dose commitment to a member of the public for radioactive materials in liquid effluents released form each unit to unrestricted areas, conforming to 10 CFR 50, Appendix I;

e. Determination of cumulative dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days. Determination of projected dose contributions from radioactive effluents in accordance with the methodology in the ODCM at least every 31 days;

f. Limitations on the functional capability and use of the liquid and gaseous effluent treatment systems to ensure that appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a period of 31 days would exceed 2% of the guidelines for the annual dose or dose commitment, conforming to 10 CFR 50, Appendix I;

g. Limitations on the dose rate resulting from radioactive material released in gaseous effluents to areas beyond the site boundary shall be in accordance with the following:

    1. For noble gases: a dose rate ≤ 500 mrem/yr to the whole body and a dose rate ≤ 3000 mrem/yr to the skin and

5.5 Programs and Manuals

5.5.2 Radioactive Effluent Control Program (continued)

2. For iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half-lives greater than 8 days: a dose rate ≤ 1500 mrem/yr to any organ;

h. Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I;

i. Limitations on the annual and quarterly doses to a member of the public from iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half lives > 8 days in gaseous effluents released from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I; and

j. Limitations on the annual dose or dose commitment to any member of the public, beyond the site boundary, due to releases of radioactivity and to radiation from uranium fuel cycle sources, conforming to 40 CFR 190.

5.5.3 Inservice Testing Program

This program provides control for inservice testing of ASME Code Class 1, 2, and 3 components including applicable supports. The program shall include the following:

a. Testing frequencies specified in the ASME OM Code and applicable Addenda as follows:

ASME OM Code and applicable Addenda Terminology for inservice testing activities	Required Frequencies for performing inservice testing activities
Weekly	At least once per 7 days
Monthly	At least once per 31 days
Quarterly or every 3 months	At least once per 92 days
Semiannually or every 6 months	At least once per 184 days
Every 9 months	At least once per 276 days
Yearly or annually	At least once per 366 days
Biennially or every 2 years	At least once per 731 days

b. The provisions of SR 3.0.2 are applicable to the above required Frequencies for performing inservice testing activities;

5.5 Programs and Manuals

5.5.3 Inservice Testing Program (continued)

c. The provisions of SR 3.0.3 are applicable to inservice testing activities;

d. Nothing in the ASME OM Code shall be construed to supersede the requirements of any TS.

5.5.4 Steam Generator (SG) Program

A Steam Generator Program shall be established and implemented to ensure that SG tube integrity is maintained. In addition, the Steam Generator Program shall include the following provisions:

a. Provisions for condition monitoring assessments. Condition monitoring assessment means an evaluation of the “as found” condition of the tubing with respect to the performance criteria for structural integrity and accident induced leakage. The "as found" condition refers to the condition of the tubing during an SG inspection outage, as determined from the inservice inspection results or by other means, prior to the plugging of tubes. Condition monitoring assessments shall be conducted during each outage during which the SG tubes are inspected or plugged, to confirm that the performance criteria are being met.

b. Performance criteria for SG tube integrity. SG tube integrity shall be maintained by meeting the performance criteria for tube structural integrity, accident induced leakage, and operational LEAKAGE.

1. Structural integrity performance criterion: All in-service steam generator tubes shall retain structural integrity over the full range of normal operating conditions (including startup, operation in the power range, hot standby, and cool down and all anticipated transients included in the design specification) and design basis accidents. This includes retaining a safety factor of 3.0 against burst under normal steady state full power operation primary-to-secondary pressure differential and a safety factor of 1.4 against burst applied to the design basis accident primary-to-secondary pressure differentials. Apart from the above requirements, additional loading conditions associated with the design basis accidents, or combination of accidents in accordance with the design and licensing basis, shall also be evaluated to determine if the associated loads contribute significantly to burst or collapse. In the assessment of tube integrity, those loads that do significantly affect burst or collapse shall be determined and assessed in combination with the loads due to pressure with a safety factor of 1.2 on the combined primary loads and 1.0 on axial secondary loads.

5.5 Programs and Manuals

5.5.4 Steam Generator (SG) Program (continued)

2. Accident induced leakage performance criterion: The primary to secondary accident induced leakage rate for any design basis accident, other than a SG tube rupture, shall not exceed the leakage rate assumed in the accident analysis in terms of total leakage rate for all SGs and leakage rate for an individual SG. Leakage is not to exceed 150 gpd per SG.

3. The operational LEAKAGE performance criterion is specified in LCO 3.4.7, "RCS Operational LEAKAGE."

c. Provisions for SG tube repair criteria. Tubes found by inservice inspection to contain flaws with a depth equal to or exceeding 40% of the nominal tube wall thickness shall be plugged.

d. Provisions for SG tube inspections. Periodic SG tube inspections shall be performed. The number and portions of the tubes inspected and methods of inspection shall be performed with the objective of detecting flaws of any type (e.g., volumetric flaws, axial and circumferential cracks) that may be present along the length of the tube, from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet, and that may satisfy the applicable tube repair criteria. The tube-to-tubesheet weld is not part of the tube. In addition to meeting the requirements of d.1, d.2, and d.3 below, the inspection scope, inspection methods, and inspection intervals shall be such as to ensure that SG tube integrity is maintained until the next SG inspection. An assessment of degradation shall be performed to determine the type and location of flaws to which the tubes may be susceptible and, based on this assessment, to determine which inspection methods need to be employed and at what locations.

1. Inspect 100% of the tubes in each SG during the first refueling outage following installation.

2. Inspect 100% of the tubes at sequential periods of 144, 108, 72, and, thereafter, 60 effective full power months. The first sequential period shall be considered to begin after the first inservice inspection of the SGs. In addition, inspect 50% of the tubes by the refueling outage nearest the midpoint of the period and the remaining 50% by the refueling outage nearest the end of the period. No SG shall operate for more than 72 effective full power months or three refueling outages (whichever is less) without being inspected.

5.5 Programs and Manuals

5.5.4 Steam Generator (SG) Program (continued)

3. If crack indications are found in any SG tube, then the next inspection for each SG for the degradation mechanism that caused the crack indication shall not exceed 24 effective full power months or one refueling outage (whichever is less). If definitive information, such as from examination of a pulled tube, diagnostic non-destructive testing, or engineering evaluation indicates that a crack-like indication is not associated with a crack(s), then the indication need not be treated as a crack.

e. Provisions for monitoring operational primary to secondary LEAKAGE.

5.5.5 Secondary Water Chemistry Program

This program provides controls for monitoring secondary water chemistry to inhibit SG tube degradation and low pressure turbine disc stress corrosion cracking. The program shall include:

a. Identification of a sampling schedule for the critical variables and control points for these variables;

b. Identification of the procedures used to measure the values of the critical variables;

c. Identification of process sampling points, which shall include monitoring the discharge of the condensate pumps for evidence of condenser in leakage;

d. Procedures for the recording and management of data;

e. Procedures defining corrective actions for all off control point chemistry conditions; and

f. A procedure identifying the authority responsible for the interpretation of the data and the sequence and timing of administrative events, which is required to initiate corrective action.

5.5.6 Technical Specifications (TS) Bases Control Program

This program provides a means for processing changes to the Bases of these Technical Specifications.

a. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.

5.5 Programs and Manuals

5.5.6 Technical Specifications (TS) Bases Control Program (continued)

b. Licensees may make changes to Bases without prior NRC approval provided the changes do not require either of the following:

1. A change in the TS incorporated in the license; or

2. A change to the updated FSAR or Bases that requires NRC approval pursuant to 10 CFR 50.59.

c. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the FSAR.

d. Proposed changes that meet the criteria of (b) above shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71(e).

5.5.7 Safety Function Determination Program (SFDP)

This program ensures loss of safety function is detected and appropriate action taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate actions may be taken as a result of the supported system inoperability and corresponding exception to entering supported system Condition and Required Actions. This program implements the requirement of LCO 3.0.6. The SFDP shall contain the following:

a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected;

b. Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists;

c. Provisions to ensure that an inoperable supported system's Completion Time is not inappropriately extended as a result of multiple support systems inoperabilities; and

d. Other appropriate limitations and remedial or compensatory actions.

5.5 Programs and Manuals

5.5.7 Safety Function Determination Program (continued)

A loss of safety function exists when, assuming no concurrent single failure, a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and:

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable; or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable; or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate Conditions and Required Actions to enter are those of the support system.

5.5.8 Containment Leakage Rate Testing Program

a. A program shall be established to implement the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50, Appendix J, Option B, as modified by approved exemptions. This program shall be in accordance with the guidelines contained in Regulatory Guide 1.163, “Performance-Based Containment Leak-Test Program, dated September 1995,” as modified by approved exceptions.

b. The calculated peak containment internal pressure for the design basis loss of coolant accident, P_a, is 58.3 psig. The containment design pressure is 59 psig.

c. The maximum allowable primary containment leakage rate, L_a, at P_a, shall be 0.10% of primary containment air weight per day.

5.5 Programs and Manuals

5.5.8 Containment Leakage Rate Testing Program (continued)

d. Leakage Rate acceptance criteria are:

1. Containment leakage rate acceptance criterion is 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are ≤ 0.60 L_a for the Type B and Type C tests and ≤ 0.75 L_a for Type A tests;

2. Air lock testing acceptance criteria are:

a) Overall air lock leakage rate is ≤ 0.05 L_a when tested at ≥ P_a,

b) For each door, leakage rate is ≤ 0.01 L_a when pressurized to ≥ 10 psig.

e. The provisions of SR 3.0.3 are applicable to the Containment Leakage Rate Testing Program.

f. Nothing in these Technical Specifications shall be construed to modify the testing Frequencies required by 10 CFR 50, Appendix J.

5.5.9 System Level OPERABILITY Testing Program

The System Level OPERABILITY Testing Program provides requirements for performance tests of passive systems. The System Level Inservice Tests specified in Section 3.9.6 and Table 3.9-17 apply when specified by individual Surveillance Requirements.

a. The provisions of SR 3.0.2 are applicable to the test frequencies specified in Table 3.9-17 for performing system level OPERABILITY testing activities; and

b. The provisions of SR 3.0.3 are applicable to system level OPERABILITY testing activities.

5.5.10 Component Cyclic or Transient Limit

This program provides controls to track the Table 3.9-1A cyclic and transient occurrences to ensure that components are maintained within the design limits.

5.5 Programs and Manuals

5.5.11 Battery Monitoring and Maintenance Program

This Program provides for battery restoration and maintenance, based on the recommendations of IEEE Standard 450-1995, "IEEE Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications," or of the battery manufacturer including the following:

a. Actions to restore battery cells with float voltage < 2.13 V, and

b. Actions to equalize and test battery cells that had been discovered with electrolyte level below the minimum established design limit.

5.5.12 Main Control Room Envelope Habitability Program

A Main Control Room Envelope (MCRE) Habitability Program shall be established and implemented to ensure that MCRE habitability is maintained such that, with an OPERABLE Main Control Room Emergency Habitability System (VES), MCRE occupants can control the reactor safely under normal conditions and maintain it in a safe condition following a radiological event, hazardous chemical release, or a smoke challenge. The program shall ensure that adequate radiation protection is provided to permit access and occupancy of the MCRE under design basis accident (DBA) conditions without personnel receiving radiation exposures in excess of 5 rem total effective dose equivalent (TEDE) for the duration of the accident. The program shall include the following elements:

a. The definition of the MCRE and the MCRE boundary.

b. Requirements for maintaining the MCRE boundary in its design condition, including configuration control and preventive maintenance.

c. Requirements for (i) determining the unfiltered air inleakage past the MCRE boundary into the MCRE in accordance with the testing methods and at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, "Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors," Revision 0, May 2003, and (ii) assessing MCRE habitability at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0.

d. Measurement, at designated locations, of the MCRE pressure relative to all external areas adjacent to the MCRE boundary during the pressurization mode of operation of one VES air delivery flow path, operating at the required flow rate of 65 ± 5 scfm, at a Frequency of 24 months on a STAGGERED TEST BASIS. The results shall be trended and used as part of the 24 month assessment of the MCRE boundary.

5.5 Programs and Manuals

5.5.12 Main Control Room Envelope Habitability Program (continued)

e. The quantitative limits on unfiltered air inleakage into the MCRE. These limits shall be stated in a manner to allow direct comparison to the unfiltered air inleakage measured by the testing described in paragraph c. The unfiltered air inleakage limit for radiological challenges is the inleakage flow rate assumed in the licensing basis analyses of DBA consequences. Unfiltered air inleakage limits for hazardous chemicals must ensure that exposure of MCRE occupants to these hazards will be within the assumptions in the licensing basis.

f. The provisions of SR 3.0.2 are applicable to the Frequencies for assessing MCRE habitability, determining MCRE unfiltered inleakage, and measuring MCRE pressure and assessing the MCRE boundary as required by paragraphs c and d, respectively.

5.5.13 Ventilation Filter Testing Program (VFTP)

A program shall be established to implement the following required testing of the VES.

Tests described in Specification 5.5.13.a and 5.5.13.b shall be performed: i) initially, ii) once each 24 months, iii) after partial or complete replacement of a HEPA filter or charcoal adsorber, iv) after any detection of, or evidence of, penetration or intrusion of water or other material into any portion of the VES that may have an adverse effect on the functional capability of the filters, and v) following painting, fire, or chemical release in any ventilation zone communicating with the VES that may have an adverse effect on the functional capability of the system.

