Because of the possible radioactive contamination of the NCWS through heat exchanger tubes connected to the reactor coolant or radwaste systems, the design pressure of the PCWS is higher than the design pressures for the NCWS. This ensures against contamination of the PCWS and the outside environment. Additionally, safety relief valves are provided to protect the containment isolation valves from overpressurization in the

event of a reactor coolant pump high pressure seal cooler tube rupture. The NCWS is required to function during normal power generation and during a normal reactor shutdown. The maximum water temperature at the outlets of the NCWS using a wet bulb temperature of 78F (0.1% summer high) during normal power generation does not exceed 105F.

Coolant flow of approximately 17,500 gallons per minute is maintained in the closed loop during normal power generation operation.

9.2.2.2.5 Component Description

Major components of the NCWS are shown in table 9.2-9 and are discussed in the following sections.

9.2.2.2.5.1 NCWS Heat Exchangers. Each of the redundant NCWS heat exchangers has a 100% load carrying capacity. The heat exchangers are of the counter flow horizontal shell and straight tube type.

Each heat exchanger is rated at 110.7 x 10^6 Btu/h, the shell side flow is 17,500 gallons per minute, and the tube side flow is 14,500 gallons per minute.

9.2.2.2.5.2 NCWS Pumps. Each of the redundant NCWS pumps has a 100% load carrying capacity. Only one pump is used and the other pump is on standby. The NCWS pumps are of the horizontal, centrifugal, single-stage, double-suction type. Each pump is rated at 17,500 gallons per minute, 180-foot design head.

Table 9.2-9

EQUIPMENT LIST NUCLEAR COOLING WATER SYSTEM

Component Description	Quantity	Type	Design Head (ft)	Design Flow (gal/min)	Motor (hp)	Design Pressure (psig)	Water Capacity (gal)	Material	Service Side
NCWS pump	2	Centrifugal	180	17,500	1000	--	--	--	--
Surge tank	1	--	--	--	--	15	1000	Carbon steel	--
Chemical addition tank	1	--	--	--	--	200	11	Carbon steel	--
NCWS heat exchanger	2	Shell and tube	--	--	--	--	--	--	Plant cooling water system

9.2.2.2.5.3 NCWS Surge Tank. A surge tank is provided in the train to automatically accommodate the closed loop water expansion and contraction due to thermal changes in the system. Level controls in the tank control a demineralized water makeup control valve to maintain the water level required in the NCWS.

The surge tank is installed on the suction side of the NCWS pump to ensure flooded suctions and NPSH requirement.

9.2.2.2.5.4 Nuclear Nonsafety-Related Equipment Heat Exchangers. Table 9.2-8 lists the nuclear nonsafety-related equipment, associated heat loads, and their water requirements. Description of these items are included in the applicable sections as noted on the table.

9.2.2.2.5.5 Piping, Valves, and Fittings. Piping to and from the NCWS heat exchangers is of carbon steel. Piping, valves, and fittings are supplied in accordance with table 3.2-1. Seismic Category I valves, which are a part of the NCWS, are listed in table 9.2-10.

a. An "A" indicates an active valve, an "N" a nonactive valve, as discussed in section 3.9.

9.2.2.2.6 System Operation

The NCWS, in conjunction with the PCWS, operates during all modes of normal power generation. Only one of the two NCWS pumps and only one of the two NCWS heat exchangers are in normal operation and the redundant pump and heat exchanger are on standby. The operator preselects the pump and heat exchangers for operation. In the event of an operating pump malfunction, the standby pump is placed in service by automatic actuation. In the event of an operating heat exchanger malfunction or a requirement for maintenance of a heat exchanger, the operator manually places the standby heat exchanger into service by operating the valves involved.

During Refueling Outages, the heat sink to the NCWS is provided by a temporary cooling water system installed on the Plant Cooling Water side of one NCWS heat exchanger. This temporary cooling water system is described in UFSAR section 9.2.10.2.3.

9.2.2.2.7 Tests and Inspections

Tests and inspections are divided into preoperational and operational phases. These are described in the following paragraphs.

9.2.2.2.7.1 Preoperational Testing. Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

9.2.2.2.7.2 Operational Tests and Inspections. Instrumentation provided for the NCWS permits continuous surveillance of the proper operation of each component in the

system, as well as a check on system performance. Adjustments are made in the operating conditions as required during operation. No tests are required during operation because of this inspection and adjustment availability.

9.2.2.2.8 Instrumentation Applications

The NCWS instrumentation facilitates automatic operation, remote control, and indication of system parameters locally and in the control room. Controls and instrumentation necessary for operation of the NCWS pumps are located in the control room. Local instrumentation and controls also are provided at the NCWS pumps and at various heat exchangers for maintenance, testing, and performance evaluation.

Instrumentation, including audible alarms and visual status indicators, are provided to indicate loss of cooling water flow to the reactor coolant pumps. This instrumentation for audible alarms are of high quality and meet the single failure criterion.

9.2.2.2.9 Safety Evaluations

Failure of a reactor coolant pump high pressure seal cooler tube may result in overpressurization and failure of the NCWS surge tank located on the auxiliary building roof. In such an event, the plant operator has sufficient event indication and time to remote manually close the NCWS containment isolation valves from the control room. Redundant safety-relief valves are provided on the NCWS piping inside containment to protect and prevent overpressurization of the NCWS containment isolation valves following their closure in such an event. NCWS containment

isolation valve closure and resultant safety relief valve actuation and discharge to the containment atmosphere result in the event scenario being bounded by the LOCA scenarios discussed in section 6.3. The dose consequences resulting from this event are bounded by the letdown line break scenario discussed in section 15.6.2. The redundant safety relief valves satisfy the single failure criteria.

9.2.3 DEMINERALIZED WATER SYSTEM

The demineralized water system (DWS) processes product water from the reverse osmosis units of the domestic water system (DS) to remove dissolved gas and solids, stores the demineralized water, and transfers it to each PVNGS unit and to common facilities in the chemical production system (CPS).

9.2.3.1 Design Bases

9.2.3.1.1 Safety Design Bases

Except where needed to provide containment isolation via containment penetrations, the DWS serves no safety function and has no safety design bases.

9.2.3.1.2 Power Generation Design Bases

A. Simultaneously supply the normal operational demands for makeup demineralized water at each PVNGS unit, for its own regeneration, and for the CPS. The design capacity of the DWS is 600 gallons per minute.

B. Provide 125,000 gallons of storage capacity in a surge-rinse tank within each DWS common facility and 125,000 gallons of storage capacity at each PVNGS unit.

C. Provide makeup demineralized water for the following systems:

- Condensate system
- Reactor makeup water system
- Nuclear cooling water system
- Essential cooling water system
- Radwaste system
- Essential chilled water system
- Chilled water system
- Stator cooling system
- Turbine cooling water system
- Diesel generator cooling water system
- Miscellaneous services

D. The design and subsequent upgrades of the demineralized water system is such that demineralized water of the following specifications can be produced:

Total dissolved solids, ppm	0.1 max
Dissolved oxygen, ppm	0.1 max
Chloride, as Cl, ppb	<0.50 max
Fluoride, as F, ppm	<0.01 max
Total silica, as $Si0_2$, ppm	<0.005 max
Sodium, as Na, ppb	<0.10 max
Conductivity, µmhos/cm	0.08 max
pH	6.0 to 8.0

Gaseous	Nondeaerated/ deaerated

Except where needed to provide containment isolation via containment penetrations, the DWS is designed to nonnuclear safety codes and standards as defined in table 3.2-1.

9.2.3.2 System Description

The DWS, as shown in engineering drawings AO-M-DWP-001 and 01, 02, 03-M-DWP-002, consists of a degasifier subsystem, a demineralizer subsystem, a regeneration subsystem, a demineralized water storage and transfer subsystem, and a sulfuric acid storage and transfer subsystem. Waste water from DWS operations is directed to a spent regenerant sump, is treated in accordance with Water Reclamation Facility operating procedures, and is pumped to the Water Reclamation Facility clarifier feed sump or the trickling filter sump emergency overflow. During Water Reclamation Facility (WRF) outages or emergencies, this wastewater can bypass the WRF clarifier feed sump or the trickling filter sump emergency overflow and be fed directly into the wet dry sump which feeds the 45 acre/or 85 acre reservoirs.

9.2.3.2.1 Component Description

9.2.3.2.1.1 Degasifier Subsystem. The degasifier subsystem includes the following components:

A. Vacuum Degasifier

The vacuum degasifier consists of a three-stage packed tower over a 6000-gallon catch tank. The tower and

tank are designed for full vacuum and 75 psig pressure. An ejector on each stage of the tower maintains the desired operating vacuum. Reverse osmosis product water enters the top of the tower and is progressively degasified to a carbon dioxide content of 5 ppm or less and an oxygen content of 0.1 ppm or less. The tower is designed to process up to 600 gallons per minute of water.

B. Vacuum Pumps

Two rotary ring vacuum pumps, one redundant, pull vacuum on the stage ejectors. The vacuum pumps are water sealed. Seal water is provided from a package cooling tower subsystem in the CPS, is discharged to an air-water separator, and is returned to the cooling tower by seal water pumps.

C. Air-Water Separator

The air-water separator receives seal water discharge from the vacuum pumps and vents the gases to atmosphere.

D. Seal Water Pumps

Two seal water pumps (one redundant) take suction from the air-water separator and return the seal water to the CPS cooling tower.

9.2.3.2.1.2 Demineralizer Subsystem. The demineralizer subsystem includes the following components:

A. Demineralizer Feed Pumps

Three centrifugal pumps take suction from the degasifier catch tank and deliver water to the mixed bed demineralizers.

B. Mixed-Bed Demineralizers

Three mixed-bed demineralizers operate two-in-series, with one bed in regeneration or standby. Each vessel contains mixed strong acid cation and strong base anion resins. The beds are designed to process a minimum of 864,000 gallons in the primary working bed position. The beds will process 200 gallons per minute up to 600 gallons per minute (maximum) forward flow.

9.2.3.2.1.3 Regeneration Subsystem. The regeneration subsystem includes the following components:

A. Regenerant Day Tank

A day tank for acid is provided which holds sufficient chemical for one regeneration. The acid day tank holds 66°Be' sulfuric acid.

B. Regenerant Feed Pumps

Two metering pumps (one redundant) are provided for acid. The chemical is metered automatically and is diluted at a mixing tee with demineralized water. Caustic is metered directly to a mixing tee with a control valve.

C. Hot Water Storage Tanks

Two storage tanks provide hot water for bed warmup and anion resin regeneration. The tanks are equipped with two electric immersion heaters per tank.

D. Surge-Rinse Tank

The surge-rinse tank is a 125,000-gallon capacity, diaphragm-sealed, stainless steel tank that provides temporary storage for regeneration rinse water and to prevent the reverse osmosis system supplying makeup to the demineralizer from cycling excessively.

E. Rinse Water Booster Pumps

Two centrifugal pumps (one redundant) supply regenerant dilution water and rinse water for bed regeneration.

The regeneration subsystem has an automatic, computerized control system for the regeneration steps, with manual override to stop, start, or repeat steps as desired by the operator to assure adequate resin regeneration and rinsing.

9.2.3.2.1.4 Demineralized Water Storage and Transfer Subsystem. The storage and transfer subsystem includes the following components:

A. Demineralized Water Booster Pumps

Three centrifugal pumps supply demineralized water to the storage tank at each PVNGS unit.

B. Demineralized Water Storage Tank

Each PVNGS unit has a 125,000-gallon capacity, nitrogen blanketed, stainless steel storage tank for makeup demineralized water.

C. Demineralized Water Transfer Pumps

Each PVNGS unit has two centrifugal pumps (one redundant) to supply makeup demineralized water on demand of the using systems.

9.2.3.2.1.5 Sulfuric Acid Storage and Transfer Subsystems. The acid storage and transfer subsystem includes the following components:

A. Sulfuric Acid Storage Tanks

Two tanks provide acid storage for the DWS and the DS. The tanks receive acid from trucks through an unloading boom. The acid is transferred to the tanks by instrument air pressurization of the tank truck.

B. Sulfuric Acid Transfer Pumps

Two pumps (one redundant) supply acid from the storage tanks to day tanks in the DWS and DS. These pumps also supply acid to the spent regenerant sump as required for neutralization of the waste water.

9.2.3.2.1.6 Pipe Materials. Piping materials in the DWS include the following:

A. Demineralized Water

The degasifier, demineralizer, and regeneration subsystems have polypropylene-lined carbon steel piping. The surge-rinse tank and the storage and transfer system have 304 stainless steel piping. PVNGS unit piping carrying makeup demineralized water is 304 stainless steel.

B. Dilute Caustic

Dilute caustic supply piping is chlorinated polyvinyl chloride (CPVC) underground and polypropylene-lined carbon steel aboveground.

C. Sulfuric Acid

The diluted regenerant acid piping is polypropylene-lined carbon steel.

9.2.3.2.1.7 Spent Regenerant Sump. The spent regenerant sump is an outdoor, underground concrete structure which collects water treatment area drains, including the DWS regenerant waste. The sump has a normal usable capacity of 60,588 gallons of waste water. Two vertical, wet pit centrifugal pumps (one redundant) are located in the sump. The sump is equipped with level controls, automatic outflow control valves, and a pH indicator-controller. Acid and caustic are supplied to the spent regenerant sump for neutralization of the waste water.

9.2.3.2.2 System Operation

9.2.3.2.2.1 Degasifier Subsystem. Water is supplied to the vacuum degasifier at 200 to 600 gallons per minute from the DS reverse osmosis units. The flow is controlled by operator diverting of reverse osmosis unit(s) and setting the reverse osmosis unit(s) product flow controllers. The tank volume provides a surge time of 10 to 15 minutes.

Vacuum is maintained continuously in the three-stage tower by one of the vacuum pumps. Vacuum seal water flows through the operating pump at 20 gallons per minute to the air-water separator, and is returned to the CPS package cooling tower for recirculation.

9.2.3.2.2.2 Demineralizer Subsystem. The demineralizer feed pumps take suction from the degasifier catch tank and provide flow through two mixed beds in series to the surge rinse tank or the suction of the demineralized water booster pumps, if in manual operation. The feed pumps are controlled manually based on demineralized water usage rates and reverse osmosis influent rate to the DW system.

Two demineralizer beds are rotated through positions of regeneration, standby, and working bed. The third demineralizer bed is used as a dedicated polisher. The working bed and polishing bed are connected in series flow between the feed pumps and the surge-rinse tank. Water is continuously recirculated through the operating beds and vacuum degasifier during standby.

Conductivity, silica, sodium and oxygen analyzer-controllers monitor water quality entering the system effluent header. High conductivity, silica, sodium or oxygen causes water to recycle back through the degasifier. The quality analyzers trip alarms to alert operators of the bed breakthrough or of an off-specification water quality condition. Flow totalizers on each bed are used to track throughout and determine when to preservice rinse the standby bed, and take the primary bed out of service for regeneration.

9.2.3.2.2.3 Regeneration Subsystem. When the working bed has reached "end of run" condition and has been removed from service, it is ready for regeneration. The operator manually initiates the regeneration process. Steps in the regeneration are automatically controlled thereafter, with stop, start, or repeat of steps optional to the operator.

The bed is backwashed to clean and separate the resin in-place, with the anion resin above the cation resin. The anion bed is prewarmed with 120F water, then simultaneously injected with dilute acid (upflow through cation bed) and dilute, 120F caustic (downflow through anion bed). The spent regenerant intermixes at the resin interface and flows to the spent regenerant sump. The regenerants are displaced from the bed by slow rinse, followed by a fast rinse step. The bed water level is reduced by blowing down, then air is introduced to remix the resins. The bed is refilled with rinse water, expelling the air, and is given a final rinse to expel air-containing rinse water. The bed is then placed on standby.

9.2.3.2.2.4 Demineralized Water Storage and Transfer Subsystem. The degasified and demineralized water is supplied from the common surge-rinse tank to unit storage tanks at each PVNGS unit. One of the three common booster pumps, taking suction from the surge-rinse tank, or mixed bed demineralizers (in manual operation only). Is operated continuously to pressurize the common pipeline to the PVNGS units. The second and third booster pumps operate as required by demand.

At each PVNGS unit, the makeup storage tank is automatically filled through a fill valve controlled by a liquid level controller on the tank. One of two transfer pumps, taking suction from the makeup tank, is operated continuously to pressurize the PVNGS unit makeup demineralized water piping. The second transfer pump operates as required by demand. PVNGS unit demands are normally met by the two transfer pumps. Check valves in the demineralized water supply headers are provided to preclude (1) siphoning from the decontamination sump in event of a loss of offsite power, or (2) cross-contamination from temporary connections with decontamination facility (Unit 1), radwaste building decontamination stations, RV head decontamination stations, and fuel cask decontamination washdown station. In addition, the condensate storage tank can be manually filled directly from the common pipeline by opening two (normally closed) isolation valves.

9.2.3.2.2.5 Sulfuric Acid Storage and Transfer Subsystem. Commercial grade 66°Be' sulfuric acid is supplied from one of two DWS storage tanks to the day tank in the DWS system. One of two transfer pumps, taking suction from the storage tanks,

is manually started by the operator on indication of low acid level in the day tank. The day tank fill is automatically stopped by closing of a fill valve controlled by a high level switch on the day tank. The transfer pump is also automatically stopped at the same time.

9.2.3.2.2.6 Waste Water. The spent regenerant sump receives waste water from the demineralizer regeneration process, the chemical production area wastes, the fire pump house oily waste sump, the water treatment building sump, and various filter backwashes.

This waste water is treated in accordance with Water Reclamation Facility operating procedures and then pumped to the Water Reclamation Facility clarifier feed sump or the trickling filter sump emergency overflow. During Water Reclamation Facility (WRF) outages or emergencies, this wastewater can bypass the WRF clarifier feed sump or the trickling filter sump emergency overflow and be fed directly into the wet dry sump which feeds the 45 acre/or 85 acre reservoirs.

9.2.3.3 Safety Evaluation

The DWS has no safety function except where needed to provide containment isolation via the containment penetrations. The malfunction or failure of a component has no adverse effect on any safety-related system or component.

9.2.3.4 Tests and Inspections

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning. The system continues to be proved functional through normal plant operations.

The regular sampling of demineralized water tank contents ensures that the limits for radioactive concentrations are not exceeded.

9.2.3.5 Instrumentation Applications

Local instrumentation, controls, and alarms are provided for monitoring and partial automatic control of the system process and for protection of system components. Pressure, level, flow, temperature, conductivity, silica, sodium, oxygen, and pH monitors, recorders, and alarms are provided for each applicable point in the various subsystems.

The system production rate is automatically paced to demand of the PVNGS units by feedback of supply line header pressure to transfer pumps and surge tank levels to processing equipment.

Pumps are protected by low level switches on the suction side and minimum flow piping or pressure relief valves on discharge lines. Effluent water quality and quantity is monitored and recorded with off-specification water returned for reprocessing and the condition alarmed. The regeneration process is automatically controlled, after manual initiation, and is fully monitored by pressure, flow, conductivity, and temperature alarms. High and low level alarms are installed on the regenerant day tank, on demineralized water surge and storage tanks and on the spent regenerant sump.

Individual alarms are annunciated on a local demineralizer control panel for shared portions of the system. A common trouble alarm is provided in the water reclamation plant control room. Alarms for the PVNGS unit storage and transfer subsystem are annunciated in the unit control room.

9.2.4 DOMESTIC WATER SYSTEM

The DS processes local onsite well water to remove suspended solids and part of the dissolved solids, chlorinates and neutralizes the processed water, stores and transfers the domestic water to each PVNGS unit and to common facilities in the plant.

9.2.4.1 Design Bases

9.2.4.1.1 Safety Design Bases

The DS serves no safety function and has no safety design bases.

9.2.4.1.2 Power Generation Design Bases

A. Prevent contamination due to potential radioactivity or due to backflow from cross-connected systems using water unfit for human consumption.

B. Provide a quantity of 50 gallons per person per day for the largest number of persons expected to be at the station during a 24-hour period of plant refueling and maintenance operations.

C. Provide potable water storage to provide surge control for the DS system and allow maintenance on the well water treatment subsystem without disrupting distribution.

D. Supply water for plant uses except makeup to the circulating water systems.

E. Provide potable water quality conforming to the requirements of the regulations of the Arizona Department of Environmental Quality and the U.S. Environmental Protection Agency.

The DS is designed to nonnuclear safety codes and standards as defined in table 3.2-1. In addition, the DS outlets are provided in compliance with the intent of Title 29, Chapter XVII, Part 1910, Occupational Safety and Health Standards of the Code of Federal Regulations. Backflow preventers are provided in conformance with state regulations.

9.2.4.2 System Description

The DS, as shown in engineering drawings AO-M-DSP-001 and 01, 02, 03-M-DSP-002, consists of a well water supply subsystem, a water treatment subsystem, and a storage and transfer subsystem which are shared facilities. Each PVNGS unit has a hot and cold water distribution system. Domestic water is also distributed to facilities in the water reclamation plant and the water treatment area. Waste water from operation of the treatment subsystem is directed to the water reclamation plant for recovery. During Water reclamation Facility (WRF) outages or emergencies, this wastewater can bypass the WRF clarifier feed sump or the trickling filter sump emergency overflow and be fed directly into the wet dry sump which feeds the 45 acre/or 85 acre reservoirs.

Major component equipment data for the DS is provided in table 9.2-13.

The DS system provides hot water to the main toilet and shower areas and other locations where needed. The storage capacity for water heaters used is based on providing an adequate supply of hot water for the anticipated maximum drawdown, which occurs during the plant personnel shift change during maintenance and refueling operations. Use of only 75% of the stored capacity of each unit is assumed, due to the addition of cold makeup during this drawdown. The recovery sections are capable of reheating the total design water storage capacity to design temperature within 6 hours.

9.2.4.2.1 Component Description

9.2.4.2.1.1 Well Water Supply Subsystem. The well water supply subsystem consists of the following components:

A. Deep Well Pumps

Two onsite deep wells are equipped with five-stage vertical turbine pumps. The wells are equipped with sanitary collars and air vent valves.

B. Well Water Transfer and Storage

The well pumps transfer water to two 500,000-gallon fire water storage tanks and to two 27,000-gallon well water storage tanks. The two well water storage tanks provide water to the domestic water system. The well pumps are connected by a common pipeline to the tanks. Branch piping from each well contains a double check backflow

preventer to stop cross-flow between the wells or backflow from the tanks and pipeline.

C. Well Water Booster Pumps

Three horizontal centrifugal pumps (one redundant) provide flow from well water storage to the treatment subsystem.

Table 9.2-13

DOMESTIC WATER SYSTEM EQUIPMENT DATA (Sheet 1 of 2)

Tanks Description	Number Required	Design Pressure (psig)	Size (gals)	Material
Well water storate tanks	2	atm	27,000	Fiberglass reinforced plastic
Domestic water storage tanks	2	atm	120,000	Carbon steel
Domestic water hypochlorite tank	1	atm	30	Fiberglass reinforced plastic
Sulfuric acid day tank	1	atm	65	Carbon steel
Flush tank	1	atm	500	Fiberglass reinforced plastic

Pumps Description	Number Required	Design Flow (gal/min)	Design Head (ft)	HP	Type
Well water booster pumps	3	750	255	75	Horizontal, centrifugal
Domestic water transfer pumps	3	500	290	60	Horizontal, centrifugal

Table 9.2-13

DOMESTIC WATER SYSTEM EQUIPMENT DATA (Sheet 2 of 2)

Pumps Description	Number Required	Design Flow (gal/min)	Design Head (ft)	HP	Type
Domestic water hypochlorite metering pumps	2	0.037	57	0.25	Positive displacement, proportioning
Deep well pumps	2	1400	412	200	Vertical turbine
Sulfuric acid injection pumps	2	0.092	150	0.25	Positive displacement, proportioning
Reverse osmosis feed pumps	5	250	1,608	200	Horizontal centrifugal

Neutralizing Filters Description	Number Required	Design Flow (gal/min)	Design Pressure (psig)	Material
Domestic water	3	200	75	Carbon steel, epoxy lined shell; neutralite fill

9.2.4.2.1.2 Water Treatment Subsystem. The water treatment subsystem consists of the following components:

A. Prefilters

Two cartridge type pressure filters (one redundant) provide suspended solids removal from the well water. Sand filtration will also be provided.

B. Sulfuric Acid Day Tank

The acid day tank has a 65-gallon capacity. 66° Be' sulfuric acid is delivered from storage by pumped-flow pipeline.

C. Sulfuric Acid Injection Pumps

Two diaphragm type metering pumps (one redundant) inject acid for pH control of the well water. The acid is injected into a mixing tee upstream of the safety prefilters.

D. Reverse Osmosis Feed Pumps

Five two-stage horizontal centrifugal pumps (one redundant) provide high-pressure feed to the reverse osmosis (RO) modules. The pumps are manifolded at suction and discharge.

E. Reverse Osmosis Modules

Four RO modules, rated at 250 gallons per minute product output each at a maximum of 80% recovery, process the well water. The modules are skid-mounted and consist of 8-inch pressure tubes manifolded in a 10-into-5 staging array. The pressure tubes contain spiral-wound membrane

elements of cellulose acetate in two stages. Product water from both stages is manifolded into a header and the brine is similarly collected in a brine header. The four skids are manifolded together at inlet, product and brine headers. Each skid has its own controls and instrumentation, with remote readout and control from a common local panel.

F. Flow-Direction Valves

The common product water header has three automatic flow-direction valves, with one valve located between each pair of RO module inlet headers. These valves direct flow to the DWS and the DS.

G. Hypochlorite Day Tank

The hypochlorite day tank has a 30-gallon capacity. Sodium hypochlorite of 8% strength is manufactured onsite and delivered by pumped-flow pipeline.

H. Hypochlorite Injection Pumps

Two diaphragm type metering pumps (one redundant) inject hypochlorite into the RO product water directed to the DS. (Water directed to the DWS is not chlorinated.)

I. Domestic Water Filters

Three pressure filters loaded with pelletized calcium carbonate (neutralite) receive RO product water and neutralize free carbon dioxide or other acidity by reaction with the neutralite. The filters are designed for 200 gallons per minute flow.

J. Flush Tank

A 500-gallon capacity tank is used for mixing and recirculating chemical solutions as required for periodic cleaning and flushing of the RO membrane modules.

K. Mixer

A propeller type mixer is mounted on the flush tank.

L. Flush Pump

One horizontal centrifugal pump is provided to recirculate the cleaning and flushing solutions through the RO membrane modules and back to the flushing tank.

9.2.4.2.1.3 Storage and Transfer Subsystem. The storage and transfer subsystem consists of the following components:

A. Domestic Water Storage Tanks

Two tanks, of 120,000-gallon capacity each, receive water from the filters for storage.

B. Domestic Water Transfer Pumps

Three horizontal centrifugal pumps (one redundant) provide flow from the domestic water tanks to the distribution system.

C. Backflow Preventers

The distribution system includes a common header from the water treatment area to a loop main around the PVNGS units. Branch mains to the PVNGS units are equipped with state regulatory approved backflow preventer assemblies

(BPA) which are installed as close as practical to potential sources of contamination.

9.2.4.2.1.4 Distribution Subsystem. The distribution subsystem consists of the following components:

A. Strainers

Pressure control valves on branch mains leading to all buildings are equipped with permanent Y-strainers and blowoff valves on the upstream side.

B. Hot Water Tanks and Heaters

Hot water tanks equipped with electric immersion heaters, thermal controls, and pressure relief valves are located in each building which requires hot water service. The PVNGS unit buildings are serviced as follows:

- Auxiliary building - one approximately 120-gallon tank plus one 200-gallon tank minimum
- Control building - one 200 to 225-gallon tank
- Service building - two 125-gallon tanks
- Administration building - one 85-gallon tank
- Main guardhouse - one 30-gallon tank
- Outage Support Facility – one 80-gallon tank

9.2.4.2.1.5 Piping Materials. Piping materials used in the DS prevent the introduction of objectionable tastes, odors, discoloration, and toxic substances into the system, and

conform to the plumbing code adopted by the Maricopa County Planning and Developing Department. Copper piping is used in the buildings for hot and cold water distribution. Underground mains and outdoor service piping are constructed of epoxy-lined carbon steel. Replacement piping or system extensions used in underground mains and outdoor service piping after January 1, 1993, will be National Sanitation Foundation (NSF) certified or will be an alternative as provided by Arizona State Laws. Process piping utilizes 316L stainless steel to the suction of the RO feed pumps and 316L stainless steel for high-pressure pipe and RO headers. Low-pressure manifolding for RO product water is done with PVC.

9.2.4.2.2 System Operation

9.2.4.2.2.1 Well Water Supply Subsystem. In normal operation, one of the two deep well pumps automatically fills the fire water/well water reserve tanks and the well water storage tanks in response to tank level control signals. These signals also open and close flow control valves on the common pipeline from the two wells. Both well pumps start on low-low level signals and both pumps continue to operate until the tanks are full.

One of the three booster pumps operates continuously to supply water to the treatment subsystem. The second and third pump operate as required by demand.

9.2.4.2.2.2 Water Treatment Subsystem. The RO feedwater is supplied by the well water booster pumps. One pump supplies

the requirements of two RO modules. A second pump is automatically started when demand requires three or four RO tank of the DWS starts the RO system in the 400-gallon per minute mode to the DWS, a low level signal from the domestic water storage tank starts the RO system in a 400-gallon per minute mode to the DS. Low-low level in either the domestic water tanks or the surge-rinse tank will start the RO in a 600-gallon per minute to the system which requires it. However, internal logic in the RO gives priority to the DWS. Flows can also be manually adjusted.

The RO feedwater is filtered in cartridge filters and acidified with sulfuric acid. High-pressure feed pumps supply the RO modules through a common header.

Reverse osmosis product to the DS system is chlorinated using sodium hypochlorite. The dissolved carbon dioxide in the RO product which results from acid pretreatment of the feedwater reacts with the neutralite in the domestic water filters to produce noncorrosive water with a pH of approximately 7.2. Continuous sampling of the chlorinated water is performed entering and leaving the filters. The controls adjust the hypochlorination rate for approximately 1 ppm of residual chlorine.

The RO system is supplied with a flushing pump and tank for periodic cleaning or flushing of the membranes. One module can be cleaned at any time without affecting operation of the remaining modules. Cleaning is a manual operation.

9.2.4.2.2.3 Storage and Transfer Subsystem. Water from the domestic water filters flows to the domestic water storage tanks.

The domestic water transfer pumps take suction from the storage tanks and deliver water to the distribution subsystem.

9.2.4.2.2.4 Distribution Subsystem. State regulatory approved backflow preventers are installed on each branch line off the domestic water loop, except lines where backflow is not possible, to prevent contamination of the distribution header. Pressure control valves reduce the distribution loop pressure to the points of use where a constant pressure is required.

9.2.4.3 Safety Evaluation

The domestic water system has no safety functions. The malfunction or failure of a component has no adverse effect on any safety-related system or component.

9.2.4.4 Tests and Inspections

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

Periodic testing of the backflow preventers will be performed per the requirements of the state of Arizona. Other system components will be used during normal operation. No inservice inspections are required.

9.2.4.5 Instrument Applications

Local instrumentation, controls, and alarms are provided for monitoring and automatic control of the system process and for protection of system components. Pressure, level, flow and chlorine analysis monitors, recorders, and alarms are provided for each applicable point in the various subsystems.

The RO system production rate is automatically paced by the demands from the DS storage tanks and DW surge-rinse tank. Pumps are protected by minimum flow piping or pressure relief valves on discharge lines. Analyzers measure the chlorine residual. High or low residuals are alarmed and, at the filters, result in shutdown of the RO and hypochlorite pumps. High and low level alarms are installed on the domestic water storage tanks and the hypochlorite day tank.

9.2.5 ULTIMATE HEAT SINK

The ultimate heat sink for each PVNGS unit consists of two independent Seismic Category I essential spray ponds (ESPs) which provide cooling water for the ESPS described in subsection 9.2.1.

Each unit is provided with a separate individual ultimate heat sink. There is no sharing of ultimate heat sinks between units.

The function of the ultimate heat sink is to provide cooling of the ESPS during a normal shutdown or during accident conditions, with no other water source available.

Each pond serves one train of the ESPS. Redundant manually operated seismically qualified butterfly valves are provided to equalize the water level between ponds, if required, and to provide the combined inventory of both ponds to the operating ESPS for a 26 day period following a postulated LOCA.

The ultimate heat sink meets the requirements of Regulatory Guide 1.27.

The ultimate heat sink will be operated in accordance with the Technical Specifications.

9.2.5.1 Design Bases

9.2.5.1.1 Safety Design Bases

Safety design bases pertinent to the ultimate heat sink are as follows:

A. Safety Design Basis One

In the unlikely event of a LOCA, the ESP in conjunction with the ESPS provides sufficient cooling for a period of 26 days without water makeup to cool down the unit and maintain it in a safe condition under the most adverse historical meteorological conditions consistent with the guidelines of Regulatory Guide 1.27 without exceeding the design basis temperature of the ESPS.

B. Safety Design Basis Two

The function of the ESP is not impaired during or after any one of the following events:

1. The most severe natural phenomena including SSE, tornado, flood, or drought taken individually
2. Nonconcurrent site-related events including transportation accidents, oil spills, and fires
3. Credible single failures of man-made structures

C. Safety Design Basis Three

Procedures for assuring continued cooling capability beyond the 26 days specified within Safety Design Basis One are available.

D. Safety Design Basis Four

The ESP in conjunction with the ESPS provides sufficient cooling for the safe shutdown and cooldown of the unit and to maintain it in a safe shutdown condition during a normal reactor shutdown.

9.2.5.1.2 Codes and Standards

Applicable codes and standards for the ultimate heat sink are as follows:

A. The ESP and associated components are Seismic Category I.

B. Codes and standards applicable to the ESP and associated components are listed in section 3.2.

C. The ESP conforms to the requirements of Regulatory Guide 1.27.

9.2.5.2 System Description

The ultimate heat sink consists of two ESPs that are adjacent to each other, and interconnected by two redundant normally closed butterfly valves. The location of the ESP with respect to the site is shown in engineering drawings 13-C-ZVA-005 and 13-P-OOB-001. The process and instrument diagram for the ESPS is shown in engineering drawings 01, 02, 03-M-SPP-001.

A detailed description of the ESPS is provided in subsection 9.2.1.

The water inventory in the ultimate heat sink is sufficient to provide 26 days of cooling capacity, using the combined water

capacity of both ESPs, without water makeup. However, separate makeup water lines are provided to each ESP from the following independent water supply sources:

- Domestic water system
- Station makeup water reservoirs via cooling tower makeup and blowdown system

The ESPs are Seismic Category I and are of concrete, watertight, vertical wall construction. The ESP Structures are made “watertight” by the quality of the concrete construction, the 2-foot minimum concrete thickness of the walls and base mat, and the use of waterstops in construction joints. The likelihood of significant seepage through the ESP concrete structure is small given the quality of the concrete, its thickness, the proven performance of the waterstop material, and the autogenous healing nature of concrete (small cracks fill with calcium carbonate that leeches form concrete exposed to water).

Spray heads over the ESPs are arranged to minimize interference between sprays. The spray heads provided are designed to develop the optimum spray drop spectrum to maximize cooling and to minimize drift losses.

Spray head piping is sized to provide approximately equal flow through each spray nozzle. Discharge from the spray pond system is directed through the spray nozzles during operation of the sprays.

Each ESP is 345 feet by 172 feet with a depth of 15 feet 6 inches. The depth of the pond includes the allowances in

table 9.2-14. The dimensions and arrangement of the ponds are shown in figure 9.2-1.

The essential spray ponds are reinforced concrete structures with vertical walls extending 3.5 feet above backfill. The maximum static water level is 1.1 feet below the top of the vertical walls as shown in figure 9.2-1. The resulting free-board is adequate to assure minimum water inventory is available during seismic or high wind conditions. The ponds are designed as Category I structures in accordance with section 3.8, including static and dynamic lateral earth pressures specified in PVNGS 1, 2, and 3 PSAR, Appendix 2T. Excessive leakage from the ponds is precluded by the thickness of the reinforced concrete walls and base slab, and by waterstops at construction joints.

Table 9.2-14

ESP DEPTH ALLOWANCES

Purpose of Allowance	Depth (ft)
Minimum Water Inventory for evaporation and drift[1]	12.0
Pump NPSH requirement	1.5
Water margin for operating range instrument uncertainty, and wind wave action	2.0
Total depth	15.5

[1]The minimum water inventory allowance contains the volume of water between elevations 94’ and 106’. This volume satisfies the minimum water inventory requirement of 26 days as discussed in Section 9.2.5.4.A and is the volume that would be lost following a LOCA due to evaporation and drift. The thermal performance analysis utilizes the entire inventory of the pond(s) since the entire volume is always available as a heat sink.

The two ESPs are interconnected with redundant valves installed in their common wall in order to permit equalization of the water levels between ESPs of the same unit. These valves are normally closed during plant operation to maintain the ESPs independent of one another. For post-LOCA cooling, at least one of the two redundant valves will need to be opened to provide combined water inventory as discussed in paragraph 9.2.5.4.A. As these valves are part of the UHS, which falls under UHS Technical Specification, and are not required for ESPS redundancy, they are not subject to the ESPS Technical Specification.

In order to prevent dissolved solids buildup due to solar evaporative losses, a blowdown line from each ESP to the circulating water system is provided.

In order to maintain the ESP water quality requirements, each ESP is provided with a closed loop water filtering recirculation system and hypochlorite injection system. Hypochlorite solution is normally injected into the ESP system from the hypochlorite header. Periodic analysis of pond water is taken to maintain the desired chemistry in the pond.

Since the water makeup lines, hypochlorite injection system, and pond filtering system are not safety-related, they are of non-Category I construction. The makeup water discharge lines are routed over the pond wall and terminate above the minimum Tech. Spec. required level in the spray pond(s). The pond filter pump suction lines, which extend below the pond surface are provided with siphon breakers to prevent drainage of water

from the pond(s) below the minimum Tech. Spec. required level in the event of a piping failure.

Table 9.2-15 lists Seismic Category I valves.

9.2.5.3 System Design

The design of the ESP is in accordance with Regulatory Guide 1.27 as discussed in the following paragraphs.

9.2.5.3.1 Meteorology

The determination of the meteorological parameters is in accordance with Regulatory Guide 1.27 for the design of the ESP.

9.2.5.3.1.1 Historical Meteorological Data. Data for the time span from 1948 through 1973 were obtained from the Sky Harbor Meteorology Station at Phoenix, Arizona, and screened to determine the worst 1 day and worst 29 consecutive days during the time span for use in establishing the thermal design of the ESP and in establishing the ESP water mass. The worst day for the thermal design of the ESP per Regulatory Guide 1.27 was August 14, 1955, and the worst 29 consecutive days were from July 30, 1955, to August 27, 1955. The worst day for the ESP design water mass was August 23, 1969, and the worst 29 consecutive days were from July 12, 1971, to August 9, 1971.

The wet bulb, dry bulb, and dewpoint temperatures and the wind speed data for these time periods are tabulated in tables 9.2-16 and 9.2-17, respectively.

The average wind speed for these two periods was 4.7 miles per hour and 10.8 miles per hour, respectively. These data were used to determine the drift loss and nozzle efficiency from the experimental data taken at the Rancho Seco Nuclear Power Station spray pond tests.(1) The average drift loss and nozzle efficiency for the meteorology in tables 9.2-16 and 9.2-17, respectively, are 0.188% and 32.86%, and 0.551% and 44.6%.

9.2.5.3.1.2 Meteorology Data Screening Methodology. For the thermal design of the ESP, Regulatory Guide 1.27 defines the use of that 30-day period for which the difference between the dry bulb temperature and the dewpoint temperature is a minimum. Since the thermal efficiency of the sprays is less at high temperatures than at low temperatures and also is less for still air than for high wind speeds, compliance with the intent of the guide requires including these two additional factors in the screening methodology. For the design of the water mass of the ESP, the guide defines the use of that 30-day period for which the difference between the dry bulb temperature and dewpoint temperature is a maximum concurrent with the highest wind speeds. Since the rate of evaporation is higher and the thermal efficiency of the nozzles is lower at high air temperatures than at lower air temperatures, compliance with the intent of the guide requires including these factors in the screening methodology.

SPB-HCV128	Lube oil cooler outlet, train B	Butterfly	6	Hand	N
SPE-HCV-207	ESP cross-connect valve [b]	Butterfly	10	Hand	A
SPE-HCV-208	ESP cross-connect valve [b]	Butterfly	10	Hand	A

a. An "A" indicates an active valve and "N" a nonactive valve, as discussed in section 3.9.

b. The ESP cross-connect valves are part of the ESP (UHS) as described in section 9.2.5.

c. Operation of these valves requires using the manual de-clutching lever and hand wheel on the existing motor operator. The power source to these motors are de-terminated and spared.

d. In units where DEC-00649 has been implemented, this valve has been removed.

In the evaluation of the minimum and maximum difference between the dry bulb and dewpoint temperatures, the moisture content of the air and the mass of water required to saturate the air at each time-dependent meteorology data point was calculated. The relative humidity of the air was determined from a correlation of dry bulb and wet bulb temperatures, wet bulb temperature depression, and relative humidity. The partial pressure of saturated steam at the dry bulb temperature was obtained from the ASME steam tables. The specific humidity of the saturated air was calculated using Dalton's Law by the equation:

$$W = \frac{Pv \quad Mw}{(P_t - P_v)\ M_a} \qquad (9.2\text{-}1)$$

where P_v is the partial pressure of the moisture M_w and M_a are respectively the mole weight of steam and air and P_t is the sum of the moisture and air partial pressures. The moisture in the air is the product of the values for the relative and specific humidities. The moisture required to saturate the air is the difference between the specific humidity and the moisture in the air.