Tests described in Specification 5.5.13.c shall be performed: i) after each 720 hours of system operation or at least once each 24 months, whichever comes first, ii) following painting, fire, or chemical release in any ventilation zone communicating with the VES that may have an adverse effect on the functional capability of the carbon media, and iii) following detection of, or evidence of, penetration or intrusion of water or other material into any portion of the VES that may have an adverse effect on the functional capability of the carbon media.

Tests described in 5.5.13.d shall be performed once per 24 months.

a. Demonstrate for the VES that an inplace test of the high efficiency particulate air (HEPA) filter shows a penetration and system bypass ≤ 0.05% when tested in accordance with Regulatory Guide 1.52, Revision 3, and ASME N510-1989 at a flow rate at least 600 cfm greater than the flow measured by VES-FT-003A/B. The flow rate being measured is a combination of the VES breathable air supply flow and the recirculation flow drawn through the eductor.

5.5 Programs and Manuals

5.5.13 Ventilation Filter Testing Program (VFTP) (continued)

ESF Ventilation System	Flow Rate
VES	≥ 600 + VES supply flow (cfm)

b. Demonstrate for the VES that an inplace test of the charcoal adsorber shows a penetration and system bypass ≤ 0.05% when tested in accordance with Regulatory Guide 1.52, Revision 3, and ASME N510-1989 at a flow rate at least 600 cfm greater than the flow measured by VES-FT-003A/B. The flow rate being measured is a combination of the VES breathable air supply flow and the recirculation flow drawn through the eductor.

ESF Ventilation System	Flow Rate
VES	≥ 600 + VES supply flow (cfm)

c. Demonstrate for the VES that a laboratory test of a sample of the charcoal adsorber, when obtained as described in Regulatory Guide 1.52, Revision 3, shows the methyl iodide penetration less than the value specified below when tested in accordance with ASTM D3803-1989 at a temperature of 30°C (86°F) and the relative humidity specified below.

ESF Ventilation System	Penetration	RH
VES	5%	95%

d. Demonstrate for the VES that the pressure drop across the combined HEPA filter, the charcoal adsorber, and the post filter is less than the value specified below when tested at the system flow rate specified below +/- 10%.

ESF Ventilation System	Delta P	Flow Rate
VES	5 in. water gauge	660 cfm

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the VFTP test frequencies.

5.5.14 Setpoint Program (SP)

a. The Setpoint Program (SP) implements the regulatory requirement of 10 CFR 50.36(c)(1)(ii)(A) that technical specifications will include items in the category of limiting safety system settings (LSSS), which are settings for automatic protective devices related to those variables having significant safety functions.

5.5 Programs and Manuals

5.5.14 Setpoint Program (SP) (continued)

b. The Nominal Trip Setpoint (NTS), As-Found Tolerance (AFT), and As-Left Tolerance (ALT) for each Technical Specification required automatic protection instrumentation function shall be calculated in conformance with WCAP-16361-P, “Westinghouse Setpoint Methodology for Protection Systems – AP1000,” February 2011.

c. For each Technical Specification required automatic protection instrumentation function, performance of a CHANNEL CALIBRATION, CHANNEL OPERATIONAL TEST (COT), or REACTOR TRIP CHANNEL OPERATIONAL TEST (RTCOT) surveillance “in accordance with the Setpoint Program” shall include the following:

1. The as-found value of the instrument channel trip setting shall be compared with the previously recorded as-left value.

i. If the as-found value of the instrument channel trip setting differs from the previously recorded as-left value by more than the pre-defined test acceptance criteria band (i.e., the specified AFT), then the instrument channel shall be evaluated to verify that it is functioning in accordance with its design basis before declaring the requirement met and returning the instrument channel to service. An Instrument Channel is determined to be functioning in accordance with its design basis if it can be set to within the ALT. This as-found condition shall be entered into the plant’s corrective action program.

ii. If the as-found value of the instrument channel trip setting is less conservative than the specified AFT, the surveillance requirement is not met and the instrument channel shall be immediately declared inoperable.

2. The instrument channel trip setting shall be set to a value within the specified ALT around the specified NTS at the completion of the surveillance; otherwise, the surveillance requirement is not met and the instrument channel shall be immediately declared inoperable.

5.5 Programs and Manuals

5.5.14 Setpoint Program (SP) (continued)

d. The difference between the instrument channel trip setting as-found value and the previously recorded as-left value for each Technical Specification required automatic protection instrumentation function shall be trended and evaluated to verify that the instrument channel is functioning in accordance with its design basis.

e. The SP shall establish a document containing the current value of the specified NTS, AFT, and ALT for each Technical Specification required automatic protection instrumentation function and references to the calculation documentation. Changes to this document shall be governed by the regulatory requirement of 10 CFR 50.59. In addition, changes to the specified NTS, AFT, and ALT values shall be governed by the approved setpoint methodology. This document, including any revisions or supplements, shall be provided upon issuance to the NRC.

5.0 ADMINISTRATIVE CONTROLS

5.6 Reporting Requirements

The following reports shall be submitted in accordance with 10 CFR 50.4.

5.6.1 Occupational Radiation Exposure Report

- NOTE -
A single submittal may be made for a multiple unit station. The submittal should combine sections common to all units at the station.

A tabulation on an annual basis of the number of station, utility, and other personnel (including contractors) receiving exposures > 100 mrem/yr and their associated collective deep dose equivalent (reported in person-rem) according to work and job functions (e.g., reactor operations and surveillance, inservice inspection, routine maintenance, special maintenance, waste processing, and refueling). This tabulation supplements the requirements of 10 CFR 20.2206. The dose assignments to various duty functions may be estimated based on pocket dosimeter, thermoluminescent dosimeter (TLD), electronic dosimeter or film badge measurements. Small exposures totaling < 20% of the individual total dose need not be accounted for. In the aggregate, at least 80% of the total deep dose equivalent received from external sources should be assigned to specific major work functions. The report shall be submitted by April 30 of each year. The initial report shall be submitted by April 30 of the year following the initial criticality.

5.6.2 Annual Radiological Environmental Operating Report

- NOTE -
A single submittal may be made for a multiple unit station. The submittal should combine sections common to all units at the station.

The Annual Radiological Environmental Operating Report covering the operation of the unit during the previous calendar year shall be submitted by May 15 of each year. The report shall include summaries, interpretations, and analyses of trends of the results of the radiological environmental monitoring program for the reporting period. The material provided shall be consistent with the objectives outlined in the Offsite Dose Calculation Manual (ODCM), and in 10 CFR 50, Appendix I, Sections IV.B.2, IV.B.3, and IV.C.

5.6 Reporting Requirements

5.6.2 Annual Radiological Environmental Operating Report (continued)

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

5.6.3 Radioactive Effluent Release Report

- NOTE -

A single submittal may be made for a multiple unit station.

The Radioactive Effluent Release Report covering the operation of the unit in the previous year shall be submitted prior to May 1 of each year in accordance with 10 CFR 50.36a. The report shall include a summary of the quantities of radioactive liquid and gaseous effluents and solid waste released from the unit. The material provided shall be consistent with the objectives outlined in the ODCM and Process Control Program and in conformance with 10 CFR 50.36a and 10 CFR 50, Appendix I, Section IV.B.1.

5.6.4 Monthly Operating Reports

Routine reports of operating statistics and shutdown experience shall be submitted on a monthly basis no later than the 15th of each month following the calendar month covered by the report.

5.6.5 CORE OPERATING LIMITS REPORT (COLR)

a. Core operating limits shall be established prior to each reload cycle, or prior to any remaining portion of a reload cycle, and shall be documented in the COLR for the following:

2.1.1, “Reactor Core SLs”
3.1.1, “SHUTDOWN MARGIN (SDM)”
3.1.3, “Moderator Temperature Coefficient”
3.1.5, “Shutdown Bank Insertion Limits”
3.1.6, “Control Bank Insertion Limits”
3.2.1, “Heat Flux Hot Channel Factor”

5.6 Reporting Requirements

5.6.5 CORE OPERATING LIMITS REPORT (continued)

3.2.2, “Nuclear Enthalpy Rise Hot Channel Factor”
3.2.3, “AXIAL FLUX DIFFERENCE”
3.2.5, “OPDMS-monitored Power Distribution Parameters”
3.3.1, “Reactor Trip System (RTS) Instrumentation”
3.4.1, “RCS Pressure, Temperature, and DNB Limits”
3.9.1, “Boron Concentration”

b. The analytical methods used to determine the core operating limits shall be those previously reviewed and approved by the NRC, specifically those described in the following documents:

1. WCAP-9272-P-A, “Westinghouse Reload Safety Evaluation Methodology,” July 1985 (Westinghouse Proprietary) and WCAP-9273-NP-A (Non-Proprietary).

   (Methodology for Specifications 3.1.4 - Moderator Temperature Coefficient, 3.1.6 - Shutdown Bank Insertion Limits, 3.1.7 - Control Bank Insertion Limits, 3.2.1 - Heat Flux Hot Channel Factor, 3.2.2 - Nuclear Enthalpy Rise Hot Channel Factor, 3.2.3 - AXIAL FLUX DIFFERENCE, and 3.9.1 - Boron Concentration.)

2a. WCAP-8385, “Power Distribution Control and Load Following Procedures - Topical Report,” September 1974 (Westinghouse Proprietary) and WCAP-8403 (Non-Proprietary).

   (Methodology for Specification 3.2.3 - AXIAL FLUX DIFFERENCE (Constant Axial Offset Control).)

   (Methodology for Specification 2.1.1 – Reactor Core Safety Limits, and 3.3.1 – Reactor Trip System (RTD) Instrumentation.)

c. The core operating limits shall be determined such that all applicable limits (e.g., fuel thermal mechanical limits, core thermal hydraulic limits, Passive Core Cooling Systems limits, nuclear limits such as SDM, transient analysis limits, and accident analysis limits) of the safety analysis are met.

d. The COLR, including any midcycle revisions or supplements, shall be provided upon issuance for each reload cycle to the NRC.

5.6 Reporting Requirements

5.6.6 Reactor Coolant System (RCS) PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)

a. RCS pressure and temperature limits for heat up, cooldown, low temperature operation, criticality, and hydrostatic testing as well as heatup and cooldown rates shall be established and documented in the PTLR for the following:

3.4.3, “RCS Pressure and Temperature (P/T) Limits”
3.4.14, “Low Temperature Overpressure Protection (LTOP) System”

b. The analytical methods used to determine the RCS pressure and temperature limits shall be those previously reviewed and approved by the NRC, specifically those described in the following document:

WCAP-14040-A, “Methodology Used to Develop Cold Overpressure Mitigating System Setpoints and RCS Heatup and Cooldown Limit Curves.” (Limits for LCO 3.4.3 and LCO 3.4.14).

c. The PTLR shall be provided to the NRC upon issuance for each reactor vessel fluency period and for any revision or supplement thereto.

5.6.7 Post Accident Monitoring Report

When a report is required by Condition B of LCO 3.3.3, “Post Accident Monitoring (PAM) Instrumentation,” a report shall be submitted within the following 14 days. The report shall outline the preplanned alternate method of monitoring, the cause of the inoperability, and the plans and schedule for restoring the instrumentation channels of the Function to OPERABLE status.

5.6.8 Steam Generator Tube Inspection Report

A report shall be submitted within 180 days after the initial entry into MODE 4 following completion of an inspection performed in accordance with the Specification 5.5.4, "Steam Generator (SG) Program." The report shall include:

a. The scope of inspections performed on each SG,

b. Active degradation mechanisms found,

c. Nondestructive examination techniques utilized for each degradation mechanism,

d. Location, orientation (if linear), and measured sizes (if available) of service induced indications,

5.6 Reporting Requirements

5.6.8 Steam Generator Tube Inspection Report (continued)

e. Number of tubes plugged during the inspection outage for each active degradation mechanism,

f. Total number and percentage of tubes plugged to date,

g. The results of condition monitoring, including the results of tube pulls and in-situ testing, and

h. The effective plugging percentage for all plugging in each SG.

5.0 ADMINISTRATIVE CONTROLS

5.7 High Radiation Area

As provided in paragraph 20.1601(c) of 10 CFR Part 20, the following controls shall be applied to high radiation areas in place of the controls required by paragraph 20.1601(a) and (b) of 10 CFR Part 20:

5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation

a. Each entryway to such an area shall be barricaded and conspicuously posted as a high radiation area. Such barricades may be opened as necessary to permit entry or exit of personnel or equipment.

b. Access to, and activities in, each such area shall be controlled by means of Radiation Work Permit (RWP) or equivalent that includes specification of radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measures.

c. Individuals qualified in radiation protection procedures and personnel continuously escorted by such individuals may be exempted from the requirement for an RWP or equivalent while performing their assigned duties provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.

d. Each individual or group entering such an area shall possess:

1. A radiation monitoring device that continuously displays radiation dose rates in the area, or

2. A radiation monitoring device that continuously integrates the radiation dose rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or

3. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area, or

5.7 High Radiation Area

5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation (continued)

4. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and,

(i) Be under the surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under the surveillance as specified in the RWP or equivalent, while in the area, by means of closed circuit television, of personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with individuals in the area who are covered by such surveillance.

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

5.7.2 <u>High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation</u>

a. Each entryway to such an area shall be conspicuously posted as a high radiation area and shall be provided with a locked or continuously guarded door or gate that prevents unauthorized entry, and, in addition:

1. All such door and gate keys shall be maintained under the administrative control of the shift supervisor, radiation protection manager, or his or her designees, and

2. Doors and gates shall remain locked except during periods of personnel or equipment entry or exit.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued)

b. Access to, and activities in, each such area shall be controlled by means of an RWP or equivalent that includes specification of radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measures.

c. Individuals qualified in radiation protection procedures may be exempted from the requirement for an RWP or equivalent while performing radiation surveys in such areas provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.

d. Each individual group entering such an area shall possess:

1. A radiation monitoring device that continuously integrates the radiation rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or

2. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area with the means to communicate with and control every individual in the area, or

3. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and,

(i) Be under surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under surveillance as specified in the RWP or equivalent, while in the area, by means of closed circuit television, or personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with and control every individual in the area.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued)

4. In those cases where options (2) and (3), above, are impractical or determined to be inconsistent with the “As Low As is Reasonably Achievable” principle, a radiation monitoring device that continuously displaces radiation dose rates in the area.

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

f. Such individual areas that are within a larger area where no enclosure exists for the purpose of locking and where no enclosure can reasonably be constructed around the individual area need not be controlled by a locked door or gate, nor continuously guarded, but shall be barricaded, conspicuously posted, and a clearly visible flashing light shall be activated at the area as a warning device.

B 2.0 SAFETY LIMITS (SLs)

B 2.1.1 Reactor Core Safety Limits (SLs)

BASES

BACKGROUND

GDC 10 (Ref. 1) requires that specified acceptable fuel design limits are not to be exceeded during steady state operation, normal operational transients, and anticipated operational occurrences (AOOs). This is accomplished by having a departure from nucleate boiling (DNB) design basis, which corresponds to a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that DNB will not occur, and by requiring that the fuel centerline temperature stays below the melting temperature.

The restriction of this SL prevents overheating of the fuel and cladding, as well as possible cladding perforation, that would result in the release of fission products to the reactor coolant. Overheating of the fuel is prevented by maintaining the steady state peak linear heat rate (LHR) below the level at which fuel centerline melting occurs. Overheating of the fuel cladding is prevented by restricting fuel operation to within the nucleate boiling regime, where the heat transfer coefficient is large and the cladding surface temperature is slightly above the coolant saturation temperature.

Fuel centerline melting occurs when the local LHR or power peaking in a region of the fuel is high enough to cause the fuel centerline temperature to reach the melting point of the fuel. Expansion of the pellet upon centerline melting may cause the pellet to stress the cladding to the point of failure, allowing an uncontrolled release of activity to the reactor coolant.

Operation above the boundary of the nucleate boiling regime could result in excessive cladding temperature because of the onset of DNB and the resultant sharp reduction in heat transfer coefficient. Inside the steam film, high cladding temperatures are reached, and a cladding water (Zirconium water) reaction may take place. This chemical reaction results in oxidation of the fuel cladding to a structurally weaker form. This weaker form may lose its integrity, resulting in an uncontrolled release of activity to the reactor coolant.

The proper functioning of the Protection and Safety Monitoring System (PMS) and steam generator safety valves prevents violation of the reactor core SLs.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation and AOOs. The reactor core SLs are established to preclude violation of the following fuel design criteria:

a. There must be at least 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience DNB; and

b. The hot fuel pellet in the core must not experience centerline fuel melting.

The Reactor Trip System (RTS) setpoints (Ref. 2), in combination with all the LCOs, are designed to prevent any anticipated combination of transient conditions for Reactor Coolant System (RCS) temperature, pressure, RCS Flow, ΔI, and THERMAL POWER level that would result in a departure from nucleate boiling ratio (DNBR) of less than the DNBR limit and preclude the existence of flow instabilities.

Automatic enforcement of these reactor core SLs is provided by the appropriate operation of the PMS and the steam generator safety valves.

The SLs represent a design requirement for establishing the RTS setpoints. LCO 3.4.1, “RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits,” or the assumed initial conditions of the safety analyses (as indicated in Section 7.2, Ref. 2) provide more restrictive limits to ensure that the SLs are not exceeded.

SAFETY LIMITS

The figure provided in the COLR shows the loci of points of THERMAL POWER, RCS pressure, and cold leg temperature for which the minimum DNBR is not less than the safety analysis limit, that fuel centerline temperature remains below melting, or that the exit quality is within the limits defined by the DNBR correlation.

The reactor core SLs are established to preclude violation of the following fuel design criteria:

a. There must be at least a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience DNB and

b. There must be at least a 95% probability at a 95% confidence level that the hot fuel pellet in the core does not experience centerline fuel melting.

BASES

SAFETY LIMITS (continued)

The reactor core SLs are used to define the various PMS functions such that the above criteria are satisfied during steady state operation, normal operational transients, and anticipated operational occurrences (AOOs). To ensure that the PMS precludes the violation of the above criteria, additional criteria are applied to the Overtemperature and Overpower ΔT reactor trip functions. That is, it must be demonstrated that the core exit quality is within the limits defined by the DNBR correlation and that the Overtemperature and Overpower ΔT reactor trip protection functions continue to provide protection if local hot leg streams approach saturation temperature. Appropriate functioning of the PMS ensures that for variations in the THERMAL POWER, RCS Pressure, RCS cold leg temperature, RCS flow rate, and ΔI that the reactor core SLs will be satisfied during steady state operation, normal operational transients, and AOOs.

APPLICABILITY

SL 2.1.1 only applies in MODES 1 and 2 because these are the only MODES in which the reactor is critical. Automatic protection functions are required to be OPERABLE during MODES 1 and 2 to ensure operation within the reactor core SLs. The steam generator safety valves or automatic protection actions serve to prevent RCS heatup to the reactor core SL conditions or to initiate a reactor trip function which forces the unit into MODE 3. Setpoints for the reactor trip functions are specified in LCO 3.3.1, “Reactor Trip System (RTS) Instrumentation.” In MODES 3, 4, 5, and 6, applicability is not required since the reactor is not generating significant THERMAL POWER.

SAFETY LIMIT VIOLATIONS

The following SL violation responses are applicable to the reactor core SLs. If SL 2.1.1 is violated, the requirement to go to MODE 3 places the unit in a MODE in which this SL is not applicable.

The allowed Completion Time of 1 hour recognizes the importance of bringing the unit to a MODE of operation where this SL is not applicable, and reduces the probability of fuel damage.

B 2.0 SAFETY LIMITS (SLs)

B 2.1.2 Reactor Coolant System (RCS) Pressure SL

BASES

BACKGROUND

The SL on RCS pressure protects the integrity of the RCS against overpressurization. In the event of fuel cladding failure, fission products are released into the reactor coolant. The RCS then serves as the primary barrier in preventing the release of fission products into the atmosphere. By establishing an upper limit on RCS pressure, the continued integrity of the RCS is ensured. According to 10 CFR 50, Appendix A, GDC 14, “Reactor Coolant Pressure Boundary,” and GDC 15, “Reactor Coolant System Design” (Ref. 1), the reactor coolant pressure boundary (RCPB) design conditions are not to be exceeded during normal operation and anticipated operational occurrences (AOOs). Also, in accordance with GDC 28, “Reactivity Limits” (Ref. 1), reactivity accidents, including rod ejection, do not result in damage to the RCPB greater than limited local yielding.

The design pressure of the RCS is 2500 psia (2485 psig). During normal operation and AOOs, RCS pressure is limited from exceeding the design pressure by more than 10%, in accordance with Section III of the American Society of Mechanical Engineers (ASME) Code (Ref. 2). To ensure system integrity, all RCS components are hydrostatically tested at 125% of design pressure, according to the ASME Code requirements prior to initial operation when there is no fuel in the core. Following inception of unit operation, RCS components shall be pressure tested, in accordance with the requirements of ASME Code, Section XI (Ref. 3).

Overpressurization of the RCS could result in a breach of the RCPB. If such a breach occurs in conjunction with a fuel cladding failure, fission products could enter the containment atmosphere, raising concerns relative to limits on radioactive releases.

APPLICABLE SAFETY ANALYSES

The RCS pressurizer safety valves, the main steam safety valves (MSSVs), and the reactor high pressurizer pressure trip have settings established to ensure that the RCS pressure SL will not be exceeded.

The RCS pressurizer safety valves are sized to prevent system pressure from exceeding the design pressure by more than 10%, as specified in Section III of the ASME Code for Nuclear Power Plant Components (Ref. 2). The transient that establishes the required relief capacity, and hence valve size requirements and lift settings, is a complete loss of external load with loss of feedwater flow, without a direct reactor trip. During the transient, no control actions are assumed except that the

BASES

APPLICABLE SAFETY ANALYSES (continued)

safety valves on the secondary plant are assumed to open when the steam pressure reaches the secondary plant safety valve settings.

The Reactor Trip System setpoints (Ref. 5), together with the settings of the MSSVs, provide pressure protection for normal operation and AOOs. The reactor high pressurizer pressure trip setpoint is specifically set to provide protection against overpressurization (Ref. 5). The safety analyses for both the high pressurizer pressure trip and the RCS pressurizer safety valves are performed using conservative assumptions relative to pressure control devices.

More specifically, no credit is taken for operation of the following:

a. RCS depressurization valves;

b. Steam line relief valves (SG PORVs);

c. Turbine Bypass System;

d. Reactor Control System;

e. Pressurizer Level Control System; or

f. Pressurizer spray.

SAFETY LIMITS

The maximum transient pressure allowed in the RCS pressure vessel, piping, valves, and fittings under the ASME Code, Section III, is 110% of design pressure; therefore, the SL on maximum allowable RCS pressure is 2733.5 psig.

APPLICABILITY

SL 2.1.2 applies in MODES 1, 2, 3, 4, and 5 because this SL could be approached or exceeded in these MODES due to overpressurization events. The SL is not applicable in MODE 6 since the reactor vessel closure bolts are not fully tightened, making it unlikely that the RCS can be pressurized.

SAFETY LIMIT VIOLATIONS

If the RCS pressure SL is violated when the reactor is in MODE 1 or 2, the requirement is to restore compliance and be in MODE 3 within 1 hour.

Exceeding the RCS pressure SL may cause immediate RCS failure and create a potential for abnormal radioactive releases.

BASES

SAFETY LIMIT VIOLATIONS (continued)

The allowable Completion Time of 1 hour recognizes the importance of reducing power level to a MODE of operation where the potential for challenges to safety systems is minimized.

If the RCS pressure SL is exceeded in MODE 3, 4, or 5, RCS pressure must be restored to within the SL value within 5 minutes. Exceeding the RCS pressure SL in MODE 3, 4, or 5 is more severe than exceeding this SL in MODE 1 or 2, since the reactor vessel temperature may be lower and the vessel material, consequently, less ductile. As such, pressure must be reduced to less than the SL within 5 minutes. The action does not require reducing MODES, since this would require reducing temperature, which would compound the problem by adding thermal gradient stresses to the existing pressure stress.

B 3.0 LIMITING CONDITIONS FOR OPERATION (LCO) APPLICABILITY

BASES

LCOs

LCO 3.0.1 through LCO 3.0.8 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.

LCO 3.0.1

LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirements for when the LCO is required to be met (i.e. when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification.)

LCO 3.0.2

LCO 3.0.2 establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. The Completion Time of each Required Action for an ACTIONS Condition is applicable from the point in time that the ACTIONS Condition is entered. The Required Actions establish those remedial measures that must be taken within specified Completion Times when the requirements of an LCO are not met. This specification establishes that:

a. Completion of the Required Actions within the specified Completion Times constitutes compliance with a Specification; and

b. Completion of the Required Actions is not required when an LCO is met within the specified Completion Time, unless otherwise specified.

There are two basic types of Required Actions. The first type of Required Action specifies a time limit in which the LCO must be met. This time limit is the Completion Time to restore an inoperable system or component to OPERABLE status or to restore variables to within specified limits. If this type of Required Action is not completed within the specified Completion Time, a shutdown may be required to place the unit in a MODE or condition in which the Specification is not applicable. (Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.) The second type of Required Action specifies the remedial measures that permit continued operation of the unit that is not further restricted by the Completion Time. In this case compliance with the Required Actions provides an acceptable level of safety for continued operation.

BASES

LCO 3.0.2 (continued)

Completing the Required Actions is not required when an LCO is met, or is no longer applicable, unless otherwise stated in the individual Specifications.

The nature of some Required Actions of some Conditions necessitates that, once the Condition is entered, the Required Actions must be completed even though the associated Conditions no longer exist. The individual LCO's ACTIONS specify the Required Actions where this is the case. An example of this is in LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits."

The Completion Times of the Required Actions are also applicable when a system or component is removed from service intentionally. The reasons for intentionally relying on the ACTIONS include, but are not limited to, performance of Surveillances, preventive maintenance, corrective maintenance, or investigation of operational problems. Entering ACTIONS for these reasons must be done in a manner that does not compromise safety. Intentional entry into ACTIONS should not be made for operational convenience. Alternatives that would not result in redundant equipment being inoperable should be used instead. Doing so limits the time both subsystems/trains of a safety function are inoperable and limits the time other conditions could exist which result in LCO 3.0.3 being entered. Individual Specifications may specify a time limit for performing an SR when equipment is removed from service or bypassed for testing. In this case, the Completion Times of the Required Actions are applicable when this time limit expires, if the equipment remains removed from service or bypassed.

When a change in MODE or other specified condition is required to comply with Required Actions, the unit may enter a MODE or other specified condition in which another Specification becomes applicable. In this case, the Completion Times of the associated Required Actions would apply from the point in time that the new Specification becomes applicable, and the ACTIONS Condition(s) are entered.