The effect of the wind on the evaporation rate of water was evaluated by determining the effect of the wind speed on the equilibrium temperature of a pond in accord with methodology of Brady, Graves, and Geyer.[2]

The mass of water leaving the pond due to the surface heat exchange was combined on a weighted basis with the mass of water required to saturate the air and used to screen the data for the maximum and minimum effects. This combined effect was not evaluated against the effect due to drift loss,

recirculation rate, time the sprays are operating, and wind speed. The detailed analysis indicates that the combined effect selected for the evaluation results in satisfying the intent of the guide.

9.2.5.3.2 ESP Design Methodology

The equations derived by Merkel[3] for the passage of heat from the water to the air are applicable to the calculation of the thermal performance of a spray pond. However, insufficient information concerning the flow of air, the amount of surface area per unit volume for heat exchange, and the variation of wet bulb temperature across the sprayed area prohibit the evaluation of the equations. Hence, the performance of a spray pond is calculated by the equation:

$$\varepsilon = \frac{T_{in} - T_{out}}{T_{in} - T_{wb}} \qquad (9.2\text{-}2)$$

where the efficiency, ε, is an experimentally determined function of windspeed and:

T_{wb} is the average ambient wet bulb temperature

T_{in} is the water temperature leaving the spray nozzles

T_{out} is the sprayed water temperature just before impacting the pond surface

The sprayed water evaporation loss, L_o, is calculated by the equation:

$$L_o = (T_{in} - T_{out})\ L\ C/h_{fg} \qquad (9.2\text{-}3)$$

where the latent heat of evaporation, h_{fg}, is evaluated from the ASME steam tables at the average value of T_{in} and T_{out} and

L is the recirculation rate of the spray pond water

C is the specific heat of water

The spray pond water drift loss is calculated from the product of the drift loss fraction and the spray flowrate where the drift loss fraction is an experimentally determined function of windspeed.

The spray nozzle efficiency and drift loss fraction correlations used for the PVNGS ESP design are those generated by testing of the Rancho Seco Nuclear Power Station spray pond(1). The PVNGS design uses the same nozzle and nozzle flowrate, spacing, and height used in the Rancho Seco design; in addition, pond boundary extensions beyond the spray pattern envelope are similar.

Convective heat transfer between ambient air and the sprayed water is included in the spray nozzle efficiency. When the sprayed water temperature exceeds the ambient air temperature (dry bulb) convective heat transfer provides a cooling effect without a corresponding evaporative mass loss. Equation 9.2-3, which attributes all spray cooling to evaporation, is conservative under these conditions which are generally prevalent for most spray pond applications. However, at the Palo Verde site there are times during the warm part of the year, specifically during the design basis meteorological conditions, when the average ambient air temperature will exceed the sprayed water temperature. Under these conditions, convective heat transfer will occur from the air to the sprayed

water causing additional evaporative water losses not computed by equation 9.2-3. The design basis water consumption analysis for PVNGS include: an added evaporative water loss term, L_s, due to sensible heat transfer calculated from:

$$L_s = hA_d \overline{\Delta T}_{aw}/h_{fg} \qquad (9.2\text{-}3A)$$

where:

- h is the air-to-water droplet convective heat transfer coefficient
- A_d is the droplet surface area of the total spray field
- $\overline{\Delta T}_{aw}$ is the average air-to-water droplet temperature difference
- h_{fg} is the latent heat of vaporization as used in equation 9.2-3

Net air-to-sprayed water sensible heat transfer does not begin until several days post-LOCA when the forced heat load on the spray pond has declined to a level where the spray water temperature is less than the average air temperature.

The equilibrium temperature of the pond both initially and throughout the transient is calculated by the equations:[2]

$$T_a = (T_s + T_{dp})/2 \qquad (9.2\text{-}4)$$

$$\beta = 0.255 - 0.0085T_a + 0.000204T_a^2 \qquad (9.2\text{-}5)$$

$$f(U) = 70 + 0.7U^2 \qquad (9.2\text{-}6)$$

$$K = 15.7 + (\beta + 0.26)\, f(U) \qquad (9.2\text{-}7)$$

$$E = T_{dp} + H_s/K \qquad (9.2\text{-}8)$$

where:

T_a is an average water temperature for use in equation 9.2-5

T_s is the water surface temperature

T_{dp} is the dewpoint temperature

β is the slope of the saturated vapor pressure curve

U is the windspeed

K is the surface heat exchange coefficient

E is the equilibrium temperature

H_s is the solar radiation

The equations are solved by an iterative procedure to obtain a value for T_s which is approximately equal to the equilibrium temperature, E. The heat exchange with the environment for the maintenance of the equilibrium temperature is calculated by the equation:

$$H_e = \frac{(K - 15.7)\,\beta\,(E - T_{dp})}{24(0.26 + \beta)} \qquad (9.2\text{-}9)$$

The mass evaporated from the pond for the maintenance of the equilibrium temperature is calculated by the equation:

$$M_e = H_e A/h_{fg} \qquad (9.2\text{-}10)$$

where the latent heat of vaporization, h_{fg}, is evaluated from the ASME steam tables at the dewpoint temperature and A is the surface area of the pond. The heat exchange with the environment due to the temperature excess resulting from the thermal load is calculated by the equation:

$$H_x = \frac{(K - 15.7)\ \beta\ (T_p - E)}{24(0.26 + \beta)} \qquad (9.2\text{-}11)$$

where:

T_p is the pond temperature

The mass evaporated from the pond due to the thermal load heat exchange is calculated by the equation:

$$M_x = H_x A/h_{fg} \qquad (9.2\text{-}12)$$

where the latent heat of vaporization, h_{fg}, is evaluated from the ASME steam tables at the pond temperature, T_p, and A is the surface area of the pond.

During the time that the sprays are operating, the thermal load is dissipated to the air by the sprays and the surface heat exchange of the unsprayed area. During the time when the sprays are not operating, a part of the thermal load is dissipated to the atmosphere by the surface heat exchange of the total pond area, whereas the remainder goes into raising the spray pond temperature.

9.2.5.4 Safety Evaluation

Safety evaluations are as follows:

A. Safety Evaluation One

The combined available water inventory of the two essential spray ponds is a minimum of 87.734 x 10^6 pounds which is equivalent to a water depth of 12.0 feet. This water capacity would be depleted following a design basis LOCA in 26 days without water makeup under the

worst historical meteorological condition listed in table 9.2-17, assuming both spray pond trains operate for the first 24hours post-LOCA followed by single train operation for the remaining 25 days. Continuous spraying of the warm return water is assumed at all times that a spray pond is in operation. The water requirements for 30 days operation under the meteorological conditions of table 9.2-17 for each ESP is given in table 9.2-18. Credit is taken for the ability to utilize water from one ESP in the other of the same unit. Establishment of makeup capability within 26 days vs. 30 days meets the intent of Regulatory Guide 1.27 (see paragraph 9.2.5.4, listing C).

Table 9.2-18

WATER CONSUMPTION FOR 30 DAYS

Meteorology	Train A lb x 10^6	Train B lb x 10^6	Total lb x 10^6
Table 9.2-17	92.3	4.8	97.1

The total sprayed area of each essential spray pond is approximately 32,500 square feet which is sufficient to maintain the ECWS temperature into the SDC heat exchanger at 135F or less, following the design basis LOCA under the worst historical meteorological conditions listed in table 9.2-16.

In determining the maximum heat load from a postulated LOCA required to be dissipated by the ESP, it is assumed

that both diesels are operating and that all safety trains are operating for the first 24 hours post-LOCA. For the remaining 29 days, it is assumed that only one ESPS train and one safety train are operating, with the exception of two HPSI pumps, and that both spray ponds are cross-connected for maximum usable mass inventory. This mode of operation ensures maximum heat removal from the core and maximum heat load on one ESPS train.

The postulated LOCA is the double-ended discharge leg slot break with maximum safety injection which is shown in subsection 6.2.1 to impose the design energy load on the ESPS. The constant heat loads on train A and train B of the ESPS are those due to equipment cooling and pump operation and are given in table 9.2-19. The blowdown energy from the design basis LOCA that is dissipated by the ESPS is given in subsection 6.2.1. For the double-ended suction leg slot break, the total energy discharged to the pond in the 30-day period is the same.

The decay heat is computed from the equations given in Branch Technical Position ASB 9-2, Residual Decay Energy for Light-Water Reactors for Long-Term Cooling. Assumptions for the decay heat calculation include 100% reactor power, and fission product uncertainty factors of +20% for decay times less than or equal to 1000 seconds and +10% for decay times greater than 1000 seconds. The assumed operating cycle is 13,200 hours of full power operation per cycle, with 110 assemblies irradiated 3 full cycles, 110 assemblies

irradiated 2 full cycles, and 21 assemblies irradiated 1 full cycle.

The total energy released to the spray ponds following the DBA for the 0 to 30-day design basis water consumption analysis is given in table 9.2-19. Table 9.2-20 gives maximum daily temperatures for this analysis for an analyzed core power of 4070 MWt.

B. Safety Evaluation Two

1. The ESP is a Seismic Category I structure. A discussion of the seismic analysis used in the design of the ESP is given in section 3.8.

   It is highly improbable that a tornado and DBA would occur simultaneously and, therefore, no water allowance or protection of the spray headers is provided. For the more probable case of a tornado occurring simultaneously with a normal shutdown, the ESP pumps and lines are protected against a tornado.

   Since the makeup water lines to the ESP are underground and two independent onsite sources of water are available, a tornado would not impair the essential function of the ESP.

   Flood design considerations for the ESP are discussed in subsection 2.4.10. Freezing design considerations for the ESP are discussed in subsection 2.4.7.

Table 9.2-19

ENERGY RELEASED TO PONDS FROM 0 TO 30 DAYS (Sheet 1 of 3)

Parameter	Energy (10^6 Btu)
Initial containment Energy inventory (avg. temp = 120F)	
Primary coolant	407.0
Safety injection tank water	42.4
Fuel	13.2
Vessel shell	93.5

Steam generator secondary coolant	237.5
Steam generator tube metal	39.0
Steam generator secondary walls	69.8
Main steam line inventory to MSIV's	4.9
Containment vapor region	0.6
Refueling water tank	199.6
Total	1,270.0
Residual containment energy inventory, 30-day post-accident	
Sump	265.4
Vapor	4.5
Reactor coolant below primary nozzles	20.1
RCS sensible energy	325.8[a]
Containment structure (avg. temp. < 120F)	-720.8
Total	-105.0

(a) Includes SG sensible energy release.

Table 9.2-19

ENERGY RELEASED TO PONDS FROM 0 TO 30 DAYS (Sheet 2 of 3)

Parameter	Energy (10^6 Btu)
Sensible and decay heat[(b)] transferred to ESP train A (0 to 720 hours)	28,332.0
Train A auxiliary equipment heat loads (0 to 720 hours)	18,831
Total heat transferred to ESP train A (0 to 720 hours)	47,163
Sensible and decay heat[(b)] transferred to ESP train B (0 to 24 hours)	1,546
Train B auxiliary equipment heat loads (0 to 24 hours)	575
Total heat transferred to ESP train B (0 to 24 hours)	2,121

(b) Including spent fuel pool decay heat.

Table 9.2-19

ENERGY RELEASED TO PONDS FROM 0 TO 30 DAYS (Sheet 3 of 3)

Notes:

1. Train A operated for 30 days; train B operated only first 24 hours post-LOCA.

2. Auxiliary heat loads (10^6 Btu/hr):

	Train A	Train B
0 to 1403 seconds	27.08	27.08
1403 sec to 1 day	25.95	25.95
1 day to 30 days	30.23	0

3. Auxiliary heat loads include (10^6 Btu/hr/train):

High-pressure SI pump	2.28
Low-pressure SI pump	1.13[(a)]
Containment spray pump	1.60
Spent fuel pool pump	0.19
Spent fuel pool decay heat	4.00[(b)]
ECWS pump	1.84
ESPS pump	1.48
Essential chiller	4.16
Diesel generator cooling system	12.40

a. Low-pressure safety injection pump off after containment sump recirculation at 1438 (1403) seconds.

b. Spent fuel pool in 4 out of 4 configuration and filled to capacity except for 241 spaces for fuel assemblies just loaded in reactor (just after last refueling outage prior to exceeding the spent fuel pool capacity). Value represents a bounding end-of-cycle spent fuel decay heat load. Also, see note for Table 9.2-1.

Table 9.2-20

30-DAY MAXIMUM DAILY TEMPERATURE (F)[a]

29	86	88	82	82
30	86	87	82	81

No credit is taken for possible rainfall in the design of the ESP minimum water inventory. The water level available at the intake of the makeup lines from the plant water wells during severe drought conditions is discussed in subsection 2.4.11. Under these drought conditions, submergence of the intake ensures an uninterrupted supply of makeup, notwithstanding that there is sufficient water available in the two ESPs for heat dissipation for a minimum of 26 days.

2. The probability that an aircraft will impact PVNGS is discussed in section 2.2. The existing rail spur is not considered a credible origin for an ESP incapacitating accident since it is used infrequently and is removed from the vicinity of the ESP. The physical remoteness of the ESP to the avenues of bulk petroleum transportation makes massive fouling of the ESP surface by an oil spill incredible.

   Inasmuch as the ESP and related equipment are largely heat resistant or noncombustible, a fire would have minimal impact upon safe shutdown cooling. Fire protection for the ESPS intake structures is provided as discussed in subsection 9.5.1.

3. The possible failure of a single structure cannot result in the loss of the ESP safety function. The redundant valves between the two ESPs provide the

capability to supply cooling water flow in the event of the failure of one intake.

4. The ESP integrity is not impaired by missile accident as discussed in section 3.5.

C. Safety Evaluation Three

Provisions for assuring the continued cooling capability beyond the nominal 30-day requirement of Safety Design Basis One have been included.

1. Two separate makeup water lines are provided to each ESP from the following independent water sources:

   - Domestic water system
   - Station makeup water reservoir via cooling tower makeup and blowdown system

   The domestic water system is supplied with water from onsite wells. The cooling tower makeup and blowdown system is supplied with water from the station makeup water reservoirs. The reservoirs are 45-acre (normal operating level capacity – 1023 acre – feet) and 85-acre (normal operating level capacity – 2191 acre-feet) and are excavated impoundments (below grade); reservoir water will be available even if the retaining walls fail.

2. Procedures for ensuring the continuing capability of the ESPs by specifying detailed steps needed to replenish the ESPs from primary and backup water sources, as recommended by the regulatory position

of Regulatory Guide 1.27, is available onsite for NRC review.

D. Safety Evaluation Four

The heat rejection capability of the ESP in conjunction with the ESPS is sufficient to provide for the safe shutdown and cooldown of the unit and to maintain it in a safe shutdown condition during and following a normal plant shutdown. Two separate and redundant ESPS trains are provided, along with two essential spray ponds, and each train alone has a full 100% heat dissipation capacity for a safe shutdown.

9.2.5.5 Tests and Inspections

Refer to section 14.2 for a discussion of preoperational test procedures. Refer to the Technical Specifications for a description of periodic surveillance testing.

9.2.5.6 Instrumentation Applications

The water level in the ESP is monitored continuously so that there is always sufficient water to ensure the continuous capability of the ESP to perform its safety functions. The water temperatures of the ESP are also monitored.

9.2.6 CONDENSATE STORAGE FACILITY

The condensate storage facility is the primary source of demineralized water for the auxiliary feedwater system, which uses it for removal of reactor decay heat during a hot standby condition and for cooling the reactor to the point where the shutdown cooling system can assume the heat load. The facility

is a redundant source of demineralized water makeup for the essential cooling water system, essential chilled water system, diesel generator system, and the spent fuel pool. It also maintains proper feedwater inventory in the secondary system during startup, shutdown, hot standby, and normal power generation operations. The condensate storage facility may not be available for severe accident scenarios where condensate is depleted by the Auxiliary Feedwater system prior to a demand for makeup from the essential cooling water system, essential chilled water system, or the diesel generator system. The essential cooling water system, essential chilled water system, and the diesel generator system are designed to be capable of operating for a minimum period of 24 hours without makeup from the condensate storage facility. (Refer to appendix 5A, Question 5A.17, for additional discussion.)

9.2.6.1 Design Bases

9.2.6.1.1 Safety Design Bases

The safety design bases for the condensate storage facility are as follows:

A. Safety Design Basis One

   Those portions of the condensate storage system required for maintaining a hot standby condition and for an orderly reactor cooldown must remain functional during and after an SSE.

B. Safety Design Basis Two

   Adverse environmental occurrences shall not impair the ability of those portions of the condensate storage

facility required to maintain the reactor at a hot standby condition and to allow an orderly reactor cooldown.

C. Safety Design Basis Three

The condensate storage facility shall be designed to ensure a sufficient reserve of steam generator feedwater for use in maintaining a hot standby condition for 8 hours and for an orderly reactor cooldown in the event of main condenser unavailability.

9.2.6.1.2 Power Generation Design Basis

The applicable power generation design bases for the condensate storage facility are as follows:

A. Power Generation Design Basis One

The condensate storage facility will provide an initial fill for the condensate and feedwater system. It also will serve as a reservoir to supply or receive condensate as required by the main condenser hotwell level control system.

B. Power Generation Design Basis Two

The condensate storage tank shall be of sufficient capacity to supply the normal anticipated secondary system condensate demands for 3 days without replenishment from the demineralized water system or other source. This capacity is in addition to the maintained reserve of auxiliary feedwater inventory required for reactor shutdown and cooldown.

9.2.6.1.3 Codes and Standards

The condensate storage facility is constructed in accordance with applicable codes and standards identified in table 3.2-1. Those portions of the system required to satisfy the safety design bases are designated Seismic Category I.

Protection from wind and tornado effects is discussed in section 3.3. Flood design is discussed in 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with postulated systems of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

9.2.6.1.4 CESSAR Interface Requirements

Refer to subsection 5.1.4 and paragraph 9.3.4.1.

9.2.6.2 System Description

The condensate storage facility (engineering drawings 01, 02, 03-M-CTP-001) for each unit consists of one condensate storage tank, two parallel condensate transfer pumps, and associated piping, valves, instrumentation, and controls. A closed piping system is provided that collects overflow and drainage from the condensate tank and transfers it to the turbine building drainage system. The turbine building drains can be directed to the liquid radwaste system. The facility is located outdoors and is situated to permit gravity feed to the auxiliary feedwater pump suction and condenser hotwell.

The condensate storage tank is missile protected as it is a concrete tank with a steel liner provided to maintain water

quality. Since the tank liner is fabricated of ductile steel, fragmentation is unlikely. Piping penetrating the tank, whose failure could result in an insufficient supply of water, is protected from missiles by a concrete structure.

The portion of the stainless steel liner that is protected by the concrete wall could be damaged locally by a missile entering through the upper portion (roof) of the tank. In the event of local damage to the stainless steel liner below the top of the exterior concrete wall, significant water loss is not possible as the tank is designed as a Seismic Category I missile resistant barrier.

The concrete tank will ensure that a minimum of 300,000 gallons of water is available for a safe shutdown of the plant following 8 hours of hot standby.

Redundant, 100% capacity condensate transfer pumps provide demineralized water to their respective trains of the essential chilled water system, essential cooling water system, and diesel generator system. Either condensate transfer pump can be manually aligned to provide demineralized water to the spent fuel pool. Design data of the condensate storage facility are presented in table 9.2-21. The pumps are also powered by the onsite diesel generators.

The 520,000-gallon condensate tank is constructed with a stainless steel liner to minimize corrosion. The storage capacity provides a total of 300,000 gallons for 8 hours of reactor hot standby, followed by an orderly reactor cooldown to 350F, plus 220,000 gallons to satisfy the normal secondary system makeup demands. Prior to reactor startup, it provides

initial fill for the secondary system. Demineralized water is supplied to the condensate tank from the demineralized water system (refer to subsection 9.2.3) through an automatic control valve that maintains the water inventory in the tank within the capacities shown in table 9.2-21.

To maintain proper main condenser hotwell level, condensate is supplied from (or returned to) the condensate tank as required by the hotwell level control system.

The two condensate transfer pumps are each 100% capacity, with one operating as required and the second on standby.

Essential portions of the condensate storage facility are constructed in accordance with the ASME Code, Section III, Class 3, and are Seismic Category I.

Wherever practical, facility leakage is minimized by using welded connections. Leakage can be detected by visual inspections and by loss of tank inventory. Level detection drains are also located in the protective concrete structure housing the condensate transfer pumps. Tank penetrations at or below the 300,000-gallon level occur within this protective structure. Leakage from the pumps, piping, or tank penetrations will be detected and alarmed by the leak detection drains. Table 9.2-22 lists the Seismic Category I valves.

Table 9.2-21

CONDENSATE STORAGE SYSTEM DESIGN DATA

Condensate Tank	
Number of tanks per unit	1
Reserve capacity provided for hot standby and reactor cooldown, gal.	300,000
Storage capacity for condensate makeup, gal	220,000
Total capacity, gal. (Reserve capacity and condensate makeup)	520,000
Material	Concrete with stainless steel liner
Piping and Valves	
Material	Stainless steel
Design pressure, psig	150
Condensate Transfer Pumps	
Number of pumps per unit	2
Type of pumps	Horizontal centrifugal
Design flow/head	130 gal/min/61 ft
Material	Stainless steel

9.2.6.3 Safety Evaluation

Safety evaluations are numbered to correspond to the safety design bases.

A. Safety Evaluation One

As defined in section 3.2 and Table 3.2-1, the condensate tank, safety-related the piping to the auxiliary feedwater pump suctions and piping supporting other essential portions of the condensate facility are designed to Seismic Category I requirements.

B. Safety Evaluation Two

The condensate tank is a Seismic Category I structure and can withstand adverse environmental occurrences, including tornadoes, that could impair its ability to maintain the reactor at a hot standby condition and to allow an orderly reactor shutdown. The Seismic Category I piping is located below grade or within a protective concrete structure.

Should a seismic event occur when the nonseismic auxiliary feedwater pump is in service, the operator can take the necessary action to locally close one of the suction line valves should the line fail. This action will be taken in sufficient time to prevent a significant loss of water from the condensate storage tank.

Table 9.2-22

C. Safety Evaluation Three

A total of 300,000 gallons of condensate is provided for maintaining the plant at hot standby for 8 hours followed by cooling the reactor to 350F, at which point the shutdown cooling system assumes the heat load. The piping that supplies the secondary system enters the tank at an elevation such that 300,000 gallons of usable water is reserved. This ensures a sufficient supply to the auxiliary feedwater pumps. A separate line is connected to the tank at a lower elevation to supply the auxiliary feedwater pumps with the reserved water supply. A single active failure analysis for the condensate storage facility is provided in table 9.2-23.

9.2.6.4 CESSAR Interface Evaluation

Refer to subsection 5.1.5 and paragraph 9.3.4.2.

9.2.6.5 Tests and Inspections

Preoperational testing is performed in accordance with the test descriptions of section 14.2. Periodic surveillance testing is described in the Technical Specifications.

The regular sampling of condensate storage tank contents ensures that the limits for radioactive concentrations are not exceeded.

9.2.6.6 Instrumentation Applications

A flow transmitter with output to the computer is provided on the condensate tank fill line.

A level detection system is installed on the condensate tank with level signals transmitted to the automatic tank level controller. Level indication is provided locally, in the control room, and at the remote shutdown panel. Low and high level alarms are provided in the control room. The low level alarms will annunciate to inform the opertors prior to the tank contents dropping below the following conditions. The setpoint calculations for these alarms include Total Plant Uncertainties and additional margin:

- The minimum normal operating level as defined in Section 9.2.6.2
- The minimum level required to maintain a hot standby condition for 8 hours followed by an orderly reactor cooldown as defined in Section 9.2.6.3.C.
- The volume of water required to provide operators time (20 minutes) to anticipate the need to either make-up water or transfer to an alternate water supply. This is approximatley 34,400 gallons.

9.2.7 SHUTDOWN COOLING SYSTEM

Refer to subsection 5.4.7.

Table 9.2-23

CONDENSATE STORAGE FACILITY SINGLE FAILURE ANALYSIS

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Condensate transfer pump	Inoperable/ mechanical or electrical failure	Low level in essential cooling, essential chilled, and diesel generator cooling water surge tanks	Low level alarm in surge tank	Redundant pump running on standby diesel generator train	There are redundant systems
Transfer piping	Line break/ corrosion or mechanical damage	Low header pressure. Tank drained through break	Low tank level alarm. Leaking water collects in leak detection drains. Drain alarms	Leak isolated. Redundant train placed in operation	
Nitrogen regulator	Fails open/ material failure or binding	None	None	Redundant breather valves discharge excess pressure	
Nitrogen regulator	Fails closed/ material failure or binding	None	None	Redundant breather valves open to equalize the tank	
NQR Piping	Line Break/Seismic Event	Low header pressure. Tank drained through break	Low tank level alarm. Leaking water collects in leak detection drains. Drain alarms	Redundant breather valves open to equalize the tank	
Breather valve	Fails closed/material failure or binding	None	None	Redundant breather valve opens to equalize vacuum	Single breather valve has the capacity to mitigate a concurrent nitrogen regulator failure.
Makeup water valve	Fails closed/ material failure or binding	Low level in storage tank	Low level alarms	Tank inventory maintained at adequate level. Only emergency services penetrate tank below 300,000 gal level	
Level control in storage tank	Fails to function/ material failure or mechanical bind	High level in storage tank	High level alarms	Overflow line	

9.2.8 TURBINE COOLING WATER SYSTEM

The turbine cooling water system (TCWS) provides cooling for the nonnuclear-related components in the various turbine plant auxiliary systems. Cooling is effected through heat exchangers with heat rejected to the PCWS. This closed cooling water system is used in lieu of direct cooling by the PCWS because the quality of the water being circulated in the PCWS could result in a greater tendency for equipment fouling and corrosion.

9.2.8.1 Design Bases

9.2.8.1.1 Safety Design Bases

The TCWS has no safety design bases.

9.2.8.1.2 Power Generation Design Bases

The TCWS is designed to cool the nonnuclear-related auxiliary components of the steam and power conversion system over the full range of normal plant operation.

9.2.8.1.3 Codes and Standards

The TCWS is designed in accordance with codes and standards set forth in table 3.2-1.

9.2.8.2 System Description

The TCWS is a single, closed-loop cooling water system. The TCWS includes two heat exchangers, two pumps, one surge tank, one chemical addition tank, piping, valves, instrumentation and controls (table 9.2-24).

The following components are cooled by the TCWS:

- Main turbine lube oil coolers
- Circulating water pump motor lube oil coolers
- Heater drain pump lube oil coolers
- Electrohydraulic control fluid coolers
- Air compressor coolers
- Feedwater pump turbine lube oil coolers
- Condensate pump motor lube oil coolers
- Gland steam packing exhauster
- Isolated phase bus cooling coils
- Main generator hydrogen coolers
- Main generator stator coolers
- Various nonnuclear-related sample coolers

Table 9.2-25 lists the above components, their heat loads, and associated cooling water requirements. In addition, table 9.2-25 cross-references the related systems and the sections where they are discussed.

The TCWS utilizes treated demineralized water to remove waste heat from the various nonnuclear-related components in the turbine plant. Refer to subsection 9.2.3 for the discussion of the demineralized water system. Discharge from the TCWS pumps supplies cooling water to the system's component coolers and returns to the TCWS heat exchangers where heat is rejected to the PCWS. A process and instrumentation diagram of the TCWS is provided in engineering drawings 01, 02, 03-M-TCP-001, -002 and -003.

9.2.8.2.1 System Operation

The TCWS is required only for power generation operations. Normally, one TCWS pump and heat exchanger are operating with a second pump and heat exchanger on standby. The standby pump is automatically brought online whenever the pump discharge header pressure falls below a preselected value. The redundant TCWS heat exchanger is placed in service manually. The surge tank is provided with a level control that signals a demineralized water makeup line control valve, which then actuates to maintain the required water level.

Instrumentation is provided for automatic temperature control of some components and manual control is provided for the other components.

9.2.8.3 Safety Evaluation

The TCWS has no safety function.

9.2.8.4 Tests and Inspections

Acceptance testing of this system is performed to demonstrate proper system and equipment function.

9.2.8.5 Instrumentation Application

Local temperature gauges and pressure/test points are provided for temperature and pressure determination. Indication of the surge tank level is provided locally. An alarm also is provided in the control room for high and low TCWS pump discharge pressure and high and low surge tank water level and pressure. Makeup water flow to the surge tank is initiated automatically by low surge tank water level and is continued until the normal level is reestablished.

9.2.9 CHILLED WATER SYSTEMS

Individual closed loop chilled water systems are provided for those buildings or rooms that require chilled water for air conditioning. Separate chilled water systems are provided for essential and normal use. There is no interconnection between essential and normal chilled water systems. The chilled water circulating loops are provided to remove the heat from the various heating, ventilating, and air conditioning (HVAC) systems, which are discussed in sections 6.4 and 9.4. The normal air handling units, which require chilled water for normal plant operation and normal shutdown (nonsafety-related operations), are indicated in engineering drawings 01, 02, 03-M-WCP-001 and are discussed in paragraph 9.2.9.1. The essential cooling units, which are used during safety-related operations and require chilled water, are indicated in engineering drawings 01, 02, 03-M-PWP-001 and are discussed in paragraph 9.2.9.2.

9.2.9.1 Normal Chilled Water System

The normal chilled water system provides the required chilled water flow for the following systems:

- Control building normal cooling system
- Containment building normal cooling system
- Auxiliary building cooling system
- Radwaste building control room cooling system
- Turbine building (various sampling points)

9.2.9.1.1 Design Bases

9.2.9.1.1.1 Safety Design Bases. There are no safety design bases for the normal chilled water system.

9.2.9.1.1.2 Power Generation Design Bases. The power generation design basis for the normal chilled water system consist of the following:

A. Power Generation Design Basic One

The normal chilled water system supplies chilled water to the various buildings listed in paragraph 9.2.9.1 during normal plant operating conditions to provide personnel comfort and the operating environment for equipment specified in section 9.4.

B. Power Generation Design Basis Two

The normal chilled water system supplies chilled water to the containment building air cooling units and to the charging pump rooms air cooling units in case of a forced shutdown with loss of offsite power.

9.2.9.1.1.3 Codes and Standards. The chilled water system is designed in accordance with codes and standards set forth in table 3.2-1.

9.2.9.1.2 System Description

The normal chilled water system is of the closed-loop type. It consists of chilled water refrigeration units (consisting of a compressor, evaporator, condenser/receiver unit, controls, and instrumentation), chilled water circulation pumps, an expansion tank, control valves, instrumentation, and insulated piping.

The system is furnished with three units of 50% capacity each (two operating and one on standby) and one unit of 213-ton capacity operating continuously in support of the two operating units. The condensers of all normal chiller units normally reject heat to the nuclear cooling water system. When the nuclear cooling water system is unavailable, the condensers reject heat to the essential cooling water system as discussed in subsection 9.2.2. The normal chilled water system supplies the chilled water to the cooling coils in the normal operating air handling units in the containment building, control building, radwaste building, auxiliary building, and nonnuclear process sampling system, as shown in engineering drawings 01, 02, 03-M-WCP-001.

The normal chilled water system operates during normal plant operation, during hot standby, and during programmed refueling or maintenance shutdown periods. Chilled water is circulated by the chilled water pumps from the chillers to the air cooling coils of the individual normal air handling units. Makeup water supply to the closed chilled water circulating loops of

the various systems is provided from the demineralized water system to the expansion tank in the loop.

Chilled water is provided for the containment building normal air cooling units and the charging pump rooms air cooling units in case of a forced shutdown with loss of offsite power.

9.2.9.1.2.1 Component Description. Design data for major components of the normal chilled water system are presented in table 9.2-26. The major components of the system are described below:

A. Chillers

   The chiller is of the self-contained package refrigeration unit type, consisting of a compressor, evaporator-cooler, condenser, oil lubricating system, oil cooler system, and controls.

B. Chilled Water Pump

   The chilled water pump is of centrifugal type.

C. Expansion Tank

   The expansion tank is a nitrogen charged water accumulator.

D. Piping, Valves, and Fittings

   Piping, valves, and fittings are supplied in accordance with table 3.2-1. Seismic Category I valves which are a part of the normal chilled water system are listed in table 9.2-27.

Table 9.2-26

NORMAL CHILLED WATER SYSTEM TABULATION

Component	Number of Units	Unit Capacity	Units Required for Operation	Remarks
Chillers	3	9.6×10^6 Btu/h, 800 tons	2	105 to 120F maximum temperature cooling water
Chilled water pumps	3	50 hp, 1200 gal/min	2	
Expansion tank	1	270 gal	1	
Chiller	1	2.556×10^6 Btu/h, 213 tons	1	105 to 120F maximum temperature cooling water
Chilled water pump	1	20 hp, 320 gal/min	1	

9.2.9.1.3 Safety Evaluation

The normal chilled water system has no safety function.

9.2.9.1.4 Tests and Inspections

Acceptance testing of this system is performed to demonstrate the proper system and equipment function.

9.2.9.1.5 Instrumentation Applications

An individual internal temperature and capacity controller which maintains a constant chilled water supply temperature is provided with each chiller unit. Flow switches prevent the chiller unit from operating unless there is water flow through the evaporator and condenser.

Makeup water for the chilled water system is controlled automatically by regulating the level in the expansion tank. Temperature and pressure indicators and test points are provided throughout the system to monitor operation and efficiency. Monitors, controls, and displays for the chilled water system are located in the control room and additional local display instruments are placed in the equipment areas for periodic checkout of the system.

9.2.9.2 Essential Chilled Water Systems

The essential chilled water system provides the required chilled water flow for the following systems:

- Control room essential ventilation system
- Electrical penetration room cooling system
- High pressure safety injection pump room cooling system

- Containment spray pump room cooling system
- Low pressure safety injection pump room cooling system
- Engineered safety features switchgear room cooling system
- Engineered safety features equipment room cooling system
- Auxiliary feedwater pump room cooling system
- Essential cooling water pump room cooling system

9.2.9.2.1 Design Bases

9.2.9.2.1.1 Safety Design Bases. The safety design bases for the essential chilled water system consist of the following:

A. Safety Design Basis One

The essential chilled water system is designed to provide chilled water to the air handling units of the systems listed in paragraph 9.2.9.2.

B. Safety Design Basis Two

The essential chilled water system is designed to satisfy the single failure requirements of 10CFR50, Appendix A, General Design Criterion 21.

C. Safety Design Basis Three

The essential chilled water system is designed to withstand an SSE.

Table 9.2-27

NORMAL CHILLED WATER SYSTEM SEISMIC CATEGORY I PROCESS VALVE LIST

(Refer to engineering drawings 01, 02, 03-M-WCP-001)

Valve Tag Number	Location	Valve Type	Line Size (in)	Actuator Type	Valve Classification
WC-UV-61	To normal chilled water system - inside containment	Gate	10	Motor	A
WC-UV-62	To normal chilled water system - outside containment	Gate	10	Motor	A
WC-UV-63	From normal chilled water system - outside containment	Gate	10	Motor	A
WC-V-039	From normal chilled water system - inside containment	Check	10	None	N

D. Safety Design Basis Four

The essential chilled water system is designed to permit inservice inspections in accordance with ASME Section XI, Inservice Inspection of ASME Code, Class 2 and 3, Nuclear Power Plant Components.

E. Safety Design Basis Five

The essential chilled water system is designed to meet the environmental and missile design requirements of 10CFR50, Appendix A, General Design Criterion 4.

9.2.9.2.1.2 Power Generation Design Bases. The essential chilled water system has no power generation design bases.

9.2.9.2.1.3 Codes and Standards. The essential chilled water system is designed to the codes and standards listed in table 3.2-1.

9.2.9.2.2 System Description

The essential chilled water system is of the closed-loop type. The chilled water system includes two independent 100% redundant systems, each consisting of a chilled water refrigeration unit, a circulating chilled water pump, control valves, instrumentation, and piping (refer to table 9.2-28). The refrigeration unit consists of a compressor, evaporator, refrigerant condenser/receiver unit, controls, and instrumentation. Cooling water from the essential cooling water system is supplied to the refrigerant condensers of the safety-related essential chilled water systems shown in engineering drawings 01, 02, 03-M-ECP-001. The cooling water

flow is regulated by the Refrigerant Head Pressure Control to ensure reliable chiller operation.

The essential chilled water system is automatically activated by the actuation signals shown in engineering drawings 01, 02, 03-M-ECP-001. Redundant chilled water units are connected to independent chilled water trains A and B which supply chilled water to the cooling coils of the essential trains A and B air conditioning units serving the control room, ESF switchgear, electrical penetration rooms, ESF equipment rooms, and ECW pump rooms in the auxiliary building and the auxiliary feedwater pump rooms in the main steam support structure. Since each train is capable of removing the total emergency heat load (100% redundancy), one of the redundant chilled water systems with its corresponding essential air conditioning units can be manually deactivated once the other train has demonstrated its capability to supply the required essential chilled water. Table 9.2-29 lists Seismic Category I valves that are installed in 1-1/2-inch and larger lines in the water side of the essential chilled water system.

The makeup water line to the essential chilled water system is connected to the demineralized water system. A backup makeup water line of Seismic Category I construction is provided from the condensate storage tank. Normally, makeup is supplied from the demineralized water system. In case of a loss of offsite power, makeup is supplied from the condensate storage tank. Additionally, a connection is provided to hook up a fire hose to the makeup line (see Section 9.2.6 for details).

In case of a major leak in one of the ECWS trains, that train is removed from service and the other train is used.

Table 9.2-28
ESSENTIAL CHILLED WATER SYSTEM

Component	Number of Units	Unit Capacity	Units Required for Operation	
Chillers	2	2.724×10^6 Btu/h. 227 tons	1	Cooling water temperature maximum of 132°F
Chilled water pumps	2	20 hp, 400 gal/ min	1	Centrifugal type
Expansion tanks	2	80 gal	1	Closed to atmosphere
Chemical addition tanks	2	11.3 gal	1	Ball feeder

9.2.9.2.2.1 Component Description. Design data for major components of the essential chilled water system are presented in table 9.2-28. The major components of each train are the chiller, chilled water pump, closed expansion tank, piping, valves, instruments, and controls.

A. Chillers

The chiller is of the self-contained package type, consisting of compressor, evaporator-cooler, condenser, oil lubricating system, oil cooler system, and controls. The oil cooler is cooled by water from the essential chilled water loop.

B. Chilled Water Pump

The chilled water pump is of the centrifugal type.

C. Expansion Tank

The expansion tank is a nitrogen charged water accumulator sized to allow for thermal expansion and contraction.

9.2.9.2.3 Safety Evaluations

The following safety evaluations are numbered to correspond to the safety design bases:

A. Safety Evaluation One

The essential chilled water system is designed to provide the chilled water at the required temperature and flowrate.

Table 9.2-30

SINGLE FAILURE MODE ANALYSIS-ESSENTIAL CHILLED WATER SYSTEM

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Condenser cooling water isolation valve or control valve	Fails closed	No cooling water flow to condenser	Temperature indication and high temperature alarm in control room	Redundant 100% capacity chilled water train available	Valve normally open except for repair
	Fails open	None			
Chiller condenser	Loss of coolant water	Refrigerant does not condense	Temperature indication and high temperature alarm in control room	Redundant 100% capacity chilled water train available	Additional local display instrumentation
Chiller compressor	Fails to operate	No cooling provided for water	Temperature indication and high temperature alarm in control room	Redundant 100% capacity chilled water train available	Additional local display instrumentation
Chiller evaporator	Chilled water coil leakage	Loss of chilled water	Expansion tank low level alarm	Redundant 100% capacity chilled water train available	Additional local display instrumentation
Chilled water pump	Fails to operate	Loss of chilled water	Pressure differential indication and alarm in control room	Redundant 100% capacity chilled water train available	Additional local display instrumentation
Thermostat 3-way valve control room	Fails closed/ mechanical binding	No chilled water flow to cooling units	Local temperature indications	Redundant 100% capacity chilled water train available	Essential to control temperature in rooms during and following emergency
	Fails open/ mechanical binding	No regulation of chilled water to coolers	Local temperature indications	Redundant 100% capacity chilled water train available	

B. Safety Evaluation Two

The essential chilled water system is divided into two trains, each supplied from redundant power sources and redundant essential cooling water system trains. No single failure can impair the ability of the system to function. (For a single failure analysis of the essential chilled water system, see table 9.2-30.)

C. Safety Evaluation Three

The essential chilled water system is designed to Seismic Category I criteria.

D. Safety Evaluation Four

The essential chilled water system is provided with sufficient access and removable insulation to permit visual inspection of the piping and equipment surfaces.

E. Safety Evaluation Five

The essential chilled water system is protected from missiles by means of physical separation of redundant units and by use of adequate building structure where it is located. Refer to section 3.5.

9.2.9.2.4 Tests and Inspections

Preoperational testing is performed in accordance with the test descriptions of section 14.2. Periodic surveillance testing is described in the Technical Specifications.

9.2.9.2.5 Instrumentation Applications

The chiller units and chilled water pumps for the essential chilled water system are automatically actuated upon receiving any of the signals shown in engineering drawings 01, 02, 03-M-ECP-001.

After automatic startup of the two essential chilled water trains, train A and train B, the operator has manual override capability on the essential trains. The operator is able to determine which train he wishes to remain in operation, which train he wishes to deactivate, and can reactivate the standby train manually, as required.