LCO 3.0.3

LCO 3.0.3 establishes the actions that must be implemented when an LCO is not met; and:

a. An associated Required Action and Completion Time is not met and no other Condition applies; or

BASES

LCO 3.0.3 (continued)

b. The condition of the unit is not specifically addressed by the associated ACTIONS. This means that no combination of Conditions stated in the ACTIONS can be made that exactly corresponds to the actual condition of the unit. Sometimes, possible combinations of Conditions are such that entering LCO 3.0.3 is warranted; in such cases, the ACTIONS specifically state a Condition corresponding to such combinations and also that LCO 3.0.3 be entered immediately.

This Specification delineates the time limits for placing the unit in a safe MODE or other specified condition when operation cannot be maintained within the limits for safe operation as defined by the LCO and its ACTIONS. It is not intended to be used as an operational convenience that permits routine voluntary removal of redundant systems or components from service in lieu of other alternatives that would not result in redundant systems or components being inoperable.

Upon entering into LCO 3.0.3, 1 hour is allowed to prepare for an orderly shutdown before initiating a change in unit operation. This includes time to permit the operator to coordinate the reduction in electrical generation with the load dispatcher to ensure the stability and availability of the electrical grid. The time limits specified to reach lower MODES of operation permit the shutdown to proceed in a controlled and orderly manner that is well within the specified maximum cooldown rate and within the capabilities of the unit. This reduces thermal stresses on components of the Reactor Coolant System and the potential for a plant upset that could challenge safety systems under conditions to which this Specification applies. The use and interpretation of specified times to complete the actions of LCO 3.0.3 are consistent with the discussion of Section 1.3, “Completion Times.”

A unit shutdown required in accordance with LCO 3.0.3 may be terminated, and LCO 3.0.3 exited if any of the following occurs:

a. The LCO is now met.

b. A Condition exists for which the Required Actions have now been performed.

c. ACTIONS exist that do not have expired Completion Times. These Completion Times are applicable from the point in time that the Condition was initially entered and not from the time LCO 3.0.3 is exited.

BASES

LCO 3.0.3 (continued)

The time limits of Specification 3.0.3 allow 37 hours for the unit to be in MODE 5 when a shutdown is required during MODE 1 operation. If the unit is in a lower MODE of operation when a shutdown is required, the time limit for reaching the next lower MODE applies. If a lower MODE is reached in less time than allowed, however, the total allowable time to reach MODE 5, or other applicable MODE is not reduced. For example, if MODE 3 is reached in 2 hours, then the time allowed for reaching MODE 4 is the next 11 hours, because the total time for reaching MODE 4 is not reduced from the allowable limit of 13 hours. Therefore, if remedial measures are completed that would permit a return to MODE 1, a penalty is not incurred by having to reach a lower MODE of operation in less than the total time allowed.

In MODES 1, 2, 3, and 4, LCO 3.0.3 provides actions for Conditions not covered in other Specifications. The requirements of LCO 3.0.3 do not apply in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken. The requirements of LCO 3.0.3 do not apply in MODES 5 and 6 because the unit is already in the most restrictive condition required by LCO 3.0.3. In MODES 5 and 6, LCO 3.0.8 provides actions for Conditions not covered in other Specifications.

Exceptions to 3.0.3 are provided in instances where requiring a unit shutdown in accordance with LCO 3.0.3, would not provide appropriate remedial measures for the associated condition of the unit. An example of this is in LCO 3.7.5, Spent Fuel Pool Water Level. This Specification has an Applicability of “At all times.” Therefore, this LCO can be applicable in any or all MODES. If the LCO and the Required Actions of LCO 3.7.5 are not met while in MODE 1, 2, or 3, there is no safety benefit to be gained by placing the unit in a shutdown condition. The Required Action of LCO 3.7.5 of “Suspend movement of irradiated fuel assemblies in the spent fuel pool” is the appropriate Required Action to complete in lieu of the actions of LCO 3.0.3. These exceptions are addressed in the individual Specifications.

LCO 3.0.4

LCO 3.0.4 establishes limitations on changes in MODES or other specified conditions in the Applicability when an LCO is not met. It precludes placing the unit in a MODE or other specified condition stated that Applicability (e.g., Applicability desired to be entered) when the following exist:

a. Unit conditions are such that the requirements of the LCO would not be met in the Applicability desired to be entered; and

BASES

LCO 3.0.4 (continued)

b. Continued noncompliance with the LCO requirements, if the Applicability were entered, would result in the unit being required to exit the Applicability desired to be entered to comply with the Required Actions.

Compliance with Required Actions that permit continued operation of the unit for an unlimited period of time in a MODE or other specified condition provides an acceptable level of safety for continued operation. This is without regard to the status of the unit before or after the MODE change. Therefore, in such cases, entry into a MODE or other specified condition in the Applicability may be made in accordance with the provisions of the Required Actions. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

The provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that results from any unit shutdown.

Exceptions to LCO 3.0.4 are stated in the individual Specifications. These exceptions allow entry into MODES or other specified conditions in the Applicability when the associated ACTIONS to be entered do not provide for continued operation for an unlimited period of time. Exceptions may apply to all the ACTIONS or to a specific Required Action of a Specification.

LCO 3.0.4 is only applicable when entering MODE 4 from MODE 5, MODE 3 from MODE 4 or 5, MODE 2 from MODE 3 or 4 or 5, or MODE 1 from MODE 2. Furthermore, LCO 3.0.4 is applicable when entering any other specified condition in the Applicability only while operating in MODE 1, 2, 3, or 4. The requirements of LCO 3.0.4 do not apply in MODES 5 and 6, or in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

Surveillances do not have to be performed on the associated inoperable equipment (or on variables outside the specified limits), as permitted by SR 3.0.1. Therefore, changing MODES or other specified conditions while in an ACTIONS Condition, in compliance with LCO 3.0.4 or where an exception to LCO 3.0.4 is stated, is not a violation of SR 3.0.1 or

BASES

LCO 3.0.4 (continued)

SR 3.0.4 for those Surveillances that do not have to be performed due to the associated inoperable equipment. However, SRs must be met to ensure OPERABILITY prior to declaring the associated equipment OPERABLE (or variable within limits) and restoring compliance with the affected LCO.

LCO 3.0.5

LCO 3.0.5 establishes the allowance of restoring equipment to service under administrative controls when it has been removed from service or declared inoperable to comply with ACTIONS. The sole purpose of this Specification is to provide an exception to LCO 3.0.2 (e.g., to not comply with the applicable Required Action(s)) to allow the performance of Surveillance Requirements to demonstrate:

a. The OPERABILITY of the equipment being returned to service; or

b. The OPERABILITY of other equipment.

The administrative controls ensure the time the equipment is returned to service in conflict with the requirements of the ACTIONS is limited to the time absolutely necessary to perform the required testing to demonstrate OPERABILITY. This specification does not provide time to perform any other preventive or corrective maintenance.

An example of demonstrating the OPERABILITY of the equipment being returned to service is reopening a containment isolation valve that has been closed to comply with Required Actions and must be reopened to perform the SRs.

An example of demonstrating the OPERABILITY of other equipment is taking an inoperable channel or trip system out of the tripped condition to prevent the trip function from occurring during the performance of an SR on another channel in the other trip system. A similar example of demonstrating the OPERABILITY of other equipment is taking an inoperable channel or trip system out of the tripped condition to permit the logic to function and indicate the appropriate response during the performance of an SR on another channel in the same trip system.

LCO 3.0.6

LCO 3.0.6 establishes an exception to LCO 3.0.2 for support systems that have an LCO specified in the Technical Specifications (TS). This exception is provided because LCO 3.0.2 would require that the Conditions and Required Actions of the associated inoperable supported system LCO be entered solely due to the inoperability of the support system. This exception is justified because the actions that are required

BASES

LCO 3.0.6 (continued)

to ensure the unit is maintained in a safe condition are specified in the support system LCO's Required Actions. These Required Actions may include entering the supported system's Conditions and Required Actions or may specify other Required Actions.

When a support system is inoperable and there is an LCO specified for it in the TS, the supported system(s) are required to be declared inoperable if determined to be inoperable as a result of the support system inoperability. However it is not necessary to enter into the supported systems' Conditions and Required Actions unless directed to do so by the support system's Required Actions. The potential confusion and inconsistency of requirements related to the entry into multiple support and supported systems' LCOs' Conditions and Required Actions are eliminated by providing all the actions that are necessary to ensure the unit is maintained in a safe condition in the support system's Required Actions.

However, there are instances where a support system's Required Action may either direct a supported system to be declared inoperable or direct entry into Conditions and Required Actions for the supported system. This may occur immediately or after some specified delay to perform some other Required Action. Regardless of whether it is immediate or after some delay, when a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

Specification 5.5.7, "Safety Function Determination Program (SFDP)," ensures loss of safety function is detected and appropriate actions are taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other limitations, remedial actions, or compensatory actions may be identified as a result of the support system inoperability and corresponding exception to entering supported system Conditions and Required Actions. The SFDP implements the requirements of LCO 3.0.6.

Cross train checks to identify a loss of safety function for those support systems that support multiple and redundant safety systems are required. The cross train check verifies that the supported systems of the redundant OPERABLE support system are OPERABLE, thereby ensuring safety function is retained. If this evaluation determines that a loss of

BASES

LCO 3.0.6 (continued)

safety function exists, the appropriate Conditions and Required Actions of the LCO in which the loss of safety functions exists are required to be entered.

This loss of safety function does not require the assumption of additional single failures or loss of offsite power. Since operations are being restricted in accordance with the ACTIONS of the support system, any resulting temporary loss of redundancy or single failure protection is taken into account.

When loss of safety function is determined to exist, and the SFDP requires entry into the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists, consideration must be given to the specific type of function affected. Where a loss of function is solely due to a single Technical Specification support system (e.g., loss of automatic start due to inoperable instrumentation, or loss of pump suction source due to low tank level) the appropriate LCO is the LCO for the support system. The ACTIONS for a support system LCO adequately addresses the inoperabilities of that system without reliance on entering its supported system LCO. When the loss of function is the result of multiple support systems, the appropriate LCO is the LCO for the support system.

LCO 3.0.7

There are certain special tests and operations required to be performed at various times over the life of the unit. These special tests and operations are necessary to demonstrate select unit performance characteristics, to perform special maintenance activities, and to perform special evolutions. Test Exception LCO 3.1.8 allows specified Technical Specification (TS) requirements to be changed to permit performance of these special tests and operations, which otherwise could not be performed if required to comply with the requirements of these TS. Unless otherwise specified, all the other TS requirements remain unchanged. This will ensure all appropriate requirements of the MODE or other specified condition not directly associated with or required to be changed to perform the special test or operation will remain in effect.

The Applicability of a Test Exception LCO represents a condition not necessarily in compliance with the normal requirements of the TS. Compliance with Test Exception LCOs is optional. A special operation may be performed either under the provisions of the appropriate Test Exception LCO or under the other applicable TS requirements. If it is

BASES

LCO 3.0.7 (continued)

desired to perform the special operation under the provisions of the Test Exception LCO, the requirements of the Test Exception LCO shall be followed.

LCO 3.0.8

LCO 3.0.8 establishes the ACTIONS that must be implemented when an LCO is not met and:

a. An associated Required Action and Completion Time is not met and no other Condition applies; or

b. The condition of the unit is not specifically addressed by the associated ACTIONS. This means that no combination of Conditions stated in the ACTIONS can be made that exactly corresponds to the actual condition of the unit.

This Specification delineates the requirements for placing the unit in a safe MODE or other specified condition when operation cannot be maintained within the limits for safe operation as defined by the LCO and its ACTIONS. It is not intended to be used as an operational convenience that permits routine voluntary removal of redundant systems or components from service in lieu of other alternatives that would not result in redundant systems or components being inoperable.

Upon entering LCO 3.0.8, 1 hour is allowed to prepare for an orderly plan of action which optimizes plant safety and equipment restoration. The Shutdown Safety Status Trees provide a systematic method to explicitly determine the status of the plant during shutdown conditions, after entering MODE 5. A set of plant parameters is monitored and if any parameter is outside of its defined limits, a transition is made to the Shutdown Emergency Response Guidelines. These guidelines provide preplanned actions for addressing parameters outside defined limits.

Examples of the required end states specified for inoperable passive systems while in MODES 5 and 6 are provided in Table B 3.0-1, Passive Systems Shutdown MODE Matrix. These requirements are specified in the individual Specifications. The required end states specified for passive systems, when the unit is in MODE 5 or 6, are selected to ensure that the initial conditions and system and equipment availabilities minimize the likelihood and consequences of potential shutdown events.

BASES

LCO 3.0.8 (continued)

ACTIONS required in accordance with LCO 3.0.8 may be terminated and LCO 3.0.8 exited if any of the following occurs:

a. The LCO is now met.

b. A Condition exists for which the Required Actions have now been performed.

c. ACTIONS exist that do not have expired Completion Times. These Completion Times are applicable from the point in time that the Condition is initially entered and not from the time LCO 3.0.8 is exited.

In MODES 5 and 6, LCO 3.0.8 provides actions for Conditions not covered in other Specifications and for multiple concurrent Conditions for which conflicting actions are specified.

As an example of the application of LCO 3.0.8, see column 2 of Table B 3.0-1, Passive Systems Shutdown MODE Matrix, for the core makeup tank. This example assumes that the plant is initially in MODE 5 with the Reactor Coolant System (RCS) pressure boundary intact. In this plant condition, LCO 3.5.3 requires one core makeup tank to be OPERABLE. The table shows the required end state established by the Required Actions of TS 3.5.3 in the event that the core makeup tank cannot be restored to OPERABLE status.

For this initial plant shutdown condition with no OPERABLE core makeup tanks, four conditions are identified in TS 3.5.3, with associated Required Actions and Completion Times. If Conditions A, B, and C cannot be completed within the required Completion Times, then Condition D requires immediately initiating action to place the plant in MODE 5 with the RCS pressure boundary open, and with pressurizer level greater than 20 percent.

LCO 3.0.8 would apply if actions could not immediately be initiated to open the RCS pressure boundary. In this situation, in parallel with the TS 3.5.3 actions to continue to open the RCS pressure boundary, LCO 3.0.8 requires the operators to take actions to restore one core makeup tank to OPERABLE status, and to monitor the Safety System Shutdown Monitoring Trees.

The Shutdown Status Trees monitor seven key RCS parameters and direct the operators to one of six shutdown ERGs in the event that any of the parameters are outside of allowable limits. The shutdown ERGs

BASES

LCO 3.0.8 (continued)

identify actions to be taken by the operators to satisfy the critical safety functions for the plant in the shutdown condition, using plant equipment available in this shutdown condition. LCO 3.0.8 monitoring would continue to be required until one core makeup tank is restored to OPERABLE status or the Required Actions for Condition D can be satisfied. In this case, once the RCS pressure boundary is open as required by Condition D, LCO 3.0.8 would be exited.

Table B 3.0-1 (page 1 of 1)
Passive Systems Shutdown MODE Matrix

LCO Applicability	Automatic Depressurization System	Core Makeup Tank	Passive RHR	IRWST	Containment	Containment Cooling[(1)]

(1) Containment cooling via PCS is not required when core decay heat ≤ 6.0 MWt.

B 3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

BASES

SRs

SR 3.0.1 through SR 3.0.4 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.

SR 3.0.1

SR 3.0.1 establishes the requirement that SRs must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. This Specification ensures that Surveillances are performed to verify the OPERABILITY of systems and components, and that variables are within specified limits. Failure to meet a Surveillance within the specified Frequency, in accordance with SR 3.0.2, constitutes a failure to meet an LCO.

Systems and components are assumed to be OPERABLE when the associated SRs have been met. Nothing in this Specification, however, is to be construed as implying that systems or components are OPERABLE when:

a. The systems or components are known to be inoperable, although still meeting the SRs; or

b. The requirements of the Surveillance(s) are known not to be met between required Surveillance performances.

Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable, unless otherwise specified. The SRs associated with a test exception are only applicable when the test exception is used as an allowable exception to the requirements of a Specification.

Unplanned events may satisfy the requirements (including applicable acceptance criteria) for a given SR. In this case, the unplanned event may be credited as fulfilling the performance of the SR. This allowance includes those SRs whose performance is normally precluded in a given MODE or other specified condition.

Surveillances, including Surveillances invoked by Required Actions, do not have to be performed on inoperable equipment because the ACTIONS define the remedial measures that apply. Surveillances have to be met in accordance with SR 3.0.2 prior to returning equipment to OPERABLE status.

BASES

SR 3.0.1 (continued)

Upon completion of maintenance, appropriate post maintenance testing is required to declare equipment OPERABLE. This includes ensuring applicable Surveillances are not failed and their most recent performance is in accordance with SR 3.0.2. Post maintenance testing may not be possible in the current MODE or other specified conditions in the Applicability due to the necessary unit parameters not having been established. In these situations, the equipment may be considered OPERABLE provided testing has been satisfactorily completed to the extent possible and the equipment is not otherwise believed to be incapable of performing its function. This will allow operation to proceed to a MODE or other specified condition where other necessary post maintenance tests can be completed.

SR 3.0.2

SR 3.0.2 establishes the requirements for meeting the specified Frequency for Surveillances and any Required Actions with a Completion Time that requires the periodic performance of the Required Action on a "once per…" interval.

SR 3.0.2 permits a 25% extension of the interval specified in the Frequency. This extension facilitates Surveillance scheduling and considers plant operating conditions that may not be suitable for conducting the Surveillance (e.g., transient conditions or other ongoing Surveillance or maintenance activities).

The 25% extension does not significantly degrade the reliability that results from performing the Surveillance at its specified Frequency. This is based on the recognition that the most probable result of any particular surveillance being performed is the verification of conformance with the SRs. The exceptions to SR 3.0.2 are those Surveillances for which the 25% extension of the interval specified in the Frequency does not apply. These exceptions are stated in the individual Specifications. The requirements of regulations take precedence over the TS. An example of where SR 3.0.2 does not apply is in the Containment Leakage Rate Testing Program. This program establishes testing requirements and Frequencies in accordance with the requirements of regulations. The TS cannot in and of themselves extend a test interval specified in the regulations.

As stated in SR 3.0.2, the 25% extension also does not apply to the initial portion of a periodic Completion Time that requires performance on a "once per …" basis. The 25% extension applies to each performance after the initial performance. The initial performance of the Required Action, whether it is a particular Surveillance or some remedial action, is

BASES

SR 3.0.2 (continued)

considered a single action with a single Completion Time. One reason for not allowing the 25% extension to this Completion Time is that such an action usually verifies that no loss of function has occurred by checking the status of redundant or diverse components or accomplishes the function of the inoperable equipment in an alternative manner.

The provisions of SR 3.0.2 are not intended to be used repeatedly merely as an operational convenience to extend Surveillance intervals (other than those consistent with refueling intervals) or periodic Completion Time intervals beyond those specified.

SR 3.0.3

SR 3.0.3 establishes the flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been completed within the specified Frequency. A delay period of up to 24 hours or up to the limit of the specified Frequency, whichever is greater, applies from the point in time that it is discovered that the Surveillance has not been performed, in accordance with SR 3.0.2, and not at the time that the specified Frequency was not met.

This delay period provides adequate time to complete Surveillances that have been missed. This delay period permits the completion of a Surveillance before compliance with Required Actions or other remedial measures that might preclude completion of the Surveillance.

The basis for this delay period includes consideration of unit Conditions, adequate planning, availability of personnel, the time required to perform the Surveillance, the safety significance of the delay in completing the required Surveillance, and the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the requirements. When a Surveillance with a Frequency based not on time intervals, but upon specified unit Conditions or operational situations, or requirements of regulations (e.g., prior to entering MODE 1 after each fuel loading, or in accordance with 10 CFR 50, Appendix J, as modified by approved exemptions, etc.) is discovered to not have been performed when specified, SR 3.0.3 allows for the full delay period of up to the specified Frequency to perform the Surveillance. However, since there is not a time interval specified, the missed Surveillance should be performed at the first reasonable opportunity. SR 3.0.3 provides a time limit for, and allowances for the performance of, Surveillances that become applicable as a consequence of MODE changes imposed by Required Actions.

BASES

SR 3.0.3 (continued)

Failure to comply with specified Frequencies for SRs is expected to be an infrequent occurrence. Use of the delay period established by SR 3.0.3 is a flexibility which is not intended to be used as an operational convenience to extend Surveillance intervals. While up to 24 hours or the limit of the specified Frequency is provided to perform the missed Surveillance, it is expected that the missed Surveillance will be performed at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying the Surveillance as well as any plant configuration changes required or shutting the plant down to perform the Surveillance) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to perform the Surveillance. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and its implementation guidance, NRC Regulatory Guide 1.182, 'Assessing and Managing Risk Before Maintenance Activities at Nuclear Power Plants.' This Regulatory Guide addresses consideration of temporary and aggregate risk impacts, determination of risk management action thresholds, and risk management action up to and including plant shutdown. The missed Surveillance should be treated as an emergent condition as discussed in the Regulatory Guide. The risk evaluation may use quantitative, qualitative, or blended methods. The degree of depth and rigor of the evaluation should be commensurate with the importance of the component. Missed Surveillances for important components should be analyzed quantitatively. If the results of the risk evaluation determine the risk increase is significant, this evaluation should be used to determine the safest course of action. All missed Surveillances will be placed in the licensee's Corrective Action Program.

If a Surveillance is not completed within the allowed delay period, then the equipment is considered inoperable or the variable is considered outside the specified limits and Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon expiration of the delay period. If a Surveillance is failed within the delay period, then the equipment is inoperable, or the variable is outside the specified limits and Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon the failure of the Surveillance.

Completion of the Surveillance within the delay period allowed by this specification, or within the Completion Time of the ACTIONS restores compliance with SR 3.0.1.

BASES

SR 3.0.4

SR 3.0.4 establishes the requirement that all applicable SRs must be met before entry into a MODE or other specified condition in the Applicability.

This Specification ensures that system and component OPERABILITY requirements and variable limits are met before entry into MODES or other specified conditions in the Applicability for which these systems and components ensure safe operation of the unit.

The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or component to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

However, in certain circumstances, failing to meet an SR will not result in SR 3.0.4 restricting a MODE change or other specified condition change. When a system, subsystem, division, component, device, or variable is inoperable or outside its specified limits, the associated SR(s) are not required to be performed, per SR 3.0.1, which states that surveillances do not have to be performed on inoperable equipment. When equipment is inoperable, SR 3.0.4 does not apply to the associated SR(s) since the requirement for the SR(s) to be performed is removed. Therefore, failing to perform the Surveillance(s) within the specified Frequency does not result in an SR 3.0.4 restriction to changing MODES or other specified conditions of the Applicability. However, since the LCO is not met in this instance, LCO 3.0.4 will govern any restrictions that may (or may not) apply to MODE or other specified condition changes.

The provisions of SR 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown.

The precise requirements for performance of SRs are specified such that exceptions to SR 3.0.4 are not necessary. The specific time frames and conditions necessary for meeting the SRs are specified in the Frequency, in the Surveillance, or both. This allows performance of Surveillances when the prerequisite condition(s) specified in a Surveillance procedure require entry into a MODE or other specified condition in the Applicability of the associated LCO prior to the performance or completion of a Surveillance. A Surveillance, that could not be performed until after entering the LCO Applicability, would have its Frequency specified such that it is not “due” until the specific conditions needed are met. Alternately, the Surveillance may be stated in the form of a NOTE as not

BASES

SR 3.0.4 (continued)

required (to be met or performed) until a particular event, condition, or time has been reached. Further discussion of the specific formats of SR's annotation is found in Section 1.4, Frequency.

SR 3.0.4 is only applicable when entering MODE 4 from MODE 5, MODE 3 from MODE 4, MODE 2 from MODE 3 or 4, or MODE 1 from MODE 2. Furthermore, SR 3.0.4 is applicable when entering any other specified condition in the Applicability only while operating in MODE 1, 2, 3, or 4. The requirements of SR 3.0.4 do not apply in MODES 5 and 6, or in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.1 SHUTDOWN MARGIN (SDM)

BASES

BACKGROUND

According to GDC 26 (Ref. 1) the reactivity control systems must be redundant and capable of holding the reactor core subcritical when shutdown under cold conditions. Maintenance of the SDM ensures that postulated reactivity events will not damage the fuel.

SDM requirements provide sufficient reactivity margin to assure that acceptable fuel design limits will not be exceeded for normal shutdown and anticipated operational occurrences (AOOs). As such, the SDM defines the degree of subcriticality that would be obtained immediately following the insertion or scram of all Rod Cluster Control Assemblies (RCCAs), assuming that the single rod cluster assembly of highest reactivity worth is fully withdrawn.

The system design requires that two independent reactivity control systems be provided, and that one of these systems be capable of maintaining the core subcritical under cold conditions. These requirements are provided by the use of movable control assemblies and soluble boric acid in the Reactor Coolant System (RCS). The Plant Control System (PLS) can compensate for the reactivity effects of the fuel and water temperature changes accompanying power level changes over the range from full load to no load. In addition, the PLS, together with the boration system, provides the SDM during power operation and is capable of making the core subcritical rapidly enough to prevent exceeding acceptable fuel damage limits, assuming that the rod of highest reactivity worth remains fully withdrawn. The soluble boron system can compensate for fuel depletion during operation and xenon burnout reactivity changes and maintain the reactor subcritical under cold conditions.

During power operation, SDM is calculated and monitored by the Online Power Distribution Monitoring System (OPDMS) and controlled by operating with RCCAs sufficiently withdrawn to meet the SDM requirement. When the OPDMS is inoperable, SDM control is ensured by operating within the limits of LCO 3.1.5 “Shutdown Bank Insertion Limits,” and LCO 3.1.6, “Control Bank Insertion Limits.” When the unit is in the shutdown and refueling modes, the SDM requirements are met by adjustments to the RCS boron concentration.

BASES

APPLICABLE SAFETY ANALYSES

The minimum required SDM is assumed as an initial condition in safety analyses. The safety analyses (Ref. 2) establish an SDM that ensures that specified acceptable fuel design limits are not exceeded for normal operation and AOOs, with the assumption of the highest worth rod stuck out on scram. For MODE 5, the primary safety analysis that relies on the SDM limits is the boron dilution analysis.

The acceptance criteria for the SDM requirements are that specified acceptable fuel design limits are maintained. This is done by ensuring that:

a. The reactor can be made subcritical from all operating conditions, transients, and Design Basis Events;

b. The reactivity transients associated with postulated accident conditions are controllable within acceptable limits (departures from nucleate boiling ratio (DNBR), fuel centerline temperature limits for AOOs, and ≤ 280 cal/gm energy deposition for the rod ejection accident); and

c. The reactor will be maintained sufficiently subcritical to preclude inadvertent criticality in the shutdown condition.