A temperature and capacity controller is provided with each essential chiller unit and maintains a constant chilled water supply temperature when the unit is working. A flow switch prevents the chiller from operating unless there is chilled water flow in the evaporator. A trip of any chiller or pump causes an alarm in the control room. Essential chilled water system differential pressure indication and alarm and essential chiller outlet temperature indication and alarm are provided in the control room to monitor system operation and efficiency. Additional local display instrumentation and test points are placed in the equipment areas for periodic checkout of the system.

The essential chilled water expansion tank is provided with a local level indicator to show low or high level condition in the closed loop. Critical conditions of the tank level and pressure are alarmed in the control room for leak detection.

Relief valves are provided, as required, for personnel and equipment protection.

9.2.10 PLANT COOLING WATER SYSTEM

The PCWS removes heat from the TCWS, the NCWS, and the condenser vacuum pump seal coolers, and rejects the heat to the circulating water system (CWS).

9.2.10.1 Design Bases

9.2.10.1.1 Safety Design Bases

The PCWS has no safety design bases.

9.2.10.1.2 Power Generation Design Bases

The power generation design basis applicable to this system is as follows:

A. Power Generation Design Basis One

   The PCWS is designed to remove heat from the nonsafety-related, normally operating, closed cooling water systems over the full range of normal plant operation.

9.2.10.1.3 Codes and Standards

The PCWS is designed in accordance with applicable codes and standards set forth in table 3.2-1.

9.2.10.2 System Description

9.2.10.2.1 General Description

The PCWS uses a portion of the CWS flow from the plant cooling towers to remove heat from the NCWS, the TCWS, and the condenser vacuum pump seal coolers. Cooled circulating water, returned from the cooling towers, is pumped in parallel through the TCWS and NCWS heat exchangers and the condenser vacuum pump seal coolers, and is discharged back into the CWS at a point between the main condenser cooling water outlet and the cooling tower inlet. Circulating water quality is maintained as discussed in subsection 10.4.5.

Because of possible radioactive contamination of the NCWS through leaks in various nuclear-related components in the system, the design operating pressure of the PCWS is higher than the design operating or transient pressures of the NCWS. This pressure differential ensures against radioactive contamination of the PCWS and outside environment. Inleakage to the NCWS is detected and alarmed as described in subsections 9.2.2 and 9.2.8, respectively.

Piping and valves in the PCWS are carbon steel and are coated with a suitable corrosion-resistant material. The NCWS and TCWS heat exchangers are constructed of corrosion-resistant materials to minimize corrosion.

A diagram of the PCWS system is provided in engineering drawings 01, 02, 03-M-PWP-001.

9.2.10.2.2 Component Description

The PCWS consists of two, 100% capacity, vertical, wet pit pumps (one on standby) which are located at the PCWS intake structure. Design data for the PCWS equipment are given in table 9.2-31.

The PCWS serves the following components with their respective flows and heat loads given in table 9.2-31:

- Two TCWS heat exchangers (one normally in service and one on standby)
- Two NCWS heat exchangers (one normally in service and one on standby)
- Four condenser vacuum pump seal coolers

9.2.10.2.3 System Operation

Normally, one PCWS pump is started manually from the main control room and is operated continuously during normal plant operating conditions.

The standby PCWS pump is started automatically in the event the normally operating pump is tripped or the discharge header pressure drops below a preset limit.

The flow through and pressure in the tube side of the TCWS, NCWS heat exchangers, and the condenser vacuum pump seal coolers are regulated manually so that the PCWS operates at a continuous, steady-state during plant operating conditions. The redundant heat exchangers are placed in service manually as required.

During Refueling Outages, the Plant Cooling Water System is shutdown for maintenance. The continued operation of the NCWS for the Refueling Outage is warranted for Spent Fuel Pool cooling and other selected components. To support NCWS operation during a Refueling Outage, the PCWS allows for the installation of a temporary cooling water system to serve as a heat sink to one NCWS Heat Exchanger.

The temporary cooling water system is made up of two cooling towers, two recirculating pumps, two make-up pumps, several manual control valves, and temporary piping. Make-up to the temporary cooling system is provided by the Essential Spray Pond (SP) System and Domestic Service Water (DS) System. The temporary cooling system has a normal power supply provided by non-class 480VAC and a back-up power supply provided by a portable diesel generator capable of 480VAC, 500KW.

The mechanical and electrical portions of the temporary cooling water system are installed and removed each outage under Maintenance Procedures. The temporary cooling water system is operated in accordance with PVNGS operating procedures.

9.2.10.3 Safety Evaluation

The PCWS has no safety function.

9.2.10.4 Tests and Inspections

Acceptance testing of this system is performed to demonstrate proper system and equipment function.

9.2.10.5 Instrumentation Application

Local pressure and temperature indicators are provided at selected points in the system. Plant cooling water system pump discharge pressure indication is provided locally and in the main control room. Pressure switches are provided at the PCWS pump discharge for standby pump auto start and for low pressure alarm in the main control room.

Table 9.2-31

DESIGN DATA FOR PCWS EQUIPMENT

	Pumps
Plant cooling water pump	
Number required	2/100%
Design flow, gal/min	29,000
Design head, ft	110
Type	Vertical

9.3 PROCESS AUXILIARIES

9.3.1 COMPRESSED AIR SYSTEM

9.3.1.1 Design Bases

9.3.1.1.1 Safety Design Bases

The compressed air system has no safety design bases.

9.3.1.1.2 Power Generation Design Bases

Each generating unit is provided with its own independent compressed air system. The system is required for normal operation but is not required for safe shutdown.

The compressed air system is divided into two subsystems, the instrument air system and the service air system.

9.3.1.1.2.1 Instrument Air System. The instrument air system provides a continuous supply of filtered, dry, oil-free air at a pressure up to 125 psig for pneumatic instrument operation and the control of pneumatic actuators. This subsystem has three air compressors and three air receivers. Each air compressor operating alone has the capacity to provide all instrument requirements of the normally operating generating unit. The total air receiver storage capacity is adequate to supply instrument air requirements during the period required for the standby air compressor to come up to full pressure, in the event of an operating air compressor failure. Two air compressors are powered from one electrical bus while the other is powered from the redundant electrical bus. The system has nitrogen backup in the event the air compressors cannot maintain adequate instrument air header pressure.

9.3.1.1.2.2 Service Air System. The service air system supplies oil-free air at a pressure of 125 psig to service air stations located throughout the generating unit. Service air stations are provided for the operating of miscellaneous pneumatic tools, stud tensioners, and stud tension hoists, and for resin transfer, refueling machine manual operation, and other service requirements. A piping connection is provided to use a portable air compressor in the event the permanent air compressor is unavailable.

9.3.1.1.3 Codes and Standards

The compressed air system is designed to the codes and standards set forth in table 3.2-1. In addition, the compressed air system is designed to meet pertinent Occupational Safety and Health Administration (OSHA) requirements and the air compressors are supplied in conformance with noise limitations defined by the Walsh-Healy Act.

9.3.1.1.4 Protection

Protection of the compressed air system from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with the postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

9.3.1.1.5 CESSAR Interface Requirements

Refer to subsection 5.1.4 and paragraphs 6.3.1.3 and 9.3.4.1.

9.3.1.2 System Description

9.3.1.2.1 General Description

The compressed air system (as shown in engineering drawings 01, 02, 03-M-IAP-001, -002 and -003) is composed of two subsystems, the instrument air system and the service air system. The major component parameters are given in table 9.3-1.

9.3.1.2.1.1 Instrument Air System. The instrument air system is provided with three 100% capacity rotary screw air compressors. Each compressor is furnished with a filter, an aftercooler, a moisture separator, and an air receiver. Cooling water for the air compressor and aftercooler is supplied by the turbine cooling water system as discussed in subsection 9.2.8.

The three air receivers are connected on the discharge side by a header with nonsafety-related isolation valves. The discharge header conducts the instrument air supply through one of two coalescing prefilters, which removes liquid aerosols and particulate, then to a duplex heatless dessiccant dryer which lowers the dewpoint of the air to between minus 20F and minus 40F, depending on flowrate and inlet air temperature. The air next passes through one of two afterfilters which removes particles greater than 0.9 microns (absolute) in size. This instrument air is then distributed to the various pneumatic control systems.

Table 9.3-1
COMPRESSED AIR SYSTEM MAJOR COMPONENT PARAMETERS
(Sheet 1 of 2)

Equipment Parameters	Value
1. Instrument Air System	
Air compressors	
Quantity	3
Capacity, standard ft^3/min	571
Pressure, psig	125
Horsepower	125
Revolutions per minute	1775
Volts/Hz/phase	460/60/3
Air receivers	
Quantity	3
Size, ft^3	151
Pressure, psig	140
Instrument air dryers	
Quantity	2
Type	Duplex, heatless desiccant
Capacity, standard ft^3/min	1000
Pressure, psig/Temperature °F	110/125
Dew point, @ 500 SCFM, °F	-40
Dew point, @1000 SCFM, °F	-20
Instrument air afterfilters	
Quantity	2
Efficiency, %	100
Micron Size	0.9 absolute
Instrument air coalescing prefilters	
Quantity	2
Efficiency, % (D.O.P. test)	99.9
Micron size	0.3
Liquid aerosols, ppmw	0.013-0.0014

Table 9.3-1
COMPRESSED AIR SYSTEM MAJOR COMPONENT PARAMETERS
(Sheet 2 of 2)

Equipment Parameters	Value
2. Service Air System	
Air compressors	
Quantity	1
Capacity, standard ft^3/min	1,019
Pressure, psig	125
Horsepower	250
Revolutions per minute	1,780
Volts/Hz/phase	460/60/3
Air receivers	
Quantity	2
Size, ft^3	214
Pressure, psig	150
Air Dryer	
Quantity	1
Type	Refrigerated
Capacity, standard ft^3/min	1220
Pressure, psig	125
Dew Point Range, °F	35 to 45
Volts/Hz/Phase	460/60/3

Carbon steel piping and carbon steel valves are used in the air lines upstream of the instrument air dryers. Copper piping and bronze valves are used in the instrument air lines downstream of the air dryers.

Should the compressors fail to maintain the instrument air header pressure in the normal operating range of 105 to 125 psig, nitrogen backup is available to assure continued pneumatic instrument operation. If the header pressure should fall below 85 psig, a solenoid valve in a nitrogen crosstie automatically opens to allow 115 psig nitrogen to repressurize the instrument air system.

The instrument air system is not required to achieve a safe reactor shutdown or to mitigate the consequences of an accident. Pneumatically operated valves that have a safety function and may be required to operate to ensure safe shutdown of the plant following an accident or to mitigate the consequences of an accident use a safety-related check valve to isolate their safety-related pneumatic backup supply from the nonsafety-related instrument air system. All other pneumatically operated valves that have a safety function are designed to fail to a safe position upon loss of instrument air and do not require a continuous air supply under emergency or abnormal conditions. Both types of valves are listed in table 9.3-2.

9.3.1.2.1.2 Service Air System. The service air system is provided with a two-stage, rotary screw air compressor furnished with a filter-silencer, an intercooler, an aftercooler, and a moisture separator. Cooling water for the

air compressor package is supplied by the turbine cooling water system as discussed in subsection 9.2.8. A refrigerated air dryer, located downstream of the two air receivers, removes moisture to a dew point between 35 to 45 °F at 125 psig.

The air compressor discharges into two air receivers. A flanged connection on the discharge piping is furnished to accommodate a portable air compressor which will be used to provide service air when the permanent air compressor is not available. The air receivers have sufficient capacity to allow safe egress of maintenance personnel after service air quality or pressure is alarmed.

Excessive temperature of the compressed air entering the air receivers is alarmed for personnel safety.

The outlets of two air receivers are piped to a common service air header which distributes service air throughout the unit. This header is normally pressurized between 115 and 125 psig. The low pressure alarm setpoint is 100 psig.

9.3.1.2.1.3 Environmental Design Conditions. The major compressed air system components are located in the turbine building and are designed to operate under all specified environmental design conditions. Refer to section 9.4 for a discussion of environmental design conditions associated with the turbine building.

9.3.1.2.1.4 Safe Shutdown. The necessary protective measures are taken to ensure that the equipment essential for a safe and maintained reactor shutdown is not jeopardized by the generation of missiles or high pressure air leakage from the compressed air system. This is accomplished by separation of the compressed air system from the engineered safety features (ESF) systems, or by use of barriers between systems. Safety valves are provided in the system to prevent or mitigate a high-pressure rupture incident.

9.3.1.2.1.5 Containment Isolation. A normally open instrument air line and a normally closed service air line penetrate the containment (two separated penetrations), as shown in engineering drawings 01, 02, 03-M-IAP-001 and -002. The instrument air line penetrating the containment serves the normally operating valves of the pressurizer spray system and the normally operating valve of the nitrogen supply to the safety injection tanks (used to maintain pressure on top of the liquid in the tanks). The penetrating instrument air line is provided with a check valve inside the containment and a solenoid-operated valve on the outside of the containment. This solenoid-operated valve closes automatically upon a containment spray actuation signal (CSAS) or in case of an electrical (train A) failure. It can also be closed manually from the control room. Should the line rupture inside the containment, airflow is limited to a flow of 10 actual ft^3/min by a restriction orifice upstream of the solenoid-operated valve.

The service air line penetrating the containment is used to support refueling operations and required maintenance. This line is provided with a check valve inside the containment and a manual block valve at the point of service connection in the containment. The line is provided with a locked closed manual isolation valve outside the containment.

9.3.1.2.2 System Operation

9.3.1.2.2.1 Instrument Air System. One compressor is normally in operation with the other two on standby. Normally, the capacity of one compressor is adequate for base load operation. The other compressors cycle on and off as required to meet increased plant demands as evidenced by a drop in the instrument air header pressure. In order to equalize wear on each compressor, the compressors are periodically rotated for base load operation.

In the event that the one operating compressor fails to supply the full air demand, or an electrical trip of an operating compressor occurs, the resulting continuous low pressure in the supply line initiates an automatic start of the standby compressors.

Instrument air is filtered and dehumidified prior to its introduction into the instrument air distribution piping. This is accomplished by two trains of prefilters, regenerative duplex air driers, and afterfilters.

If plugging of a filter occurs, a high differential pressure alarm is provided to warn the operator who may then divert the air stream to the other train through manually operated valves.

Normally, filter elements are replaced on a regular basis to prevent plugging during operation.

The duplex (two tower) drier is operated in such a manner that one tower regenerates while the other tower is in service. The two towers interchange automatically based on the moisture load on the desiccant bed of the in-service tower. A standard timed cycle operating mode is also available.

9.3.1.2.2.2 Service Air System. Normally the service air compressor will maintain the header pressure in the 115 to 125 psig range. If the compressor runs unloaded for 30 minutes the drive motor is tripped.

The moisture collected downstream of the compressor intercooler and aftercooler and in the air receivers is automatically drained. Manual bypasses are to be used when the drain traps or automatic drain valves are out of service.

Letdown lines are provided for each air receiver to perform necessary maintenance with the receiver depressurized.

A refrigerated air dryer, located downstream of the air receivers, cools the air for removal of moisture, which is automatically drained.

9.3.1.2.3 CESSAR Interface Evaluation

Refer to subsections 5.1.5 and 6.3.3 and paragraph 9.3.4.2.

9.3.1.3 Safety Evaluation

Because the compressed air system has no safety design basis, no safety evaluation is provided. Paragraph 9.3.1.2 provides

an assessment of the compressed air system design and operation.

9.3.1.4 Tests and Inspections

The compressors, aftercoolers, receivers, filters, air dryers, and control panel are shop inspected, or tested, prior to installation. The complete, installed compressed air system is inspected, tested, and then operated to verify its performance requirements including operational sequences and alarm functions.

The containment isolation valves, and piping between isolation valves, are tested in accordance with paragraph 6.2.6.3.

9.3.1.5 Instrumentation Requirements

9.3.1.5.1 Instrument Air

Local indication is provided for the following changes in instrument air quality:

1. High differential pressure across the prefilter
2. High differential pressure across the dryer
3. High differential pressure across the afterfilter
4. Loss of power
5. Dryer bed is too wet (high alarm)
6. Dryer bed is too dry (low alarm)
7. Probe cable disconnected
8. Inlet valve malfunction
9. Exhaust valve malfunction

Items 1 through 9 have a common trouble alarm in the control room.

APS utilizes ISA-S7.3 (1975), "Quality Standard for Instrument Air" as guidance for controlling air quality. This instrumentation is adequate for monitoring air quality to this standard. The afterfilter removes particulate matter in excess of 0.9 microns absolute. These specifications meet air supply requirements for safety-related valves. All valves fail in their safe position upon loss of instrument air.

An instrumentation package accompanies each of the air compressors and air dryer packages. Each package consists of locally mounted temperature and pressure switches, indicators, and automatic protection devices. The temperature and pressure instruments support the automatic control modes of compressor and dryer operation. A manual or hand mode of operation is also provided for each control room. The instrument air system also includes additional local instrumentation and controls necessary to ensure the ability of the system to perform its design functions.

9.3.1.5.2 Service Air

An instrumentation package accompanies the air compressor. The package consists of locally mounted temperature and pressure switches, indicators, and automatic protection devices. The temperature and pressure switches support the automatic control mode of compressor operation. A manual or hand mode of operation is also provided from the control room. The service air system also includes additional local instrumentation and

controls necessary to ensure the ability of the system to perform its design functions.

9.3.2 PROCESS SAMPLING SYSTEM

9.3.2.1 Design Bases

The process sampling system design bases are as follows:

A. General

The normal sampling system is designed to collect samples from the reactor coolant and auxiliary systems for analysis. It permits sampling during reactor operation and cooldown without requiring access to the containment. As a secondary function of the normal sampling system, the pressurizer team space sample line is capable of degassing the RCS by recirculating the pressurizer steam space to the VCT via the sample line. Remote samples of fluids in high radiation areas can be taken without requiring access to these areas. Neither sampling system performs a safety function. The radiological (shielding) evaluation for normal operation of the process sampling system is provided in section 12.2. The sample analyses may be performed:

1. Under normal conditions by drawing samples at a sample sink and conducting the analysis in the hot laboratory

2. Under post-accident conditions by obtaining grab samples and performing the required analyses in an appropriate laboratory facility.

B. Reactor Coolant System Samples

Samples are taken from one hot leg, the pressurizer surge line, and the pressurizer steam space. Sampling lines are connected to the reactor coolant system (RCS) piping downstream of a passive flow restriction device. Provisions can be made to permit sampling of the RCS during startup.

The sample line from the RCS hot leg is delayed in transit to the secondary shield wall to allow sufficient time for the decay of N^{16} to less than 10% of the total activity in the line.

C. Sample Temperature and Pressure

The high-pressure, high-temperature reactor coolant samples and intermediate pressure and temperature samples are cooled to 120F or less and depressurized. This permits analysis by standard sampling methods.

D. Verification of Boron Concentration

To verify the boron concentration of the water recirculated via the safety injection and shutdown cooling system, provisions for extracting, processing, and analyzing samples from the following points are provided: each of the two shutdown cooling suction lines and the safety injection pump miniflow lines.

Table 9.3-3

Pressurizer Steam Space	Rough	H_2 Hydrogen, Radioactivity,	Yes	None	Remote Aux Bldg El-140'	2500	700	01, 02, 03-M-RCP-001, -002 and -003 01, 02, 03-N-SSP-001
Shutdown Cooling Suction Lines 1 & 2	Rough	Boron, Radio-activity, Chloride, Fluoride, Sulfate	No	None	Remote Aux Bldg El-140'	485	350	01, 02, 03-M-SIP-001, -002 and -003 01, 02, 03-N-SSP-001
ESF A&B Train Safety Injection Pump Mini Flow Line	Rough	Boron, Radio-activity, Chloride, Fluoride, Sulfate	No	None	Remote Aux Bldg El-140'	2050	350	01, 02, 03-M-SIP-001, -002 and -003 01, 02, 03-N-SSP-001
Purification Filter Inlet	None	pH, NH_3 Lithium, Boron, Radioactivity, Chloride, Fluoride, Suspended Solids	No	None	Remote Aux Bldg El-140'	60	120	01, 02, 03-M-CHP-001, -002, -003, -004 and -005 01, 02, 03-N-SSP-001
Purification Filter Outlet, Ion Exchanger Inlet	None	Suspended Solids, Radioactivity	No	Radio-activity(c)	Remote Aux Bldg El-140'	50	120	01, 02, 03-M-CHP-001, -002, -003, -004 and -005 01, 02, 03-N-SSP-001

a. Pressure value in psia.
b. Radioactivity samples can be analyzed for gross activity, isotopic composition, tritium or alpha activity.
c. Refer to section 11.5 for detailed descriptions of process and effluent radiation monitors.
d. Refer to section 11.3 for a description of the explosive mixtures monitoring.
e. Sample required to comply with NUREG-0737, Item II.B.3, and/or Reg. Guide 1.97, Rev. 2.
f. Sample not required - redundant or alternate sampling means.

Table 9.3-3
SAMPLING SYSTEM DESIGN PARAMETERS (Sheet 2 of 11)

Sample Origin	Type of Sample Cooler	Typical Discrete Sample Analysis[(b)]	Pressurized Sample Capability	Continuous On Line Analysis Provided	Mode of Sample Removal and Location	Design Parameters: Pressure (psig)	Design Parameters: Temperature (°F)	Engineering Drawing
<u>Primary Sampling System (Cont'd)</u>								
Purification Ion Exchanger Outlet	None	pH, Lithium, Boron, , Radioactivity, Sulfate, Decon Factor Chloride, Fluoride	No	None	Remote Aux Bldg El-140'	50	120	01, 02, 03-M-CHP-001, -002, -003, -004 and -005 01, 02, 03-N-SSP-001

E. Chemical and Volume Control System Samples (Normal Sampling Only)

Both liquid and gas sampling provisions are required to monitor chemical and volume control system (CVCS) performance.

1. In order to monitor the overall purification effectiveness, liquid samples are taken from the purification filter inlet stream for filterable corrosion products, the outlet stream for soluble activity, and the purification ion exchanger outlet for soluble activity.

2. Deleted

F. Representative Samples

In order to ensure that representative samples are obtained, the sampling lines are purged prior to sampling. Purge flow shall be high enough (i.e., turbulent) to inhibit deposition of suspended solids and to remove crud from sampling lines.

G. Relief Protection

Relief protection is provided to limit the sample pressure to a value below the design rating of the sampling system.

H. The seismic design classification and quality group classification of sample lines and components conform to the classification of the system to which each sampling line and component is connected out to such a point where classification to lower seismic and quality group

classification is justified on the basis that adequate isolation valving or flow restriction is provided.

I. Sample lines penetrating the containment are provided with isolation valves in accordance with 10CFR50, Appendix A, General Design Criterion 55 or 56. Containment isolation is described in subsection 6.2.4.

J. The configuration of the process sampling system provides the sample points and capability outlined in table 9.3-3.

K. The process sampling system provides the capability to conduct the continuous analyses indicated in table 9.3-3.

L. The process sampling system shall provide the capability to conduct discrete analyses on samples as indicated in table 9.3-3.

M. For the process sampling system, the reactor coolant sample lines shall be sized to assure complete turbulent flow during purging (i.e., Reynolds Number ≥4.000). This ensures particle suspension.

N. The process sampling system shall be designed to direct most reactor coolant sample purge fluids to the volume control tank or the recycle drain header. Other radioactive samples that purge and overflow a sample collector are directed to the liquid radwaste system discussed in section 11.2.

O. Sample lines connected to ASME Section III code class lines or vessels shall be constructed in accordance with

ASME Section III code class up to and including the first normally closed manual, automatic isolation, or throttling valve.

P. Consistency with the recommendations of Regulatory Guide 1.21, Revision 1, and ANSI N13.1-1969 is discussed in section 11.5.

Q. Codes and standards applicable to the process sampling system are listed in table 3.2-1.

9.3.2.2 System Description

The normal process sampling system is illustrated in engineering drawings 01, 02, 03-N-SSP-001. The secondary sampling system and local sampling points are illustrated on the piping and instrumentation diagrams (P&IDs) referred to in table 9.3-3 and in engineering drawings 01, 02, 03-M-SCP-005, -006 and -007.

Locations of sample points are shown on the appropriate system P&IDs for the systems to be sampled. The process sampling system includes sampling lines, heat exchangers, sample vessels, sample sinks or racks, analysis equipment, and instrumentation.

The sampling points have been selected to provide the required chemical and radiological information while keeping the system simple for reliability and ease of maintenance. Separate lines from the various sampling points to the sample sink or sample vessel are provided to allow for simultaneous sampling. The normal process sampling system is operated from the cold or hot laboratory's sampling room, with the exception of the

containment isolation valves which are operated from the control room.

Chemical and radiochemical analyses are performed to determine boron concentration, fission and corrosion product activity, crud concentration, dissolved gas and corrosion product concentrations, chloride concentration, coolant pH, conductivity of the reactor coolant, and noncondensable gas concentration in the pressurizer. Analyses results from the normal process sampling system are used to regulate the boron concentration, monitor the fuel cladding integrity, evaluate ion exchanger and filter performance, specify chemical additions to the various systems, and maintain the proper hydrogen concentration in the reactor coolant systems.

9.3.2.2.1 Normal Operation

Reactor coolant system samples are taken from the hot leg piping of one reactor coolant loop, the pressurizer surge line, and the pressurizer steam space. These high-pressure, high-temperature samples are individually routed to the sampling room where they are first cooled in a sample heat exchanger to 120F or less, and then reduced in pressure by a throttling valve to approximately 25 psig. The reactor coolant flows to the volume control tank or to the equipment drain tank through a purge line until sufficient volume has passed to permit the collection of a representative sample. The purge flow is normally directed to the volume control tank in the CVCS to minimize waste generation.

The hot leg is sampled to check reactor coolant chemistry and radioactivity. Piping is arranged so that the overall transit

time from the loop to the containment wall is sufficient to permit decay of short-lived radioactivity. Two types of samples may be collected from the hot leg: a high-pressure, low-temperature sample may be collected in a sample vessel where amounts of oxygen, nitrogen, helium, hydrogen, and fission gases can be determined; or a low-pressure, low-temperature sample may be collected at the sampling sink where an analysis of the chloride and boron concentration can be made. The pressurizer surge line sample checks the boron concentration at the pressurizer surge line. This low-pressure, low-temperature sample is collected in the sampling sink only. Pressurizer steam space samples can be collected in a sample vessel at a high pressure and low temperature. These samples give a representation of fission products and noncondensable gases in the pressurizer steam space.

Liquid samples taken from the safety injection system are at intermediate temperature and pressure and are routed through a sample heat exchanger and a manually set throttling valve in the sampling room. Remote or local (dependent on RCS pressure) samples are taken separately from each of the two shutdown cooling suction lines. Remote samples are taken from the safety injection pump miniflow lines to check the boron concentration of the recirculated water. The safety injection pump sample points permit sampling during the recirculation period following a postulated loss-of-coolant accident (LOCA), while the shutdown cooling samples allow for the verification of the reactor coolant boron concentration prior to and during shutdown cooling.

Low-pressure, low-temperature samples from the CVCS and the secondary chemistry control system (SCCS) are routed directly to the hot laboratory and cold laboratory. The purification filter inlet and outlet samples from the CVCS verify filter performance for crud removal. The purification ion exchanger outlet sample, together with the purification filter outlet sample, verify ion exchange removal of soluble activity.

In order to assure that a representative sample is obtained, the sampling lines are purged prior to withdrawing the sample. The volume of the purge flow must be at least twice sampling line volume. This purge must be accomplished for two different sections of the sampling system. First, the lines are purged, usually to the volume control tank to minimize waste or to the equipment drain tank. Second, the lines to the sample sink are purged prior to withdrawing a hand sample. The pressure and flowrate of these purge flows are indicated in the sampling room.

The sample volume will vary according to the type of analysis to be performed. The hot leg and pressurizer steam space samples that will be collected as high-pressure, low-temperature samples within the sample vessel will have a volume of 1 liter. From this type of sample, corrosion product concentrations and activity levels, fission products and gases, or other noncondensable gases can be determined. However, these same samples can be collected at the sample sink as low-pressure, low-temperature samples. In this case, the sample volume required would be approximately 250 ml for a boron or chloride concentration analysis and could be as large as 5 liters for a crud concentration analysis. When testing for

coolant pH and conductivity at the various sample points, a sample volume of 250 ml will also be sufficient.

Samples can be collected at the sample sink located in a hooded, ventilated enclosure equipped with a fan exhausting to the plant vent system. A demineralized water line is routed to the sink for flushing purposes. The sink drains to the liquid radwaste system.

Relief protection is provided to limit the sample pressure to 140 psig. The relief valve discharge to the equipment drain tank located in the CVCS.

9.3.2.2.2 Post-Accident

Post accident, PVNGS will use the normal sampling system to secure samples. This will be performed in accordance with ALARA guidelines.

9.3.2.2.3 Secondary Systems Drain Sampling

There are eight sumps in or near turbine building structures with potential for transferring radioactivity to flow paths leading to the retention tanks/evaporation ponds.

In addition to the eight sumps, the Blowdown Flash Tank Overboard path and the Condensate Polishers Pre-Service Rinse Overboard path have the potential for transferring radioactivity to the retention tanks. These two paths discharge through a common line into the CWNT header. Prior to entering the CWNT header, the effluent is sampled by a continuous-acting radiation monitor, JSQN-RU0200. This monitor alarms in the control room and automatically closes the

discharge valve, JSCN-HV1283, when radioactivity in the liquid effluent exceeds predetermined limits. In the event of a radiation monitor failure or loss of power to the monitor or the isolation valve, the isolation valve will close and terminate this path. There are three drainage sumps in the turbine building: the north sump, the south sump, and the turbine building sump. Each sump has an analysis point on its discharge piping and can transfer fluids to the liquid radwaste system (LRS), either of two chemical waste neutralizing tanks (CWNTs), or to an oil/water separator. Each CWNT has separate analysis points and can be sampled prior to discharge. Each CWNT can discharge to the LRS or the retention tanks. The oil/water separator discharges to its sump (sump four), which in turn discharges to the retention tanks.

There is not a very great potential of introducing significant radioactivity to these sumps, and it is not likely that the sumps would be aligned to discharge radioactivity to the retention tanks. The following are the sources to these sumps:

<u>North Sump</u>

Battery room neutralizing pit (nonradioactive)

Floor drains (equipment leakage and cleaning liquids)

Feedwater heaters Heater drain tank and pump

Instrument air compressor drains (nonradioactive)

Air dryer/prefilter drains (nonradioactive)

Blowdown flash tank liquid drain

Turbine cooling water heat exchanger drain (nonradioactive)

Turbine cooling water surge tank drain (nonradioactive)

Heater blowdown stack Condensate storage tank

Condenser drains

Generator stator cooler drain (nonradioactive)

South Sump

Floor drains (equipment leakage and cleaning liquids)

Low-pressure heaters and condenser drains

Condenser evacuation drain

Steam seal exhauster drain

Isophase bus cooler drain (nonradioactive)

H_2 seal oil cooler (nonradioactive)

Condensate pump drainage

Turbine Building Sump

Feedwater pump lube oil reservoir drains (nonradioactive)

Feedwater pump drain

Turbine lube oil drains (nonradioactive)

Oil/Water Separator Sump

North, south, and turbine building sumps

Control building sumps (nonradioactive)

The only sources noted above that could contain any radioactivity are secondary system component sources -- condensate or blowdown. No regenerant chemicals are present. Thus, any radioactivity which is present must be at least as dilute as the secondary system.

The activity level in the secondary system is monitored at two points. Steam generator blowdown monitors 13-J-SQN-RU-4 and RU-5 will detect abnormal activity in the secondary as it is diverted to the blowdown processing equipment. The condenser gland seal exhauster monitor 13-J-SQN-RU-141 will detect abnormal activity in the condenser.

If abnormal activity levels are present, sump transfer paths will be aligned to transfer to the LRS or the CWNTs with subsequent alignment to the LRS. However, if it is determined during operating (by sampling or monitoring) that the sumps do not contain significant radioactivity, they may be realigned to discharge to the CWNTs (aligned to the retention tanks) or the oil water separator and thence to the retention tanks.

The remaining four sumps are the high and low total dissolved solids (TDS) sumps that receive regenerant wastes from the condensate polishing demineralizers or the blowdown demineralizers, respectively. Each sump has local drains that will be used for grab sampling. For either processing stream, initial regenerant effluent is fed to the resin and subsequently directed to the high TDS sumps. These discharge to the CWNTs. As noted previously, the CWNTs can discharge to the LRS or retention tanks and are sampled prior to discharge. Only after the TDS level of the regenerant has dropped (associated with activity levels), as measured by online conductivity cells, would flow be directed to the low TDS sumps or the circulating water system (and thence to the evaporation ponds via blowdown). Thus, the systems are designed to send radioactive waste to the LRS and yet recover clean liquid for recycle to the greatest extent practical.

To ensure that abnormal levels of activity are not sent to clean systems, design provisions for sampling have been clarified. Table 9.3-3 has been revised to show the sampling capabilities at these sumps. Operationally, when significant activity is present in the secondary (as detected by the steam generator or condenser gland seal exhaust monitors), the low TDS sumps will be aligned to discharge to the high TDS sumps. A grab sample analysis for radioactivity will be required prior to changing this alignment to allow discharge to the circulating water.

In summary, the secondary systems are continuously monitored for activity. If abnormal activity is present, this will lead to alignment of leakage and cleanup stream discharge to the LRS. If, after grab sampling, no abnormal activity is present in effluents, they can be directed to the circulating water or retention tanks.

9.3.2.2.4 Retention Tanks Sampling

The divided retention tank is located south of the Unit 3 spray ponds. It has approximately a 1-million gallon capacity and is divided into two identical compartments. The compartments are approximately 123 feet x 93 feet with a nominal depth of 8 feet which includes a 2 foot freeboard. To avoid ponding on the bottom of the tank during dewatering cycles, the tank is sloped 1/8 inch per foot from North to South.

The tanks act as storage in the event the effluent is not within the standards for pH, Hydrazine, and radioactivity prior to discharge to the evaporation pond. One retention tank can store the normal waste effluent of 800 gallons per minute for a

10-hour period. The offline tank is monitored, chemically treated (if necessary), and discharged to the evaporation pond. The waste effluent which meets the Offsite Dose Calculation Manual (ODCM) release limits will be pumped into evaporation ponds numbers 1 and/or 2.

Sampling can be conducted directly by dip grab sampling or by sampling the retention tank pump discharge (engineering drawing A0-M-OWP-004, valve V227 or V229.)

If a portable ion exchanger is used to purify the retention tank, expended resins will be disposed of in one of two ways. If resins are radioactive, they will be transferred by truck or drum to the solid radwaste system of either Unit 1, 2, or 3. If resins are not radioactive, they will be hauled to a licensed disposal site. Regeneration is not currently contemplated due to the low frequency projected for this operation.

9.3.2.3 Component Description

9.3.2.3.1 Sampling Lines

Sampling points are at locations where turbulence ensures representative sampling. Sampling nozzles are provided where deemed required as shown on the appropriate system P&ID. The sample line from the RCS hot leg has a delay that ensures adequate N-16 decay through a transit time of approximately 90 seconds to the secondary shield wall. Sampling lines from the primary coolant loop are provided with flow restriction orifices to limit coolant loss from a rupture of the sample line.

Fail-closed containment isolation valves are provided for sampling lines that penetrate the containment.

Relief valves provide protection to limit the pressure to a value below the design rating of the sampling system.

Waste handling is provided for purging the primary sample lines with sample fluid and flushing with demineralized water.

9.3.2.3.2 Sample Coolers

Rough and fine sample coolers are provided for remote sampling. These coolers are heat exchangers. Cooling is provided by the nuclear cooling water system for the primary sampling system and by the nuclear cooling water system, turbine cooling water system, and chilled water system for the secondary sampling system.

Where temperatures are above 140F, portable coolers are used for local grab sample points to prevent injury to sampling personnel.

The primary sampling heat exchangers are located in the hot laboratory in the auxiliary building.

The maximum sample temperature out of the heat exchangers is 120F for all operating modes.

Table 9.3-5 stipulates the primary sampling system design parameters.

Table 9.3-6 contains the operating parameters for the sample heat exchangers.

9.3.2.3.3 Sample Vessels

9.3.2.3.3.1 Normal. A capability is provided to take pressurized samples from the sources indicated in table 9.3-3. Each sample line from these sources is provided with connections for a sample pressure vessel to provide the capability to sample at the local RCS operating pressure. The vessel is sized to contain a sufficient volume to perform an analysis of reactor coolant for dissolved hydrogen or fission gas content. The vessel material is chemically compatible with reactor coolant.

Table 9.3-5 stipulates the sample vessel design parameters.

9.3.2.3.3.2 Post-Accident. The capability is provided to take depressurized samples from the RCS.

9.3.2.3.4 Primary Sample Sinks

The primary sample sinks are located in the hot laboratory along with the sample vessels and associated control panels. The sample sink is drained to the liquid radwaste system through a water trap. Demineralized water is provided at the sample sink to flush and clean the sink. The sampling room and sample hood are ventilated. Additional ventilation requirement

9.3.2.3.5 Gas Analyzers

Dual oxygen gas analysis equipment located in the radwaste building has the capability to analyze selected sample points.

Continuous sampling capability is provided for the gaseous radwaste system (GRS) surge tank and the waste gas header. The

surge tank sample provides a representative sample of a mixture of gases that accumulate in the surge tank while the GRS compressor is not in operation.

These analyzers provide a direct readout of oxygen concentration. The dual oxygen monitors have automatic control functions which preclude the formation of explosive hydrogen and oxygen mixtures. Alarms are provided in the radwaste panel and main control room to notify the operators of high oxygen. Samples may be collected in a sample vessel and taken to the hot laboratory for further analysis.

It is assumed that the waste gas holdup system contains greater than 4% hydrogen whenever the system is in service.

Automatic control functions are provided to stop compressor operation on high-high oxygen alarm at 3.75%. Analyses are provided on the suction side of the compressor (by sampling the surge tank and waste gas surge header).

The O_2 content of the sampled gas is indicated in the radwaste control room. Annunciating alarms are provided locally in the radwaste control room for each train of the gas analyzer, and a common radwaste trouble alarm is provided in the main control room via the plant computer. The O_2 high alarm is set at 2% and the high-high alarm is set at 3.75%.

9.3.2.3.6 Analysis Equipment and Instruments

Modern chemistry instrumentation including ion chromatographs, auto-titrators, atomic absorption spectrophotometers, analytical balances and other common laboratory equipment and glassware are maintained in the both hot and cold chemistry laboratories. Certain laboratory instrumentation is utilized inline (continuous monitoring of the sample stream). Many samples can be drawn in the laboratory, however certain samples must be taken locally. Some inline instrumentation is located outside of the laboratory such as the hotwell monitoring skids located in the turbine building. Instruments for monitoring flow and pressure on the purge discharge line downstream of the common purge header are provided. The pressurizer steam space sample line, which is not connected to the header, has its own pressure and flow instruments. Post-accident analysis will be performed by laboratory analysis in an appropriate laboratory facility.

9.3.2.4 System Operation (For normal sampling only unless noted)

Except as discussed in paragraph 9.3.2.3.6, all primary and secondary sampling points can be sampled in the auxiliary building cold and hot laboratories. Secondary sampling points inside the turbine building can also be sampled in the turbine building cold laboratory. Remotely operated valves are controlled from the main control room or from the sampling laboratories.

9.3.2.4.1 Sample Line Purging

Prior to discrete samples being taken, the sample line for the normal sampling system is purged with the fluid to be sampled so that a representative sample may be obtained. For RCS samples, initial purge of most of the sample line length can be directed to the equipment drain tank for normal sampling. Secondary sampling purge can be directed to the liquid radwaste system. Final purging for the RCS during normal sampling is directed to the sample sinks. Sampling lines that are used for continuous samples do not require additional purging prior to taking a sample.

9.3.2.4.2 Discrete Atmospheric Pressure Liquid Sampling (Normal sampling only)

Each sample container is rinsed with the liquid to be collected prior to sample collection. The container is then stoppered with a stopper previously rinsed with the sample water.

9.3.2.4.3 Discrete Pressurized Liquid or Gaseous Sampling (Normal sampling only)

After the sample vessel is purged, samples are collected by closing valves at each end of the sample vessel. Venting to achieve atmospheric pressure within the sample container is required prior to some analyses.

9.3.2.4.4 Continuous Sampling (Normal sampling only)

Liquids or gases that require constant monitoring are directed through pressure-reducing devices, sample coolers, and ion exchanger, as required, prior to flowing through the inline device.

9.3.2.4.5 Analysis of Samples (Normal sampling only)

A capability is provided to determine such reactor coolant parameters in discrete samples as boron concentration, fission and corrosion product activity, dissolved gas concentration, chloride concentration, pH and conductivity, fission gas content, and gas compositions in various vessels. Analytical results are used to regulate boron control adjustments, monitor fuel rod integrity, evaluate ion exchanger and filter performance, specify chemical additions to the various systems, maintain the proper hydrogen overpressure in the volume control tank, and establish conformance with applicable technical specifications. Water quality analyses are performed on discrete and/or continuous secondary system samples as appropriate to determine such parameters as pH specific and cation conductivity, dissolved oxygen, residual hydrazine, sodium ion concentrations, and radioactivity. Conductivity and

pH measurements in the circulating water system are used to control chemical addition and blowdown to maintain acceptable water chemistry. The remainder of the analyses are recorded to permit appropriate monitoring by the operating staff.

9.3.2.5 Post Accident Operation

The operation of the sampling system requires communication between the chemistry technician and operators in the control room. Prior to sampling a specific point, the chemistry technician verifies with the control room operator to ensure that the system isolation valves are in the appropriate position to allow for sampling. This may involve overriding a CIAS to reopen certain valves.