The most limiting accidents for the SDM requirements are based on a main steam line break (SLB) and inadvertent opening of a steam generator (SG) relief or safety valve, as described in the accident analyses (Ref. 2). The increased steam flow in the main steam system causes an increased energy removal from the affected SG, and consequently the RCS. This results in a reduction of the reactor coolant temperature. The resultant coolant shrinkage causes a reduction in pressure. In the presence of a negative moderator temperature coefficient (MTC), this cooldown causes an increase in core reactivity. The positive reactivity addition from the moderator temperature decrease will terminate when the affected SG boils dry, thus terminating RCS heat removal and cooldown. Following the SLB or opening of an SG relief or safety valve, a post trip return to power may occur; however, no fuel damage occurs as a result of the post trip return to power, and the THERMAL POWER does not violate the Safety Limit (SL) requirement of SL 2.1.1.

In addition to the limiting SLB and inadvertent opening of an SG relief or safety valve transients, the SDM requirement must also protect against:

a. Inadvertent boron dilution;

b. An uncontrolled rod withdrawal from subcritical or low power condition;

BASES

APPLICABLE SAFETY ANALYSES (continued)

c. Rod ejection.

Each of these events is discussed below.

In the boron dilution analysis, the required SDM defines the reactivity difference between an initial subcritical boron concentration and the corresponding critical boron concentration. These values, in conjunction with the configuration of the RCS and the assumed dilution flow rate, directly affect the results of the analysis. This event is most limiting when critical boron concentrations are highest.

The uncontrolled rod withdrawal transient is terminated by a high neutron flux trip. Power level, RCS pressure, linear heat rate, and the DNBR do not exceed allowable limits.

The ejection of a control rod rapidly adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The ejection of a rod also produces a time-dependent redistribution of core power.

SDM satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). Even though it is not directly observed from the main control room, SDM is considered an initial condition process variable because it is periodically monitored to provide assurance that the unit is operating within the bounds of accident analysis assumptions.

LCO

SDM is a core design condition that can be ensured during operation through calculations by the OPDMS and RCCA positioning and through the soluble boron concentration.

The SLB and the boron dilution accidents (Ref. 2) are the most limiting analyses that establish the SDM value of the LCO. For SLB accidents, if the LCO is violated, there is a potential to exceed the DNBR limit and to exceed 10 CFR 50.34 limits (Ref. 3). For the boron dilution accident, if the LCO is violated, the minimum required time assumed for automatic action to terminate dilution may no longer be applicable.

BASES

APPLICABILITY

In MODE 2 with k_{eff} < 1.0, and in MODES 3, 4, and 5, the SDM requirements are applicable to provide sufficient negative reactivity to meet the assumptions of the safety analyses discussed above. In MODE 6, the shutdown reactivity requirements are given in LCO 3.9.1, "Boron Concentration." In MODES 1 and 2, SDM is ensured by complying with LCO 3.1.5, "Shutdown Bank Insertion Limits," and LCO 3.1.6, "Control Bank Insertion Limits."

ACTIONS

A.1

If the SDM requirements are not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. It is assumed that boration will be continued until the SDM requirements are met.

In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon as possible, the boron concentration should be a concentrated solution. The operator should begin boration with the best source available for the plant conditions.

In determining the boration flow rate, the time in core life must be considered. For instance, the most difficult time in core life to increase the RCS boron concentration is at hot shutdown conditions when boron concentration is highest at 1502 ppm. Assuming that a value of 1.0% Δk/k must be recovered and the boration flow rate is 100 gpm, it is possible to increase the boron concentration of the RCS by 111 ppm in approximately 21 minutes utilizing boric acid solution having a concentration of 4375 ppm. If a boron worth of 9 pcm/ppm is assumed, this combination of parameters will increase the SDM by 1.0% Δk/k. These boration parameters of 100 gpm and 4375 ppm represent typical values and are provided for the purpose of offering a specific example.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.1.1

In MODES 1 and 2 with $k_{eff} \geq 1.0$, SDM is verified by observing that the requirements of LCO 3.1.5 and LCO 3.1.6 are met. In the event that an RCCA is known to be untrippable, however, SDM verification must account for the worth of both the untrippable RCCA as well as another RCCA of maximum worth.

In MODES 3, 4, and 5, the SDM is verified by performing a reactivity balance calculation, considering at least the listed reactivity effects:

a. RCS boron concentration;

b. RCCA and GRCA position;

c. RCS average temperature;

d. Fuel burnup based on gross thermal energy generation;

e. Xenon concentration;

f. Samarium concentration; and

g. Isothermal Temperature Coefficient (ITC).

Using the ITC accounts for Doppler reactivity in this calculation because the reactor is subcritical and the fuel temperature will be changing at the same rate as the RCS.

The Frequency of 24 hours is based on the generally slow change in required boron concentration and the low probability of an accident occurring without the required SDM. This allows time for the operator to collect the required data, which includes performing a boron concentration analysis, and complete the calculation.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.2 Core Reactivity

BASES

BACKGROUND

According to GDC 26, GDC 28, and GDC 29 (Ref. 1), reactivity shall be controllable, such that subcriticality is maintained under cold conditions, and acceptable fuel design limits are not exceeded during normal operation and anticipated operational occurrences. Therefore, reactivity balance is used as a measure of the predicted versus measured core reactivity during power operation. The periodic confirmation of core reactivity is necessary to ensure that Design Basis Accident (DBA) and transient safety analyses remain valid. A large reactivity difference could be the result of unanticipated changes in fuel, control rod worth, or operation at conditions not consistent with those assumed in the predictions of core reactivity and could potentially result in a loss of SDM or violation of acceptable fuel design limits. Comparing predicted versus measured core reactivity validates the nuclear methods used in the safety analysis and supports the SDM demonstrations (LCO 3.1.1, “SHUTDOWN MARGIN (SDM)”) in ensuring the reactor can be brought safely to cold, subcritical conditions.

When the reactor core is critical or in normal power operation, a reactivity balance exists and the net reactivity is zero. A comparison of predicted and measured reactivity is convenient under such a balance since parameters are being maintained relatively stable under steady-state power conditions. The positive reactivity inherent in the core design is balanced by the negative reactivity of the control components, thermal feedback, neutron leakage, and materials in the core that absorb neutrons, such as burnable absorbers producing zero net reactivity. Excess reactivity can be inferred from the boron letdown curve (or critical boron curve), which provides an indication of the soluble boron concentration in the Reactor Coolant System (RCS) versus cycle burnup. Periodic measurement of the RCS boron concentration for comparison with the predicted value with other variables fixed (such as rod height, temperature, pressure, and power), provides a convenient method of ensuring that core reactivity is within design expectations and that the calculation models used to generate the safety analysis are adequate.

In order to achieve the required fuel cycle energy output, the uranium enrichment, in the new fuel loading and in the fuel remaining from the previous cycle, provides excess positive reactivity beyond that required to sustain steady state operation throughout the cycle. When the reactor is critical at RTP and a negative moderator temperature coefficient, the

BASES

BACKGROUND (continued)

excess positive reactivity is compensated by burnable absorbers (if any), control rods, whatever neutron poisons (mainly xenon and samarium) are present in the fuel, and the RCS boron concentration.

When the core is producing THERMAL POWER, the fuel is being depleted and excess reactivity is decreasing. As the fuel depletes, the RCS boron concentration is reduced to compensate reactivity and maintain constant THERMAL POWER. The boron letdown curve is based on steady state operation at RTP. Therefore, deviations from the predicted boron letdown curve may indicate deficiencies in the design analysis, deficiencies in the calculational models, or abnormal core conditions, and must be evaluated.

APPLICABLE SAFETY ANALYSES

The acceptance criteria for core reactivity are that the reactivity balance limit ensures plant operation is maintained within the assumptions of the safety analyses.

Accurate prediction of core reactivity is either an explicit or implicit assumption in the accident analysis evaluations. Certain accident evaluations (Ref. 2) are, therefore, dependent upon accurate evaluation of core reactivity. In particular, SDM and reactivity transients, such as control rod withdrawal accidents or rod ejection accidents, are sensitive to accurate predictions of core reactivity. These accident analysis evaluations rely on computer codes that have been qualified against available test data, operating plant data, and analytical benchmarks. Monitoring reactivity balance provides additional assurance that the nuclear methods provide an accurate representation of the core reactivity.

Design calculations and safety analysis are performed for each fuel cycle for the purpose of predetermining reactivity behavior and the RCS boron concentration requirements for reactivity control during fuel depletion.

The comparison between measured and predicted initial core reactivity provides a normalization for the calculational models used to predict core reactivity. If the measured and predicted RCS boron concentrations for identical core conditions at beginning of cycle (BOC) do not agree, then the assumptions used in the reload cycle design analysis or the calculation models used to predict soluble boron requirements may not be accurate. If reasonable agreement between measured and predicted core reactivity exists at BOC, then the prediction may be normalized to the measured boron concentration. Thereafter, any significant deviations in the measured boron concentration from the predicted boron letdown

BASES

APPLICABLE SAFETY ANALYSES (continued)

curve that develop during fuel depletion may be an indication that the calculational model is not adequate for core burnups beyond BOC, or that an unexpected change in core conditions has occurred.

The normalization of predicted RCS boron concentration to the measured value is typically performed after reaching RTP following startup from a refueling outage, with the control rods in their normal positions for power operation. The normalization is performed at BOC conditions so that core reactivity relative to predicted values can be continually monitored and evaluated as core conditions change during the cycle.

Core reactivity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

Long term core reactivity behavior is a result of the core physics design and cannot be easily controlled once the core design is fixed. During operation, therefore, the Conditions of the LCO can only be ensured through measurement and tracking, and appropriate actions taken as necessary. Large differences between actual and predicted core reactivity may indicate that the assumptions of the DBA and transient analyses are no longer valid, or that the uncertainties in the Nuclear Design Methodology are larger than expected. A limit on the reactivity balance of ± 1% $\Delta k/k$ has been established based on engineering judgment. A 1% deviation in reactivity from that predicted is larger than expected for normal operation and should therefore be evaluated.

When measured core reactivity is within 1% $\Delta k/k$ of the predicted value at steady state thermal conditions, the core is considered to be operating within acceptable design limits. Since deviations from the limit are normally detected by comparing predicted and measured steady state RCS critical boron concentrations, the difference between measured and predicted values would be approximately 100 ppm (depending on the boron worth) before the limit is reached. These values are well within the uncertainty limits for analysis of boron concentration samples, so that spurious violations of the limit due to uncertainty in measuring the RCS boron concentration are unlikely.

APPLICABILITY

The limits on core reactivity must be maintained during MODES 1 and 2 because a reactivity balance must exist when the reactor is critical or producing THERMAL POWER. As the fuel depletes, core conditions are changing, and confirmation of the reactivity balance ensures the core is operating as designed. This specification does not apply in MODE 3, 4, and 5 because the reactor is shutdown and the reactivity balance is not changing.

BASES

APPLICABILITY (continued)

In MODE 6, fuel loading results in a continually changing core reactivity. Boron concentration requirements (LCO 3.9.1, “Boron Concentration”) ensure that fuel movements are performed within the bounds of the safety analysis. An SDM demonstration is required during the first startup following operations that could have altered core reactivity (e.g., fuel movement, control rod replacement, control rod shuffling).

ACTIONS

A.1 and A.2

Should an anomaly develop between measured and predicted core reactivity, an evaluation of the core design and safety analysis must be performed. Core conditions are evaluated to determine their consistency with input to design calculations. Measured core and process parameters are evaluated to determine that they are within the bounds of the safety analysis, and safety analysis calculational models are reviewed to verify that they are adequate for representation of the core conditions. The required Completion Time of 7 days is based on the low probability of a DBA occurring during this period and allows sufficient time to assess the physical condition of the reactor and complete the evaluation of the core design and safety analysis.

Following evaluations of the core design and safety analysis, the cause of the reactivity anomaly may be resolved. If the cause of the reactivity anomaly is a mismatch in core conditions at the time of RCS boron concentration sampling, then a recalculation of the RCS boron concentration requirements may be performed to demonstrate that core reactivity is behaving as expected. If an unexpected physical change in the condition of the core has occurred, it must be evaluated and corrected, if possible. If the cause of the reactivity anomaly is in the calculation technique, then the calculational models must be revised to provide more accurate predictions. If any of these results are demonstrated and it is concluded that the reactor core is acceptable for continued operation, then the boron letdown curve may be renormalized and power operation may continue. If operational restriction or additional SRs are necessary to ensure the reactor core is acceptable for continued operation, then they must be defined.

The required Completion Time of 7 days is adequate for preparing whatever operating restrictions or Surveillances that may be required to allow continued reactor operation.

BASES

ACTIONS (continued)

B.1

If the core reactivity cannot be restored to within the 1% Δk/k limit, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. If the SDM for MODE 3 is not met, then the boration required by SR 3.1.1.1 would occur. The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.2.1

Core reactivity is verified by periodic comparisons of measured and predicted RCS boron concentrations. The comparison is made considering that other core conditions are fixed or stable, including control rod position, moderator temperature, fuel temperature, fuel depletion, xenon concentration, and samarium concentration. The Surveillance is performed prior to entering MODE 1 as an initial check on core conditions and design calculations at BOC. The Note indicates that the normalization of predicted core reactivity to the measured value must take place within the first 60 effective full power days (EFPDs) after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. The required subsequent Frequency of 31 EFPDs following the initial 60 EFPDs after entering MODE 1 is acceptable based on the slow rate of core changes due to fuel depletion and the presence of other indicators (QPTR, AFD, etc.) for prompt indication of an anomaly.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.3 Moderator Temperature Coefficient (MTC)

BASES

BACKGROUND

According to GDC 11 (Ref. 1), the reactor core and its interaction with the Reactor Coolant System (RCS) must be designed for inherently stable power operation even in the possible event of an accident. In particular, the net reactivity feedback in the system must compensate for any unintended reactivity increases.