9.3.2.5.1 Post Accident Sampling

The chemistry technician will then operate the sampling system to obtain the desired sample. Once the sample arrives at the remote grab sampler, the chemistry technician will obtain a sample for laboratory analysis. The grab sample is then transported to the appropriate laboratory for analysis.

9.3.2.6 Design Evaluation

The normally closed containment isolation valves are designed to fail closed, in addition to closing on a containment isolation signal. These valves can only be operated from the main control room.

Connections made to ASME Section III code class systems are fitted with flow restriction devices to satisfy NRC General Design Criterion 33. Sample system piping, up to and including

the passive flow restrictors, is designed and fabricated in accordance with the same code class as the system to which it is connected. The piping and components near the sample sink are of low pressure design and are provided with pressure relief for protection of personnel.

The sampling room and the sample hood are ventilated to reduce the potential for airborne radioactivity exposure. Operating procedures specify the precautions to be observed when purging and drawing samples.

9.3.2.7 Testing, Inspection, and Training

The containment isolation valves associated with any sampling system will undergo inservice inspection as described in section 6.6.

9.3.2.8 Instrumentation Applications

For the normal sampling system, pressure, temperature, and flow indicators and/or flow switches are used where required to facilitate manual operation and to verify sample conditions before samples are drawn.

A radiation sensing element monitors the steam generator sample for primary-to-secondary tube leaks (applicable to normal sampling only). A data logger records radiation levels and a high-radiation alarm in the control room warns of out-of-specification radioactivity.

Continuous analyzers monitor for normal sampling specific water quality conditions in the secondary plant. Alarms are sounded

when these sensors detect parameters that are out-of-specification.

9.3.2.9 CESSAR Interface Requirements

Refer to paragraphs 5.4.7.1 and 6.3.1.3.

9.3.2.10 CESSAR Interface Evaluations

Refer to paragraphs 5.4.7.2 and 6.3.1.4.

9.3.3 EQUIPMENT AND FLOOR DRAINAGE SYSTEMS

The equipment and floor drainage system is divided into individual and segregated systems:

A. Radioactive waste drainage system

B. Chemical waste system -- This system consists of five subsystems as follows:

- The radioactive chemical waste subsystem
- The cooling water waste subsystem
- The condensate polishers regeneration waste subsystem
- The spent regenerant waste subsystem
- The chemical tank drains

C. Oily waste and nonradioactive waste system

D. Sanitary drainage and treatment system

9.3.3.1 Design Bases

9.3.3.1.1 Safety Design Bases

The safety design bases pertinent to equipment and floor drainage systems are as follows:

A. Safety Design Basis One

The equipment and floor drainage system provided for each ESF equipment compartment shall not be interconnected to any other ESF compartment's equipment and floor drainage system unless check valves are utilized to prevent cross-flow.

B. Safety Design Basis Two

The equipment and floor drainage system shall be capable of preventing a backflow of water that might exist from maximum flood levels resulting from external or system leakage to areas of the plant containing ESF equipment.

9.3.3.1.2 Power Generation Design Bases

Power generation design bases pertinent to equipment and floor drainage systems are as follows:

A. Power Generation Design Basis One

Radioactive or potentially radioactive contaminated waste materials are selectively collected by drainage and collection systems that are separated and isolated from the drainage and collection systems provided for handling of strictly nonradioactive waste materials.

B. Power Generation Design Basis Two

A leak detection system is provided in the containment radwaste sumps where the flowrate can be established and monitored during plant operation. The sumps are instrumented with level alarms and indicators capable of monitoring the rate of leakage.

C. Power Generation Design Basis Three

A leakage detection system is provided to determine cask load pit, refueling pool and fuel pool liner plate leakage.

D. Power Generation Design Basis Four

Conduit drains for safety channel excore detectors are separated and protected from overfill to enable operation of the nuclear instrumentation following a LOCA.

E. Power Generation Design Basis Five

Watertight rooms are equipped with level switches in floor drains and room walls. Should a line rupture in the room, the control room would be informed by an annunciator activated by these switches. Each water-tight room is designed to contain water from a flood in that room until plant conditions are such that it can be drained into the normal drainage system.

F. Power Generation Design Basis Six

With the exception of the containment building, fuel building, and holdup tanks area, the sumps of collection systems for potentially radioactive drainage

are vented to the respective area's HVAC exhaust system.

G. Power Generation Design Basis Seven

Drainage lines from areas that are required to maintain an air pressure differential but drain into the same collection sump are provided with a water seal at the sump. This is accomplished by running separate branch drains with all inlets to the sump turned down and terminated at least 12 inches below the level at which the sump pump stops in pumping down the sump.

H. Power Generation Design Basis Eight

Sump pumps are designed to discharge at a flowrate adequate for preventing sump overflow during normally anticipated drainage periods.

I. Power Generation Design Basis Nine

Sump capacities provide a live storage capacity consistent with an operating period of not less than 5 minutes with one pump operating. Where necessary, additional live storage capacity is provided to minimize the possibility of drainage backup through floor drains.

9.3.3.1.3 Codes and Standards

Generally, equipment and floor drainage collection piping from areas of potential radioactivity and nonradioactivity within the power block is constructed in accordance with ANSI B31.1.0. All other drainage systems comply with the plumbing code adopted by the Maricopa County Plumbing and Developing

Department regarding permits, materials of construction, installation, tests, inspections, and approval. All drainage systems comply with the intent of the following sections of Title 29, Chapter XVII, Part 1910 (OSHA) of the Code of Federal Regulations, as set forth in the Federal Register, Volume 37, Number 202, Sections 1910.96, 1910.106, 1910.141, 1910.151, 1910.156, and 1910.159 (c) (3), dated October 18, 1972.

9.3.3.2 System Description

9.3.3.2.1 General Description

9.3.3.2.1.1 Radioactive Waste Drainage System. The radioactive waste drain system collects and transports noncorrosive, radioactive, or potentially radioactive liquid wastes from equipment and floor drains of the containment building, the auxiliary building, the fuel building, the radwaste building, the holdup tank area, and the decontamination and laundry facilities. The wastes collected are pumped to the liquid radwaste system for processing.

9.3.3.2.1.1.1 Containment Building. The radioactive waste drain system within the containment building consists of floor and equipment drains, vertical drain risers, sloped horizontal drain pipes, two containment radwaste sumps interconnected by piping, each with one 100%-capacity sump pump, one reactor cavity sump with two 100%-capacity sump pumps, piping, valves, controls, and instrumentation serving the equipment and areas shown in engineering drawings 01, 02, 03-M-RDP-001.

The maximum normal leakage to the containment radwaste sumps is estimated to be 30 gallons per day. During refueling

operation, equipment decontamination is estimated to result in a total flow of 54 gallons per minute for 30 minutes directed to the containment radwaste sumps. The maximum reactor vessel seal ring leakage is estimated at 0.5 gallon per minute and is directed to the reactor cavity sump.

The reactor cavity sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected waste from the sump to the containment radwaste sump east. The containment radwaste sumps (east and west) are interconnected with a 4-inch line. Each containment radwaste sump is provided with one sump pump. Both sump pumps, operating automatically under control of their own level instrumentation, pump the collected waste from the sumps to the liquid radwaste system holdup tanks.

Leak detection is done by time level measurements in the reactor cavity sump and in the containment radwaste east and west sumps. Flowrate changes, which exceed a preset rate limit, are readily detected by monitoring the changes in sump water level. In the event that the rate of fill of the sumps exceeds the preset rate limit, an alarm will annunciate in the control room.

A leak detection station is provided to monitor leakage through the refueling pool liner plate. The detection system is divided into six leak chase zones such that a leak in the liner plate can be isolated to a specific zone. The leak chases for each zone are manifolded into one detection test station having a normally closed valve. The test station for each leak chase zone is monitored periodically for leakage.

Excore detector drains are provided to remove condensate buildup within the excore detectors. The conduit drains for the safety channel excore detectors are separated and protected from overfill in the sump to enable operation of the nuclear instrumentation following a LOCA.

9.3.3.2.1.1.2 Auxiliary Building. The radioactive waste drain system within the auxiliary building consists of floor and equipment drains, vertical drain risers, sloped horizontal drain pipes, three sumps, each with two 100%-capacity sump pumps, piping, valves, controls, and instrumentation serving the equipment and areas as shown in engineering drawings 01, 02, 03-M-RDP-002 and -003.

The drainage system for the rooms containing redundant ESF equipment are provided with separate drainage subsystems, utilizing independent drain trains (train A and train B), so that flooding of the redundant ESF rooms of one train will not jeopardize the operation of the remaining train of redundant ESF equipment. The two drainage subsystems providing drainage for the ESF equipment rooms are separate from the drains serving the non-ESF equipment rooms.

The ESF drain headers empty into independent and segregated sumps. A separate drain header is provided for the non-ESF equipment which empties into a separate sump. Engineered safety features train A sump, ESF train B sump, and the non-ESF sump are each equipped with two 100%-capacity sump pumps. The sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected waste from the sump to the liquid radwaste holdup tanks.

The maximum normal leakage to the non-ESF sump is estimated at 116 gallons per day. Maximum abnormal leakage to the non-ESF sump is estimated at 10 gallons per minute. The maximum normal leakage to each ESF sump is estimated to be 10 gallons per day. The maximum abnormal leakage to each ESF sump is estimated to be 50 gallons per minute.

The abnormal leakage of 50 gallons per minute conservatively bounds the total leakage from all ESF components, such as pumps, valves, etc. The auxiliary building is sized to accept 400,000 gallons of non-ESF leakage before any leakage would affect ESF components. For flooding considerations, all nonseismic piping was assumed to have failed. The water volume released will not exceed the design 400,000-gallon capacity. The auxiliary building rooms, including the ESF pump rooms on elevation 40, were analyzed for flooding due to rupture of the largest nonsafety-related piping for a duration of 30 minutes. Flooding was also analyzed based on operation of fire protection systems, such as hoses and sprinklers, for 15 minutes without operator action or without operation of the sump pumps.

To assure train separation of ESF equipment necessary for the safe shutdown of the plant, each train-oriented piece of equipment is placed in its own room. These rooms prevent excessive amounts of water, from a tank or pipe rupture, from flooding redundant train-oriented equipment in the building. These rooms are designed to handle a limited duration single failure of the heaviest flowing line in any compartment containing safety-related piping or equipment. A single

failure of any line in an equipment area will affect, at worst, only one train of operation.

Engineered safety features equipment rooms are equipped with Class 1E level switches in leak detecting floor drains. Should a line rupture in the room, the control room would be informed by an annunciator activated by these switches (refer to section 7.6). The auxiliary building drains are run so that leakage external to the ESF equipment room does not flow into the rooms. Each room is protected from backflow by a check valve located in the drain line.

9.3.3.2.1.1.3 Radwaste Building. The radioactive waste drain system within the radwaste building consists of floor and equipment drains, vertical drain risers, sloped horizontal drain pipes, one sump with two 100%-capacity sump pumps, piping, valves, controls, and instrumentation serving the equipment and areas as shown on engineering drawings 01, 02, 03-M-RDP-004.

The maximum normal leakage to the sealed sump is estimated at 12 gallons per day. Maximum abnormal leakage is estimated at 400 gallons per day.

The sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected waste from the sump to the LRS holdup tanks.

The room containing the antifoam, caustic, and acid tanks and pumps has its floor and equipment drains routed to a neutralizer tank prior to draining to the building sump. The neutralizer tank is located in a concrete pit. Its

neutralization medium can either be lump limestone or marble chips with a high calcium carbonate equivalent content in excess of 85%. Since this area of the radwaste building has insignificant potential for radioactive contamination, a trap is installed in the drain line upstream of the neutralizer tank to prevent acidic or caustic fumes from entering the room.

The LRS holdup tanks and the LRS recycle monitor tanks are located outside in the yard adjacent to the radwaste building in concrete compartments that are open to the atmosphere. The floor drains for these compartments are isolated from the radwaste building sump by means of a normally closed valve to prevent rainwater from entering the sump. In the event of a rainstorm, a pipe and closed valve are provided to drain the contained water to ground surface, or the rainwater may be pumped to portable containers and disposed of in accordance with station procedures. A level switch is provided in each compartment which will alarm high level to the radwaste control panel in the event of a leaking or ruptured tank flooding the area. A local sample point is located upstream of the normally closed drain valve to provide an indication of whether the content of the compartment is either rainwater or radioactive waste.

An oil interceptor is provided to prevent the potential oily waste from the controlled machine shop and tool room from entering the LRS system via the building sump. The floor drains and sink are routed to the oil interceptor prior to draining to the sump. An isolation valve is located downstream of the oil interceptor in order to provide for oil removal and maintenance of the oil interceptor.

9.3.3.2.1.1.4 Fuel Building. The radioactive waste drain systems within the fuel building consist of floor and equipment drains, vertical drain risers, sloped horizontal drains, one sump with two 100%-capacity sump pumps, piping valves, controls, and instrumentation serving the equipment and areas as shown in engineering drawings 01, 02, 03-M-RDP-005.

The maximum normal leakage to the sump is estimated at 10 gallons per day. The decontamination washdown of the transfer cask and transportable storage canister is estimated to result in a flow of 200 gallons per minute for a 5-minute operation. The sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected waste from the sump to the LRS holdup tanks.

A leak detection station is provided to monitor leakage through the fuel pool liner plate. The detection system is divided into ten leak chase zones such that a leak in the liner plate can be isolated to a specific zone. The leak chases for each zone are manifolded into one detection test station having a normally closed valve. Provisions are included upstream of the valve to provide helium leak testing of the liner plate in the event leakage is detected at the test station. The test station for each leak chase zone is monitored periodically for leakage.

A leak detection station is provided to monitor leakage through the cask load pit liner plate. The detection system consists of a wet-side leak chase over the floor of the CLP and use of the existing open W6 columns/horizontals behind the liner plate which are utilized to provide the main leak path for wall leakage. The leak chase system drains to one detection test

station having a normally closed valve. Provisions are included upstream of the valve to provide pressurized leak testing of the liner plate in the event leakage is detected at the test station. The test station is monitored periodically for leakage and is adjacent to the test station for the fuel pool.

9.3.3.2.1.1.5 Holdup Tank Area. The radioactive waste drain system within the holdup tank area consists of hardpipe overflow drains from the holdup tank, the reactor makeup tank, the refueling water tank, hardpipe equipment drains, floor drain from the holdup pumps and room, one sump with two 100%-capacity sump pumps, piping, valves, and control and instrumentation as shown in engineering drawings 01, 02, 03-M-RDP-005.

Maximum normal leakage to the sealed sump is estimated at 20 gallons per day. Maximum abnormal leakage is estimated at 200 gallons per minute.

The sump pumps, operating automatically under the control of level instrumentation in the sump, pump the collected waste from the sump to the LRS holdup tanks.

9.3.3.2.1.1.6 Decontamination and Laundry Facilities. The radioactive waste drain system within the decontamination and laundry facilities consists of floor, equipment and sink drains, sloped horizontal embedded drainage pipe, one sump with two 100%-capacity sump pumps, piping, controls, and instrumentation serving equipment and areas as shown in engineering drawing A0-M-RDP-006.

The sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected waste from the sump to the chemical drain tanks of the LRS system.

9.3.3.2.1.1.7 Main Steam Support Structure. The radioactive waste drain system within the main steam support structure (MSSS) consists of floor and equipment drains, vertical drain risers, sloped horizontal drain pipes, valves, and leak detecting instrumentation as shown in engineering drawings 01, 02, 03-M-RDP-002.

Each auxiliary feedwater pump room is provided with a separate drain. Each drainage line to the auxiliary feedwater pump rooms is provided with a check valve so that the flooding of one room will not jeopardize the operation of the redundant train.

A common drain header carries the drainage from the MSSS to the non-ESF sump in the auxiliary building.

The maximum normal leakage from the MSSS drainage is estimated at 5 gallons per day. The maximum abnormal leakage is estimated at 10 gallons per minute.

9.3.3.2.1.2 Chemical Waste System. The chemical waste system consists of five subsystems as follows:

A. The radioactive chemical waste subsystem which collects by gravity the corrosive radioactive waste from the chemical laboratory and decontamination stations.

B. The cooling water waste subsystem which collects by gravity the chemically treated cooling water from the auxiliary and radwaste buildings for reuse or disposal.

C. The condensate polishers regeneration waste subsystem which collects and neutralizes the potentially radioactive waste for disposal. Those wastes exceeding the release limits stated in the Offsite Dose Calculation Manual (ODCM) will be sent to the liquid radwaste system for disposal.

D. The spent regenerant waste subsystem which collects and neutralizes the rinse wastes from the makeup demineralizers for disposal.

E. The chemical tank drains in the yard areas.

Engineering drawings 01, 02, 03-M-CMP-001 and -002 show a piping and instrumentation diagram for the chemical waste system.

9.3.3.2.1.2.1 Radioactive Chemical Waste Subsystem. The radioactive chemical waste subsystem is a gravity collection system and includes only drains and piping as shown in engineering drawings 01, 02, 03-M-CMP-001 and -002.

The subsystem transports the liquid waste and drainage by gravity flow to the chemical drain tanks.

9.3.3.2.1.2.2 Cooling Water Waste Subsystem. The cooling water waste subsystem consists of drains, one cooling water holdup tank, two 100%-capacity cooling water holdup tank pumps, piping, controls, and instrumentation.

Separation and isolation of the drain headers from the ESF rooms are provided along with a separate drain header from the non-ESF rooms.

The system drains into the cooling water holdup tank. Since the cooling water holdup tank is a common collection point, valving is provided to prevent backflooding into the ESF rooms. Two redundant holdup tank pumps take suction from this tank and discharge to the chemical waste neutralizer tanks. Branch lines are provided for diverting the pump discharge to the essential cooling water surge tanks or to the nuclear cooling water surge tanks.

9.3.3.2.1.2.3 Condensate Polishing Demineralizer Waste Subsystem. The condensate polishing demineralizer waste subsystem consists of drains, two condensate polishing demineralizer sumps, each provided with two 100%-capacity sump pumps, two chemical waste neutralizer tanks, each equipped with an agitator, two neutralizer transfer pumps, piping, valves, controls, and instrumentation.

The subsystem collects liquid waste and drainage in the condensate polisher demineralizer sumps. The condensate polisher regeneration waste can be divided into two types: high and low TDS. The high TDS waste is the acid and caustic rinses when chemically regenerating the spent resin. Low TDS results from two operations:

- The final rinsing of the regenerated resin to remove all traces of acid or caustic

- The overflow from the resin cleaning operation which removes particulates from the condensate polisher resins

High TDS waste is collected in one sump, and low TDS waste in the other. The high TDS waste is pumped to the neutralizer tanks. The low TDS waste is normally pumped to the circulating water return line for reuse unless there is radioactive contamination, in which case the water is discharged to the low TDS LRS holdup tanks. The low TDS waste can also be diverted to the neutralizer tanks. The neutralizer tanks also receive waste from the cooling water holdup tank and from the condenser area sumps.

Each neutralizer tank can receive the largest single batch of high and low TDS waste without processing so that a polisher may be regenerated without the necessity of operating the neutralizer transfer pumps.

The neutralizer tanks are provided with acid and caustic supply lines from the acid transfer pumps and the dilute caustic supply lines, respectively. Acid or caustic, as required, is added to the waste in the neutralizer tanks. The neutralized waste is then pumped to the retention tank by the neutralizer transfer pumps. The subsystem also has the capability for diverting the pump discharge to the liquid radwaste holdup tanks.

9.3.3.2.1.2.4 Spent Regenerant Waste Subsystem. The spent regenerant waste subsystem consists of drains, one spent regeneration sump provided with two 100%-capacity sump pumps, piping, valves, controls, and instrumentation.

The major discharge to the sump is the waste from the makeup demineralizers. The waste is treated in accordance with Water Reclamation Facility operating procedures and then pumped to the Water Reclamation Facility clarifier feed sump or the trickling filter sump emergency overflow. During Water Reclamation Facility (WRF) outages or emergencies, this wastewater can bypass the WRF clarifier feed sump or the trickling filter sump emergency overflow and be fed directly into the wet dry sump which feeds the 45 acre/or 85 acre reservoirs.

9.3.3.2.1.2.5 Yard Area Chemical Tank Drains Subsystem. The yard area chemical tanks and pumps, which are located outside, are installed on concrete slabs with retaining curbs. Small sumps are provided inside to collect equipment leakage. Portable pumps or disposal tankers are used to dispose of the effluent.

9.3.3.2.1.3 Oily Waste and Nonradioactive Waste System. The oily waste and nonradioactive waste (OW) system collects and transports liquid waste from equipment and floor drains of the turbine building, the control building, the diesel generator buildings, the fire pumphouse, and the yard area.

The system removes entrained oil from the wastewater for disposal and conveys the oil-free water to the evaporation pond.

Engineering drawings 01, 02, 03-M-OWP-001, -002, -003, A0-M-TBP-003 and A0-M-OWP-004 show piping and instrumentation diagrams for the oily waste and nonradioactive waste system.

9.3.3.2.1.3.1 Turbine Building. The OW system within the turbine building consists of floor drains, equipment drains, one turbine building sump with two sump pumps, two condenser area sumps with two sump pumps each, one turbine building oil/ water separator, one oil/water separator sump with two sump pumps, piping, valves, instrumentation, and controls.

The maximum normal leakage to each condenser sump is estimated at 380 gallons per day. The maximum normal leakage to the turbine building sump is estimated at 170 gallons per day.

Sump pumps, operating automatically under control of level instrumentation in each sump, pump the collected wastes from the sumps into a common discharge header. The discharge header normally conveys the wastes to the turbine building oil/water separator, but lines are provided for diverting the flow to either the chemical waste neutralizer tank or to the liquid radwaste system holdup tanks when required by the presence of chemicals or radioactivity greater than the Offsite Dose Calculation Manual (ODCM) release limits in the wastes.

The oil/water separator receives effluent from the turbine building and condenser area sump pumps, the control building sump pumps, and the diesel generator building sump pumps. The oil/water separator is a gravity and coalescing separator system for removing free dispersed, and mechanical emulsified oils from water.

The wastewater from the turbine building oil/water separator gravity flows into the oil/water separator sump.

Sump pumps, operating automatically under control of level instrumentation in the sump, pump the wastewater to the duplex

retention tank. A duplex retention tank is provided to act as a storage tank in the event the effluent is not within standards for pH, Hydrazine, and radioactivity prior to discharge to the evaporation pond. The radioactivity standard is the release limits in the ODCM. The retention tank also serves to retain the wastes in order to allow treatment to remove chromates when present.

In addition, the retention tank, along with the low TDS sumps and the chemical waste neutralizer tank, provide samples for radioactivity tests if online radiation monitors for the condenser air removal system or steam generator indicate primary-to-secondary leakage. If radioactivity greater than the release limits in the ODCM is present in the wastes, they will be sent to the liquid radwaste system for processing.

When the chemistry of the waste in one section of the retention tank is acceptable, or has been treated to make it acceptable, the pumps are manually started and discharge valves aligned to pump the waste from the retention tank to the evaporation ponds. The pumps are normally started manually, but stop automatically on low level signal from level instrumentation in the tank.

A connection for a temporary (portable) ion exchanger is provided in the unlikely event that radioactivity (i.e., activity greater than the ODCM release limits) is detected in one of the retention tanks: In this situation the effluent is pumped through a portable ion exchanger and returned to the other retention tank where it is eventually discharged to the evaporation pond.

9.3.3.2.1.3.2 Control Building. The OW system within the control building consists of floor drains, equipment drains, two control building sumps with two sump pumps each, piping, valves, instrumentation and controls serving the equipment and areas shown in engineering drawings 01, 02, 03-M-OWP-001, -002, -003 and A0-M-OWP-004.

Waste from the battery rooms flows through an acid neutralizer sump before flowing to the control building sumps.

The maximum normal leakage to the west sump is estimated at 1000 gallons per day. The maximum normal leakage to the east sump is estimated at 275 gallons per day.

Sump pumps, operating automatically under control of level instrumentation in the sumps, pump the collected wastes from the two sumps into a common discharge header, which conveys the wastes to the turbine building oil/water separator.

Wastes from the train A and train B cable spreading rooms do not flow to the control building sumps. These areas are each drained separately to the outside area.

9.3.3.2.1.3.3 Diesel Generator Building. The OW system within the diesel generator building consists of floor drains, equipment drains, the diesel generator west building sump with two sump pumps, piping, valves, instrumentation, and controls serving the equipment and areas as shown in engineering drawings 01, 02, 03-M-OWP-004 and A0-M-OWP-004.

The maximum normal leakage to each sump is estimated at 15 gallons per day.

Sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected wastes from the sump to the oil/water separator via the discharge headers of the control building sump pumps.

9.3.3.2.1.3.4 Fire Pumphouse. The OW system for the fire pumphouse consists of floor drains, equipment drains, an oil/water separator, the fire pumphouse sump with two sump pumps, and piping, valves, controls, and instrumentation.

This subsystem is entirely separate from the other parts of the OW system.

The wastes from the floor and equipment drains flow to the fire pumphouse oil/water separator. The wastewater flows from the oil/water separator to the fire pumphouse sump.

The sump pumps, operating automatically under control of level instrumentation in the sump, pump the wastewater from the sump to the spent regenerant sump.

9.3.3.2.1.3.5 Yard Area. The OW system in the yard area consists of equipment drains, one sump with two sump pumps, piping, valves, instrumentation, and controls.

The yard area sump normally receives drainage and liquid waste from the following equipment and areas:

- Demineralized water storage tank and pumps
- The abandoned auxiliary boiler and deaerator area
- Turbine building normal air handling units at elevation 100’

The maximum normal input to the yard sump is approximately 30 gallons per minute of domestic water which is based upon a maximum continuous flow of 5 gallons per minute per normal air handling unit.

Sump pumps, operating automatically under control of level instrumentation in the sump, pump the collected effluent from the sump to the circulating water intake structure.

9.3.3.2.1.3.6 Roof Drainage. Except for turbine building roof drains, water resulting from precipitation is collected on all building roofs and open areaways within the buildings and is conveyed to the storm drainage. Turbine building roof drainage and Turbine building normal air handling units at elevation 176’ can be aligned to drain to the CW System intake canal or yard sump.

9.3.3.2.1.3.7 Storm Drainage. Except for the Turbine building roof drains rainwater from the roof drainage and surfaces outside the building is collected and conveyed to the natural site drainage. Turbine building roof drainage and Turbine building normal air handling units at elevation 176’ can be aligned to drain to the CW System intake canal or yard sump.

9.3.3.2.1.4 Sanitary Drainage and Treatment System. The sanitary drainage and treatment system consists of drains, drain piping, one wet well, one sewage lift station, one surge tank, three package sewage treatment plants, one chlorine contact chamber, one sanitary waste water sump with two sump

pumps, and piping, valves, controls, and instrumentation as shown in engineering drawing A0-M-STP-001.

The sanitary waste flows from facilities throughout the plant to the wet well at the sewage lift station. The wet well is equipped with bar screens and air bubblers. The bubbler level control system has been abandoned in place and their function has been replaced by a more advanced level control system.

Two vertical centrifugal dry pit type pumps, taking suction from the wet well, transfer the waste to the surge tank.

In the surge tank, the waste is again aerated by a bubbler system, and two submersible type surge pumps transfer the waste to a stilling well located in the surge tank. From the stilling well, three airlift pumps transfer the waste to the three package sewage treatment units.

In the sewage treatment unit, the waste is treated and clarified. The sludge is removed by air lifts, and the clarified wastewater overflows a weir into the discharge line which transports it to the chlorine contact chamber.

In the chlorine contact chamber, the wastewater is chlorinated (only when the effluent is pumped to the retention tanks) and overflows a weir into a discharge line which conveys it to the sanitary wastewater sump.

Two sump pumps, operating automatically under control of level instrumentation in the sump, pump the wastewater from the sanitary wastewater sump to the water reclamation plant for further treatment and reuse. If the water reclamation plant is not in service, the effluent is pumped to the retention tanks.

9.3.3.2.2 Component Description

9.3.3.2.2.1 Cleanouts. Cleanouts are provided, when practicable, where the change in direction in horizontal lines is 90 degrees, at offsets where the aggregate change is 135 degrees or greater, and at maximum intervals of 50 feet. Cleanouts are welded directly to the piping and are located with their access covers flush with the finished floor.

9.3.3.2.2.2 Floor Drains. All floor drains are installed with their rims flush with the low point elevation of the finished floor. Floor drains in areas of potential radioactivity are welded directly to the collection piping. Floor drains in areas not restricted, due to potential radioactivity, are provided with caulked or threaded connections.

9.3.3.2.2.3 Equipment Drains. Equipment vent and drain lines control valve station vent and drain lines handling radioactive fluids are welded directly to the collection piping. High point vents and low point drains of process piping handling radioactive fluids, when utilized, are routed to the collection piping with flexible hoses. Drain lines from equipment that may be pressurized during drainage, and where the flow is by a direct or indirect connection to the floor drain system, are equipped with valves that may be throttled, so that the equipment discharge flow will not exceed the gravity flow capacity of the drainage header at atmospheric pressure.

9.3.3.2.2.4 Traps. Inlets to chemical drainage systems, and sanitary sewage treatment systems, except those in areas of potential radioactivity and those in storm drainage, are provided with a water seal in the form of a vented P-trap to minimize entry into the building of vermin, foul odors, and toxic, corrosive, or flammable vapors. Air pressure vent lines to the outside atmosphere are provided downstream of the P-traps to prevent excessive backpressures that could cause blowout or siphonage of the water seal. Traps are not installed at inlets in areas of potential radioactivity in order to preclude either a potential for an accumulation of radioactivity in the trap or difficult maintenance of seal water level.

9.3.3.2.2.5 Collection Piping. In areas of potential radioactivity, the collection system piping for the liquid system is stainless steel. Potentially radioactive chemical waste and detergent waste collection system piping is stainless steel. Where necessary to vent potentially radioactive liquid waste collection systems, connections are provided to the gaseous radwaste system. Offsets in the piping are provided where necessary for radiation shielding. The fabrication and installation of the piping provides for a uniform slope that induces waste to flow in the piping at a velocity of not less than 2 feet per second. Equipment drainage piping is terminated not less than one and one-half nominal pipe diameters above the finished floor or drain receiver at each location where the discharge from equipment is to be collected, except in locations where hose manifolds are installed. The

final connections are made after the equipment is installed in its proper location.

Note: Drain manifolds 13MRDNM01 – 13MRDNM18 discharge into the floor drains below floor grade, a minimum of 1” above the highest level of the floor drain pipe (collection piping). Plant systems will be connected to the drain manifolds via hoses.

9.3.3.2.2.6 Pumps. Redundant sump pumps are provided in each sump. Individual pump capacities are determined by the expected normal maximum inflow from the associated drainage subsystem. Alternating dual pumps are employed to even wear and eliminate operator responsibility for manual alternating of pumps. Sump pumps are designed to discharge at a flowrate adequate for preventing sump overflow during normal anticipated drainage periods. Normal drainage is that drainage expected to occur from equipment maintenance, leakage, and washdown during normal plant operation. The sump pump operating conditions are tabulated in table 9.3-8.

9.3.3.2.2.7 Collection Sumps. Drains located at a higher elevation than the designated receiving tanks are conveyed by gravity directly to the receiving tanks. All other drainage is conveyed by gravity to sumps and then is pumped to the appropriate receiving station.

Sump capacities provide a minimum active storage volume equal to at least the volume required for the operation of one pump for 5 minutes.

The various sump dimensions and capacities are tabulated in table 9.3-9.

9.3.3.3 Systems Operation

9.3.3.3.1 Sump Pumps

Each sump is equipped with two duplex type sump pumps with the exception of the containment radwaste east and west sumps. However, the containment radwaste east and west sumps are interconnected with a 4-inch pipe that serves to treat both sumps as one.

The sump pumps are controlled by one control displacer type level switch per sump. When the sump level rises to a preset point, the pump selected by the alternator is started by the displacement action of the level switch. If the level continues to rise, a second displacer starts the second pump.

Failure of one pump to start will not prevent the second pump from starting. If the level continues to rise, a separate high-high level switch is incorporated in the design to activate an annunciator in the control room advising the operators that a flooding condition is imminent. After the pumps lower the level to a point just above the pump suction, a third displacer on the control level switch stops both pumps.

9.3.3.3.2 Radioactive Waste Drainage System

The radioactive waste is gravity drained directly to the respective sumps. Sump pumps are started automatically when a predetermined high level in the sump is reached. The waste

effluent is pumped to the LRS holdup tanks for processing and reuse.

9.3.3.3.3 Radioactive Chemical Waste Subsystem

The radioactive chemical waste subsystem is designed to gravity flow directly to the chemical drain tanks.

9.3.3.3.4 Cooling Water Waste Subsystem

The chemically treated cooling water waste is gravity drained directly to the cooling water holdup tank. When the liquid contents of the tank reach a preset level, a high level switch will alarm in the control room. A sample is taken of the tank contents to determine if radioactivity is present. The system is normally aligned to transfer the contents of the tank to the chemical waste neutralizer tanks. The pumps are manually started and will be automatically stopped by a low-low level signal from the holdup tank. The pumps can also be manually stopped.

In addition to collecting leakage, the system operates, during maintenance of plant equipment containing chemical treated cooling water, to accept drainage from such equipment. The holdup tank is sized to hold the capacity from the equipment item having the largest volume of cooling water. Piping is provided to the surge tanks of the essential cooling water system - train A and train B, and the nuclear cooling water system, for use only during maintenance, to return cooling water drained from equipment to the appropriate cooling water loop.

Table 9.3-8
SUMP PUMP OPERATING CONDITIONS (Sheet 1 of 2)

Sump Pump	Flow (gal/min)	Total Differential Head	Location Bldg	Location Elevation (ft)
Reactor cavity	30	45	Containment	55
Auxiliary building ESF (train A)	50	110	Auxiliary	40
Auxiliary building ESF (train B)	50	110	Auxiliary	40
Auxiliary building non-ESF	50	110	Auxiliary	40
Radwaste building	50	65	Radwaste	88
Fuel building	100	65	Fuel	100
Control building (west)	50	65	Control	74
Control building (east)	50	65	Control	74

9.3.3.3.5 Condensate Polishing Demineralizer Waste Subsystem

Rinse washes from the condensate polishing demineralizers are automatically sent to the high or low TDS sumps as determined by conductivity. The rinse water can also be sent directly to the retention tank by manually lining up the condensate polisher pre-service rinse overboard line. Low conductivity waste is routed to the low TDS sump and high conductivity waste is routed to the high TDS sump. Conductivity values to determine High and Low TDS are included in station operating procedures. Each sump is equipped with dual pumps and level instrumentation to actuate the lead pump upon high level. The level switch assembly will start (and stop) the pump alternately by a contact closure on rising level at a preset high level, and stop on opening of the same contact on decreasing level at a preset low level.

The low TDS waste is normally pumped to the circulating water return line.

In the event the low TDS waste becomes radioactive due to steam generator leakage, manually operated valves are provided to reroute the waste effluent to the low TDS LRS holdup tank or high TDS LRS holdup tank. Radioactivity in the secondary side is detected by monitoring the air condenser removal system or steam generator by use of online radiation monitors. When these monitors indicate a steam generator tube leakage, periodic samples of the low TDS sump are taken for analyses. Should the activity level exceed a predetermined level, the low TDS sump is manually diverted to the liquid radwaste system.

The high TDS waste is pumped directly to one of the two chemical waste neutralizing tanks. The pH of the waste and the radioactivity in the tanks are determined by analysis of samples taken manually from a sampling point valve on each tank. The high TDS waste is neutralized on a batch basis, by injection of concentrated acid or caustic solution into each tank.

After neutralization the waste can be gravity drained from the waste tanks to the retention tank, or the neutralizer transfer pump can be manually started to pump the waste to the retention tank. The pump discharge can be manually valved to divert the neutralized waste to the liquid radwaste system holdup tanks in the event the waste exceeds the release limits stated in the Offsite Dose Calculation Manual (ODCM).

The low-low level switch is interlocked with the pumps' suction crossover valve. When the crossover valve is closed, each pump shuts off automatically by its associated low-low level switch. When the crossover valve is open, a low level in either tank will automatically stop both pumps. Both pumps can also be manually shut off.

9.3.3.3.6 Spent Regenerant Waste Subsystem

Rinse washes from the makeup demineralizers are automatically sent to the spent regenerant sump. The sump is equipped with dual pumps and level instrumentation to actuate the lead pump upon high level. The level switch assembly will start (and stop) the pump alternately by a contact closure on rising level at a preset high level, and stop by opening the same contact on decreasing level at a preset low level.

The waste collected in the sump is treated in accordance with Water Reclamation Facility operating procedures and then pumped to the Water Reclamation Facility clarifier feed sump or the trickling filter sump emergency overflow. During Water Reclamation Facility (WRF) outages or emergencies, this wastewater can bypass the WRF clarifier feed sump or the trickling filter sump emergency overflow and be fed directly into the wet dry sump which feeds the 45 acre/or 85 acre reservoirs.

9.3.3.3.7 Yard Area Chemical Tank Drains Subsystem

The yard area chemical tanks and pumps are located outside on concrete slabs and surrounded by concrete curbs that function as secondary containments. Small sumps are provided inside the secondary containments to collect the equipment drainage. In the event of rain, equipment drainage, or chemical spills, the collected liquids will be removed from the secondary containment according to environmental requirements or procedures. The removal of the liquids may be through pumping or through an embedded drainpipe.

9.3.3.3.8 Oily Waste and Nonradioactive Waste System

The oily waste and nonradioactive waste system collects in sumps, via equipment drains and floor drains, nonradioactive waste from the diesel generator building, turbine building, and the control building and pumps the waste to an oil/water separator. Each turbine building sump is provided with valving for diverting the flow to either the chemical waste neutralizer tank or to the LRS holdup tanks when required by the presence

of chemicals or radioactivity in the waste. Waste is pumped to the LRS holdup tanks when activity levels are greater than the release limits in the Offsite Dose Calculation Manual (ODCM).

From the oily/water separator, after the oil is removed, the clarified effluent is pumped to the retention tanks. A divided retention tank is provided to act as a storage tank in the event the effluent is not within standards for pH, conductivity, and radioactivity prior to discharge to the evaporation pond. The standard for radioactivity is the release limit values in the Offsite Dose Calculation Manual (ODCM). The waste water in the first section is treated as required until its chemistry is acceptable for discharge to the evaporation pond. When the chemistry is acceptable, the waste water is pumped to the evaporation pond by manually starting the retention tank pump and aligning the discharge valves. A line is also provided for recirculating the waste from the pump to the supply end of the retention tank if required for mixing during treatment.

9.3.3.3.9 Sanitary Sewage and Treatment System

The liquid waste and entrained solids discharged by all plumbing fixtures located in areas not restricted due to potential radioactivity are conveyed by gravity to the onsite sewage treatment facility.

9.3.3.4 Safety Evaluations

The safety evaluations pertinent to the equipment and floor drainage systems are as follows:

A. Safety Design Basis One

   Equipment and floor drainage provided for each ESF equipment compartment are not interconnected to any other equipment or floor drainage unless check valves are utilized to prevent cross-flow.

B. Safety Design Basis Two

   Each ESF equipment room drainage system is equipped with backflow check valves.

9.3.3.5 Radiological Considerations

The radiological considerations for normal operation and accidents are discussed in sections 11.2, 11.3, and 12.3.

9.3.3.6 Tests and Inspections

9.3.3.6.1 Preoperational Testing

All waste collection systems from areas of no radioactivity potential are tested for 15 minutes at a hydrostatic test pressure equal to a 10-foot head of water. All collection systems from areas with a radioactivity potential are tested to 75 psig in accordance with ANSI B31.1.0, Power Piping, dated 1967.

9.3.3.6.2 Operational Testing Capability

The operability of equipment and floor drainage systems dependent on gravity flow can be checked by normal usage. Portions of these systems, dependent upon pumps to raise liquid waste to gravity drains, may be checked through instrumentation and alarms in the control room.

9.3.3.7 Instrumentation Application

Seismic Category I level alarms are provided for those safety feature sumps in the auxiliary building that serve safety feature pump rooms as described in paragraph 7.6.1.1.3.3. High temperature alarms and high level indication, in addition to the level-operated switch used for pump control, are provided for all sumps in the containment and the auxiliary building to provide backup indication of the presence of large leaks and to provide information as to the source. Level alarm is provided for all other sumps as well. Level alarms are displayed and monitored in the control room.

9.3.4 CHEMICAL AND VOLUME CONTROL SYSTEM

The following system description incorporates all of the critical licensing attributes of the Chemical and Volume Control System (CVCS) formally contained in CESSAR and CESSAR SER section 9.3.4. Since the following text now contains all of the current licensing commitments, the subject portions of the CESSAR and CESSAR SER are superseded and are no longer considered part of the active licensing basis.