The MTC relates a change in core reactivity to a change in reactor coolant temperature (a positive MTC means that reactivity increases with increasing moderator temperature; conversely, a negative MTC means that reactivity decreases with increasing moderator temperature). The reactor is designed to operate with a non-positive MTC over the range of fuel cycle operation. Therefore, a coolant temperature increase will cause a reactivity decrease, so that the coolant temperature tends to return toward its initial value. Reactivity increases that cause a coolant temperature increase will thus be self limiting, and stable power operation will result.

MTC values are predicted at selected burnups during the safety evaluation analysis and are confirmed to be acceptable by measurements. Both initial and reload cores are designed so that the MTC is less than zero when THERMAL POWER is at RTP. The actual value of the MTC is dependent on core characteristics such as fuel loading and reactor coolant soluble boron concentration. The core design may require additional fixed distributed poisons (burnable absorbers) to yield an MTC within the range analyzed in the plant accident analysis. The end of cycle (EOC) MTC is also limited by the requirements of the accident analysis. Fuel cycles designed to achieve high burnups that have changes to other characteristics are evaluated to ensure that the MTC does not exceed the EOC limit.

The limitations on MTC are provided to ensure that the value of this coefficient remains within the limiting conditions assumed in the Chapter 15 accident and transient analyses (Ref. 2).

If the LCO limits are not met, the plant response during transients may not be as predicted. The core could violate criteria that prohibit a return to criticality, or the departure from nucleate boiling ratio criteria of the approved correlation may be violated, which could lead to a loss of the fuel cladding integrity.

BASES

BACKGROUND (continued)

The SRs for measurement of the MTC at the beginning and near the end of the fuel cycle are adequate to confirm that the MTC remains within its limits since this coefficient changes slowly due principally to the RCS boron concentration associated with fuel burnup and burnable absorbers.

APPLICABLE SAFETY ANALYSES

The acceptance criteria for the specified MTC are:

a. The MTC values must remain within the bounds of those used in the accident analysis (Ref. 2); and

b. The MTC must be such that inherently stable power operations result during normal operation and accidents, such as overheating and overcooling events.

Chapter 15 (Ref. 2) contains analyses of accidents that result in both overheating and overcooling of the reactor core. MTC is one of the controlling parameters for core reactivity in these accidents. Both the least negative value and most negative value of the MTC are important to safety, and both values must be bounded. Values used in the analyses consider worst case conditions to ensure that the accident results are bounding (Ref. 3).

The consequences of accidents that cause core heat-up must be evaluated when the MTC is least negative. Such accidents include the rod withdrawal transient from either zero (Ref. 2) or RTP, loss of main feedwater flow, and loss of forced reactor coolant flow. The consequences of accidents that cause core overcooling must be evaluated when the MTC is negative. Such accidents include sudden feedwater flow increase and sudden decrease in feedwater temperature.

In order to ensure a bounding accident analysis, the MTC is assumed to be its most limiting value for the analysis conditions appropriate to each accident. The bounding value is determined by considering rodded and unrodded conditions, whether the reactor is at full or zero power, and whether it is BOC or EOC. The most conservative combination appropriate to the accident is then used for the analysis (Ref. 2).

MTC values are bounded in reload safety evaluations assuming steady state conditions at the limiting time in cycle life. An EOC measurement is conducted at conditions when the RCS boron concentration reaches approximately 300 ppm. The measured value may be extrapolated to project the EOC value, in order to confirm reload design predictions.

BASES

APPLICABLE SAFETY ANALYSES (continued)

MTC satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). Even though it is not directly observed and controlled from the control room, MTC is considered an initial condition process variable because of its dependence on boron concentration.

LCO

LCO 3.1.3 requires the MTC to be within specified limits of the COLR to ensure that the core operates within the assumptions of the accident analysis. During the reload core safety evaluation, the MTC is analyzed to determine that its values remain within the bounds of the accident analysis during operation.

Assumptions made in safety analyses require that the MTC be more negative than a given upper limit and less negative than a given lower limit. The MTC is least negative near BOC; this upper bound must not be exceeded. This maximum upper limit occurs at all rods out (ARO), hot zero power conditions. At EOC the MTC takes on its most negative value, when the lower bound becomes important. This LCO exists to ensure that both the upper and lower bounds are not exceeded.

During operation, therefore, the conditions of the LCO can only be ensured through measurement. The surveillance checks at BOC and EOC on MTC provide confirmation that the MTC is behaving as anticipated so that the acceptance criteria are met.

The BOC limit and the EOC limit are established in the COLR to allow specifying limits for each particular cycle. This permits the unit to take advantage of improved fuel management and changes in unit operating schedule.

APPLICABILITY

Technical Specifications place both LCO and SR values on MTC, based on the safety analysis assumptions described above.

In MODE 1, the limits on MTC must be maintained to assure that any accident initiated from THERMAL POWER operation will not violate the design assumptions of the accident analysis. In MODE 2, with the reactor critical, the upper limit must also be maintained to ensure that startup and subcritical accidents (such as the uncontrolled CONTROL ROD assembly or group withdrawal) will not violate the assumptions of the accident analysis. The lower MTC limit must be maintained in MODES 2 and 3, in addition to MODE 1, to ensure that cooldown accidents will not violate the assumptions of the accident analysis. In

BASES

APPLICABILITY (continued)

MODES 4, 5, and 6, this LCO is not applicable, since no Design Basis Accidents (DBAs) using the MTC as an analysis assumption are initiated from these MODES.

ACTIONS

A.1

If the upper MTC limit is violated, administrative withdrawal limits for control banks must be established to maintain the MTC within its limits. The MTC becomes more negative with control bank insertion and decreased boron concentration. A Completion Time of 24 hours provides enough time for evaluating the MTC measurement and computing the required bank withdrawal limits.

As cycle burnup is increased, the RCS boron concentration will be reduced. The reduced boron concentration causes the MTC to become more negative. Using physics calculations, the time in cycle life at which the calculated MTC will meet the LCO requirement can be determined. At this point in core life, Condition A no longer exists. The unit is no longer in the Required Action, so the administrative withdrawal limits are no longer in effect.

B.1

If the required administrative withdrawal limits at BOC are not established within 24 hours, the unit must be placed in MODE 2 with $k_{eff} < 1.0$ to prevent operation with an MTC which is less negative than that assumed in safety analyses.

The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

C.1

Exceeding the EOC MTC limit means that the safety analysis assumptions for the EOC accidents that use a bounding negative MTC value may be invalid. If the EOC MTC limit is exceeded, the plant must be placed in a MODE or Condition in which the LCO requirements are not applicable. This is done by placing the plant in at least MODE 4 within 12 hours.

The allowed Completion Time is a reasonable time based on operating experience to reach the required MODE from full power operation in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.3.1

This SR requires measurement of the MTC at BOC prior to entering MODE 1 in order to demonstrate compliance with the most limiting MTC LCO. Meeting the limit prior to entering MODE 1 assures that the limit will also be met at higher power levels.

The BOC MTC value for ARO will be inferred from isothermal temperature coefficient measurements obtained during the physics tests after refueling. The ARO value can be directly compared to the MTC limit of the LCO. If required, measurement results and predicted design values can be used to establish administrative withdrawal limits for control banks.

SR 3.1.3.2

In similar fashion, the LCO demands that the MTC be less negative than the specified value for EOC full power conditions. This measurement may be performed at any THERMAL POWER, but its results must be extrapolated to the conditions of RTP and all banks withdrawn in order to make a proper comparison with the LCO value. Because the RTP MTC value will gradually become more negative with further core depletion and boron concentration reduction, a 300 ppm SR value of MTC should necessarily be less negative than the EOC LCO limit. The 300 ppm SR value is sufficiently less negative than the EOC LCO limit value to provide assurance that the LCO limit will be met at EOC when the 300 ppm Surveillance criterion is met.

SR 3.1.3.2 is modified by three Notes that include the following requirements:

a. The SR is not required to be performed until 7 effective full power days (EFPDs) after reaching the equivalent of an equilibrium RTP all rods out (ARO) boron concentration of 300 ppm.

b. If the 300 ppm Surveillance limit is exceeded, it is possible that the EOC limit on MTC could be reached before the planned EOC. Because the MTC changes slowly with core depletion, the Frequency of 14 effective full power days is sufficient to avoid exceeding the EOC limit.

c. The Surveillance limit for RTP boron concentration of 60 ppm is conservative. If the measured MTC at 60 ppm is more positive than the 60 ppm surveillance limit, the EOC limit will not be exceeded because of the gradual manner in which MTC changes with core burnup.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.4 Rod Group Alignment Limits

BASES

BACKGROUND

The OPERABILITY (e.g., trippability) of the RCCAs is an initial assumption in all safety analyses which assume rod insertion upon reactor trip. Maximum rod misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM. Gray Rod Cluster Assemblies (GRCAs) are excluded from this LCO during the planned GRCA bank sequence exchange, with the Online Power Distribution Monitoring System (OPDMS) operable. The bank sequence exchange of GRCA banks will be periodically necessary to prevent excessive burnup shadowing of fuel rods near the gray rod assemblies. The bank sequence exchange maneuver will purposefully misalign GRCAs from their bank for a short period of time. The exclusion from this LCO is acceptable due to SHUTDOWN MARGIN being calculated exclusive of GRCAs, the relative low worth of individual gray rod assemblies, the short time duration anticipated for the bank sequence exchange maneuver and with OPDMS operable, power peaking and xenon redistribution effects will be monitored and controlled.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, “Reactor Design,” GDC 26, “Reactivity Control System Redundancy and Protection” (Ref. 1), and 10 CFR 50.46, “Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants” (Ref. 2).

Mechanical or electrical failures may cause a control rod to become inoperable or to become misaligned from its group. Control rod inoperability or misalignment may cause increased power peaking due to the asymmetric reactivity distribution and a reduction in the total available rod worth for reactor shutdown. Therefore, control rod alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on control rod alignment have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

Rod cluster control assemblies (RCCAs) and GRCAs are moved by their control rod drive mechanisms (CRDMs). Each CRDM moves its RCCA or GRCA one step (approximately 5/8 inch) at a time but at varying rates (steps per minute) depending on the signal output from the Plant Control System (PLS).

BASES

BACKGROUND (continued)

The rod control assemblies are divided among control banks and shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A group consists of two or more rod control assemblies that are electrically paralleled to step simultaneously. A bank of rod control assemblies consists of two groups that are moved in a staggered fashion, but always within one step of each other. The AP1000 design has seven control banks and four shutdown banks.

The shutdown banks are maintained either in the fully inserted or fully withdrawn position. The control banks are part of the MSHIM (Mechanical Shim) Control System which utilizes two independently OPERABLE groups of control banks for control of reactivity and axial power distribution.

Certain control rods will be pre-selected for inclusion in the Rapid Power Reduction (RPR) system. The purpose of the RPR is to initiate a rapid decrease in the core power during load rejection transients.

Reactivity control is provided primarily by the M banks. The M Banks consist of several control banks operating with a fixed overlap. The bank worth and overlap are defined so as to minimize the impact on axial offset with control bank maneuvering and still retain the reactivity required to meet the desired load changes.

The axial power distribution control is provided by the AO Bank, a relatively high worth bank.

In order to avoid boron adjustment for load follow operation, gray rods are utilized.

There are 16 GRCAs in the AP1000, each composed of 24 rodlets mounted on a common RCCA spider. These have been subdivided into what has been termed as MA, MB, MC, and MD Banks with 4 GRCAs in each.

Each of the MA, MB, MC, and MD Banks has almost the same worth. The primary gray bank function is to provide additional reactivity during the transition periods. During base load operation, two of the gray banks may be fully inserted into the core. Each of the gray banks consists of a relatively low worth bank.

The MA, MB, MC, MD, M1 and M2 Banks function together with a single variable (i.e., criticality or temperature) driving these groups as if they are in one control group.

BASES

BACKGROUND (continued)

The control rods are arranged in a radially symmetric pattern so that control bank motion does not introduce radial asymmetries in the core power distributions.

The axial position of shutdown rods and control rods is indicated by two separate and independent systems, which are the Bank Demand Position Indication System (commonly called group step counters) and the Digital Rod Position Indication (DRPI) System.

The Bank Demand Position Indication System counts the pulses from the rod control system that moves the rods. There is one step counter for each group of rods. Individual rods in a group all receive the same signal to move and should, therefore, all be at the same position indicated by the group step counter for that group. The Bank Demand Position Indication System is considered highly precise (± 1 step or ± 5/8 inch). If a rod does not move one step for each demand pulse, the step counter will still count the pulse and incorrectly reflect the position of the rod.

The DRPI System provides a highly accurate indication of actual control rod position, at a lower precision than the step counters. This system is based on inductive analog signals from a series of coils spaced along a hollow tube. To increase the reliability of the system, the inductive coils are connected alternately to data system A or B. Thus, if one data system fails, the DRPI will go on half-accuracy. The DRPI System is capable of monitoring rod position within at least ± 12 steps with either full accuracy or half accuracy.

APPLICABLE SAFETY ANALYSES

Control rod misalignment accidents are analyzed in the safety analysis (Ref. 3). The acceptance criteria for addressing control rod inoperability or misalignment is that:

a. There be no violations of:

   1. Specified acceptable fuel design limits, or

   2. Reactor Coolant System (RCS) pressure boundary integrity; and

b. The core remains subcritical after accident transients.

Two types of misalignment are distinguished. During movement of a control rod group, one rod may stop moving, while the other rods in the group continue. This condition may cause excessive power peaking. The second type of misalignment occurs if one rod fails to insert upon a

BASES

APPLICABLE SAFETY ANALYSES (continued)

reactor trip and remains stuck fully withdrawn. This condition requires an evaluation to determine that sufficient reactivity worth is held in the control rods to meet the SDM requirement with the maximum worth rod stuck fully withdrawn.

Two types of analysis are performed in regard to static rod misalignment (Ref. 3). With control banks at or above their insertion limits, one type of analysis considers the case when any one rod is completely inserted into the core. The second type of analysis considers the case of a completely withdrawn single rod from a bank inserted to its insertion limit. Satisfying limits on departure from nucleate boiling ratio in both of these cases bounds the situation when a rod is misaligned from its group by 12 steps.

Another type of misalignment occurs if one RCCA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition is assumed in the evaluation to determine that the required SDM is met with the maximum worth RCCA also fully withdrawn (Ref. 3).

The Required Actions in this LCO assure that either deviations from the alignment limits will be corrected or that THERMAL POWER will be adjusted so that excessive local linear heat rates (LHRs) will not occur, and that the requirements on SDM and ejected rod worth are preserved.

Continued operation of the reactor with a misaligned control rod is allowed if the OPDMS indicates margin to limits or, if the OPDMS is inoperable, the heat flux hot channel factor ($F_Q(Z)$) and the nuclear enthalpy hot channel factor ($F^N_{\Delta H}$) are verified to be within their limits in the COLR and the safety analysis is verified to remain valid. When a control rod is misaligned, the assumptions that are used to determine the rod insertion limits, AFD limits, and quadrant power tilt limits are not preserved. Therefore, the limits may not preserve the design peaking factors, and $F_Q(Z)$ and $F^N_{\Delta H}$ must be verified directly by incore mapping. Bases Section 3.2 (Power Distribution Limits) contains more complete discussions of the relation of $F_Q(Z)$ and $F^N_{\Delta H}$ to the operating limits.

Shutdown and control rod OPERABILITY and alignment are directly related to power distributions and SDM, which are initial conditions assumed in safety analyses. Therefore they satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The limits on shutdown or control rod alignments assure that the assumptions in the safety analysis will remain valid. The requirements on control rod OPERABILITY assure that upon reactor trip, the assumed reactivity will be available and will be inserted. The control rod OPERABILITY requirements (i.e., trippability) are separate from the alignment requirements, which ensure that the RCCAs and banks maintain the correct power distribution and rod alignment. The rod OPERABILITY requirement is satisfied provided the rod will fully insert in the required rod drop time assumed in the safety analysis. Rod control malfunctions that result in the inability to move a rod (e.g., rod lift coil failures), but that do not impact trippability, do not result in rod inoperability.

The requirement to maintain the rod alignment to within plus or minus 12 steps is conservative. The minimum misalignment assumed in safety analysis is 24 steps (15 inches), and in some cases a total misalignment from fully withdrawn to fully inserted is assumed.

Failure to meet the requirements of this LCO may produce unacceptable power peaking factors and linear heating rates (LHR), or unacceptable SDMs, which may constitute initial conditions inconsistent with the safety analysis.

The LCO is modified by a Note to relax the rod alignment limit on GRCAs during GRCA bank sequence exchange operations. This operation which occurs frequently throughout the fuel cycle would normally violate the LCO.

APPLICABILITY

The requirements on RCCA OPERABILITY and alignment are applicable in MODES 1 and 2 because these are the only MODES in which neutron (or fission) power is generated, and the OPERABILITY (i.e., trippability) and alignment of rods have the potential to affect the safety of the plant. In MODES 3, 4, 5, and 6, the alignment limits do not apply because the control rods are bottomed and the reactor is shut down and not producing fission power. In the shutdown MODES, the OPERABILITY of the shutdown and control rods has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the RCS. See LCO 3.1.1, “SHUTDOWN MARGIN (SDM),” for SDM in MODES 3, 4, and 5 and LCO 3.9.1, “Boron Concentration,” for boron concentration requirements during refueling.

BASES

ACTIONS

A.1.1 and A.1.2

In this situation, SDM verification must include the worth of the untrippable rod as well as a rod of maximum worth.

When one or more rods are inoperable (i.e., untrippable), there is a possibility that the required SDM may be adversely affected. Under these conditions, it is important to determine the SDM, and if it is less than the required value, initiate boration until the required SDM is recovered. The Completion Time of 1 hour is adequate to determine SDM and, if necessary, to initiate boration to restore SDM.

A.2

If the inoperable rod(s) cannot be restored to OPERABLE status, the plant must be brought to a MODE or condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner without challenging plant systems.

B.1

When a rod becomes misaligned, it can usually be moved and is still trippable. With the OPDMS OPERABLE adverse peaking factors resulting from the misalignment can be detected. If the rod can be realigned within the Completion Time of 8 hours adverse burnup shadowing in the location of the misaligned rod can be avoided. With the OPDMS inoperable xenon redistribution can potentially cause adverse peaking factors which may not be detected. However, if the rod can be realigned within the Completion Time of 1 hour, local xenon redistribution during this short interval will not be significant and operation may proceed without further restriction.

An alternative to realigning a single misaligned RCCA to the group average position is to align the remainder of the group to the position of the misaligned RCCA. However, this must be done without violating the bank sequence, overlap, and insertion limits specified in LCO 3.1.5, “Shutdown Bank Insertion Limits,” and LCO 3.1.6, “Control Bank Insertion Limits.” The Completion Time of 1 hour gives the operator sufficient time to adjust the rod positions in an orderly manner.

BASES

ACTIONS (continued)

B.2.1.1 and B.2.1.2

With a misaligned rod, SDM must be verified within limit or boration must be initiated to restore SDM within limit.

In many cases, realigning the remainder of the group to the misaligned rod may not be desirable. For example, realigning control bank M2 to a rod that is misaligned 15 steps from the top of the core could require insertion of the M1 bank to maintain overlap limits.

Power operation may continue with one RCCA trippable but misaligned, provided that SDM is verified within 1 hour. The Completion Time of 1 hour represents the time necessary to determine the actual unit SDM and, if necessary, aligning and starting the necessary systems and components to initiate boration.

B.2.2, B.2.3, B.2.4, B.2.5, and B.2.6

For continued operation with a misaligned rod, RTP must be reduced, SDM must periodically be verified within limits, hot channel factors ($F_Q(Z)$ and $F^N_{\Delta H}$) must be verified within limits, and the safety analyses must be re-evaluated to confirm continued operation is permissible. A note has been added indicating that Required Actions B.2.4 and B.2.5, F_Q and $F_{\Delta H}$ verification, are only required when the OPDMS is inoperable and therefore unavailable to continuously monitor the core power distribution.

Reduction of power to 75% of RTP ensures that local LHR increases due to a misaligned RCCA will not cause the core design criteria to be exceeded (Ref. 3). The Completion Time of 2 hours gives the operator sufficient time to accomplish an orderly power reduction without challenging the Protection and Safety Monitoring System.

When a rod is known to be misaligned, there is a potential to impact the SDM. Since the core conditions can change with time, periodic verification of SDM is required. A Frequency of 12 hours is sufficient to ensure this requirement continues to be met.

Online monitoring of core power distribution by the OPDMS, or verifying that $F_Q(Z)$ and $F^N_{\Delta H}$ are within the required limits when the OPDMS is inoperable, ensures that current operation at 75% of RTP with a rod misaligned is not resulting in power distributions which may invalidate safety analysis assumptions at full power. The Completion Time of

BASES

ACTIONS (continued)

72 hours allows sufficient time to restore OPDMS operable or to obtain and analyze offline flux maps of the core power distribution using the incore detector system and to calculate $F_Q(Z)$ and $F^N_{\Delta H}$.

Once current conditions have been verified acceptable, time is available to perform evaluations of accident analysis to determine that core limits will not be exceeded during a Design Basis Accident (DBA) for the duration of operation under these conditions. The accident analyses presented in Chapter 15 (Ref. 3) that may be adversely affected will be evaluated to ensure that the analysis results remain valid for the duration under these conditions. A Completion Time of 5 days is sufficient time to obtain the required input data and to perform the analysis.

C.1

When Required Actions cannot be completed within their Completion Times, the unit must be brought to a MODE or Condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours, which obviates concerns about the development of undesirable xenon or power distributions. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power condition in an orderly manner and without challenging the plant systems.

D.1.1 and D.1.2

More than one control rod becoming misaligned from its group average position is not expected, and has the potential to reduce SDM. Therefore, SDM must be evaluated. One hour allows the operator adequate time to determine SDM.

Restoration of the required SDM, if necessary, requires increasing the RCS boron concentration to provide negative reactivity, as described in the bases of LCO 3.1.1. The required Completion Time of 1 hour for initiating boration is reasonable based on the time required for potential xenon redistribution, the low probability of an accident occurring, and the steps required to complete the action. This allows the operator sufficient time to align the required valves and start the CVS makeup pumps. Boration will continue until the required SDM is restored.

BASES

ACTIONS (continued)

D.2

If more than one rod is found to be misaligned or becomes misaligned because of bank movement, the unit conditions fall outside of the accident analysis assumptions. Since automatic bank sequencing would continue to cause misalignment, the rods must be brought to within the alignment limits within 6 hours or the unit must be brought to a MODE or Condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.4.1

Verification that individual rod positions are within alignment limits at a Frequency of 12 hours provides a history that allows the operator to detect that a rod is beginning to deviate from its expected position. The specified Frequency takes into account other rod position information that is continuously available to the operator in the main control room so that during actual rod motion, deviations can immediately be detected.

SR 3.1.4.2

Verifying each control rod is OPERABLE would require that each rod be tripped. However, in MODES 1 and 2, tripping each control rod would result in radial or axial power tilts, or oscillations. Exercising each individual control rod every 92 days provides increased confidence that all rods continue to be OPERABLE without exceeding the alignment limit, even if they are not regularly tripped. Moving each control rod by 10 steps will not cause radial or axial power tilts, or oscillations, to occur. The 92 day Frequency takes into consideration other information available to the operator in the control room and SR 3.1.4.1, which is performed more frequently and adds to the determination of OPERABILITY of the rods. Between required performances of SR 3.1.4.2 (determination of control rod OPERABILITY by movement), if a control rod(s) is discovered to be immovable, but remains trippable and aligned, the control rod(s) is considered to be OPERABLE. At any time, if a control rod(s) is immovable, a determination of the trippability (OPERABILITY) of the control rod(s) must be made, and appropriate action taken. GRCA are excluded from this Surveillance because they are not considered in the calculation of SDM in MODES 1 and 2.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.1.4.3

Verification of rod drop times allows the operator to determine that the maximum rod drop time permitted is consistent with the assumed rod drop time used in the safety analysis. Measuring rod drop times prior to reactor criticality, after each reactor vessel head removal and each earthquake requiring plant shutdown, ensures that the reactor internals and rod drive mechanism will not interfere with rod motion or rod drop time, and that no degradation in these systems has occurred that would adversely affect control rod motion or drop time. This testing is performed with all RCPs operating and the average moderator temperature ≥ 500°F to simulate a reactor trip under conservative conditions. GRCA are excluded from this Surveillance because they are not considered in the calculation of SDM in MODES 1 and 2.

This Surveillance is performed during a plant outage due to the plant conditions needed to perform the SR and the potential for an unplanned plant transient if the Surveillance were performed with the reactor at power.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.5 Shutdown Bank Insertion Limits

BASES

BACKGROUND

The insertion limits of the shutdown and control rods are initial assumptions in the safety analyses which assume rod insertion upon reactor trip. The insertion limits directly affect core power and fuel burnup distributions and assumptions of available ejected rod worth SDM and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, “Reactor Design,” GDC 26, “Reactivity Control System Redundancy and Protection,” GDC 28, “Reactivity Limits” (Ref. 1), and 10 CFR 50.46, “Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors” (Ref. 2). Limits on control rod insertion have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

The rod cluster control assemblies (RCCAs) are divided among control banks and shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A group consists of two or more RCCAs that are electrically paralleled to step simultaneously. A bank of RCCAs consists of two groups that are moved in a staggered fashion, but always within one step of each other. The AP1000 design has seven control banks and four shutdown banks. See LCO 3.1.4, “Rod Group Alignment Limits,” for control and shutdown rod OPERABILITY and alignment requirements, and LCO 3.1.7, “Rod Position Indication,” for position indication requirements.

The control banks are used for precise reactivity control of the reactor. The positions of the control banks are normally automatically controlled by the Plant Control System (PLS), but they can also be manually controlled. They are capable of adding negative reactivity very quickly (compared to borating). The control banks must be maintained above designed insertion limits and are typically near the fully withdrawn position during normal full power operations. Hence, they are not capable of adding a large amount of positive reactivity. Boration or dilution of the Reactor Coolant System (RCS) compensates for the reactivity changes associated with large changes in RCS temperature. The design calculations are performed with the assumption that the shutdown banks are withdrawn first. The shutdown banks can be fully withdrawn without the core going critical. This provides available negative reactivity in the event of boration errors. The shutdown banks

BASES

BACKGROUND (continued)

are controlled manually by the control room operator. During normal unit operation, the shutdown banks are either fully withdrawn or fully inserted. The shutdown banks must be completely withdrawn from the core, prior to withdrawing any control banks during an approach to criticality. The shutdown banks are then left in this position until the reactor is shut down. They affect core power and burnup distribution, and add negative reactivity to shut down the reactor upon receipt of a reactor trip signal.

APPLICABLE SAFETY ANALYSES