9.3.4.1 Design Bases

9.3.4.1.1 Functional Requirements

The Chemical and Volume Control System (CVCS) is designed to perform the following functions:

A. Maintain the chemistry and purity of the reactor coolant during normal operation and during shutdowns;

B. Maintain the required volume of water in the Reactor Coolant System (RCS) compensating for reactor coolant contraction or expansion resulting from changes in reactor coolant temperature and for other coolant losses or additions;

C. Receive, store, separate, and process reactor grade, borated waste for reuse or discharge.

D. Control the boron concentration in the RCS to obtain optimum Control Element Assembly (CEA) positioning and compensate for reactivity changes associated with major changes in shutdown margin for maintenance and refueling operations;

E. Provide auxiliary pressurizer spray for operator control of pressurizer pressure whenever main sprays were not available and to provide a means for pressurizer cooling;

F. Provide a means for functionally testing the check valves that isolate the Safety Injection System (SIS) from the RCS;

G. Provide continuous measurement of reactor coolant fission product activity;

H. Provide seal injection water at the proper temperature, pressure, and purity for the reactor coolant pumps' seals and collect the controlled bleed-off;

I. Leak test the RCS;

J. Supply demineralized reactor makeup water to various auxiliary equipment;

K. Provide a means for sluicing ion exchanger resin to the Solid Radwaste System (SRS);

L. Provide a means for continuous removal of noble gases from the RCS;

M. Provide a source of borated water for engineered safety feature pump operation;

N. Provide makeup to the spent fuel pool;

O. Provide purification of shutdown cooling flow;

P. Provide makeup for losses from small leaks in RCS piping.

9.3.4.1.2 Design Criteria

The CVCS is designed in accordance with the following criteria:

A. The CVCS is designed to accept letdown and provide makeup in response to changes in reactor coolant volume resulting from normal plant heatup and cooldown. Rates of temperature change are administratively controlled within the CVCS capacity to maintain pressurizer level within Technical Specification limits.

B. The CVCS is designed to supply makeup water or accept letdown to support 10% step power increases between 15% and 90% of full power, 10% step power decreases between 100% and 25% of full power, and ramp changes of ±5% of full power per minute between 15 and 100% power.

C. The CVCS Volume Control Tank (VCT) is sized with sufficient capacity to accommodate the inventory change resulting from a 100% to 0% power decrease (reactor trip) with no makeup system operation, assuming that the VCT level is initially in the normal operating level band.

D. The CVCS provides a means for suitably controlling the concentration of radioactivity in the reactor coolant:

- The CVCS is operated as required to maintain the Technical Specification limits on RCS specific activity in order to ensure offsite dose consequences from postulated accidents are bounded by the analyses in Chapter 15. The operational limit for Dose Equivalent Iodine-131 corresponds to nominal ~0.2% failed fuel at steady-state, full power conditions.

- Nominal CVCS performance was credited in the calculation of expected RCS radionuclide concentrations used to evaluate the effectiveness of radwaste treatment systems and plant shielding design in Chapters 11 and 12, respectively. The analyses conservatively assume continuous full power operation with 1.0% failed fuel.

E. The CVCS is operated to maintain reactor coolant chemistry within the limits specified in the EPRI PWR Primary Water Chemistry Guidelines, as endorsed by NEI 97-06, Steam Generator Program Guidelines.

F. Letdown and charging portions of the CVCS are designed to withstand the design transients defined in Table 3.9-1 without any adverse effects.

G. The CVCS has the capacity to accommodate all liquid wastes generated due to the operations identified in Section 9.3.4.4.10.

H. The CVCS is designed to provide 30 GPM of filtered flow to the reactor coolant pump seal cavities and to accept a 22 GPM controlled bleed-off flow.

I. Components of the CVCS are designed in accordance with the requirements for the safety class and seismic class specified in Table 3.2-1. The applicable design codes are identified in that table as well.

J. The environmental design conditions of the CVCS components are given in Section 3.11.

K. The CVCS is designed to operate with no boric acid concentration above the point where precipitation could occur. The boric acid batching tank and the boric acid concentrator concentrate discharge line to the SRS are the only portions of the system requiring heat tracing to preclude boric acid precipitation. These portions of the system can contain fluid concentrated to 12 weight percent boric acid. The remaining portions of the system contain a lower boric acid concentration solution

(less than 4400 ppm) so heat tracing to prevent precipitation is not required.

L. The CVCS is configured as shown in engineering drawings 01, 02, 03-M-CHP-001, -002, -003, -004 and -005.

M. As described in UFSAR 9.3.4.4.11, the charging subsystem has a capacity sufficient to replace the flow lost to the containment due to breaks in small RCS lines, such as instrument and sample lines.

N. The CVCS is designed to receive discharges from drains and relief valves in the RCS, SIS and SCS.

O. The CVCS provides for boron concentration adjustment in the Reactor Coolant System by feed and bleed. The maximum possible rate of boron dilution is limited, such that the operator has sufficient time to identify and terminate a boron dilution incident prior to reaching criticality during any refueling operations.

P. The CVCS provides an emergency boration capability for recovery of lost shutdown margin (SDM). As described in the basis of the Technical Specifications, the CVCS can nominally add 1% $\Delta k/k$ of negative reactivity in less than 4 hours.

Q. The CVCS boric acid reserve is sufficient to make the reactor subcritical in the cold condition with the most reactive CEA withdrawn.

R. The CVCS is designed so that the minimum volume of borated water available in the Refueling Water Tank (RWT) is sufficient to support Emergency Core Cooling

System (ECCS) and Containment Spray System (CSS) operation as described in the Technical Specifications bases.

S. The CVCS has been designed with the appropriate vents, drains, connections and other provisions necessary to permit the performance of inservice testing and inspection of Safety Class components in accordance with ASME OM Code and Section XI programs described in Technical Specifications.

T. The CVCS design supports the plant capability for conducting a natural circulation cooldown in accordance with the requirements of Branch Technical Position (BTP) RSB 5-1 for a Class 2 plant.

9.3.4.2 System Description

The normal process flow paths through the CVCS may be traced on the Piping and Instrumentation Diagrams, 01, 02, 03-M-CHP-001, -002, -003, -004 and -005.

9.3.4.2.1 Process Overview

Letdown originates from the suction of reactor coolant pump 2B and passes through a letdown delay "coil," actually two parallel sections of large diameter pipe. The resulting reduction in flow velocity provides sufficient delay to ensure that N-16 gamma emissions have a negligible contribution to the external dose rate of letdown piping outside the containment. Letdown then flows through two inboard, air-operated isolation valves in series before entering the tube side of the

Regenerative Heat Exchanger. To enhance reliability, solenoids for the isolation valves receive control power from opposite trains of class 1E electrical service. The Regenerative Heat Exchanger provides the initial process temperature reduction before letdown flow reaches the containment penetration. Outside of containment, the fluid passes through an outboard, class-powered, air-operated isolation valve and goes to the letdown control valves.

There are two letdown control valves arranged in parallel, only one of which is normally in service during power operation. A warm-up bypass line around the control valves is provided for re-establishing letdown flow after its isolation and cooldown. The in-service letdown control valve adjusts flow rate based on input from the Pressurizer Level Control System (PLCS) to help keep pressurizer level at setpoint. In addition, flow through the valve also reduces process pressure within the operating range of the letdown heat exchanger. By rejecting heat to the Nuclear Cooling water system, the letdown heat exchanger provides a final reduction of temperature to that suitable for purification subsystem operation. Downstream of the letdown heat exchanger are two letdown backpressure control valves arranged in parallel. Normally, only one backpressure control valve is in service. It controls intermediate or "back" pressure to ensure that the piping between the letdown and backpressure control valves is adequately subcooled.

The properly conditioned flow then passes through a mechanical filter, one of three parallel ion exchangers, and an effluent strainer to remove resin fines. After filtration, but prior to demineralization, a portion of the flow also goes through the

Boronometer* (abandoned in-place) and by the Process Radiation Monitor. Flow valve CH-204 located in the main letdown line is automatically controlled to ensure that the minimum flow is provided to the process instruments. The processed letdown goes directly into the Volume Control Tank via the three-way valve CH-500. This valve is normally aligned to the VCT but will automatically divert letdown to the Holdup Tank upon high-high VCT level. The VCT inlet valve may also be manually repositioned to support reactor feed and bleed for adjustment of reactor coolant reactivity, inventory, and chemistry. In addition to letdown, the VCT also receives the reactor grade controlled bleed-off flow from the reactor coolant pump seals. The seal vendor has calculated that the design controlled bleed-off flow rate (total seal outflow) for all four pumps combined is 12.0 gpm at steady state and 13.6 gpm under transient conditions.

The VCT is maintained with a nominal 15-25 psig hydrogen overpressure to promote dissolution of hydrogen in letdown for the purpose of oxygen scavenging in the reactor coolant. The letdown flow enters the VCT via a spray nozzle to enhance mixing of the process fluid with the gas overpressure. The pressure of hydrogen (or nitrogen during shutdown conditions) is controlled by adjustment of a supply pressure regulation valve side or a discharge isolation valve, which allows venting of excess gas to the Gaseous Radwaste System (GRS) surge header.

Diverted letdown normally passes through the Pre-Holdup Ion Exchanger (PHIX) and the Gas Stripper prior to its direction to the Holdup Tank (HUT). Under normal conditions, the PHIX

inlet/bypass valve is positioned to bypass the PHIX. The PHIX is normally loaded with a mixed bed to remove ionic impurities, including radionuclides, prior to their concentration in the boric acid recovery subsystem. The resins are normally both lithiated and borated to prevent pH or reactivity changes in the coolant. Once the VCT inlet valve shifts to the divert position on high VCT level, letdown flow will be automatically directed through the PHIX. In addition, the PHIX may be manually aligned to process the contents of the Holdup Tank, Reactor Drain Tank, or Equipment Drain Tank, if necessary. The PHIX may also be bypassed if not required for chemistry control.

Flow through or around the PHIX may then pass through the Gas Stripper where hydrogen, gaseous fission products, and other non-condensable gases are removed with high efficiency. Stripping may be used to preclude the buildup of explosive gas mixtures in the Holdup Tank, minimize the release of radioactive fission product gases, and also to limit the concentrations of dissolved gases in the reactor coolant during startup and shutdown. Normally, the degassed liquid is automatically pumped from the Gas Stripper to the Holdup Tank. In the event that the Gas Stripper is not available, up to 20 minutes of full flow letdown may be directed into the Equipment Drain Tank. If gas stripping is not required, the Gas Stripper may be bypassed using a manual valve alignment. When continuous degasification of the RCS is desired, the letdown flow is diverted from the VCT to the Gas Stripper and then returned to the VCT. Sufficient hydrogen absorption

occurs via the Volume Control Tank hydrogen overpressure to replace the hydrogen removed during the gas stripping process.

The radioactive water processing subsystem also contains the Reactor Drain Tank (RDT) and Equipment Drain Tank (EDT). Reactor coolant quality water from equipment and valve (pressurizer spray control and bypass valve) leakoffs, drains, and reliefs within the containment are collected in the RDT. Recoverable reactor coolant quality water outside the containment from various equipment leakoffs, reliefs, and drains are collected in the EDT. The contents of the RDT and EDT are periodically pumped to the Holdup Tank using the Reactor Drain Pumps on a batch basis through the reactor drain filter, pre-holdup ion exchanger, and gas stripper, if necessary. Diverted letdown flow has priority over processing of the RDT, EDT, or the HUT. Once diversion occurs, the Reactor Drain Pumps and Holdup Pumps (only if CH-686 is open) are automatically secured.

When a sufficient volume accumulates in the Holdup Tank, the contents are pumped by one of two holdup pumps to the Boric Acid Concentrator in the boron recovery subsystem. If abnormal quantities of radionuclides or chemical impurities are present, the Holdup Tank contents may be recirculated back through the pre-holdup ion exchanger for further cleanup. Concentrator bottoms are continuously monitored for proper boron concentration and are normally pumped directly to the Refueling Water Tank when the bottoms reach 4000-4400 ppm boron. In the event that chemical impurity or radionuclide concentrations are too high, the bottoms may be processed further in the Liquid Radwaste System (LRS). If additional processing is not

economical, the bottoms are concentrated to 12 wt percent boric acid and discharged to the Solid Radwaste System (SRS) for disposal. The vapor from the boric acid concentrator is condensed and cooled into a distillate, which then passes through a boric acid condensate ion exchanger to remove boric acid carryover. The distillate is collected in the Reactor Makeup Water Tank for reuse in the plant. If recycle is not desired, concentrator vapor may be directed to the Plant Vent for discharge to the atmosphere, or the distillate may be diverted to the LRS.

The inventories stored in Refueling Water Tank (RWT) and Reactor Makeup Water Tank (RMWT) are reused as reactor coolant makeup. Boric acid solution in the RWT is supplied via the Boric Acid Makeup Pumps while the reactor makeup water in the RMWT is supplied via the Reactor Makeup Water Pumps. The normal makeup control system has four operational modes. Except for the automatic mode, the makeup water may be lined up to the VCT via CH-512 or directly to the charging pump suction via the VCT bypass valve CH-527. In the dilute mode, a preset quantity of reactor makeup water is introduced at a preset rate. In the borate mode, a preset quantity of boric acid is introduced at a preset rate. In the automatic mode, a preset blended boric acid solution from both tanks is automatically introduced into the Volume Control Tank upon demand from the VCT level controller. The preset solution concentration is adjusted periodically by the operator to match the existing boric acid concentration in the RCS so that makeup for lost RCS inventory produces no net reactivity effect on the reactor core. The manual mode is used as an alternate method for

accomplishing all of the makeup functions. In the manual mode, the flow rates of the reactor makeup water and the boric acid can be preset to give a blended boric acid solution with a concentration between zero and that in the RWT (4000-4400 ppm).

Boron may be added to the RWT using the boric acid batching tank (BABT). Reactor makeup water is first added to the BABT via the Reactor Makeup Water Pumps. After the fluid has been heated by electric immersion heaters, boric acid powder is added to the heated fluid while the solution is agitated by a mechanical mixer. Concentrations as high as 12 weight percent can be prepared. Immersion heaters and heat tracing of both the batching lines and the piping downstream of the eductor maintain the temperature of the batched solutions high enough to preclude precipitation. The level and/or boron concentration of the RWT is increased by drawing boric acid solution from the BABT into the RWT return flow by directing either the Boric Acid Makeup Pump or Reactor Makeup Water Pump discharge as motive flow through the boric acid batching eductor.

Of the three parallel charging pumps, two are normally in service taking suction from the Volume Control Tank and delivering that inventory to the RCS. With two pumps running, the design charging pump discharge rate or "total charging flow" is 88 gpm. With the pump controls in automatic, signals from the PLCS may automatically secure a running charging pump or start another (third) charging pump in order to maintain pressurizer level. Seal injection water is supplied to the Reactor Coolant Pump seal packages by diverting a portion of

the total charging flow upstream of the outboard containment isolation valve.

The seal injection flow is filtered and monitored for proper temperature prior to distribution to the Reactor Coolant Pump seals. The nominal flow rate is 6.6 gpm per RCP with the typical flow varying between 6.0 and 7.5 gpm. The combined nominal flow through the four RCPs is 26.4 gmp, and the design flow is 30 gpm. A Chemical Addition Tank and Chemical Addition Metering Pump are used to transfer chemical additives to charging downstream of the seal injection diversion. A separate connection is provided for the injection of hydrogen gas directly into the charging line. Isolation of the charging line containment penetration is provided by a class-powered, motor-operated outboard valve and by an inboard check valve. The motor-operated outboard valve is normally open and de-energized to ensure the functionality of charging following a transient.

The charging fluid (approximately 62 gpm) goes to the shell side of the regenerative heat exchanger to recover some heat from the letdown fluid before introduction into the RCS on the discharge side of Reactor Coolant Pump 2A. The nominal temperature of the heat exchanger charging side outlet is 455°F. Some portion of the return flow may also be manually directed to the auxiliary pressurizer spray. The charging line contains a differential pressure (backpressure) control valve in series with an isolation valve and in parallel with a spring-loaded check valve. In case the differential pressure control loop fails, the isolation valve can be closed forcing charging flow through the spring-loaded check valve. The

setpoints of the differential pressure controller and the spring-loaded check valve ensure that return backpressure is sufficient to maintain functionality of auxiliary pressurizer spray and seal injection.

The majority of the CVCS was designed to contain borated water solutions of 3.6% by weight. The exceptions include the BAC bottoms and the boric acid batching equipment, which are designed for 12% boric acid solutions, and the dilute makeup portions, which are designed for demineralized water. The latter would include the RMWT, the RMW pumps, and associated piping. The components and piping associated with the BAC distillate pathway are designed to accommodate 10 ppm boron solutions.

All of the major CVCS components in Table 9.3.4-2 are fabricated from austenitic stainless steel except the shell (NC) side of the letdown heat exchanger which is made of carbon steel. With respect to pumps, this description only applies to the wetted surface.

9.3.4.2.2 Components

The major components of the CVCS are described in this section. Supplemental component design data are provided in Table 9.3.4-2. Component seismic and safety classification as well as applicable design codes are discussed in Section 3.2.

The design transients used in the thermal fatigue analysis of Class 1 CVCS components are listed in Table 3.9.1-1, and design transients for Class 2 and 3 components are in Table 9.3.4-1.

A. Regenerative Heat Exchanger: The regenerative heat exchanger is a vertically mounted, shell and U-tube heat exchanger. The regenerative heat exchanger conserves RCS thermal energy by transferring heat from the letdown flow to the charging flow. Heating the charging flow serves to minimize thermal transients on the charging nozzle that penetrates the RCS cold leg. Reducing letdown temperature with both the regenerative and letdown heat exchangers allows proper operation of the purification ion exchangers and process instruments. The regen heat exchanger is designed to maintain letdown outlet temperature below 450°F under all normal operating conditions.

B. Letdown Heat Exchanger: The letdown heat exchanger is a horizontally mounted, shell and tube heat exchanger that transfers heat from letdown to the nuclear cooling water (NC) system. Nominal NC flow is 582 gpm. With NC at its design flow of 1500 gpm and the outlet temperature of the regenerative heat exchanger at its maximum of 450°F, the letdown heat exchanger is sized to cool the letdown flow down to the maximum allowable operating temperature of the ion exchange resins (140°F).

C. Purification Filters: Each of the two purification filters is designed to remove insoluble particulates from the letdown flow. Each filter is designed to pass the maximum letdown flow without exceeding the allowable differential pressure across the filter elements in the maximum fouled condition. Due to the high radiation

dose rates possible from the buildup of activity levels during filter operation, each filter is designed for efficient remote removal of the disposable cartridges.

D. Purification Ion Exchangers: The two purification ion exchangers are essentially identical, and each is designed to pass the maximum letdown flow. The ion exchange vessel normally contains mixed bed resins to remove radioactivity and corrosion products. The necessary connections are provided to replace resins by sluicing. Under normal conditions, one ion exchanger is usually in service continuously to control activity and impurity levels in the reactor coolant while the other is used intermittently to reduce the lithium concentration. The retention screen size is in the range from 80-300 mesh.

E. Deborating Ion Exchanger: The deborating ion exchanger is identical to the purification ion exchangers in mechanical design; however, the deborating ion exchanger is normally loaded with anion resin. The deborating ion exchanger is used to reduce the reactor coolant boron concentration at the end of core life when the low prevailing boron concentrations may make feed-and-bleed dilution impractical. The retention screen size is in the range from 80-300 mesh.

F. Volume Control Tank: The Volume Control Tank is designed to accumulate letdown and RCP controlled bleed-off water from the RCS, to adjust hydrogen concentration in the reactor coolant, and to provide a

reservoir of reactor coolant for the charging pumps. The tank has sufficient capacity below the normal operating level band to provide makeup for a swing from Hot Full Power (HFP) to Hot Zero Power (HZP) without automatic makeup operation. The minimum tank level also ensures that operation of all three charging pumps will not result in vortexing and gas entrainment into the charging pump suction. The normal operating level band is sized so that a normal makeup at a VCT pressure of 50 psig will not result in a lift of the associated safety relief valve. The volume above the minimum operating band is sufficient to receive the thermal expansion of the reactor coolant in a swing from HZP to HFP under nominal plant conditions without lifting the associated safety relief valve. The tank has hydrogen and nitrogen gas supplies and provisions that allow venting of hydrogen, nitrogen, gaseous fission products, and other non-condensable gases to the Gaseous Radwaste System (GRS).

G. Charging Pumps: The three charging pumps are positive displacement (triplex) pumps with both primary and secondary sets of packing. The primary packing is cooled primarily by process flow. In addition, each pump contains a cooling and lubricating system that recirculates reactor makeup water over the secondary packing and otherwise non-wetted portions of the primary packing. Each pump is provided with vent, drain, and flushing connections to minimize radiation levels during maintenance operations. The wetted surface is composed

of austenitic stainless steel. The design flow of each pump is 44 gpm. After the effects of pump inefficiencies are considered, the nominal flow rate is about 42 gpm. Each charging pump possesses an associated suction stabilizer and pulsation dampener in order to reduce the magnitude of pressure fluctuations and the resulting cyclic stresses common to reciprocating pump operation.

H. Boric Acid Batching Tank: The Boric Acid Batching Tank allows the operator to mix, store, and process concentrated boric acid solutions. The tank is insulated and has a reactor makeup water supply. The associated mechanical mixer, 45 kW electric immersion heaters, temperature controller, heat tracing, and sampling connections allow handling of boric acid solutions of up to 12 percent by weight without precipitation. The contents of the batching tank may be transferred to the Refueling Water Tank or the Spent Fuel Pool with an eductor using either the boric acid makeup pumps or the reactor makeup water pumps as the motive fluid.

I. Refueling Water Tank: The Refueling Water Tank is sized to allow total boric acid recycle, to support back-to-back cold shutdowns to five percent subcritical with the most reactive CEA withdrawn and subsequent startups at 90% core life, to fill the refueling pool and transfer canal, to provide sufficient volume for engineered safety features pump operation, and to provide sufficient volume above the high outlet nozzle

to support a natural circulation cooldown per the requirements of Branch Technical Position RSB 5-1.

J. Holdup Tank: The holdup tank is sized to store all recoverable reactor coolant generated by back-to-back cold shutdowns to five percent subcritical with the most reactive CEA withdrawn and subsequent startups at 90 percent core life. The minimum pump operating level is sufficient to provide adequate NPSH to either holdup pump.

K. Reactor Makeup Water Tank: The Reactor Makeup Water Tank capacity is based on providing dilution to allow total boric acid recycle. The low level alarm for the Reactor Makeup Water Tank warns the operator that the tank may not contain the volume needed as the backup supply to the essential auxiliary feedwater pumps (if the Condensate Storage Tank becomes inoperable).

L. Boric Acid Makeup Pumps: The two Boric Acid Makeup Pumps are single stage, centrifugal pumps with induction, squirrel-cage motors. The capacity of each boric acid makeup pump is greater than the combined capacity of two charging pumps. The pumps are arranged in parallel and interlocked so that only one pump operates at a time.

M. Reactor Makeup Water Pump: The two Reactor Makeup Water Pumps are single stage centrifugal pumps with induction, squirrel-cage motors. The capacity of each reactor makeup water pump is greater than the combined capacity of two charging pumps. The pumps are arranged in

parallel and interlocked so that only one pump operates at a time.

N. Holdup Pumps: The two Holdup Pumps are single stage, centrifugal pumps with induction, squirrel-cage motors.The pumps are arranged in parallel and interlocked so that only one pump operates at a time.

O. Chemical Addition Package: The chemical addition package consists of a Chemical Addition Tank, Chemical Addition Pump, and a strainer. The capacity of the Chemical Addition Tank is nominally sized so that the maximum anticipated amount of lithium (or hydrazine under cold conditions) could be added to the RCS in one batch. The Chemical Addition Pump is a positive displacement pump with a variable capacity.

P. Boric Acid Filter: The boric acid filter is designed to remove insoluble particulates from the normal borated makeup flow and may also be used for limited cleanup of the refueling water tank.

Q. Reactor Makeup Water Filter: The reactor makeup water filter is designed to remove insoluble particulates from the reactor makeup water supply to the resin sluice supply header, makeup header, and makeup system.

R. Reactor Drain Pumps: The two Reactor Drain Pumps are single stage, centrifugal pumps with induction, squirrel-cage motors. The pumps are arranged in parallel and interlocked so that only one pump operates at a time.

S. Reactor Drain Filter: The reactor drain filter is designed to remove insoluble particulates from the contents of the Reactor Drain Tank, Equipment Drain Tank, and Holdup Tank.

T. Reactor Drain Tank: This horizontal, cylindrical tank is designed to receive and quench the discharge from the pressurizer safety valves. The minimum tank level has sufficient inventory (and volume) to quench the relief expected during a loss of load event under nominal plant conditions without exceeding the rupture disc setpoint. This quench volume is also sufficient to receive the maximum expected thermal relief valve discharge from the Shutdown Cooling/Safety Injection System without blowing the tank rupture disc. The tank is intended to receive gravity drains and leakage of reactor grade quality water from components located within containment and to receive gravity drains from the RCS. To comply with the manufacturer's recommended limit on the frequency of reactor drain pump starts, the normal operating volume is sufficient to accommodate the maximum expected leakage from the RCS for 1 hour. This means the operating volume leaves sufficient room to accumulate the normally expected leakage from all sources for several days. The tank volume above the operating band is sufficient to receive reactor coolant pump (RCP) seal controlled bleed-off (CBO) flow for approximately 30 minutes without blowing the rupture disc. This is sufficient time for operator action in the event that the normal CBO pathway to the VCT becomes isolated. The

minimum tank level is also sufficient to prevent vortexing and provide adequate NPSH for the reactor drain pumps. The tank has a nitrogen blanket with a normal operating pressure of about 1 psig.

U. Equipment Drain Tank: This horizontal, cylindrical tank receives gravity drains from the Recycle Drain Header and the Ion Exchanger Drain Header. The normal operating band corresponds to the volume of resin sluice water produced during two sluice evolutions under nominal conditions. The tank also accepts discharge from miscellaneous relief valves via the Recycle Vent Header. The volume above the operating band is sufficient to accommodate either the discharge from the largest safety relief valve for 10 minutes or gas stripper bypass flow for 30 minutes. The minimum tank level is also sufficient to prevent vortexing and provide adequate NPSH for the reactor drain pumps. The tank has a nitrogen blanket with a normal operating pressure of about 3 psig.

V. Preholdup Ion Exchanger: The preholdup ion exchanger is identical to the purification ion exchangers in mechanical design. The component is used as required to provide additional removal of radioactivity and impurities in letdown/diversion flow before return to the VCT or direction to the Holdup Tank. The ion exchanger may be used to process the contents of the RDT and EDT as they are transferred to the Holdup Tank. Cleanup of the Holdup Tank or the Refueling Water Tank in a recirculation mode is also permissible. The vessel

normally contains mixed bed resin that is both borated and lithiated. It is designed to pass the maximum letdown flow.

W. Gas Stripper: The Gas Stripper achieves efficient gas stripping by heating the process fluid and passing it down through a packed tower. The stripping medium is steam produced by heating a portion of the degassed process fluid with auxiliary steam. Transfer pumps included on the gas stripper package take suction on the degassed process fluid and send it to the heat recovery heat exchanger and aftercooler. Once cooled, the fluid is then directed to the Holdup Tank or to the VCT during continuous degassing of letdown flow. Non-condensable gases, along with trace quantities of fission gases and water vapor, are directed to the Gaseous Radwaste System. The design decontamination factor (ratio of inlet to outlet gas concentration) is 1,000. When the unit operates at its design flow rate of 140 gpm, it requires about 13,500 lbm/hour of auxiliary steam at 50 psig and 500 gpm of nuclear cooling water flow.

X. Boric Acid Concentrator Package: The Boric Acid Concentrator concentrates the process flow boron concentration by means of evaporation. The process flow enters the concentrator and is recirculated through a steam heater. The vapor evolved from the heated recirculation flow is normally stripped of entrained liquid by demisters, condensed, demineralized, and pumped to the Reactor Makeup Water Tank. In order to facilitate water management or reduce primary tritium

concentrations, the BAC vapor may also be directed to the Plant Vent for offsite release. The concentrate (bottoms) is cooled and pumped to the Refueling Water Tank. The design decontamination factor (ratio of boron concentration in the bottoms to that in the distillate) is 10,000. The maximum distillate effluent boron concentration is less than 10 ppm. When the unit operates at its design flow rate of 20 gpm, it requires about 13,500 lbm/hour of auxiliary steam and 700 gpm of nuclear cooling water flow.

Y. Boric Acid Condensate Ion Exchanger: The boric acid condensate ion exchanger normally contains anion resin to remove boron carryover and ionic impurities from the boric acid concentrator distillate. It is designed to pass the maximum expected flow from a single distillate pump.

Z. Seal Injection Filters: These two redundant filters are designed to remove insoluble particles from the seal injection flow to the reactor coolant pumps. Each unit is designed to pass the maximum anticipated flow without exceeding the allowable differential pressure across the element in the defined maximum fouled condition. The media size is sufficiently small to meet the warranty requirements of the RCP seal vendor.

aa. Seal injection Heat Exchanger: The seal injection heat exchanger is a vertical heat exchanger that was intended to use auxiliary steam to heat the seal injection flow. Operational experience has shown that the heat exchanger

is not necessary to maintain seal injection water temperature stable in the desired range. Therefore, the auxiliary steam supply to the heat exchanger and its return have been capped off.

9.3.4.2.3 Process Instrumentation and Control

The notes in the following discussion are located at the end of this section. They refer to instruments and controls that are required for safe shutdown and/or are located at the Remote Shutdown Panel.

9.3.4.2.3.1 Temperature

A. Holdup Tank Temperature: The temperature of the tank contents is indicated in the main control room, and an alarm annunciates in the main control room to warn the operator of low temperature conditions.

B. Reactor Makeup Water Tank Temperature: The temperature of the tank contents is indicated in the main control room, and an alarm annunciates in the main control room on low temperature.

C. Refueling Water Tank Temperature: Two temperature channels are installed in the Refueling Water Tank. One provides temperature indication in the control room, and the other provides indication locally. Both instruments provide an alarm in the control room to warn the operator of low temperature conditions in the tank.

D. Boric Acid Batching Tank Temperature: The batching tank temperature measurement channel controls the tank

heaters. Local indication is provided to facilitate batching operations.

E. Letdown Line Temperature: The regenerative heat exchanger letdown outlet temperature is indicated in the control room and at the Remote Shutdown Panel (note 2). A high alarm is provided to alert the operator to degraded regen heat exchanger performance or abnormal charging/letdown temperatures or flows. The high regen heat exchanger letdown outlet temperature alarm has been specifically identified in UFSAR 15.6.2 as a potential indication of a letdown line break outside of containment. The instrument also provides a signal that automatically closes a letdown isolation valve at a setpoint above the high temperature alarm. The valve must be manually opened to restore letdown flow.

F. Letdown Heat Exchanger Outlet Temperature: This channel is used to control the Nuclear Cooling Water System (NC) flow through the letdown heat exchanger in order to maintain the proper letdown temperature for purification system operation. This temperature is indicated in the control room.

G. Ion Exchanger Inlet Temperature: This channel provides indication at the Remote Shutdown Panel (see note 2). It alarms in the control room if the letdown exiting the Letdown Heat Exchanger is above normal. On a high process temperature, the channel protects temperature sensitive equipment by terminating letdown with automatic closure of the outboard containment isolation

valve. When letdown flow is stopped, high temperature fluid may be trapped by the temperature sensor. Once proper letdown cooling has been re-established, the operator may override the temperature interlock at the isolation valve hand switch if restoration of letdown flow is needed to clear the high temperature condition. The channel also initiates a signal to bypass letdown flow around the purification and deborating ion exchangers, the boronometer and the process radiation monitor. Letdown flow through these components must be manually restored when the temperature decreases below the setpoint. On a high-high temperature, another control room alarm is generated. If the letdown backpressure controller is in automatic, purification flow is terminated by closure of the backpressure control valves.

H. Volume Control Tank Temperature: The Volume Control Tank is provided with temperature indication in the control room. An alarm is provided to alert the operator to abnormally high water temperature conditions in the tank.

I. Charging Line Temperature: The regenerative heat exchanger charging outlet temperature is indicated in the control room. This indication is used to evaluate heat exchanger performance and monitor the thermal condition of auxiliary spray.

J. Preholdup Ion Exchanger Inlet Temperature: This channel provides control room indication of the temperature of

influent to the Pre-Holdup Ion Exchanger (PHIX). A high temperature alarm is provided in the control room, and, on high inlet temperature, the flow is diverted to bypass the ion exchanger to preclude degraded resin performance.

K. Reactor Drain Tank Temperature: The Reactor Drain Tank is provided with temperature indication in the control room. A high temperature alarm is provided to alert the operator to possible relief valve discharge into the tank and the need for cooling the tank contents.

L. Seal Injection Temperature: This channel is used to monitor thermal conditions at the seal injection heat exchanger outlet. Indication is provided in the control room. Both high and low alarms are also provided in the control room to identify abnormal process conditions. High-high or low-low outlet temperature signals will automatically isolate the seal injection flow by closure of valve CH-231P if temperature falls beyond acceptable limits for the reactor coolant pump seals.

M. Equipment Drain Tank Temperature: The Equipment Drain Tank is provided with temperature indication in the control room. A high temperature alarm is provided to alert the operator to possible relief valve discharge into the tank and the need for cooling the tank contents.

9.3.4.2.3.2 Pressure and Differential Pressure

A. Letdown Backpressure Controller: This channel measures pressure between the letdown heat exchanger and the letdown backpressure control valves. The controller, located in the control room, adjusts the letdown backpressure control valve(s) to maintain proper intermediate pressure. Backpressure must be sufficiently high to ensure subcooled conditions throughout the intermediate letdown piping and sufficiently low to prevent unnecessary lifts of the associated pressure relief valve. This pressure is indicated in the control room, locally, and at the Remote Shutdown Panel (see note 2). Both high and low pressure alarms are provided in the control room. The low backpressure alarm may serve as the "low letdown pressure" alarm described in UFSAR 15.6.2 as a potential indication of a letdown line break outside of containment.

B. Purification Filter Differential Pressure: Pressure taps are provided to monitor the differential pressure across the purification filters. The differential pressure indicator has a local readout and a high differential pressure alarm in the control room. Periodic readings of the instrument will indicate any progressive particulate loading of the filter.

C. Purification Ion Exchanger and Letdown Strainer Differential Pressures: Pressure taps and valves are provided to monitor the pressure loss across the

purification ion exchangers (including the deborating ion exchanger) or across the purification ion exchangers and letdown strainer combination in series. The differential pressure channel provides a local indicator and a high differential pressure alarm in the control room. Periodic readings of the instrument will indicate any progressive loading of the components.

D. Boric Acid Makeup Pump Discharge Pressure: Discharge pressure of each pump is indicated in the control room and locally. Low pressure alarms provided in the control room may be indicative of a pump failure. In the event of a sustained low pressure condition, the affected pump is stopped automatically and the alternate pump is automatically started to prevent significant interruption of borated makeup flow.

E. Charging Line Pressure: This safety grade channel monitors the pressure immediately downstream of the charging pumps. Indication is provided in the control room and at the Remote Shutdown Panel (see note 1). The instrument at the Remote Shutdown Panel is used primarily to verify proper charging pump operation. A low pressure alarm is provided in the control room. Such an alarm during normal operation may indicate charging pump failure, safety relief valve lift, valve misalignment, or charging line break.

F. Reactor Coolant Pump Controlled Bleed-off (CBO) Header Pressure: Pressure is measured at the reactor coolant pump controlled bleed-off header in order to monitor the

status of CBO flow. Indication and high/high-high alarms are provided in the control room. The high alarm indicates that a valve in the normal flowpath to the Volume Control Tank has been closed, and CBO flow has been redirected to the Reactor Drain Tank via CH-507 and the CH-199 relief valve. The high-high alarm indicates that controlled bleed-off flow has stopped entirely.

G. Charging Pump Suction Pressure Switches: A pressure switch on the inlet to each charging pump suction trips the associated charging pump on low suction line pressure thus preventing damage due to cavitation.

H. Letdown Line Pressure: The letdown line pressure between the backpressure control valves and the purification filter is indicated in the control room, and both high and low pressure alarms are provided. The low backpressure alarm may be used as the "low letdown pressure" alarm described in UFSAR 15.6.2 as a potential indication of a letdown line break outside of containment.

I. Ion Exchanger Drain Header Strainer Differential Pressure: A local differential pressure indicator is provided with a local alarm. Periodic reading of this instrument will indicate any progressive loading of the strainer due to resin fines and other particulates.

J. Equipment Drain Tank Pressure: Indication of EDT pressure and a high pressure alarm are both provided in the main control room. On high-high pressure conditions, the channel automatically isolates the

equipment drain tank. Isolation occurs through closure of valves in lines to or from the gas analyzer in the gaseous radwaste system, the recycle drain header, and the reactor drain pumps.

K. Reactor Drain Pump Discharge Pressure: The pump discharge pressures are indicated locally and in the control room.

L. Reactor Drain Filter Differential Pressure: Pressure taps are provided to permit measurement of differential pressure across the filter. Periodic readings of this instrument will indicate any progressive loading of particulates. The differential pressure is indicated locally, and a high differential pressure alarm is provided in the control room.

M. Preholdup Ion Exchanger and Strainer Differential Pressures: A differential pressure channel and valves are provided to measure the pressure loss across the PHIX or across the PHIX and its outlet strainer in series. Periodic review of these readings will indicate any progressive loading of particulates on the components. Differential pressure is indicated locally, and a high differential pressure alarm is provided in the control room.

N. Reactor Drain Tank Pressure: The RDT possesses separate narrow and wide range pressure channels. Both instrument transmitters feed a dual indicator in the control room that displays both values simultaneously. The narrow range instrument monitors the nitrogen

blanket pressure and provides a control room alarm on high pressure. The wide range instrument is needed to monitor the pressure response during safety or relief valve discharges into the tank. On high-high pressure, the associated wide range switch will close the isolation valve on the vent to the GRS (CH-540) and the inboard containment isolation valve on the tank outlet (CH-560). The operator should then take action to control the situation causing safety or relief valve operation and restore the tank to normal operating conditions.

O. Holdup Pumps Discharge Pressure: The pump discharge pressures are indicated locally.

P. Boric Acid Condensate Ion Exchanger and Strainer Differential Pressure: Pressure taps and valves allow measurement of the pressure drop across either the ion exchanger itself or the ion exchanger in series with its outlet strainer. A local differential pressure indicator with a high alarm at a local panel is provided. Periodic reading of this instrument will indicate any progressive loading on the components.

Q. Seal Injection Filter Differential Pressure: Local differential pressure indication and high differential pressure annunciation in the control room are provided to monitor the pressure loss across the seal injection filters. Periodic readings of this instrument will indicate any progressive loading of the filters.

R. Reactor Makeup Water Pump Discharge Pressure: The reactor makeup water pump discharge pressure is indicated locally and in the control room. Low pressure alarms provided in the control room may be indicative of a pump failure. In the event of a sustained low pressure condition, the affected pump is stopped automatically, and the alternate pump is automatically started to prevent significant interruption of dilute makeup flow.

S. Volume Control Tank Gas Pressure: This channel provides Volume Control Tank pressure indication in the control room. High and low pressure conditions are annunciated in the control room as well. The low pressure alarm protects against loss of charging pump suction. The high alarm setpoint is established below the setpoint of the safety relief valve on the tank gas supply and so helps protect against tank overpressurization. Either alarm alerts the operator to the need to restore nominal pressure conditions in the tank by adjusting the inflow and outflow rate of cover gas and/or process liquid.

T. Charging Backpressure Control Valve Differential Pressure: Differential pressure across the charging isolation valve CH-239 and charging backpressure control and isolation valve CH-240 in series is indicated in the control room. This channel maintains sufficient backpressure upstream of the valves to ensure reactor coolant pump seal injection flow is adequate and the auxiliary spray subsystem remains functional. The range of permissible backpressure is defined by the channel

high and low alarms in the control room. The controller setpoint and the high alarm are less than the differential pressure needed to open the spring-loaded check valve CH-435.

U. Boric Acid Filter Differential Pressure: The channel contains a local differential pressure indicator to monitor the buildup of particulate matter on the boric 153

acid filter. A high differential pressure alarm in the control room indicates the need for filter replacement.

V. Reactor Makeup Water Filter Differential Pressure: The channel contains a local differential pressure indicator to monitor the buildup of particulate matter on the reactor makeup water filter. A high differential pressure alarm in the control room indicates the need for filter replacement.

9.3.4.2.3.3 Level

A. Holdup Tank Level: Level indication and alarms for this tank are provided in the control room. On low-low level in the Holdup Tank, the holdup pumps are automatically stopped. The high level alarm indicates that processing should be commenced, and the high-high level alarm indicates that filling of the tank should be secured.

B. Reactor Makeup Water Tank Level: Level indication and alarms for this tank are provided in the control room. The low level alarm for the Reactor Makeup Water Tank warns the operator that the tank may not contain the volume needed as the backup supply to the essential

auxiliary feedwater pumps (if the Condensate Storage Tank becomes inoperable). On low-low level in the tank, the reactor makeup water pumps are automatically stopped. The high level alarm in the Reactor Makeup Water Tank indicates that filling of the tank should be secured.

C. Volume Control Tank (VCT) Level: The VCT level is measured by two instrument channels utilizing the same high and low instrument taps. Although both are differential pressure type instruments, one has a dry reference leg and the other has a wet reference leg for enhanced reliability. A control room alarm is provided to alert the operators when the two channels differ by a significant amount.

- The dry reference leg instrument (CH-226) provides VCT level indication and associated alarms in the control room. This channel controls the starting and stopping of the automatic makeup system to maintain VCT level in its normal operating band. The high level alarm set above the level at which letdown diversion should have occurred. The low level alarm is established below the level at which automatic makeup should have occurred. An alarm is also provided whenever a VCT makeup demand signal is present.

- The wet reference leg instrument (CH-227) provides indication locally and at the Remote Shutdown Panel (see note 2). Associated switches actuate CVCS

components to keep VCT level within design limits. On high level, the channel automatically diverts letdown flow to the Holdup Tank. In addition, diversion will automatically send a stop signal to the reactor drain pumps and to the holdup pumps if CH-686 is open (that is, holdup pump discharge is aligned to the reactor drain filter). On a low-low level, CH-227 transfers charging pump suction from the VCT to the Refueling Water Tank by opening valve CH-514, closing VCT outlet valve CH-501, starting a boric acid makeup pump, and closing recirculation valve CH-510. If the low-low level occurs while CH-514 has no power, then CH-536 will open automatically to allow RWT inventory to gravity feed to the suction of the charging pumps.

D. Equipment Drain Tank Level: A differential pressure type instrument indicates EDT level and activates high and low-low level alarms in the control room. A low-low EDT level automatically stops the reactor drain pumps if the EDT outlet valve CH-563 is open.

E. Reactor Drain Tank Level: A differential pressure type instrument provides RDT level indication as well as high and low-low level alarms in the control room. A low-low RDT level will automatically stop the reactor drain pumps if both RDT outlet containment isolation valves, CH-560 and CH-561, are open.

F. Refueling Water Tank Level:

- Two high level band instruments are provided to monitor level above the high suction nozzle with indication in the control room. In addition, these two independent channels provide safety grade indication of borated water supply status at the Remote Shutdown Panel (see note 1). Both channels provide high and low level annunciation in the control room. The low level alarm warns the operator of entering the volume required for engineered safety features pump operation. A low-low level alarm secures the boric acid makeup pumps.

- There are four independent, safety grade level indicators provided on the Refueling Water Tank with readout in the main control room. On a low Refueling Water Tank level, these level channels initiate the recirculation actuation circuitry as described in UFSAR sections 7.3 and 6.3.3. Any two of four independent signals are required to initiate the signal thereby precluding spurious actions resulting from failure of one measurement channel. This arrangement results in a high degree of protective measurement channel reliability in terms of initiating safeguards action when required while avoiding unnecessary action.

9.3.4.2.3.4 Flow

A. Letdown Flow: An orifice-type flow meter indicates letdown flow locally, at the Remote Shutdown Panel (note 2), and in the control room. This channel actuates a high flow alarm in the control room. High flow conditions may result from improper letdown flow or backpressure control or from a line break downstream of the instrument.

B. Process Radiation Monitor Flow: A rotameter located downstream of the boronometer* (abandoned in-place) is used to control the flow rate through the unit by adjustment of flow control valve CH-204. Indication is provided locally and in the control room. High and low alarm annunciation is provided in the control room as well. The process instrument low flow alarm is described in UFSAR 15.6.2 as a potential indication of a letdown line break outside of containment.

C. Reactor Makeup Water Flow Switch: A flow switch located downstream of the makeup flow element FE-210X alarms in the control room if dilute makeup water flow occurs during refueling operations when dilute makeup should be secured. During normal operations, the flow switch is disabled.

D. Boric Acid Flow: A coriolis type sensor is provided to measure the flow rate of borated water to the blending tee. This associated control channel positions the borated makeup water flow control valve CH-FV-210Y to obtain a flow rate preset by the operator. When the

flow controller is in automatic, excessive deviation of borate flow rate from setpoint (Hi-Lo) produces a control room alarm to indicate improper control loop operation. When the makeup mode selector switch is in the AUTO mode, additional protection against unplanned changes in the reactor coolant boric acid concentration is provided by a trip signal on flow deviation from setpoint (Hi-Hi/Lo-Lo) which terminates both borate and dilute flow. To prevent unnecessary alarms and trips from expected setpoint deviations during initiation of flow, these signals are delayed to permit control action to establish the flow rate at setpoint. Since the maximum expected borate flow is less than the design flow of the boric acid filter, the high-high flow alarm and trip functions described in the CESSAR have been removed. A flow rate recorder and a borated water flow totalizer are provided in the main control room.

E. <u>Reactor Makeup Water Flow</u>: A coriolis type sensor is provided to measure the flow rate of dilute makeup water to the blending tee. The associated control channel positions the dilute makeup water flow control valve CH-FV-210X to obtain a flow rate preset by the operator. When the flow controller is in automatic excessive deviation of dilute flow rate from setpoint (Hi-Lo) produces a control room alarm to indicate improper control loop operation. When the makeup mode selector switch is in the AUTO mode, additional protection against unplanned changes in the reactor coolant boric acid concentration is provided by a trip signal on flow

deviation from setpoint (Hi-Hi/Lo-Lo) which terminates both borate and dilute flow. To prevent unnecessary alarms and trips from expected setpoint deviations during initiation of flow, these signals are delayed to permit control action to establish the flow rate at setpoint. Since the maximum expected dilute flow is less than the design flow of the reactor makeup water filter, the high-high flow alarm and trip functions described in the CESSAR have been removed. A flow rate recorder and a dilute water flow totalizer are provided in the main control room.

F. Charging Flow: A safety grade orifice-type flow meter is installed in the charging line just downstream of the pumps. Indication of combined charging pump discharge (total charging) flow rate is provided in the control room and at the Remote Shutdown Panel (see note 1). At the Remote Shutdown Panel, the instrument is used primarily to verify proper charging pump operation. The setpoint for the low alarm provided in the control room is set below the nominal flow rate of a single charging pump in order to identify degraded pump operation.

G. Ion Exchanger Drain Header Flow Switch: A flow switch is provided with a flow present/non-present indicating light on a local panel. The indicator light is on whenever draining is in progress and goes off when an ion exchanger draining operation is complete. When refilling an ion exchanger after charging new resin, the light indicates overflow from the vent line drain and therefore completion of the filling evolution.

H. Seal Injection Flow Rate: Orifice-type flow meters provide control room indication of seal injection supply flows to each reactor coolant pump. This channel controls the seal injection flow at a setpoint established by the operator in accordance with the recommendations of the pump seal vendor. Alarms for high, high-high, and low flow are provided in the control room to indicate abnormal seal flow conditions.

I. Boric Acid Batching Flow: This instrument indicates locally the flow of concentrated boric acid from the boric acid batching tank to the boric acid batching eductor. This instrument is used in combination with measurement of the motive fluid flow rate through the eductor from either FE-210X or Y to ensure the solution exiting the eductor is at the desired concentration.

J. Letdown Heat Exchanger Nuclear Cooling System Flow Switch: This instrument has been removed and its alarm and interlock functions have been moved to the Purification Ion Exchanger Inlet temperature channel described in Section 9.3.4.2.3.1.G.

K. Reactor Makeup Water Supply Header: This instrument provides local indication of reactor makeup water flow to the recycle drain header, equipment drain tank, and the reactor drain tank.

9.3.4.2.3.5 Boronometer (abandoned in-place)

A slip stream off the letdown flowpath flows through the abandoned boronometer. A throttling valve, CH-204, located in

the letdown line in parallel with the boronometer, is automatically controlled to ensure the proper slip stream flow rate through the instrument. A three-way valve located upstream of the boronometer bypasses flow around the instrument on high letdown heat exchanger outlet temperature.

The unit is provided with shielding as required to limit the maximum external radiation level from its neutron source to a low value. All wetted surfaces that contact reactor coolant are constructed of austenitic stainless steel for enhanced corrosion resistance. The unit's rated pressure and temperature of 200 psig and 200°F, respectively, are consistent with the design values of the letdown line.

9.3.4.2.3.6 Radiation Monitoring

9.3.4.2.3.6.1 Process Radiation Monitor. The Process Radiation Monitor provides a continuous reading in the control room of reactor coolant gross gamma radiation as a measure of fuel cladding integrity. The channel detector is an ion chamber mounted adjacent to the letdown piping, specifically the slip stream around CH-204. Since letdown piping external dose rate is roughly proportional to fuel defect, increasing trends in dose rate can be used as an indication of fuel element cladding failure. Verification of the Process Radiation Monitor reading is done by grab sample measurements.

Since the detector is located downstream of the Letdown Delay Coil, its response is not significantly affected by N-16 gamma radiation. Its process location upstream of the purification ion exchangers enhances sensitivity. However, it is positioned

downstream of the purification filters to reduce monitor response due to insoluble corrosion activation products, whose concentrations are not a function of fuel defect. The monitor is ranged to detect the radiation levels expected for 0.1% to 1% failed fuel.

The characteristic time of the detector is on the order of seconds; therefore, the overall response time of the monitor is limited by the sample transport time from the core. Since the transit time of the coolant from the reactor core to the detector is less than 6 minutes, the monitor can provide relatively rapid indications of degraded fuel cladding conditions.

The monitor is part of the Radiation Monitoring System (RMS) described in section UFSAR 11.5. All of the RMS capability for data acquisition, data storage, display, and trending are available. The monitor alert alarm setpoint is discretionary and is established high enough to prevent spurious actuation and low enough to identify significant changes in reactor coolant activity levels. The high alarm setpoint corresponds to a failed fuel fraction of 1% at steady state with the UFSAR Section 11.1 radionuclide distribution.

NOTE 1: These subject safety related instruments are identified in UFSAR 7.4.1.1.10, Emergency Shutdown Outside the Control Room, and are required to be operable per Technical Specifications.

NOTE 2: The subject instruments, although also identified in UFSAR 7.4.1.1.10, are non-safety related components located in a non-safety grade process instrument panel adjacent to

Train A/C of the class Remote Shutdown Panel. These instruments are supplementary devices used to enhance pressurizer level control during shutdowns where letdown remains in service. Letdown and the associated process instruments described above are neither required nor credited for either safe shutdown or remote shutdown outside the control room.

9.3.4.3 System Operation

The Chemical and Volume Control System is designed to be operated as follows:

9.3.4.3.1 Reactor Coolant Inventories

During normal power operations, the volume of water in the RCS is regulated automatically by the Pressurizer Level Control System (PLCS). To minimize the transfer of fluid between the RCS and CVCS during power changes, the pressurizer level setpoint or target RCS volume is programmed to vary as a function of the average RCS temperature. The relationship between the pressurizer level setpoint and Tavg is shown in Figure 5.4-2. The PLCS master controller generates a level error signal by comparing the programmed setpoint with the measured pressurizer water level. Based on the level error signal, the controller regulates the inservice letdown control valve(s) as needed to keep pressurizer level on program. Large changes in pressurizer level due to power changes or abnormal operations will also result in PLCS operation of the normally running and/or standby charging pumps if needed to supplement letdown control valve action. Under steady state conditions,

letdown flow rate will be the difference between the total charging flow rate and the controlled bleed-off flow.

The Volume Control Tank is provided to accommodate small and/or temporary mismatches between letdown and charging flow. The level in the Volume Control Tank is normally controlled by the makeup system in the automatic mode of operation. When the control band high level is reached, letdown flow is diverted to the holdup tanks via the preholdup ion exchanger and gas stripper. In the automatic mode, makeup flow of a preset blend of boric acid from the RWT and demineralized water from the Reactor Makeup Water Tank (RMWT) is initiated by the Volume Control Tank low level signal. A low-low level signal automatically closes the outlet valve on the Volume Control Tank (CH-501), opens the boric acid feed valve (CH-514), and starts the boric acid makeup pumps. This alignment of an alternate borated water supply prevents charging pump trip due to loss of net positive suction head or gas-binding.

The CVCS is also used to handle thermally induced volume changes of the reactor coolant during normal plant heatups and cooldowns. As coolant volume expands during plant heatup, letdown flow is increased to keep pressurizer level on program, and the surplus inventory is diverted to the Holdup Tank. Letdown may also be sent to the Equipment Drain Tank for small temperature changes. In a cooldown, the makeup system supplies the additional inventory needed to compensate for thermal contraction of the coolant and maintain pressurizer level. The makeup system can also replace reactor coolant inventory lost due to allowable system leakage. The overall RWT, RWMT, and HUT capacities are sufficient to support back-to-back shutdowns

as noted in the individual tank descriptions in section 9.3.4.2.2. The CVCS design supports nominal heatup and cooldown rates. Regardless of system capacity, the operator limits the rate of temperature change in order to maintain pressurizer operability as required in the Technical Specifications. Rates are also adjusted as required to comply with Technical Specification pressure/temperature limits.

9.3.4.3.2 Reactivity Control

The boron concentration of the reactor coolant is normally controlled using the feed and bleed method. To change RCS boron concentration, the makeup system supplies either dilute water from the Reactor Makeup Water Tank, boric acid solution from the Refueling Water Tank, or a blend of both. The makeup water goes to the Volume Control Tank or directly to the charging pump suction. Toward the end of a fuel cycle, with low boric acid concentration in the coolant, feed and bleed becomes inefficient, and the deborating ion exchanger is used to reduce the RCS boron concentration. The deborating ion exchanger contains an anion resin in the hydroxyl form initially and converts to a borate form as boron is removed from the reactor coolant.

9.3.4.3.3 Primary System Chemistry Control

The reactor coolant system chemistry is controlled to reduce corrosion that may result in subsequent system leakage/failure, degradation of heat transfer surfaces, or increase in radionuclide specific activity concentration. Operational limits for reactor coolant impurities are established in

accordance with the Technical Requirements Manual and the EPRI PWR Primary Water Chemistry Guidelines as endorsed by NEI 97-06, Steam Generator Program Guidelines. The EPRI guidelines and their bases represent the industry best practice, as developed from evaluation of the most recent experimental data and plant operating experience. Exceptions from that guidance required as a result of site specific circumstances are fully evaluated and documented prior to implementation.

The rate of both general and localized corrosion in carbon steel, 300 series stainless steel, and alloys used in the reactor coolant system increases with the concentration of dissolved oxygen in the coolant. In addition, if chlorides and fluorides are present concurrently, then localized stress corrosion cracking is possible. Dissolved oxygen is expected in the reactor coolant following refueling when the system is open and exposed to atmosphere. Once the system is closed, filled, and vented, then oxygen may be introduced into the system through makeup water (both the RMWT and RWT are exposed to atmosphere) and possibly by air intrusion via in-leakage through the charging pump suction, which may operate at sub-atmospheric conditions. During power operations, oxygen is also produced from the decomposition of water due to exposure of neutron and high-energy gamma flux in the core. During plant heatup and at power, the dissolved oxygen concentration is limited by maintaining a hydrogen overpressure on the Volume Control Tank. The partial pressure of the hydrogen overpressure creates an excess of dissolved hydrogen gas in the coolant that favors the recombination of dissolved hydrogen and

oxygen into water. Although not normally required, dissolved oxygen may be reduced by operation of the gas stripper during plant heatup if needed.

The pH of the reactor coolant is kept in the neutral and slightly basic region at system temperature in order to enhance passivation of system metals and to minimize the deposition of crud on core heat transfer surfaces. Operating experience has shown that the corrosion rates of Ni-Cr-Fe Alloy-600 and 300 series stainless steels decrease with time when exposed to normal reactor coolant chemistry conditions due to the development of passive oxide film on reactor coolant system surfaces. Most of the film is established within 7 days at hot, high pH conditions and approaches low steady state values within approximately 200 days. Elevated pH conditions within the reactor coolant at operating temperature have the added benefit of reducing corrosion product solubility. This both decreases the dissolved crud inventory circulating in the reactor coolant and promotes selective deposition of corrosion products on cooler surfaces of the steam generator, rather than on hotter surfaces in the core. Higher pH environments also form a more stable and tenacious passive oxide layer on out-of-core system surfaces.

At low temperature, high pH conditions may be maintained through the addition of hydrazine (and ammonia formed through its decomposition) which also acts as an oxygen scavenger. Thereafter, pH is adjusted by controlling RCS lithium concentration to values consistent with the concentration of boric acid maintained for reactivity control. For a given boron concentration, the coordinated boron-lithium program

described in the EPRI guidelines prescribes an allowable range for lithium concentration, nominally 1-3 ppm. The lower limit on lithium concentration ensures that sufficient lithium hydroxide is present during operation to achieve the target pH while the upper limit provides a wide margin to the threshold for the accelerated attack of zircalloy. Although zircalloy attack does not occur until lithium concentration approaches approximately 35 ppm lithium, a large margin is appropriate in the event that any concentrating phenomena exist in the system. During plant heatup and low power operation, lithium in the form of lithium hydroxide (LiOH) is added to the coolant to increase pH. The LiOH is enriched in the lithium-7 isotope to minimize tritium production via the Li-6(n,α)H-3 reaction. During power operation, lithium is normally produced by the activation and decay of Boron-10 through the B-10(n,2α)H-3 mechanism. As a result, periodic removal of lithium by ion exchange is required to keep lithium below the upper limit. Late in core life, when large dilutions are necessary to maintain coolant temperature on program, lithium additions may again be necessary to keep lithium within the control band. Lithium is not controlled during refueling operations, and no minimum concentration applies in that mode.

Particulates and other insoluble contaminants have the potential to increase reactor coolant specific activity by activation and to foul heat transfer surfaces. They are removed in part by the in-service purification filter located in the letdown line. In addition, the resin bed of the in-service ion exchanger provides some mechanical filtration of the process as well.

The presence of ionic impurities is associated with a variety of localized corrosion mechanisms. Of particular concern are halide induced stress corrosion cracking of sensitized austenitic stainless steels and Primary Water Stress Corrosion Cracking (PWSCC). The letdown line contains three ion exchange beds, and only one is usually in service at a time. The principal strategy for operation of the ion exchangers may be described as follows. Removal of ionic impurities is accomplished by the (essentially) continuous operation of a mixed bed whose cation resin is lithium saturated and whose anion resin is borated in order to prevent changes in either pH or reactivity. A second purification ion exchanger, a mixed bed whose cation/anion resins are in the hydroxide/borate form, is operated intermittently to reduce lithium concentration. The third ion exchanger is used to reduce the reactor coolant system boron concentration. This deborating bed is only used at the end of the core cycle when the quantities of waste water produced to adjust boron concentration through feed and bleed operations become excessive. The vessel contains an anion resin initially in the hydroxyl form that is converted to a borate form as boron is removed. While deviations from this strategy are not common, the design of both purification filters and ion exchangers provides a great deal of flexibility with respect to resin selection, process flowpath, and service times. Operations and Chemistry will operate the described purification equipment as needed to economically meet the requirements for reactor coolant water quality, water management, radwaste treatment, in-plant radiation exposure, and radioactive effluent release.

The reactor coolant also contains radioactive contaminants produced from fission, activation, and decay. The coolant specific activity may be limited by feed and bleed evolutions, radioactive decay, and operation of the purification filters and ion exchangers. The types and quantities of radioactive materials expected in the coolant and connecting systems are described in UFSAR Section 11.1.

9.3.4.3.4 Shutdown Purification

When the unit is on shutdown cooling, portions of the CVCS may be aligned as required to control reactor coolant chemistry and specific activity. In the process known as shutdown purification, a fraction of the Shutdown Cooling Heat Exchanger outlet flow or its bypass is directed to the CVCS by opening cross-connect valve CH-363 and either SIB-420 and/or SIA-421.

To simplify reactor coolant inventory control, normal letdown is secured by closure of one or more of the letdown containment isolation valves while shutdown purification is in service.

The diverted shutdown cooling flow enters the letdown line upstream of the letdown heat exchanger, which is used as needed to reduce temperature to levels suitable for proper operation of the process instruments and the purification ion exchangers. The fluid is mechanically filtered and ion exchanged to reduce impurity and radioactivity levels per station chemistry control requirements. The processed fluid is returned to the suction of the in-service shutdown cooling pump(s) via CH-397 and either SIB-418 and/or SIA-419.

The differential pressure created by the shutdown cooling pump(s) provides the motive force needed to circulate coolant through the CVCS purification equipment. Coarse flow adjustment may be accomplished through positioning of manual valves in the purification flowpath or through repositioning of the cold leg injection valves provided that minimum required shutdown core cooling flow is maintained. The CVCS backpressure control valves permit fine control of purification flow from the control room. The normal letdown flow rate instrument is configured so that it also measures shutdown purification flow if in service. The purification flow may also be monitored continuously for radioactivity using the normal letdown process instruments.

With shutdown cooling in service, the shutdown purification flowpath may be modified to permit resumption of reactor coolant pump seal injection if desired. In the modified flow path, the purification flow exiting the ion exchangers is lined up to the VCT, instead of the SDC pump suction. One or more charging pumps is then used to supply seal injection flow and RCS makeup. This configuration may also be used to control reactor coolant inventory and boron concentration by coordinated use of the backpressure control valves, the letdown diversion valve, and the normal makeup subsystem.

While shutdown cooling is in service, the total dissolved gas in the coolant is controlled to prevent gas binding and degraded performance of the shutdown cooling pumps. Total gas concentration is limited by proper filling and venting of the system and the use of chemical additives if necessary. With the system in the modified shutdown purification lineup, the

gas stripper may also be employed to reduce dissolved and otherwise entrained gases in solution.

When the reactor coolant system is in a drained condition (pressurizer level less than 10%), portions of the CVCS may be used to adjust level/inventory. Of the various methods for raising RCS level, the following utilize CVCS components: (1) the normal charging lineup, (2) the alternate charging discharge pathway through the hot leg injection path, (3) BAMP discharge through a SDC suction line, and (4) gravity drain of the RWT through a SDC suction line. RCS level can be lowered by diversions of shutdown purification flow to either the Holdup Tank (HUT) or Refueling Water Tank (RWT) via CH-500. When inventory is added during either drained operations or system fill evolutions, the boron concentration and temperature of the makeup water are checked to ensure that shutdown margin and pressure/temperature limits are maintained.

9.3.4.3.5 Plant Startup

Plant startup is the series of operations that bring the plant from a cold shutdown condition to a hot standby condition at normal operating pressure and zero power temperature with the reactor critical at a low power level.

Typically, shutdown purification or modified shutdown purification is used to control pressurizer level once recovered from drained conditions. Normal letdown may be placed in service as needed to support reactor coolant system fill and vent, including drawing a steam bubble in the pressurizer, reactor coolant pump sweeps, and subsequent depressurizations to enhance evolution of gas out of solution.

The objective of the fill and vent process is to establish a "loops filled" condition where sufficient inventory is available in the hot and cold legs to support heat transfer from the core to the steam generators via natural circulation. To help achieve this condition, the total gas concentration in the coolant may be controlled below that which may result in degraded natural circulation flow even if the system were depressurized to atmospheric conditions. Additional reduction of dissolved or entrained gas may be accomplished by further venting or by operation of the gas stripper. If the RCS is intact and the dissolved gas concentration is too high, then other administrative controls are required to establish the "loops filled" condition. This may include procedural restraints against lowering pressurizer pressure below that needed to support natural circulation or by maintaining a functional HPSI pump available to pressurize the system if forced circulation were lost.

The Volume Control Tank is initially purged with nitrogen. Under most circumstances, this sweep gas contains very low concentrations of radioactivity. Therefore, the gas is normally directed to the plant vent for release offsite under the normal effluent control procedures. If necessary, high activity sweep gas can be sent to the GRS for holdup and decay before release. Once the VCT is swept, the nitrogen sweep gas is replaced with a hydrogen overpressure to control dissolved oxygen in the coolant.

During the initial stages of heatup, both letdown control valves are in service. When pressurizer pressure reaches 1200 psia, the safety relief valve downstream of the letdown

control valves may not have sufficient capacity to relieve the flow through two letdown control valves. Therefore, one letdown control valve is closed by the operator when the RCS pressure exceeds 1200 psi.

Pressurizer water level can be controlled by manually adjusting the output of the pressurizer level master controller or by using the controller in local automatic mode. When using the latter, the operator must adjust the control setpoint to compensate for the fact that the pressurizer level instruments are calibrated for normal operating temperature and pressure. The heatup results in thermal expansion of the reactor coolant. Since the operators maintain pressurizer level in its normal operating band, the expansion volume and dilution water result in an increase in Volume Control Tank level. To accommodate the additional inventory, the operators may divert letdown manually; otherwise, letdown flow is automatically diverted to holdup tanks when the highest permissible level is reached in the Volume Control Tank.

The RCS boron concentration may be reduced during heatup in accordance with shutdown margin limitations. The makeup controller is operated in the dilute mode to inject a predetermined amount of reactor makeup water at a preset rate. Blended makeup is also permitted to control reactivity, but this method is less preferred because pure dilution generates smaller volumes of radwaste per ppm change in boron concentration. Compliance with the shutdown margin limitations is verified by sample analysis.

9.3.4.3.6 Normal Plant Shutdown

Plant shutdown is the series of operations that bring the reactor plant from a hot standby condition at normal operating pressure and zero power temperature to a cold shutdown condition for maintenance or refueling.

Prior to and during plant cooldown, the gas space of the Volume Control Tank is vented as needed to reduce fission gas activity and hydrogen concentration in the coolant. Degasification continues until station ALARA objectives are met and until RCS dissolved hydrogen concentration is low enough to provide reasonable protection against the formation of explosive pockets of gas when the system is finally depressurized. Degassing the reactor coolant is accomplished by sweeps of the Volume Control Tank (VCT), venting of the pressurizer steam space, and diverting letdown flow to the gas stripper and returning the process fluid to the VCT. During the cooldown, purification rate may be increased to accelerate the degasification, ion exchange, and filtration processes.

Although not required, chemicals (other than boric acid) may be added to the reactor coolant during a plant shutdown in order to reduce short and long term corrosion rates, control in-plant and offsite radiological exposure, and enhance radwaste system efficiency. Such chemicals are evaluated for material and system compatibility prior to use. The amount and timing of chemical additions are controlled by procedure or Chemical Control Instruction.

During a normal cooldown, the contraction of reactor coolant tends to decrease pressurizer level. In response the operators

will use charging pumps and letdown control valves to maintain pressurizer level in the normal range. The consequent mismatch between charging and letdown flow results in a low level in the Volume Control Tank. Borated makeup water may be manually or automatically aligned to the VCT or directly to the suction of the charging pumps for inventory and reactivity control. Since a refueling shutdown requires a greater concentration in the RCS than can easily be obtained by the feed and bleed method, the suction on the charging pumps is normally switched to the Refueling Water Tank using one of the gravity feed pathways. The concentration of boric acid in the makeup water is controlled so that temperature dependent shutdown margin requirements are met throughout the cooldown.

Charging flow may be used for auxiliary spray to reduce system pressure and to cool the pressurizer when main spray is not available.

After the reactor vessel head is removed, the Shutdown Cooling Pumps take the borated water from the Refueling Water Tank and inject the water into the reactor coolant loops via the normal flow paths thereby filling the refueling pool. The resulting concentration of the refueling pool and the RCS will be maintained above the minimum refueling concentration specified in Technical Specifications. However, the pool concentration may be lower than the minimum operating boron concentration for the RWT. Thus, when the refueling pool contents are returned to the RWT, use of the CVCS boric acid batching equipment may be required to return the tank to operability prior to entry into mode 6.

During refueling shutdown, the reactor makeup water supply piping is monitored and alarmed for flow to prevent dilution of the refueling pool.

9.3.4.3.7 Testing and Inspection

Pre-operational testing of the CVCS consisted of the following major elements:

- Each component was inspected and cleaned prior to installation into the CVCS.
- A high velocity flush using demineralized water was used to flush particulate material and other potential contamination from all lines in this system.
- Instruments were calibrated.
- Automatic controls were tested for actuation at the proper setpoints.
- Alarm functions were checked for functionality and proper setpoints.
- The relief valve settings were checked and adjusted as required.
- All sections of the CVCS were operated and tested initially with regard to flow paths, flow capacity and mechanical functionality.
- Pumps were tested to demonstrate head and capacity.

In addition, the CVCS was tested for integrated operation with the RCS during hot functional testing. This included the following elements:

- Heat exchanger performance was verified
- Proper control of letdown flow and charging pumps by the pressurizer level control system was tested.
- The charging line was checked to assure that the piping was free of excessive vibration.
- Response of the makeup portion of the CVCS in the automatic, dilute, and borate modes was verified.

Defects in operation that could have affected plant safety were corrected before fuel loading. During the operational phase of plant life, the CVCS will be checked and tested to a comparable level of detail following system modification or major maintenance. If these activities could affect the performance requirements of CVCS equipment important to safety, then proper system operation will be verified by post-modification or post-maintenance testing prior to return of the equipment to service.

As part of normal plant operation, tests, inspections, data collection, and instrument calibrations are made to evaluate the condition and performance of the CVCS equipment and instrumentation. Appropriate vents, drains, instruments, test connections, and sampling capabilities are provided to permit inservice testing of active safety components such as pumps and valves. Inservice inspection and testing of class components in the CVCS will be conducted in accordance with the provisions

of the ASME OM Code and Section XI. A listing of active valves in the CVCS is provided in Table 3.9.3-3.

In addition, sufficient instrumentation and sampling capabilities are provided to collect data on heat transfer capabilities and purification efficiency if required to evaluate system or component performance.

9.3.4.4 Design and Safety Evaluation

9.3.4.4.1 Availability and Reliability

A high degree of functional reliability is assured by providing standby components and by assuring fail-safe responses to the most probable modes of failure. Redundancy is provided as follows:

Component	**Redundancy**
Purification and Deborating Ion Exchangers	Three identical mechanical components
Charging Pumps	One standby, two operating pumps
Auxiliary Spray Valves	Two parallel valves
Letdown Control Valve	One parallel standby valve
Letdown Backpressure Control Valve	One parallel standby valve
Boric Acid Makeup Pump	One parallel standby pump
Reactor Makeup Water Pump	One parallel standby pump
Holdup Pump	One parallel standby pump
Reactor Drain Pump	One parallel standby pump
Gas Stripper	The gas stripper package includes redundant standby pumps
Boric Acid Concentrator Package	The concentrator package includes redundant standby pumps
Seal Injection Filter	One parallel standby filter
Purification Filter	One parallel standby filter

Component	Redundancy
Letdown Containment Isolation Valves	Three valves in series (two required for operability)
Controlled Bleed-Off Containment Isolation Valves	Two valves in series
Charging Containment Isolation Valves	One motor operated valve and one check valve in series
Seal Injection Containment Isolation Valves	One motor operated valve and one check valve in series

In addition to the normal makeup pathways, two independent, gravity-feed lines from the Refueling Water Tank to the charging pump suctions are provided to assure makeup, even during a loss of offsite power. In addition to the RWT, the charging pumps have an alternate source of borated water in the spent fuel pool, which is maintained above 4000 ppm boron concentration. While the normal charging path is through the regenerative heat exchanger, it is also possible to charge through the high pressure safety injection header, although seal injection and auxiliary spray would not be functional in this lineup.

In addition to the component redundancy, the CVCS may be operated in a manner such that some components are bypassed. Transfers boric acid to the charging pump suction header (bypassing the Volume Control Tank) are permissible. The letdown filter and purification and deborating ion exchangers can be bypassed. The pre-holdup ion exchanger (PHIX) and/or the gas stripper may be bypassed if not required to control chemistry or coolant activity. The contents of the Holdup Tank may be recirculated through the PHIX if the process chemistry is not suitable for feed to the boric acid concentrator. The

charging line backpressure control valve can be bypassed with the spring loaded check valve in the alternate pathway ensuring the functionality of auxiliary spray and seal injection (if required). Controlled bleed-off flow can be routed to the Reactor Drain Tank rather than Volume Control Tank.

Most of the valves in the system are air-operated and designed to fail in a safe condition. In the unlikely event of a loss of all three instrument air compressors, a backup nitrogen supply can be automatically or manually aligned in order to restore functionality of the CVCS air-operated valves.

9.3.4.4.2 Emergency Boration

The requirements for minimum shutdown margin are contained in the Technical Specifications and Core Operating Limits Report (COLR). When the reactor is critical (operational modes 1 and 2), shutdown margin requirements are met by maintaining control rods above the Power Dependent Insertion Limits (PDILs) presented in the COLR. In lower modes 3-5 and during refueling, shutdown margin is achieved by keeping the reactor coolant soluble boron concentration above the limits provided in the Core Data Book. If the minimum shutdown margin requirements are not maintained, then the reactor coolant system must be borated at a rate of approximately 26 gpm with a minimum 4000 ppm boric acid solution. This process of borating to recover shutdown margin is known as emergency boration. When required, it must be commenced within 15 minutes and continued until the margin is recovered. Emergency boration can be accomplished using components within either the Chemical and Volume Control System (CVCS) or the Safety Injection System

(SIS). The Technical Requirements Manual contains functionality requirements for borated water sources, gravity-feed boration flowpaths, and charging pumps within CVCS to ensure that the emergency boration capability exists if needed.

9.3.4.4.3 Accident Response

This section describes the response of CVCS components to Engineered Safety Features Actuation Signals (ESFAS) generated by challenges to the principal fission product barriers. Those that interface with CVCS include Safety Injection Actuation Signal (SIAS), Containment Isolation Actuation Signal (CIAS), Containment Spray Actuation Signal (CSAS), and Loss of Power (LOP). Detailed descriptions of the Reactor Protective System and ESFAS are presented in UFSAR Chapter 7.0.

Upon receipt of a SIAS the safety injection pumps take suction from the Refueling Water Tank. These pumps continue to drain the refueling water tank until a Recirculation Actuation Signal (RAS) occurs, at which point the ESF pumps switch suction to the containment sump. The operator then manually isolates the RWT by shutting CH-530 and CH-531. This action is time critical to prevent ingress of air in the ESF pump suction piping during switchover to recirculation.

Charging pump status may change in response to the SIAS, CSAS, and LOP ESFAS signals in accordance with the various modes of BOP ESFAS Sequencer operation. The LOP signal in this case refers to that generated by loss of power on the class 1E 4160 bus that energizes the pump. Response to the signal combinations may be summarized as follows:

- Upon receipt of a SIAS or CSAS without a LOP, any running charging pump will continue to run. Idle pumps will be locked out from any automatic start signals for 40 seconds. After 40 seconds, the pump can respond to start demands from the Pressurizer Level Control System (PLCS).

- If a SIAS or CSAS is received, and a LOP signal is present with the associated emergency diesel generator output breaker closed, then all charging pumps on the bus are load shed. Following a 40 second time delay, the pumps will automatically start as required by the PLCS.

- If a LOP occurs and the associated diesel generator output breaker is closed with no SIAS or CSAS, then idle charging pumps on the bus are unaffected while running pumps are tripped and placed in an "anti-pump" breaker configuration and can only be manually restarted.

Automatic operation of the charging pumps is not required for any analyzed accident or malfunction. The control logic design provides improved availability of the charging pumps for reactivity control, makeup, seal injection, and auxiliary spray without affecting the loading and sequencing requirements of the emergency diesel generators.

The charging line contains a motor-operated, outboard containment isolation valve in series with an inboard check valve. A handwheel is provided to allow local operation of the valve, if necessary. Because the availability of reactor coolant makeup, boration, and auxiliary spray enhances overall

plant safety, the motor-operated containment isolation valve CH-524 does not receive any automatic close signals. In addition, the valve is locked in the open position with power removed. This administrative control is established to prevent loss of safety functions due to inadvertent valve closure. Therefore, a CIAS, SIAS, CSAS, or LOP does not isolate the charging line. A sufficient volume of fluid exists in the VCT to provide sufficient time to manually align the gravity feed lines from the borated water sources to the charging pump suction header. Within the containment the charging line branches into two major pathways: direct charging flow to the reactor coolant loop or auxiliary spray to the pressurizer. Both of these lines are provided with check valves that preclude back flow from the reactor coolant loop.

The seal injection line branches from the main charging line outside of the containment. Similar to the charging line itself, the seal injection line also contains a motor-operated outboard containment isolation valve in series with an inboard check valve. The motor-operated valve CH-255 does not receive any automatic close signals and is provided with a handwheel for local operation of the valve, if required. The four seal injection flow control valves in the distribution header are normally open valves that fail open on loss of instrument air, solenoid power, or control power. Maintaining charging and seal injection flow following a CIAS reduces the potential for damage to the reactor coolant pump seals. Note that the seals may be further jeopardized following a CSAS due to the additional loss of nuclear cooling water.

The letdown line and the reactor coolant pump controlled bleed-off line penetrate the reactor containment with flow in the outward direction. The letdown line contains two air operated valves inside the containment and one air operated valve outside the containment. The two air-operated valves inside containment are automatically closed on a SIAS. One of the air-operated valves inside containment and the air operated valve outside containment are automatically closed on a CIAS.

The combined Controlled Bleed-Off (CBO) line from the reactor coolant pump seals to the Volume Control Tank contains two air-operated isolation valves (CH-506 and CH-505), which are located inboard and outboard of the containment penetration, respectively. These valves close automatically upon receipt of a CSAS, as do nuclear cooling water and instrument air containment isolation valves. On CSAS, the concurrent isolation of instrument air to containment will result in the CBO line relief isolation valve (CH-507) failing open and thus directing CBO flow through the relief valve to the reactor drain tank (inside containment). Isolation of these valves on CSAS instead of CIAS is an enhancement of the original CESSAR design that reduces operator actions needed to implement the "trip two/leave two" reactor coolant pump strategy when offsite power is still available. The modification allows use of reactor coolant pumps during steam generator tube ruptures, main steam line breaks, and other accident sequences where continued forced circulation is desired and the containment is not pressurized to the CSAS setpoint. The CH-507 valve is designed to fail open to prevent catastrophic damage to the RCP

seals should the combined CBO flow be inadvertently isolated with a pump running.

The inboard and outboard containment isolation valves on the Reactor Drain Tank (RDT) outlet as well as the makeup supply header and the post-accident sampling inputs to the tank all close automatically on a CIAS. DMWO 2529758 removes piping and valves (manual and/or solenoid) from selected portions of the PASS System piping that are connected to safety-related piping and/or components. In Units where DMWO 2529758 has been implemented for the appropriate isolation points, both the PASS System/Piping and PASS containment isolation valves have been removed and/or de-terminated with lines capped as appropriate.

9.3.4.4.4 Safe Shutdown

As described in UFSAR 7.4.1.1.9, the boron addition portions of the CVCS are required to achieve safe shutdown. Specifically, in the cooldown from normal operating temperature and pressure to shutdown cooling entry conditions, operation of the charging subsystem components is rquired to support three safety functions. The addition of borated water adds negative reactivity and thereby ensures that shutdown margin requirements are met as coolant temperature decreases. The makeup water volume is needed to maintain pressurizer level (RCS inventory control) as the coolant contracts during cooldown. Use of auxiliary pressurizer spray is required to reduce RCS pressure within the design limit of the shutdown cooling subsystem. The specific functionality requirements for borated water sources, boration flowpaths, charging pumps, and auxiliary pressurizer spray are contained in the Technical

Requirements Manual. The control logic for these safety related portions of CVCS are provided in Figure 9.3-1.

Letdown and controlled bleed-off portions of CVCS are in service during normal operations but are not required for safe shutdown. Because these reactor coolant losses may actually jeopardize the inventory control safety function, they are isolated during most design events. Closure of at least one containment isolation valve in both the letdown and the reactor coolant pump controlled bleed-off pathways is required for proper CVCS operation during safe shutdown. The operability of containment isolation valves in CVCS is controlled in the Technical Specifications. In events where reactor coolant pumps are idle and complete isolation of the controlled bleed-off (including closure of CH-507) cannot be assured, then increased RCS leakage due to reactor coolant pump seal damage must also be considered.

CVCS instruments required for safe shutdown are identified in UFSAR Table 7.4-1. Their associated indicators are provided both in the main control room and at the Remote Shutdown Panel (RSP). There are also five non-safety related CVCS instruments identified in UFSAR Table 7.4-1. These instruments, located in a non-safety grade panel adjacent to safety train A/C Remote Shutdown Panel, are supplementary devices used to enhance pressurizer level control during shutdowns where letdown remains in service. These non-safety instruments are neither required nor credited for either safe shutdown (UFSAR 7.4.1.1.9) or shutdown outside the control room (UFSAR 7.4.1.1.10).

CVCS controls and status indications required for safe shutdown include those listed in Table 7.4-1 plus the controls for the charging pumps and remotely operated valves in the gravity feed boration flowpaths. While all CVCS controls required for safe shutdown are available in the main control room, only the ones in Table 7.4-1 are also provided at the RSP. The rest (e.g., the charging pumps and remotely operated valves in the boration flowpaths), however, may be controlled locally from associated breakers or disconnect switches. This is consistent with SRP 7.4 and UFSAR SER 7.4, which state that limited local actions are acceptable for providing a remote shutdown capability as required in GDC 13 and 19.

Because of the CVCS role in achieving safe hot and cold shutdown, portions of CVCS are credited in the Appendix R fire protection analysis. The use of various safety related and non-safety related components within CVCS to mitigate the effects of postulated fires is described in UFSAR Appendix 9B and its supporting basis documents.

9.3.4.4.5 Natural Circulation Cooldown

Portions of the CVCS are utilized to achieve safe shutdown under the natural circulation cooldown conditions described in Branch Technical Position RSB 5-1. In a cooldown from normal operating temperature/pressure to shutdown cooling entry conditions, operation of the borated water sources, boration flowpaths, charging pumps, and the auxiliary pressurizer spray within the CVCS are required to support three safety functions. The addition of borated water adds negative reactivity and thereby ensures that shutdown margin requirements are met as

coolant temperature decreases. The makeup water volume is needed to maintain pressurizer level (RCS inventory control) as the coolant contracts during cooldown. Use of auxiliary pressurizer spray is required to reduce RCS pressure within the design limit of the shutdown cooling subsystem. The specific functionality requirements for these CVCS components are contained in the Technical Requirements Manual.

For Class 2 plants, the use of non-safety grade equipment to achieve safe shutdown may be acceptable if it can be shown that the effects of single failures may be corrected by manual actions outside the control room. Reliance on non-safety grade CVCS components at PVNGS has been conditionally accepted based on the implementation of the following engineering and administrative controls:

- The power supplies to CH-501 (VCT outlet valve) and CH-536 (RWT gravity feed to the charging pump suction valve) were upgraded to class 1E sources.
- An interlock was added to ensure that, in the event of a Lo-Lo VCT level with a concurrent loss of power to the non-class valve CH-514 in the alternate boration pathway, the class 1E powered valve CH-536 would automatically open to provide a gravity feed pathway from the RWT to the charging pump suction.
- A second VCT level instrument was installed, and an alarm was added to detect excessive deviation between the two readings. Use of separate dry and wet reference legs reduces the chance of level instrument failure leading to loss of the charging pumps on low pump

suction pressure. Note: low VCT level has the potential to allow dissolved hydrogen to come out of solution and gas bind the pumps.

- To ensure availability of the charging pumps, valves CH-532 (RWT to BAMP suction valve) and CH-524 (charging line outboard containment isolation valve) were locked open and their actuators de-energized.
- Procedures were developed for venting the charging pumps if they were to become gas-bound. Since the normal Auxiliary Building ventilation system above the 100' elevation is not available after a loss of offsite power, venting the hydrogen gas directly into the charging pump rooms is a fire and occupational safety hazard. Therefore, hardware provisions were made to vent the gas to the Essential Pipe Density Tunnel via an intermediate Vent Receiving Tank. This configuration also ensures that the gas would be monitored for radioactivity before discharge to atmosphere.
- Calculations were performed to verify that one train of the high pressure injection in combination with one train of the reactor head vent system were capable of cooling the reactor from Hot Standby to shutdown cooling entry conditions within the specified time. Thus, these subsystems provide a diverse, safety-grade backup method for natural circulation cooldown in the event CVCS was not functional.

While not all credited CVCS components are safety grade, these enhancements give the system an acceptable level of reliability

following a loss of offsite power, and only limited operation of system components outside the control room is required to mitigate the consequences of a single failure. As required by BTP RSB 5-1, the ability to perform a natural circulation cooldown using CVCS components was demonstrated by a test conducted at Unit 1 in January 1986. Therefore, the PVNGS design and operating limits provide reasonable assurance that a natural circulation cooldown could be conducted as described in Branch Technical Position RSB 5-1 for a Class 2 plant.

A complete summary of the RSB 5-1 Natural Circulation Cooldown Analysis is included at the end of Chapter 5 as Appendix 5C.

9.3.4.4.6 Overpressure Protection

In order to provide for safe operation of the CVCS, the following relief valve protection is provided.

A. Intermediate Pressure Letdown Relief Valve: The relief valve downstream of the letdown control valves protects the intermediate pressure letdown piping and letdown heat exchanger from overpressure. The valve capacity is equal to the flow expected through one letdown control valve in the full open position at normal operating system pressure. For a given valve position, letdown flow decreases with RCS pressure. When RCS pressure falls below 1200 psia, the relief valve will be capable of discharging the combined flow through two fully open letdown control valves. Consequently, operation of both letdown control valves in parallel is procedurally permitted only when RCS pressure is less than 1200 psia. Above that pressure, one letdown control valve must be

closed. The relief valve set pressure is equal to the design pressure of the intermediate letdown piping.

B. Low Pressure Letdown Relief Valve: The relief valve downstream of the letdown backpressure control valves protects the low pressure piping, purification filters, ion exchangers, letdown strainer, and associated letdown components from overpressure. The valve capacity is equal to the capacity of the intermediate pressure letdown relief valve. The set pressure is equal to the design pressure of the low pressure piping and components.

C. Charging Pump Discharge Relief Valves: The relief valves on the discharge side of the charging pumps are each sized to pass the maximum rated flow of the associated pump against maximum backpressure without exceeding the rated head of the pump. The valves are set to open when the discharge pressure exceeds the RCS design pressure by 10 percent.

D. Charging Pump Suction Relief Valves: A relief valve is located on the suction side of each charging pump. Each is sized to pass the maximum fluid thermal expansion rate that would occur if the associated pump were operated with the suction and discharge isolation valves closed. The set pressure is equal to the design pressure of the charging pump suction piping.

E. Volume Control Tank Relief Valve: The set pressure of the relief valve on the Volume Control Tank (liquid) is equal to the tank design pressure. The valve is sized to

pass a liquid flow rate equal to the sum of the following inputs with one charging pump in operation: (1) maximum operating reactor coolant pump controlled bleed-off flow, (2) letdown flow at the high letdown flow alarm setpoint, (3) design purge flow rate of the Sampling System (SS), and the maximum flow rate from a boric acid makeup pump with the VCT at its relief pressure setpoint.

F. Volume Control Tank Gas Supply Relief Valve: The relief valve is sized to exceed the combined maximum capacity of the nitrogen and hydrogen gas regulators. The set pressure is lower than the Volume Control Tank design pressure.

G. Reactor Coolant Pump Controlled Bleed-off Header Relief Valve: The relief valve located on the RCP controlled bleed-off header redirects flow to the Reactor Drain Tank in the event that the normal flowpath to the Volume Control Tank is isolated. It serves no overpressure protection function. The valve is sized to pass the flow rate from the failure of two seal stages in one reactor coolant pump plus the normal bleed-off from the other three reactor coolant pumps. The relief valve set pressure is greater than the normal operating pressure of the header (aligned to the VCT) and less than the controlled bleed-off high-high pressure alarm.

H. Heat Traced Piping Relief Valves: Relief valves are provided for those heat-traced portions of the boric acid system (e.g., boric acid batching and the Boric Acid Concentrator bottoms) that can be individually isolated.

The set pressure is equal to the design pressure of the corresponding portion of the system piping. Each valve is sized to relieve the fluid thermal expansion rate that would occur if maximum duplicate heat tracing power were inadvertently applied to the isolated line.

I. Equipment Drain Tank Relief Valve: The Equipment Drain Tank relief valve is sized to pass the liquid flow rate equivalent to the maximum expected tank input. The set pressure is equal to the design pressure of the Equipment Drain Tank.

J. Reactor Drain Tank Rupture Disc: An installed rupture disc, which vents to the containment atmosphere, provides overpressure protection for the Reactor Drain Tank if the discharge from pressurizer safety valves exceeds the quenching capacity of the tank. The rupture disc is designed to relieve at 120 psig tank pressure (with the containment at atmospheric pressure) and is sized to pass the rated flow from all four pressurizer safety valves.

K. Charging Line Spring-Loaded Check Valve: A spring-loaded check valve is arranged in parallel with the charging line differential pressure control valve and its associated isolation valve. In the event that flow through the normal pathway is blocked by closure of either the control or isolation valve, the check valve provides an alternate pathway for charging flow to enter the RCS. The differential set pressure and capacity of the spring-loaded check valve are established to ensure that (1) charging pressure remains below the charging

pump discharge relief valve setpoints, (2) auxiliary spray remains functional, and (3) minimum acceptable RCP seal injection flow is maintained.

9.3.4.4.7 Leakage Detection and Control

The components in the CVCS are provided with welded connections wherever possible to minimize leakage to the atmosphere. However, flanged connections are provided on all pump suction and discharge lines, on relief valve inlet and outlet connections, on the boric acid batching eductor, and on some flow meters to permit removal for maintenance.

All valves larger than 2 inches and all actuator-operated valves were provided with double-packing, lantern rings, and leakoff connections unless the valves are diaphragm (packless) valves. During original plant design, an evaluation determined that leakoffs piped to the equipment drain tank present a greater ALARA concern than capping the valve leakoff. The cap has been designed as part of the CVCS pressure boundary. Diaphragm valves are utilized around the Volume Control Tank gas space. Thus, activity release due to valve leakage is minimized.

The CVCS may also be used to monitor the total RCS water inventory. The system role in the detection and quantification of RCS leakage is described in UFSAR 5.2.5. During refueling shutdown, reactor makeup water flow is monitored to detect leakage past isolation valve CH-195 (locked shut during refueling shutdown). If leakage occurs, an alarm is annunciated in the control room.

9.3.4.4.8 Failure Mode and Effects Analysis

Table 9.3.4-3 shows a Failure Mode and Effects Analysis (FMEA) for the CVCS. At least one failure is postulated for each major component of the CVCS. Additionally, various line breaks throughout the system are also considered. In each case, the possible cause of such a failure is presented as well as the local effects, detection methods and compensating provisions.

9.3.4.4.9 Radiological Evaluation

Frequently used manually operated valves located in high radiation or inaccessible areas are provided with extension stem or "reach-rod" handwheels terminating in low radiation and accessible control areas. Manually operated valves are provided with locking provisions if unauthorized operation of the valve is considered a potential hazard to plant operation or personnel safety. A radiological evaluation of the CVCS is presented in Section 12.2.

9.3.4.4.10 Boron Recovery

To reduce the amount of radioactivity that must be discharged from the site as radioactive waste or effluent, the boron recovery subystem has been sized to process the nominal borated waste water generation rates. The annual volume of water directed to the Holdup Tank during normal operation has been estimated to be:

Plant Evolution	Volume (gal/yr)
Refueling, Startup and Shutdown	204,300
Cold Shutdowns and Startups (at 30%, 60% and 90% core life)	364,300
Hot Critical Shutdowns and Startups (at 55% and 65% core life)	115,400
Boron Dilution/Fuel Burnup Waste (out to approximately 97% core life)	240,800
Back to Back Cold Shutdowns to 5% subcritical and Startups (at 90% core life)	364,500
Average Leakage to Reactor Drain Tank and Equipment Drain Tank (250 gal/day)	91,250
Total	1,380,550

The capacities of CVCS tanks and the processing rate of the boric acid concentrator have been sized to allow complete boric acid recycle. However, full boron recovery may not be achievable under all operational conditions.

9.3.4.4.11 Small Line Break

General Design Criterion (GDC) 33 requires that the normal makeup system be able to supply sufficient reactor coolant makeup in the event of a small line break to assure that Specified Acceptable Fuel Design Limits (SAFDLs) are not exceeded. Small lines at PVNGS, such as those used for instrumentation and sample collection, are connected to the reactor coolant pressure boundary via appropriately sized flow restricting devices. These devices limit the potential break

flow within the capacity of the charging system, which provides reactor coolant makeup during normal plant operation.

The CVCS design incorporates a high degree of functional reliability by provision of redundant components. The charging subsystem contains three pumps when only two of charging pumps are required to be functional in modes 1-4. In addition, the CVCS will function with either onsite or offsite electric power available. The charging pumps and auxiliary pressurizer spray valves are powered from vital electrical buses fed either from offsite power or from the emergency diesel generators. The charging pump suction pathway is gravity fed from multiple pathways using manual valves or valves that can be energized from vital power sources.

During the transient, charging flow is needed to compensate for inventory lost out of the break, contraction of coolant volume during cooldown, as well as anticipated system losses from controlled bleed-off and leakage. The maximum flow through the orifice is initially estimated to be approximately 45 gpm, which is less than the nominal capacity of the minimum number of functional charging pumps. Once letdown is isolated, analysis shows that the nominal capacity of two charging pumps provides sufficient makeup to allow pressurizer pressure to be stabilized above the SIAS setpoint.

The operators are then assumed to initiate a cooldown to cold shutdown entry conditions. During the cooldown, the capacity of charging and auxiliary spray are sufficient to control pressurizer level and RCS subcooling margin within the limits prescribed by the emergency operating procedures. Since the

core remains covered and no bulk boiling occurs in the fuel region, the SAFDL on Departure of Nucleate Boiling Ratio (DNBR) cannot be exceeded. The event terminates with entry into cold shutdown, which is achieved using only the minumum inventory of borated water stored in the RWT above the high suction nozzle.

Thus, analysis demonstrates that a small line break can be mitigated without challenging the emergency core cooling systems. Note that, as an evaluation of normal makeup system performance, the effects of a single failure and instrument uncertainty were not considered. Based on the analysis summarized above, it is concluded that the CVCS normal makeup system meets the requirements of GDC 33.

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
1)	Letdown Stop Valve Inside Containment, CH-515	a) fails open	Mechanical binding	Failure to automatically terminate letdown flow on high temperature. Loss of double isolation for letdown line on SIAS.	Position indicator in control room; temperature indicator, TIC-221; flow indicator, FI-202.	Remote manual closure of redundant valve for Hi temp. condition: Series redundant valve automatically closes on SIAS	Temp. indicator/ controller TIC-223, will increase component cooling water (CCW) flow through letdown heat exchanger (LHX) to compensate for Hi. temp. letdown flow. Problem only if regenerative heat exchanger (RHX) discharge temp. exceeds 413°F
		b) fails closed	Loss of air or power supply, spurious signal, operator error	Loss of letdown flow, possible overcharging of RCS. Increase in pressurizer (PZR) level. Possible overpressurization of RCS during startup.	Letdown low pressure alarm (PIC 201), letdown flow indication (FI-202), PZR level alarms, position indication in control room, PZR pressure indicators T-229 indication FSHL-204 low flow alarm.	None	Letdown not required for Safe Shutdown
2)	Letdown Containment Isolation Valve Inside Containment, CH-516	a) fails open	Mechanical binding	Loss of redundance for letdown isolation on CIAS and/or SIAS.	Position indication in control room	Series redundant valve, CH-515, for SIAS; series redundant valve, CH-523 for CIAS.	
		b) fails closed	Same as 1b)	Same as 1b)	Same as 1b)	Same as 1b)	Same as 1b)
3)	Regenerative Heat Exchanger, RHX	a) plugged tubes	Corrosion buildup, boron buildup, foreign material in RCS	Reduced letdown flow	Flow indicator FI-202	None	Complete plugging of all tubes is unlikely. Flow deterioration would be detected long before complete plugging occurs
		b) insufficient heat transfer	Scale buildup, fouling	Letdown temperature may exceed 450°F. Possible thermal damage to downstream components.	Hi temp alarm and indication on TIC-221. Possible Hi temp alarm on TIC-224	TIC-223 will increase NC flow to LHX. TIC-221 will isolate letdown by closing CH-515 on Hi temp.	TIC-224 will isolate letdown by closure of CH-523 if TIC-223 cannot maintain LHX outlet temperature limits.

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		c) external leakage	Casing crack, weld crack, seat leakage on vent valve CH-393	Possible reduction in charging/letdown flow, primary coolant released inside containment	Containment radiation monitor, local leak detectors, excessive make up rate. Possible high temp T-221.	None, except series redundant valve for seat leakage on CH-393	When leak is detected, the RHX can be isolated for repair by terminating letdown/charging
		d) cross leakage	Corrosion, vibration wear mfg defect	Reduced charging efficiency.	Disparity between letdown samples and RCS samples during boration or deboration	None	When leak is detected, letdown must be terminated to effect repair
4)	Temperature Indicator/ Controller, TIC-221	a) reads high	Electro-mechanical setpoint drift	Possible erroneous Hi letdown temp. alarms, possible termination of letdown flow by closure of CH-515	Hi temp. alarm from TIC-221 without corresponding changes in indications from TIC-223, TIC-224, or PIC-201	None	Letdown not required for safe shutdown
		b) false indication of low or normal temp	Electro-mechanical failure	Loss of ability to detect Hi letdown temp condition and terminate letdown flow. Possible thermal damage to downstream components	Hi temperature alarm on TIC-224, Hi temp. indication on TIC-223. Routine periodic test.	TIC-223 will increase CCW flow thru LHX to help compensate. TIC-224 will isolate letdown flow by closure of CH-523 on Hi temp.	Letdown flow can be terminated by remote manually closing of valves CH-515 or CH-516.
5)	Letdown Isolation Valve Outside Containment; CH-523	a) fails open	Mechanical binding	Loss of redundancy for letdown isolation on CIAS. Failure to secure letdown on Hi LHX outlet temp, with possible damage to downstream components.	Position indicator in control room. Possible high temperature alarm from TIC-224.	Series redundant isolation valve CH-516 on CIAS.	On Hi temp, TIC-224 will divert CH-521 and 520 to bypass PIX, PRM, and Boronometer.
		b) fails closed	Same as 1 b)	Same as 1 b)	Same as 1 b)	Spurious Hi temp signal may be manually overridden from HS-523.	Same as 1 b)

6)	Letdown Control Valve; CH-110P, CH-110Q	a) regulates low	Valve operator failure, mech. failure, false signal	Reduced letdown flow. PZR level increases, volume control tank (VCT) level decreases	PZR level indications, Lo flow indication from FI-202.	Parallel redundant control valve	One of the two (CH-110Q) control valves is normally isolated by manual isolation valves while the other valve controls flow. Flow control can be switched by opening the isolation valves for the “non operating” control valve and isolating the “operating” valve.
		b) regulates high	Valve operator failure, false signal	Increased letdown flow, PZR level decreases, VCT level increases. Possible increase in letdown temperature	PZR and VCT level indications, Hi flow indication from FI-202, Hi temp indication from TIC-221.	Parallel redundant control valve. Also, if RHX discharge temp. exceeds 413°F TIC-221 will close valve CH-515, thereby terminating letdown	
		c) fails closed	Air or power failure, spurious signal	Loss of letdown flow, possible overcharging of RCS, possible RCS over pressurization during shutdown, PZR level increase, VCT level decrease	Lo flow indication from FI-202, Lo press. indication from PIC-201, PZR and VCT level indications, valve position indicator in control room.	Parallel redundant control valve	Rapid pressure transient if failure occurs during shutdown if solid plant. Letdown not required for safe shutdown.
7)	Letdown Control Valve Isolation Valve; CH-340, CH-341, CH-342, CH-343	a) fails open	Mechanical failure	No impact on system operation, unable to isolate one valve for maintenance of standby condition	Operator	Two series redundant isolation valves for each control valve	One set of isolation valves normally closed, (for standby control valve), other set is normally open (for operating control valve).
		b) fails closed	Mechanical failure	Unable to transfer letdown flow control to standby control valve	Operator	None, if operating control valve has malfunctioned	
		c) seat leakage	Contamina-tion, mechan-ical damage	No impact on operation	None	None	
8)	Letdown Flow Control Bypass Valve; CH-526	a) fails closed	Mechanical failure, valve operator failure	Unable to warm up letdown line downstream of flow control valves prior to instituting letdown	Position indicator in control room (CR).	None	Operator can warm up letdown lines using letdown control valve under manual control

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails open	Mechanical binding, spurious signal	No impact on operation	CH-526 position indication in control room	PZR level control will regulate letdown control valve to compensate for increased flow. Flow orifice will restrict flow to low level	
9)	Isolation Valve Inlet Line from Shutdown Cooling System (SDCS) CH-363	a) fails closed	Mechanical binding, mech. failure	Unable to divert shutdown cooling flow to IXs for purification	Operator	Purification during shutdown can be accomplished via letdown and charging	
		b) fails open	Mech. binding, mech. failure	No impact on operation.	Operator	Series redundant valve in SDCS	
		c) seat leakage	Contamination	No impact on operation.	None	Series redundant check valve in SDCS	
10)	Letdown Heat Exchanger LHX	a) tube leak	Corrosion, mfg defect	Contamination of CCW with primary coolant	CCW radiation monitors, CCW surge tank level increases, increased make up, possibly low flow indication from FI-202.	None	
		b) tubes plugged	Buildup of corrosion, boron, or RCS contaminants	PLCS will gradually open letdown control valve (LCV) to compensate for increased flow resistance. Degraded PZR level control once LCV is fully open.	Mismatch between letdown flow FI-202 and PLCS master controller output demand. Periodic Hx inspections.	PLCS will open LCV to control PZR level. TIC-223 will adjust NC flow to control LHX outlet temp.	Letdown not required for safe shutdown.
		c) insufficient heat transfer	Scale buildup, fouling	Hi temperature in LHX letdown outlet. Possible thermal damage to downstream components.	Hi temp alarm on TIC-224. Periodic Hx inspections.	TIC-223 will increase NC flow thru LHX to maintain letdown outlet temp.	TIC-224 will isolate letdown on Hi temperature.
		d) external leakage	Casing crack, seat leakage from vent valve CH-444	Primary coolant or CCW released outside containment.	Area radiation monitors, local leak detectors, Lo flow indication from FI-202, excessive makeup to VCT or CCW.	None	
		e) degraded cooling flow	Loss of NC flow, NC flow control valve malfunction, NC line break.	Hi temperature in LHX letdown outlet. Possible thermal damage to downstream components.	Hi temp alarm from TIC-224, Lo flow indication on NC-F208, Hi temp alarm and indication on NC-T207. Numerous alarms for complete loss of NC flow.	TIC-224 will isolate letdown on either Hi temperature or LOOP.	Once NC flow recovered, operator can over ride and open CH-523 to restore letdown if flow needed to clear high temp condition in stagnant piping.

11)	Temperature Indicator/ Controller, TIC-223	a) false low temperature	Electro-mechanical failure	TIC-223 will throttle back NC flow to LHX resulting in decreased LHX heat removal. Resulting high letdown outlet temp with possible damage to downstream components.	Hi temp alarm from TIC-224.	TIC-224 will isolate letdown flow on Hi temperature.	Letdown not required for safe shutdown.
		b) false high tempera-ture	Electro-mechanical failure	TIC-223 will increase CCW flow to LHX, increasing heat removal and resulting in lower letdown outlet temperature.	High flow indication on NC-F208, Low temp indication on NC-T207. Low VCT temperature indication on TIC-225.	None required. Low temp discharge from LHX not considered a problem.	Letdown temp cannot be lower than NC supply temp.
12)	NC Flow Sensor FSL-613 --Component Removed						
13)	Backpressure Indicator/ Controller, PIC-201	a) false low pressure indication	Electrical or mechanical malfunct.	Letdown backpressure control valve will start to close, reducing letdown flow. Letdown control valve will open to compensate, increasing pressure in LHX, may lift safety valve, CH-345	Possible Lo press. alarm from PIC-201, Lo press alarm from PI-220, Lo flow indication from FI-202	None	CH-345 will protect the letdown line from exceeding design pressure
		b) false high pressure indication	Electrical or mechanical malfunction	Letdown backpressure control valve will start to open, increasing letdown flow and decreasing backpressure on LHX. Flashing will occur downstream of letdown control valve. Possible water hammer with damage to instrument tap, valves and CVCS piping	High flow alarm from FI-202, possible Hi pressure alarm from PI-220, PZR and VCT level indication	None	This transient will continue until the operator terminates letdown, or takes manual control of PIC-201 possible loss of primary coolant outside containment if water hammer occurs and breaks an instrument line or small pipe
		c) reverts to manual control	Loss of power	The letdown backpressure control valve closes. When power is restored controller reverts to manual control.	Lo (No) flow indication from FI-202. Low pressure alarm and indication from CH-PI-220	None	Letdown can not be restored without operator intervention. When power is restored, PSV-345 & PSV-354[2] may relieve to the EDT depending on PIC-201 dial setting.

NOTE[2] PSV-345 and PSV-354 provide over-pressure protection for the intermediate and low pressure letdown SSCs, respectively. See UFSAR Section 9.3.4.4.6, Items A & B.

Table 9.3.4-3
(Sheet 6 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
14)	Letdown Backpressure Control Valve; CH-201Q, CH-201P	a) fails to close properly on decreased upstream pressure	Valve operator malfunction, mechanical binding	Possible flashing between letdown control valve and backpressure control valve, possible water hammer in letdown piping. Increased letdown flow, with PZR level decrease and VCT level increase	Lo pressure alarm from PIC-201, Hi pres. alarm from PI-220, Hi flow alarm from FI-202, PZR & VCT level indications	Parallel redundant control valve	Two parallel backpressure control valves, one standby. Standby control valve is isolated by manual valves
		b) fails to open properly on increased upstream pressure	Valve operator malfunction, mech. binding	Pressure increase upstream, may lift safety valve, CH-345. Reduced letdown flow. Increase in PZR LVL and decrease in VCT level	Hi pressure alarm from PIC-201, Lo pres alarm from PI-220, Lo flow indication on FI-202, PZR and VCT level indications	Parallel redundant control valve	Same as 14a)
		c) fails closed	Air or power failure, spurious signal	Loss of letdown flow. Hi pres. upstream may lift safety valve CH-345. PZR level increase and VCT level decrease. Possible RCS overpress., especially during shutdown cooling or startup.	Hi press. alarm from PIC-201, Lo press. alarm from P-220 PZR and VCT level indications	Parallel redundant control valve. PZR level control to stop charging pumps (except the always running pump).	If letdown and charging in progress during startup or shutdown cooling, this failure will result in a rapid RCS over press. transient if the RCS is "solid". Letdown not required for safe shutdown.
15)	Temperature Indicator/ Controller; TIC-224	a) false low tempera- ture	Electro- mechanical failure	Loss of LHX outlet temp protection. If high letdown temp exists, possible damage to down-stream components.	CH-523 fails to close with high temp indication on TIC-223. Hi temp alarm/indication on NC-T207. Low flow indication on NC-F208.	TIC-223 will adjust NC flow to control temperature in response to letdown initiated transients.	Operator action required to isolate letdown for concurrent loss of NC flow to LHX.
		b) false high temperature .	Electro- mechanical failure	Letdown isolates by auto closure of CH-523. PIX, PRM, and boronometer are bypassed. Backpressure control valves CH-201P/Q go closed. Buildup of primary contaminants. Loss of process monitoring. Loss of letdown effects as described in 1b).	High alarm from TIC-224, low flow alarm on FI-204; Auto actuations occur with normal indication on TIC-223.	TIC-223 provides redundant temp reading. On partial actuation or high temp override, CH-523 will still close on CIAS.	Letdown not required for safe shutdown. If CH-201P/Q closes without auto or manual isolation of letdown, PSV-345 will lift and letdown flow will be diverted to the EDT.
16)	Letdown Pressure Control Valve Isolation Valves; CH-347, CH-348, CH-349, CH-350	a) fails open	Mechanical binding	No impact on system operation. Unable to isolate backpressure control valve for maintenance or standby status	Operator	Series redundant isolation valve	Two sets of isolation valves, one set normally closed (for standby backpressure control valve) and the other set is normally open (for operating backpressure control valve)

NOTE(1) The boronometer is abandoned in-place.

Table 9.3.4-3
(Sheet 7 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mechanical binding	Unable to transfer letdown backpressure control to standby valve	Operator	None if operating backpressure control valve has malfunctioned	
		c) seat leakage	Contamina-tion, mechan-ical damage	No impact on operation	None	Series redundant isolation valve	
17)	Pressure Indicator, PI-220	a) Spurious Hi pressure alarm	Electrical or mechanical malfunction	No direct impact on system operation	Hi pressure alarm from PI-220 with normal indications from FI-202, TIC-223 and TIC-224	None required	PI-220 serves no control function
		b) Spurious Lo pressure alarms	Electrical or mechanical malfunctions	No direct impact on system operation	Lo pressure alarm from PI-220 with normal indications from FI-202, TIC-223 and TIC-224	None required	
18)	Purification Filter; Filter 1, Filter 2	a) does not filer	"Punch through" of element	Particle and radiation level buildup in IXs. Eventually high differential pressure across IXs.	Lo differential pressure indication from PDI-202	Parallel redundant purification filter, can be valved in	Unlikely failure
		b) blocked	Element plugged with particles	Reduced letdown flow	Hi differential pressure indication from PDI-202, Hi pressure indication from PI-220	Parallel redundant filter can be valved in. Filters can be bypassed through valve CH-355 if both need maintenance.	
		c) external leakage	Casing crack, seat leakage from vent valve CH-359 or CH-366	Loss of primary coolant outside containment. Possible reduced letdown flow.	Local leak detectors, Lo flow indications from FI-202, Lo differential pressure indication from PDI-202	Parallel redundant filter can be valved in. Filters can be bypassed thru valve CH-355 if both need maintenance	
19)	Purification Filter Isolation Valves; CH-358, CH-360, CH-373, CH-376	a) fails open	Mech. binding	No direct impact on system operation. Unable to isolate filter for maint. or cartridge replacement	Operator	Series redundant isolation valve	Two sets of manual valves. One set normally open (for on-line purification filter) Other set normally closed (for standby filter)
		b) fails closed	Mech. binding	Unable to put standby filter on line	Operator	None	
		c) seat leakage	Contamina-tion, mech. damage	No impact on system operation	None	Series redundant isolation valve

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
20)	Differential Pressure Indicator; PDI-202	a) spurious Hi differential pressure alarm	Electrical or mechanical malfunction	No direct impaction operation. Early replacement of a purif. filter cartridge	Hi differential pressure alarm from PDI-202 with normal indications from FI-202, PI-220, PI-225	None required	
		b) false Lo differential pressure indications	Electrical or mechanical malfunction	No direct impact on system operation	Lo differential pressure indication from PDI-202 with normal indications from FI-202, PI-220, and PI-225	None required	
21)	Differential Pressure Indicator Isolation Valves; CH-356 CH-357	a) fails open	Mech. binding	No direct impact on system operation. Unable to isolate PDI-202 for maint.	Operator	None	
		b) fails closed	Mech. binding	Unable to place PDI-202 back on line after maint.	Operator	None	
22)	Purification Filter Bypass Valve CH-355	a) fails closed	Mech. binding	Unable to divert letdown flow past purif. filters, during maint. or cartridge replacement	Operator	Two full capacity purif. filters; should never have to use bypass valve.	
		b) fails open	Mech. binding	Continued diversion of letdown flow past purif. filters when attempt to place filter back on line. Build-up of particles in IXs	Operator	Same as above	
		c) seat leakage	Contamination, mech damage, valve not seated properly	Minor diversion of letdown flow past purif. filters. Gradual particle buildup in IXs	In long term, IX diff. pres. indicator, PDI-203, otherwise, none.	None	IXs designed to remove particulate matter. Any diversion should be minor
23)	Flow Indicator FI-202	a) spurious Hi flow alarm	Electrical or mechanical malfunction	No direct impact on system operation	Hi flow alarm from FI-202 with normal indications from FIC-204, PI-220, PIC-201, and L-110X, Y (PZR level).	None	
		b) spurious Lo flow indication	Electrical or mechanical malfunction	No direct impact on system operation	Lo flow indication from FI-202 with normal indic. from PI-220, PIC-201, FIC-204, and L-110X, Y (PZR level).		
24)	Upstream Isolation Valve for Diversion Valve; CH-364	a) fails open	Mech. binding	No direct impact on system operation. Unable to isolate diversion valve, CH-521 for maint.	Operator	None	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. binding	Unable to reestablish flow thru boronometer(1) and past PRM after maint. on diversion valve, CH-521	Operator	None	
25)	Diversion Valve; CH-521	a) fails in the straight thru position	Mech binding, valve operator malfunction	Unable to divert Hi temp letdown flow around PRM and Boronometer(1).	Position indicator in control room. Flow indication from FI-204 during Hi temp condit.	High letdown temperature would cause CCW to the LHX to increase to maintain a normal temperature to the PRM	Letdown would have to be terminated to provide protection for PRM
		b) fails to the bypass position	Loss of air or power, spurious signal	Letdown flow diverted around PRM and boronometer. Loss of continuous radiation monitoring	No flow indication from FI-204, valve position indicator in control room	None	
26)	Isolation valve; CH-413	a) fails open	Mech. binding	Partial loss of isolation capability for diversion valve CH-521	Operator	Downstream isolation valve for FIC-204 can be used.	
		b) fails closed	Mech. binding	Unable to divert Hi temp letdown flow around PRM and Boronometer(1)	Operator	PRM not affected by process Temp changes	Flow past PRM and Boronometer(1) should not be re-established after maint on CH-521 unless this valve is open
27)	Isolation Valves; CH-409, CH-410	a) fails open	Mechanical binding	Unable to isolate PRM (CH-409) or Boronometer(1) (CH-410) after maint.	Operator	Entire PRM/boronometer(1) Loop can be isolated using valve CH-364	
		b) fails closed	Mech. binding	Unable to reestablish flow through PRM (CH-409) or Boronometer(1) (CH-410) after maint.	Operator	None	
28)	Process Radiation Monitor (PRM)	a) spurious Hi radiation alarms	Elect. malfunction	No direct impact on system operation	Comparison with grab sample iodine analysis	Sampling system backup	
		b) false Lo radiation level indi-cation	Elect. malfunction	No direct impact on system operation. May not detect fuel element failure if one occurs.	Iodine analysis of grab sample	Sampling system backup	
29)	Boronometer(1)						

NOTE(1) The boronometer is abandoned in-place

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
30)	DELETED						
31)	Throttle Isolation Valve CH-245	a) fails closed	Mech. binding, mech failure	Unable to establish flow through boronometer[1] after maint.	Operator	None required	
		b) fails open	Mechanical binding	Unable to isolate boronometer[1] or flow indicator/controller, FIC-204 (CH-245) for maintenance	Operator	boronometer[1] and flow indicator, FIT-204 can be isolated using valves CH-422, CH-410, and CH-413	
		c) won't throttle properly	Mechanical binding	Unable to obtain proper flow rates thru boronometer[1] CH-409, CH-245 for given back pressure.	Operator flow indicator/controller FIC-204 flow indicator, FI-202	Valve CH-410 and CH-409 can be used to throttle flow thru the boronometer[1]	
32)	Isolation Valve CH-422	a) fails open	Mech. binding	Unable to isolate flow indicator/controller FIC-204 (CH-422) for maint.	Operator	Boronometer[1] loop can be isolated using isolation valve CH-364, and check valve CH-449	
		b) fails closed	Mech. binding	Unable to reestablish flow through boronometer[1] and past PRM (CH-422) after maint. on flow indicator	Operator	None	
33)	DELETED						
34)	Flow Indicator/ Controller, FIC-204	a) false Indications of high flow rate	Elect. or mech. malfunction	FIC-204 will open valve CH-204 thereby reducing flow past PRM and boronometer[1]. This will reduce the accuracy of their indications	Lo flow alarm from FIC-204	None	Sampling system is backup for radioactivity concentration determination
		b) false Indication of low flow rate	Elect or mech. malfunction	FIC-204 will close valve CH-204 increasing flow thru PRM, thereby altering the accuracy of its indications	Hi flow alarm from FIC-204	None	Same as 34) a)
35)	Check Valve, CH-449	a) fails closed	Mech. binding	Unable to establish flow through boronometer[1] and past PRM	Lo flow alarms from FIC-204	None	Sampling system is backup for radioactivity concentration determination
		b) fails open	Mech. binding	No direct impact on system operation	None	None	

NOTE[1] The boronometer is abandoned in-place

(Sheet 11 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
36)	Diversion valve; CH-424	a) fails closed	Mech. binding	Unable to divert letdown flow around control valve CH-204 when maint. required on CH-204	Operator	None	Sampling system is backup for radioactivity concentration determination and iodine analysis
		b) fails open	Mech. binding	Letdown flow will be diverted around control valve CH-204, thereby eliminating ability to properly regulate flow thru boronometer[1].	Operator, Low flow indication/alarm from FIC-204	None	Same as 36) a)
37)	DELETED						
38)	Control Valve, CH-204	a) won't regulate back-pressure properly	Valve operator malfunction mech binding, loss of air power	Unable to maintain proper flow rates thru boronometer[1].	Flow Indicator/ controller, FIC-204	None	Proper flow required to ensure slip stream is representative of letdown process.
		b) fails to closed position	Sheared valve stem	Sudden diversion of full letdown flow thru boronometer[1]	Hi flow alarm from FI-204	None	
39)	Isolation Valves; CH-367, CH-368	a) fails open	Mech. binding	No direct impact on system operation. Unable to isolate control valve, CH-204 for maint.	Operator	None	
		b) fails closed	Mech. binding	Unable to re-establish flow thru valve, CH-204 after maint. Unable to properly regulate flow thru boronometer[1]	Operator	None	
40)	Ion Exchanger bypass Valve; CH-520	a) fails in "IX" position	Mech. binding valve operator failure	No direct impact on system operation. Unable to divert Hi temp letdown flow past IXs. Possible damage to IX resin	None until demand, then, Hi temp alarm from TIC-224 with no change in valve position indic. in control room or in the diff. press indic. from PDI-203	None	Alternate Bypass flow paths can be manually established
41)	Ion Exchanger Differential Pressure PDI-203	a) false Lo differential Pres indication	Elect. malfunct; mech malfunct	No direct impact on system operation. Unable to detect clogged ion exchangers	None	None	
		b) false Hi. diff. pres indication	Elect or mech malfunct.	No direct impact on system operation	No change in indic. when IXs are switched. Possible high ΔP alarm	None	

NOTE[1] The boronometer is abandoned in-place

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
42)	Isolation Valves; CH-407; CH-408	a) fails open	Mech. binding	No impact on system operation. Unable to isolate IX Diff. Pres Indic., PDI-203, for maint	Operator	None	
		b) fails closed	Mech. binding	Unable to put PDI-203 back on line after maint	Operator	None	
43)	Ion Exchangers Inlet Isolation Valves; CH-369, CH-383, CH-404	a) fails open	Mech. binding	Unable to isolate associated IX for maint or when capacity is not required	Operator	Valves, CH-374 and CH-392 for valves CH-383 and CH-404. For valve CH-369 letdown flow would have to be diverted past IXs until valve was repaired	
		b) fails closed	Mech. binding	Unable to place associated IX in service	Operator	None	
44)	Ion Exchangers Inlet Check Valves; CH-370, CH-384, CH-403	a) fails closed	Mech. binding	Same as 43 b)	Operator	None	
		b) fails open	Mech. binding	No impact on system operation. Possible release of gas to letdown line during flush and drain of associated IX	None	Inlet isolation valves CH-369, CH-383, and CH-404, respectively	
45)	Ion Exchanger Resin Addition Valves; CH-372, CH-387, CH-402	a) fails closed	Mech. binding	Unable to add new resin to associated IX	Operator	None	
		b) fails open	Mech. binding	No impact on system operation. Valve would be repaired before IX would be returned to service	Operator	None	
46)	Ion Exchanger Vent Valves; CH-377, CH-386, CH-401	a) fails closed	Mech binding	Unable to vent associated IX to gaseous waste management system (GWMs) during flush and drain. No impact on system operation	Operator	None	
		b) fails open	Mech binding	No impact on system operation. Valve would be repaired before IX returned to service	Operator	None

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
47)	Ion Exchanger Discharge Isolation Valves; CH-378, CH-389, CH-398	a) fails closed	Mech binding	Unable to place associated IX in service	Operator	None	CH-382 can be used to isolate PIX #1.
		b) fails open	Mech binding	Unable to isolate associated IX	Operator	None	
48)	Ion Exchanger Resin Drain Valves; CH-380, CH-391, CH-400	a) fails closed	Mech binding	No direct impact on system operation. Unable to flush resin from associated IX	Operator	None	
		b) fails open	Mech binding	No direct impact on system operation. Unable to refill associated IX with new resin until valve repaired	Operator	None	
49)	Ion Exchanger Drain and flush Valves; CH-379, CH-390, CH-399	a) fails closed	Mech binding	Unable to drain or flush associated IX	Operator	None	
		b) fails open	Mech binding	No impact on system operation. Valve would be repaired before returning IX to service	Operator	None	
50)	IX Drain and Flush Header to Drain Header Isolation Valve; CH-377	a) fails closed	Mech. binding	Unable to drain IXs to drain header. No impact on normal system operation	Operator	None	
		b) fails open	Mech. binding	No impact on system operation IX flush water diverted to drain header during resin sluicing	Operator	None	
51)	Purification Ion Exchanger (PIX) 1 and 2 Outlet Cross-connect, CH-382	a) fails open	Mech. failure	Unable to establish effective series flow through PIX's 1 and 2	Operator	PIX 2 can be used independently if lithium removal required	
		b) fails closed	Mech. failure	Unable to re-establish independent flow thru PIX 1	Operator	PIX 2 is capable of full spectrum ion removal	
52)	PIX 2 to Deborating Ion Exchanger (DIX) Outlet Cross-Connect Valve, CH-395	a) fails open	Mech. failure	Unable to establish series flow thru PIX(s) and DIX	Operator	None if lithium removal required. Otherwise, series flow can be established thru PIX 1 and DIX	

Table 9.3.4-3
(Sheet 14 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. failure	Unable to re-establish independent flow thru PIX 1 and 2	Operator	None	
53)	PIX Series Flow Cross-over Valve CH-381	a) fails closed	Mech. failure	Unable to establish PIX 1/PIX 2 series flow	Operator	Can establish PIX 2/PIX 1 series flow using valve, CH-385	
		b) fails open	Mech. failure	Partial diversion of letdown flow if either PIX is being used independently	Operator	Other manual valves provide adequate isolation to prevent flow diversion	
54)	PIX Series Flow Crossover Valve, CH-385	a) fails closed	Mech. failure	Unable to establish PIX 2/PIX 1 series flow	Operator	PIX 1/PIX 2 series flow can be established using valve CH-381	
		b) fails open	Mech. failure	Letdown flow diverted past PIX's if PIX 1/PIX 2 series flow is in progress. Letdown flow diverted past PIX 1 if it is being used independently	Operator	Return to PIX 2/PIX 1 series flow or, for independent use of PIX 1, other isolation valves provide adequate isolation.	This failure could occur only when transferring from PIX 2/PIX 1 series flow to another flow configuration
55)	PIX 1, PIX 2 Inlet Crossover Isolation Valve, CH-374	a) fails closed	Mech. failure	Unable to establish independent flow through PIX 2 or DIX, or PIX 2/PIX 1 series flow configurations	Operator	PIX 1/PIX 2 series flow config. can be used unless PIX 1 plugged	
		b) fails open	Mech. failure	Unable to establish PIX 1/PIX 2 series flow	Operator	PIX 2/PIX 1 series flow can be established, or PIX 1 or 2 can be used independently (using PIX 1 independently requires additional manual value operation)	
56)	PIX 2, DIX Inlet Crossover Isolation Valve; CH-392	a) fails closed	Mech. failure	Unable to establish independent flow thru DIX	Operator	Alternate flow path can be manually aligned	
		b) fails open	Mech. failure	Unable to establish series configurations PIX 1/PIC 2/DIX, or PIX 2/DIX	Operator	None if lithium removal required, otherwise series flow can be established thru PIX 1 and DIX with additional manual valve operation	
57)	PIX 2 Outlet to DIX Inlet Cross-over Isolation Valve; CH-394	a) fails closed	Mech. failure	Unable to establish series flow thru PIX 2 and DIX	Operator	None if lithium removal required, otherwise series flow can be established thru PIX 1 and DIX	
		b) fails open	Mech. failure	Diversion of letdown flow if in any IX config. other than PIX/DIX series flow	Operator	Other manual valves provide adequate isolation capability

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
58)	Purification Ion Exchangers; PIX 1, PIX 2	fails to remove contamination	Resin exhausted	Buildup in RCS activity	PRM Hi activity alarm, sample analysis for radioactivity	Redundant IXs except for lithium removal. IXs can be bypassed for resin replacement	
59)	Deborating Ion Exchanger, DIX	fails to remove boron	Resin exhausted	Decreased boron removal capability at end of life. Unable to maintain power at end of core cycle	Sample analysis for boron, decrease in power.	Continue feed and bleed while restore DIX resin	
60)	Letdown Strainer	a) plugged	Contaminant buildup	Reduced letdown flow	Hi diff pres alarm from PDI-203	IXs and strainer can be bypassed while strainer element replaced	
		b) fails to strain properly	Element "punch through", wrong size element	Possible deposition of particles and resin in VCT. Possible contam. of charging pumps	Lo diff pres. indic from PDI-203, sample analysis	Same as above	
		c) external leakage	Mfg. defect, corrosion	Primary coolant released outside containment	Local leak detectors, radiation monitors	Same as above	
61)	Isolation Valve; CH-415	a) fails open	Mech. failure	Unable to isolate letdown strainer for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to restore letdown flow through IXs and letdown strainer after maint. on letdown strainer	Operator	None	
62)	Letdown Strainer Drain Valve, CH-419	a) fails closed	Mech. failure	No impact on system operation. Unable to drain letdown strainer for maint.	Operator	None	
		b) fails open	Mech. failure	Part of letdown flow diverted to SRS. VCT level decreases	VCT level indications, operator	None	
63)	Check Valve CH-396	a) fails open	Mech. failure	No impact on system operation	None	None	
		b) fails closed	Mech. failure	Unable to route shutdown cooling flow through IXs for purification	Lo flow indications from FI-202, and flow indicator in SDCS	Purification during shutdown cooling can be accomplished via normal letdown and charging	
64)	Discharge Valve to SDCS; CH-397	a) fails closed	Mech. failure	Same as 63 b)	Operator	Same as 63 B)	
		b) fails open	Mech. failure	Diversion of letdown flow to SDCS during normal operation. VCT level decrease	Operator, VCT level indications	Series redundant isolation valve in SDCS	
65)	Isolation Valve, CH-414	a) fails closed	Mech. failure	No impact on system operation. Unable to get a differential pressure reading across just the IXs	Operator	None	

Table 9.3.4-3
(Sheet 16 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails open	Mech. failure	Unable to transfer PDI-203 from reading diff. pres across IXs and letdown strainer	Operator	None	
66)	Letdown Line Sample Valves; CH-426, CH-353, CH-420	a) fails open	Mech failure	No impact on system operation. Unable to isolate affected sample line	Operator	Series redundant isolation valves in sampling system (SS)	
		b) fails closed	Mech. failure	Unable to obtain sample at specified point	Operator	None	Sample valves are normally open
67)	Letdown Line Safety Valves; CH-345, CH-354	a) fails closed	Mech. binding, blockage	No impact on system operation. Loss of over pres. protection for potentially closed line section	High pressure alarm from P-201 and P-220 respectively, on demand. Periodic tests	None	
		b) fails open	Broken spring, setpoint drift	Letdown flow diverted to equipment drain tank (EDT)	VCT and EDT level indications, Lo flow indication from FI-202 Lo pressure alarm P-201, P-220	None	
68)	Letdown Line Test Connection CH-853, CH-855	a) fails closed	Mech. failure	No impact on system operation. Unable to drain line section or test valves per ASME OM Code.	Operator	None	
		b) fails open	Mech. failure, seat leakage	Possible loss of primary coolant	None	These drain valves/test conn. blind flanged	
69)	VCT Bypass Valve Isolation Valve; CH-418	a) fails open	Mech. failure	Unable to isolate VCT bypass valve, CH-500, for maint. No impact on normal system operation	Operator	Valve CH-415 and CH-520 can be used	
		b) fails closed	Mech. failure, binding	Unable to reestablish letdown flow after maint. on CH-500	Operator	None	
70)	VCT Bypass Valve; CH-500	a) fails to VCT	Valve operator malfunct., Mech. failure, Loss of air or	Unable to divert letdown flow to pre-holdup ion exchangers (PHIX) during feed and bleed operations or for degassing of letdown flow	Hi VCT level indications/alarm from LIC-226 or LIC-227.	None. Letdown would have to be terminated to repair valve	Letdown not required for safe shutdown.
		b) fails to the PHIX position	Operator error, spurious signal	Decreasing VCT level during normal charging and letdown operations. Excessive amounts of primary coolant diverted for boron reclamation	Low VCT level alarms from LIC-227 and LIC-226 excessive use of boric acid make up	Makeup system will maintain VCT level. Letdown would have to be terminated to repair valve	Note: Normal letdown and charging could continue via the gas stripper
71)	VCT Inlet Check Valve, CH-101	a) fails open	Mech. binding	No impact on normal system operation. Unable to perform maintenance on CH-500 with pressure in VCT.	None	None	

Table 9.3.4-3
(Sheet 17 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. binding, mech. failure blockage	Unable to establish normal letdown flow to VCT. PZR level increases, VCT level decreases	Low flow indication from FI-202, Hi pres indic from PI-220, VCT and PZR level alarms	Continuous bypass to the PHIX with return to VCT can be used, but letdown would have to be terminated and the valve repaired before normal letdown and charging could resume.	
72)	Gas Stripper (GS) to VCT Inlet Check Valve, CH-139	a) fails closed	Mech. binding blockage	Unable to establish return flow from GS to VCT. Loss of continuous degasification capability for letdown flow. VCT level decrease during continuous degasification. No impact on normal operation	VCT level alarms, possibly Lo flow indic from FI-202, and Hi pressure indic from PI-220	None	
		b) fails open	Mech. binding	Possible diversion of letdown flow to GS discharge line. Unable to perform maintenance on CH-567 with pressure in VCT.	VCT Lo Level indications	None	This failure mode is unlikely
73)	H_2 Supply Valve Isolation Valves CH-107, CH-108	a) fails open	Mech. binding	No impact on normal system operation. Unable to isolate VCT H_2 supply valve for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to re-establish H_2 supply to VCT. Loss of 0_2 control for primary coolant	Operator	O_2 control can be maintained by H_2 injection into the charging line	
74)	VCT H_2 Supply Valve, CH-502	a) regulates VCT pres. low	Mech. mal-funct. Elect. malfunct. mech. binding	Decreased H_2 pres. in VCT and RCS, partial loss of RCS 0_2 control	Low VCT pressure indication/alarm from PI-225	Same as above	
		b) regulates VCT pres Hi.	Elect. or mech. malfunct.	Increased H_2 pres. in VCT. possible overpressurization of VCT and increased H_2 concen-tration in RCS	Hi VCT pres. alarm from PI-225	Relief valve, CH-105 will keep H_2 addition header pres. down. VCT can be vented to GRS	CH-502 can be isolated and 0_2 control can be maintained by H_2 injection into the charging line.
75)	H_2 Flow indicator, FI-206	a) Erro-neously H_2 flow indications	Elect. or mech. malfunct.	No impact on system operation. Local readout only	Operator	None	
76)	VCT N_2 Supply Valve Isolation CH-109, CH-644	a) fails closed	Mech. binding	No impact on normal operation. Unable to purge VCT with N_2 during shutdown	Operator	None	
		b) fails open	Mech. binding	Unable to isolate N_2 supply purging VCT	Operator	Series redundant valve	

Table 9.3.4-3
(Sheet 18 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
77)	VCT N_2 Supply Valve, (CH-503)	a) regulates pressure low	Elect. or mech. malfunction	No impact on normal operation. Insufficient N_2 supply to VCT during purge. Incomplete VCT purge	Lo pres alarm from PI-225	None	
		b) regulates pressure high	Elect. or mech. malfunction	Possible overpressurization while purging VCT. No impact during normal operation	Hi pres alarm from PI-225	Vent control valve will open to maintain VCT pres. Valve CH-105 provides overpres. protection for gas supply header	
78)	N_2 Flow Rate Indicator, FI-215	erroneous flow indi-cations	Elect. or mech. malfunction	No impact on system operation. Local indication only	Operator	None	
79)	Gas Supply Header Safety Valve; CH-105	a) fails closed	Mech. binding, blockage	No impact on normal operation. Loss of overpressure protection for gas supply header	None	None	
		b) fails open	Mech. failure setpoint drift	H_2 or N_2 diverted to GRS. Possible decrease in H_2 concentrate, in RCS and increase in RCS 0_2 concentration	Possibly Hi pres alarms from GRS otherwise none.	High pressure H_2 injection into charging line is backup source	
80)	Gas Supply Header Check Valve; CH-112	a) fails closed	Mech. binding, blockage	Unable to add H_2 (or N_2) to VCT, H_2 concentration in RCS decreases and RCS O_2 concentration increases, possible VCT press. decrease	RCS sampling. Possibly, Lo pres alarm from PI-225	H_2 injection into charging line	
		b) fails open	Mech. binding mech. failure	No impact of normal operation. Possible diversion of radioactive gasses to GRS or H_2 supply	None	None	
81)	Gas Supply Header Isolation Valve; CH-645	a) fails open	Mech. binding	No impact on system operation. Unable to isolate gas supply header for maintenance	Operator	None	
		b) fails closed	Mech. failure, mech. binding	Unable to add H_2 (or N_2) to VCT. Decrease in RCS H_2 concentration and Increase in RCS 0_2 concentration	Operator	H_2 injection into charging lines	
82)	Gas Analyzer Isolation Valve, CH-104	a) fails open	Mech. binding	No impact on system operation. Unable to isolate gas analyzer for maintenance	Operator	None	
		b) fails closed	Mech. binding	No impact on system operation. Unable to sample VCT with gas analyzer.	Operator	None

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
83)	VCT Pressure Indicator, PI-225	a) spurious high pressure alarms	Elect. or mech. malfunct.	No Direct impact on system operation. Operator may vent VCT, resulting in Lo VCT pres and excessive use of H_2	Hi pressure alarms from PI-225 with normal H_2 flow indication from FI-206 (local readout only)	H_2 supply valve will maintain VCT pres.	
		b) spurious low pres alarms	Elect. or mech. malfunct.	No direct impact on system operation	Lo pres alarm from PI-225 with normal H_2 flow indic. from FI-206 (local readout only)	Same as above	
84)	VCT Vent Line Control Valve CH-513	a) fails closed	Mech. fail Loss of air or power	Unable to vent VCT to GRS during purge. Possible overpres. of VCT during purge. No impact on normal indication	Valve position indicator in control Rm. Hi pres. indic. from PI-225	N_2 supply valve should prevent overpres. of VCT by closing	
		b) fails open	Spurious signal mech. malfunct.	For spurious signal: unwanted venting of VCT, loss of VCT pres. decreased H_2 concen-tration in RCS with increased RCS O_2 concentrat. for mech. malfunct. Unable to terminate venting of VCT during purge	Lo pres. alarm from PI-225, valve position indicator in control room. Valve position indicator in control room	Manual isolation valve, HC can be closed. H_2 supply valve (or N_2 supply valve) will maintain VCT pressure	
85)	VCT Vent Line Pressure Regulator, CH-643	a) regulates pressure Hi	Elect. or mech. malfunct.	No impact on normal operation. Excessive use of N_2 during NCT purge	Lo pres. alarm from PI-225, Hi N_2 flow indic. from FI-215 (local readout only)	None	
		b) regulates pres. Lo	Elect. or mech. malfunct.	No impact on normal system operation. During VCT purge VCT pres. too high and the N_2 supply valve will close to counteract VCT pres. increase. Incomplete VCT purge	Hi pres alarm from PI-225, Lo N_2 flow indic. from FI-215 (local readout only)	None	
86)	Vent Line Isolation Valves CH-100	a) fails open	Mech. failure	No impact on normal operation. Unable to isolate vent line for maint.	Operator	None	
		b) fails closed	Mech. failure	No impact on normal operation. Unable to vent or purge VCT	Operator	None	
87)	Reactor Coolant Pump Controlled Bleedoff Excess Flow Check Valves, CH-301, CH-302, CH-303, CH-304	a) fails closed	Hi or Lo spring tension, plugged, mech. failure	Loss of controlled seal bleedoff for reactor coolant pump (RCP). Possible damage to RCP seals due to overpressurization of seals	Flow and pressure indicators on bleedoff lines	None	Associated RCP must be shut down

Table 9.3.4-3
(Sheet 20 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
88)	Pressure Indicator, PI-215	a) erroneous high or high-high pressure alarms	Elect. or mech. failure, setpoint drift	No direct impact on system operation. Erroneous indication of loss of controlled bleedoff flow.	Hi pres alarms from PI-215 with normal readings from all other bleedoff line instruments	Redundant instruments on bleedoff lines inside containment	PI-215 is used to determine bleed-off throttle valve setting during startup. Once throttle valve is set it is rarely changed.
		b) false Lo pressure Indications	Elect. or mech. malfunction	No direct impact on system operations. Loss of bleedoff header pres. indication needed for setting throttle valve during startup	Bleedoff line instrumentation	None	
89)	RCP Controlled Bleedoff Line Containment Isolation Valves; CH-506, CH-505.	a) fails in open position	Mech. failure	No impact on normal operation. Loss of redundant isolation capability for bleedoff lines on CIAS	Valve position indicator in control room	Redundant isolation valve	
		b) fails to closed position	Loss of air or power, spurious signal, mech. failure	Sudden loss of normal RCP controlled bleedoff flowpath. Safety valve CH-199 will lift	Valve position indicator in control room, Hi pres alarm from bleedoff line instrumentation	CH-199 will lift, directing bleedoff flow to reactor drain tank (RDT).	
90)	RCP Controlled Bleedoff Relief Valve Stop Valve; CH-507	a) fails in open position	Loss of air or power, mech. failure	No impact on normal operation. Unable to isolate relief valve if relief valve starts to leak	Valve position indicator in control room on valve demand	None	
		b) fails closed	Spur signal, mech. failure	No impact on normal operation. Loss of backup controlled bleedoff flow path.	Valve position indicator in control room	Normal controlled bleedoff via CH-505, CH-506	
91)	RCP Controlled Bleedoff Header Relief Valve; CH-199	a) fails open	Mech. failure	Controlled bleedoff flow diverted to RDT	Lo pres indication from PI-215, temp. pres. and level indications on RDT	Valve CH-507 can be closed to isolate CH-199	
		b) fails closed	Mech. failure blockage	No impact on system operation. Loss of backup controlled bleedoff flow path	Periodic Test	Normal controlled bleedoff via CH-505, CH-506	
92)	Controlled Bleedoff Throttle Valve; CH-198	a) fails closed	Mech. failure	Unable to establish controlled bleedoff flow to VCT on startup	Operator	Backup controlled bleedoff flow path via CH-199	Startup delayed until valve repaired.
		b) fails open	Mech. binding	Unable to throttle controlled bleedoff flow properly	Operator	None	Throttle valve is set during startup, and is rarely changed during operation

Table 9.3.4-3
(Sheet 21 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
93)	Controlled Bleedoff Line Check Valve; CH-646	a) fails closed	Mech. binding blockage	Unable to establish controlled bleedoff flow to VCT during startup	Hi pres alarm from PI-215	Backup controlled bleedoff flow path via CH-199	
		b) fails open	Mech. failure	No impact on normal operation. Possible reverse flow in bleedoff line during shutdown if VCT is at higher pressure than bleedoff lines	None	Excess flow check valves will be closed during shutdown	
94)	Controlled Bleedoff Line Test Connec-tions, CH-740, CH-741, CH-742, CH-743	a) fails closed	Mech. failure	No impact on normal operation. Unable to drain bleedoff line for one pump or inservice test CH-505 or 506	Operator	None	
		b) fails open	Seat leakage, mech. failure	Possible loss of primary coolant inside containment	Local leak detectors containment radiation monitors. Bleedoff line flow indicators	Valves are all blind flanged	
95)	Primary Sample Purge Check Valve; CH-197	a) fails closed	Mech. failure blockage	No impact on normal operation. Unable to purge primary sample system before obtaining primary sample	Operator	None	
96)	VCT Temperature Indicator, TI-225	a) spurious Hi temp alarms	Elect. or mech. failure, setpoint drift	No direct impact on system operation. False indication of Hi temp in VCT	Hi temp alarm from TI-225, with normal pressure and temp. Indication from letdown, charging, and controlled bleedoff instruments	None	
		b) false lo temp. indications	Elect. or mech. failure, setpoint drift	No impact on normal operation. Unable to detect Hi temp condition in VCT	Periodic test	None	
97)	VCT Level Indicator/ Controller LIC-226	a) spurious low level indication and alarm	Elect or mech failure setpoint drift	Possible overfilling of VCT due to actuation of automatic makeup. Letdown diverted to PHIX on High level in VCT	Excessive use of makeup. Diversion valve position indicator in control room, in combination with Lo level alarm from LIC-226	LIC-227 will alarm on Hi level and divert letdown flow to PHIX to prevent overfilling VCT	Excessive use of makeup and excessive generation of liquid waste
		b) spurious Hi level indication and alarm	Elect or mech failure, setpoint drift	Early termination of makeup flow, RCS losses not compensated for. Possible PZR level decrease. Gradual emptying of VCT	Hi level alarm from LIC-226 with diversion valve not changing position	On Lo-Lo VCT level, LIC-227 will switch charging pump suction to refueling water tank (RWT)	

Table 9.3.4-3
(Sheet 22 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
98)	VCT Level Controller, LC-227	a) spurious Lo level alarms	Elect. or mech. malfunction setpoint drift	VCT will be isolated and charging pump suction aligned to RWT. VCT will be overfilled because letdown will not be diverted	Lo Level alarm from LIC-227 with normal or Hi level indic. from LIC-226	CH-115 will relieve, if necessary	
		b) spurious Hi level alarms	Elect. or mech. malfunction setpoint drift	Letdown flow will be diverted to PHIX and holdup tank, VCT will start to empty	Hi level alarm from LIC-227 with normal or low level indications from LIC-226	LIC-226 will initiate automatic makeup on Lo level.	
99)	Volume Control Tank	a) breach	Weld failure, mfg defect	Loss of primary coolant outside containment	Low level alarms from LIC-226 and LIC-227. Local leak detectors	None	Operator action required to terminate this event. VCT not required for safe shutdown.
100)	VCT Discharge Relief Valve; CH-115	a) fails closed	Blockage. mech. failure	No impact on normal operation. Loss of overpressure protection for VCT and VCT discharge line	Periodic test	None	
		b) fails open	Mech. failure	Minor losses of primary coolant to equipment drain tank (EDT). Possible trip of charging pumps on low suction pressure	EDT level indications, possibly VCT level indicator LIC-226, possible charging pump trouble alarm.	Makeup system compensates for minor coolant losses. LIC-227 will switch charging pump suction to RWT via BAMP on low low level in the VCT	
101)	VCT Discharge Local Sample Valve, CH-116	a) fails closed	Mech. failure	No impact on normal operation. Unable to sample VCT contents	Operator	None	
		b) fails open	Seat leakage	Minor loss of primary coolant outside containment	Local leak detectors, radiation monitors	None	
102)	VCT Drain Valve CH-117	a) fails closed	Mech. failure mech. binding	No impact on normal operation. Unable to drain VCT	Operator	Other drain valves available downstream	
		b) seat leakage	Contamination mech. damage	Minor loss of primary coolant to drain header	Possibly low level indications from LIC-226	None	
103)	VCT Discharge Isolation Valve, CH-501	a) fails open	Mech. failure loss of power	Unable to isolate VCT on low level signal from LIC-227. Possible emptying of VCT. Possible charging pump trip on low suction pressure with loss of charging flow	Valve position indication in control room	LIC-227 will switch charging pump suction to RWT via boric acid makeup pumps (BAMP) on Lo-Lo level in the VCT	
		b) fails to closed position	Mech. failure, spur signal	Sudden loss of charging flow. PZR level decreases, loss of letdown due to high temp. trip (TIC-221) of CH-515	VCT and PZR level indicators, charging pump trip indications	None	Charging Pump Suction can be switched to RWT by opening valve CH-514 and starting BAMP

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		c) fails in closed position	Mech. failure, loss of power	Unable to switch charging pump suction back to VCT	Valve position indicator in control room	Charging pump can still be aligned to RWT	Valve normally aligned to VCT
104)	VCT Discharge Check Valve; CH-118	a) fails open	Mech. failure	No impact on normal operation. Possible leakage into VCT when charging pumps taking suction from RWT via BAMP	None	Valve CH-501 will be closed when charging pumps taking suction from RWT	
		b) fails closed	Mech. failure, mech. binding, blockage	Unable to switch charging pump suction back to VCT. Possible charging pump trip on Lo suction pres.	Charging pump trip, VCT level indications	Charging pumps can still be aligned to RWT	
105)	Charging Pump Isolation Valves, CH-316, CH-339, CH-319, CH-337, CH-322, CH-335	a) fails open	Mech. binding	Unable to isolate one charging pump for maint. No impact on normal operation	Operator	None	
		b) fails closed	Mech. binding, blockage	Unable to return charging pump to service after maint.	Operator	Redundant charging pumps	
106)	Charging Pump Drain Valves; CH-317, CH-329, CH-320, CH-332, CH-323, CH-336	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to drain pump for maint.	Operator	Some redundance between suction and discharge drain valves	
		b) seat leakage	Contamina-tion, Mech. damage	Minor loss of primary coolant to recycle drain header	Possibly Hi level indications from EDT, or low level indic. from VCT	Makeup system compensates for minor coolant losses	
107)	Charging Pump Discharge Check Valves; CH-328, CH-331, CH-334	a) fails open	Mech. failure	No impact on normal operation. Possible reverse flow into standby pump. Possible damage to pump	None	Charging pump discharge relief valves provide overpressure protection	
		b) fails closed	Mech binding blockage	Unable to use affected charging pump. Possible pump damage due to dead heading	Charging line flow indicator, Lo flow indication	Redundant charging pumps. Charging pump discharge relief valves provide recirculation for charging pumps	
108)	Charging Pump Discharge Relief Valves; CH-326, CH-325, CH-324	a) fails open	Mech. failure, setpoint drift	Charging pump discharge diverted to charging pump suction. Reduced charging flow from affected pump	Lo flow indication from charging line flow indicator, FI-212	Redundant charging pumps	

Table 9.3.4-3
(Sheet 24 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. binding blockage	No impact on normal operation. Loss of discharge overpressure protection.	Periodic test	None	
109)	Charging Pump Suction Relief Valves; CH-315, CH-318, CH-321	a) fails closed	Mech. failure, blockage	No affect on normal system operation. Loss of overpressure protection for potentially closed suction line	Periodic test	None	
		b) fails open	Setpoint drift spring failure	Loss of primary coolant to EDT. Gradual VCT level reduction	EDT level indications, VCT level indications	Makeup System Compensates for minor coolant losses	
110)	Charging Pump, Suction Pressure Switches; PS-216, PS-217, PS-218	a) erron-eously senses Lo press.	Mech. failure, setpoint drift	Spurious charging pump trip	Charging pump trip indications. Low flow indication from FI-212, PZR and VCT level indic.	Redundant charging pumps	
		b) senses pressure too high	Mech. failure, setpoint drift point drift	No impact on normal system operation. Failure to sense Lo suction pressure. Possible cavitation damage to charging pump	Periodic test	None	
111)	Charging Pumps (CP) CP-1, CP-2, CP-3	a) operating pump stops	Loss of power, seizure, other mech. failure	Reduced charging flow, VCT level increase, PZR level decrease. Letdown temp. increases	Lo flow alarm from FI-212, VCT and PZR level indications, letdown temp indications	PZR level control will start standby CP	Normally two pumps are always running.
		b) standby pump fails to start	Loss of power mech. failure	Unable to deliver maximum charging flow when needed. PZR level drop. Possible SIAS if PZR empties	Lo PZR level alarm CP run indicator	Letdown Control Valves CH-110P, Q modulate letdown flow to maintain PZR level.	
		c) spurious startup of standby pump	Spurious signal, operator error	Excess charging flow, PZR level increase, possible overpres. of RCS	CP run indicator, Hi flow indication from FI-212, PZR level and pres. alarms	PZR level control could shut down one pump, or open letdown control valve further. PZR spray would come on to hold pres. down	
112)	Charging Pump to HPSI Header Isolation Valves; CH-796, CH-797, CH-798	a) fails closed	Mech. binding	Unable to test HPSI check valves or to establish alternate charging path using associated CP	Operator	Any one of the three CP's can be used through the associated valve	
		b) fails open	Seat leakage	Part of charging flow routed through HPSI header	Lo flow indication from FI-212, flow indications from HPSI indicators	Series redundant isolation valve in the SI System	

Table 9.3.4-3
(Sheet 25 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
113)	Charging Pump to HPSI Header Check Valve; CH-440	a) fails closed	Mech. failure blockage	No impact on normal operation. Unable to use charging pumps to test HPSI check valves or to establish alternate charging path.	No flow through HPSI check valves during test and subsequent check valve inspec.	None	
		b) fails open	Mech. failure	No impact on normal operation. Possible diversion of HPSI flow to charging pumps during safety injection	None	Series isolation valves are normally closed	
114)	Hydrostatic Test Connect. Isolation Valve; CH-314, CH-642	a) fails closed	Mech. failure	No impact on normal system operation	Operator	None	
		b) seat leakage	Contamination mech. damage	Minor loss of primary coolant outside containment	Local leak detectors	Test connections are blind flanged	For Units where DMWO 4304156 has been implemented, CH-314 is not a Hydrostatic Test Connect, Isolation Valve.
114A)	RC Alternate Suction Isolation Valve CH-1004 (Effective for Units where DMWO 4304156 has been implemented)	a) Fails closed	Mech. Failure blockage	No impact on normal system operation	Operator	Not required	
		b) Fails Open	Mech. failure	Loss of RWT fluid, possible charging pump performance reduction	Local leak detectors	Valve is normally closed	Multiple failures required to affect charging performance.
115)	Charging Pressure Indicator, PI-212	a) spurious Lo pres. alarm	Elect. or mech. failure	No direct impact on system operation. False indication of charging pump degradation or charging line break	Low pres. alarm from PI-212 with normal indications from FI-212, TI-229, and PDIC-240	None	
		b) erroneous Hi or normal pres. indication	Elect. or mech. failure	No impact on system operation failure to detect CP degradation or charging line break	Periodic test	FI-212 will provide indication of CP degradation or charging line break	
116)	Charging Flow Indicator FI-212	a) spurious Lo flow alarms	Elect. or mech. failure setpoint drift	No direct impact on system operation	Lo flow alarm with normal indication from PI-212, and stable PZR level	None	
		b) erroneous Hi or normal flow indications	Elect. or mech. failure setpoint drift	No impact on system operation. Failure to detect decreased charging flow	Periodic test, charging pump run indicator	None	
117)	H_2 Inject. Isolation Valves, CH-436, CH-828	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to inject H_2 directly into charging line	Operator	H_2 concentration normally maintained by H_2 blanket in VCT	
		b) fail open	Mech. failure	Unable to terminate H_2 injection directly into charging line	Operator	Redundant isolation valves	

Table 9.3.4-3
(Sheet 26 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
118)	H_2 Inject. Check Valve, CH-827	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to inject H_2 directly into charging line	Lo flow alarm from FI-207	Same as 117 a)	
		b) fails open	Mech. binding	No impact on normal operation. Possible diversion of charging flow to H_2 header	None	Manual isolation valves CH-436, CH-828	
119)	H_2 Inject. Flow Indicator, FI-207	a) spurious Hi flow alarms	Elect. or mech. malfunct. setpoint drift	No impact on normal operation. Incorrect indication of H_2 addition rate	Alarm and RCS sample analysis for H_2	None	H_2 blanket in VCT is preferred method of H_2 concentration control in RCS
		b) spurious Low flow alarms	Elect. or mech. malfunction, setpoint drift	Same as above	Same as above	Same as above	Same as above
120)	Charging Line Manual Isolation Valve; CH-429	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate charging line for maint. or for alternate path charging thru HPSI header	Operator	Valve, CH-524 can be closed	
		b) fails closed	Mech. binding	Unable to reestablish charging flow thru normal path	Operator	Alternate charging path thru HPSI header	
121)	Charging Line Isolation Valve; CH-524	a) fails open	Mech. binding, valve operator failure, loss of power	No impact on normal operation. Unable to isolate charging line for maint. or alternate path charging thru HPSI header	Valve position indicator in control room, flow indicator, FI-212	Manual isolation valve, CH-429	Handwheel on valve can be used to close valve if operator malfunction.
		b) fails closed	Mech. binding, valve operator failure	Unable to reestablish charging thru normal path; if this occurs during normal operation the chg. pump disch relief will lift.	Valve position indicator in control room, flow indicator, FI-212	Alternate path charging thru HPSI header	
122)	Test Connection CH-854	a) fails closed	Mech. binding	No impact on normal operation. Unable to test charging line isolation valves IAW ASME XI.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Minor loss of primary coolant outside containment	Local leak detectors	Drain line is blind flanged	
123)	Temperature Indicator, TI-229	erroneous temperature indications	Elect. or mech. malfunct., setpoint drift	No impact on system operation TI-229 has no control function	Periodic test	None	
124)	Auxiliary Spray Valves; CH-203, CH-205	a) fails closed	Mech. binding, valve operator failure, loss of power	No impact on normal operation. Unable to use the charging pumps to provide aux. PZR spray for PZR pres. control during plant shutdown	Valve position indication in control room	Redundant valves from separate power supplies	Cold shutdown can be achieved without auxiliary spray.
		b) fails open	spurious signal, operator error	Excess PZR spray flow, resulting in reduction of RCS pres.	Valve position indicators in control room	None	PZR heaters will come on to maintain PZR pres

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
125)	Charging Line Pressure Control Valve, CH-240	a) fails closed	Mech. failure, spurious signal	Sudden loss of charging flow, VCT level increases, PZR level decreases. Pressure increases in charging line	VCT and PZR level indications, Lo flow alarms from FI-212, Hi pres indic. from PI-212	Alternate charging path through HPSI header. Spring check valve CH-435 will open to maintain charging flow	
		b) regulates back pressure too low	Valve operator malfunction, mech. binding	Short term decrease in RCP seal injection flow and increase in charging flow	Lo flow indications or alarms from seal injection flow indicators. Lo delta pres. indication or alarm from PDIC-240	Seal injection flow control valves will open to increase flow, thereby reestablishing flow balance	
		c) regulates back pressure too high	Valve operator malfunction, mech. binding partial blockage	Short term increase in RCP seal injection flow and decrease in charging flow. Increase in charging line pres.	Hi flow indications or alarm from seal injection flow indicators. Hi delta pres. indication or alarm from PDIC-240	Seal injection flow control valves will close to limit flow. Spring check valve CH-435 will open to maintain charging flow if necessary.	
126)	Auxiliary Spray Line Check Valve; CH-431	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to provide aux. PZR spray for PZR pressure control during plant shutdown	Lo flow indication from FI-212, PZR pres., not decreasing.	None	Plant can be brought to cold shutdown without auxiliary spray.
		b) fails open	Mech. failure	Diversion of PZR spray flow to charging line. Possible PZR pres. increase	PZR pres. indicators	Aux. spray valves CH-203 and CH-205 are closed during normal operation	
127)	Differential Pressure Indicator/ Controller; PDIC-240	a) spurious Lo diff. pres readings	Elect. or mech. malfunct., setpoint drift	PDIC-240 will drive CH-240 closed trying to maintain a DP of 30 lbs. seal injection flow will increase, charging line pressure will increase	Hi flow alarms from seal injection flow indicators, Hi pres indic. from PI-212, CH-240 position indicator	Seal injection flow control valves will maintain seal inject. flow. Spring check valve, CH-435 will open to maintain charging flow if necessary.	
		b) spurious Hi diff press. reading	Elect. or mech. malfunct., setpoint drift	PDIC-240 will drive CH-240 open trying to maintain proper DP. Charging flow will increase and seal injection flow will decrease	Low flow alarms from seal inject flow indic., Lo pres. indic. from PI-212, CH-240 position indic.	Seal inject flow control valves will open to maintain seal inject flow, thereby reestablish charging flow balance	
128)	PDIC-240 Isolation Valves; CH-405, CH-406	a) fails open	Mech. binding	No impact on system operation. Unable to isolate PDIC-240 for maint	Operator	None	
		b) fails closed	Mech. binding	Unable to place PDIC-240 back in service after maint	Operator	None	
129)	Spring Check Valve; CH-435	a) fails closed	Mech. failure, blockage	No impact on normal operation. Loss of pressure surge protection for charging line and CH-240	None	None	

Table 9.3.4-3
(Sheet 28 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails open	Mech. binding	Charging flow diverted past CH-240. Short term reduction in seal inject. flow	Low flow alarms from seal inject flow indic., Lo DP alarm from PDIC-240	Seal inject flow control valves will open to maintain seal inject. flow. CH-435 can be isolated using valve, CH-434	
130)	Isolation Valve, CH-434	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate spring check valve, CH-435	Operator	None	
		b) fails closed	Mech. failure	Same as 129 a)	Operator	None	
131)	Charging Line Check Valve; CH-433	a) fails closed	Mech. binding, blockage	Unable to establish charging flow via normal path	Lo flow indic. from FI-212, Lo DP alarm from PDIC-240	Alternate charging path through HPSI header	Unlikely event since valve is normally open.
		b) fails open	Mech. binding	No impact on normal operation	None	None	
132)	Seal Injection Isolation Valve; CH-231P	a) fails open	Mech. failure, valve operator malfunct., loss of air or power	No impact on normal operation. Unable to terminate seal injection on Hi-Hi or Lo-Lo seal injection flow temp. Possible damage to RCP seals	Periodic test, CH-231P position indication on Hi-Hi or Lo-Lo SIHX outlet temp.	RCP component cooling flow will provide protection for RCP seals	Steam supply to SIHX has been flanged off.
		b) fails closed	Mech. failure, spurious signal	Sudden loss of RCP seal injection flow. Possible damage to RCP seals	Lo flow alarms from RCP seal inject. flow indicators	RCP component cooling water flow will provide protection for RCP seals	
133)	Seal Injection HX Isolation Valves; CH-839, CH-836	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate seal injection heat exchanger (SIHX) for maint.	Operator	Valve CH-231P and CH-255 can be closed	
		b) fails closed	Mech. failure	Unable to reestablish seal inject. flow after maint on SIHX	Operator	None	
134)	Vent Valves; CH-612, CH-613	a) fails closed	Mech. failure	No impact on normal operation. Unable to vent SIHX during maint.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Minor loss of primary coolant outside containment	Local leak detectors	Series redundant isolation valves	
135)	Seal Injection Heat Exchanger, SIHX	a) improper seal injection temp	VCT or RCS makeup temp variation	Seal injection temp changes, possible thermal damage to RCP seals.	Hi-Lo temp alarms from TSHL-231.	CH-231P auto closes on Hi-Hi or Lo-Lo seal inject. temp. NC flow to RCPs provides adequate seal cooling without seal inject.	Steam supply to SIHX has been flanged off. Letdown isolates before Hi-Hi seal inject temp occurs. RMWT and RWT have heaters to raise makeup temp.
		b) cross leakage	Tube corrosion, manufact. defect	Contamination of condensate with primary coolant.	Hi alarm on RU-7, chem analysis, RCS leak rate test, possible low seal injection flow alarms.	Aux steam condensate return from SIHX can be manually isolated.	If needed, closure of CH-231P will terminate leak without damage to RCP seals.

Table 9.3.4-3
(Sheet 29 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
	Seal Injection Heat Exchanger, SIHX	c) external leakage	Weld failure, casing crack	Release of primary coolant outside CTMT.	RCS leak rate test, local leak indication, possible low seal injection flow indications	Manual closure of CH-231P will terminate leak without damage to RCP seals.	
136)	Relief Valve CH-865 (Component Removed)	N/A	N/A	N/A	N/A	Relief valves on CHG pumps' discharge provide adequate protection.	Steam supply to SIHX has been flanged off. Over-pressure due to high seal injection temp not credible.
137)	Temperature Indicator/ Controller; TIC-231	a) Spurious Hi-Lo indication	Elec/Mech malfunct., setpoint drift	CH-231P auto closes on Hi-Hi or Lo-Lo temp. The resulting termination of seal injection may possibly damage RCP seals.	Hi-Lo temp alarms from TSHL-231, valve CH-231P position indication, low flow alarms from seal inject. controllers.	NC flow to RCPs provides adequate seal cooling without seal injection.	Steam supply to SIHX has been flanged off. TIC-231, which regulates AS-TV231 in the steam return line, produces no control action.
		b) False indication of normal SIHX discharg e temp	Elect. or mech. malfunction	No impact on normal operation, but possible RCP seal thermal shock if SIHX discharge temp. is Hi or Low	Periodic tests	None	
138)	Seal Injection Filters, SIF 1, SIF 2	a) plugged	Normal contaminant buildup	Reduced seal injection flow. Possible RCP seal damage	Hi Delta P alarm from PDI-241, Lo flow alarms from seal inject. flow indicators	Parallel redundant full capacity filters	Seal inject flow normally comes from VCT which has relatively Lo particulate concentrations
		b) doesn't filter properly	Mfg. defect, wrong filter cartridge	Contamination of RCP seals, possible seal damage. Contaminant buildup in RCS	RCS chemistry analysis	Parallel redundant filter	Same as above
139)	SIF Isolation Valves; CH-816, CH-8I8, CH-819, CH-821	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate one SIF for element replacement	Operator	None	
		b) fails closed	Mech. failure	Unable to return filter to service after element replacement	Operator	None if other filter needs element replacement	
139A)	SIF fill and vent Valves; CH-1000, CH-1001	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate one SIF for element replacement	Operator	None	Valves are used for fill and vent only. Normally closed
		b) fails closed	Mech. failure	Unable to fill and vent per normal procedures	Operator	Utilize SIF isolation valves for fill and vent	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
140)	SIF Drain Valves; CH-822, CH-823	b) fails closed	Mech. failure	No impact on normal operation. Unable to drain filter for element replacement	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Seal injection flow diverted to recycle drain header	EDT Level indications, Lo flow indications from seal inject. flow indicators	Seal inject. flow control valves will open to maintain seal inject. flow rate. Makeup system will compensate for losses	
141)	Differential Pressure Indicator; PDI-241	a) false indications of Lo Delta pres.	Elect. or mech malfunct., setpoint drift	No impact on system operation	Periodic test	None	
		b) false Hi Delta P alarms	Elect. or mech. malfunct., setpoint drift.	No direct impact on system operation. Possible early replacement of filter element	Hi Delta P alarm	None	
142)	PDI-241 Isolation Valves; CH-825, CH-826	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate PDI-241 for maint	Operator	None	
		b) fails closed	Mech. failure	Unable to return PDI-241 to service after maint	Operator	None	
143)	Local Drain Valves; CH-833, CH-834, CH-848, CH-849, CH-859, CH-860	a) fails closed	Mech. binding	No impact on normal operation. Unable to drain affected line section or test isolation valves IAW ASME OM Code.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on system operation	None	Drain lines are blind flanged	
144)	Seal Injection Line Isolation Valve; CH-255	a) fails closed	Spurious signal, mech failure	Same as 132 b)	Same as 132 b)	Same as 132 b)	Same as 132 b)
		b) fails open	Mech. binding, valve operator failure	No impact on normal operation. Loss of redundant seal injection line isolation capability	Periodic test	Check valve, CH-835. Isolation valve, CH-231P provide isolation	CH-255 can be closed via handwheel if problem is operator failure.
145)	Seal Injection Line Check Valve, CH-835	a) fails open	Mech. binding	No impact on normal operation. Partial loss of seal injection line isolation	None	Redundant check valves in individual seal injection lines	
		b) fails closed	Mech. binding, blockage	Unable to establish seal injection flow on startup	Lo flow alarms from seal injection flow indicators	None	Startup delayed until valve repaired

Table 9.3.4-3
(Sheet 31 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
146)	Seal Injection Flow Indicator/ Controllers; FIC-241, FIC-242, FIC-243, FIC-244	a) false indication of Lo flow rate	Elect. or mech. malfunction, setpoint drift	Flow indicator/controller will drive associated control valve open, causing excess flow to associated RCP seal	Lo flow alarm, and valve position indicator in control room (if fully open).	None	
		b) false indication of Hi flow rate	Elect. or mech. malfunction, setpoint drift	Flow indicator/controller will drive associated control valve closed, resulting in a loss of seal injec. to one RCP. Possible seal damage	Hi flow alarm, and valve position indicator in control	RCP component cooling water flow provides protection for RCP seal on loss of seal injection	
147)	Seal Injection Flow Control Valves; CH-241, CH-242, CH-243, CH-244	a) fails open	Loss of air power	Seal injection flow to one RCP seal will increase	Hi flow alarm from associated flow indicator valve position indicator in control room	None	
		b) fails closed	Mech. failure, spurious signal	Loss of seal injection flow to one RCP seal. Possible seal damage	Lo flow alarm from associated flow indic., valve indic. in control room	RCP component cooling water flow provides protection for RCP seal	
		c) won't respond to control signal	Mech. binding, valve operator failure	Results are similar to a) or b), but less severe			
148)	Seal Injection Check Valves; CH-787, CH-866, CH-802, CH-867, CH-807, CH-868, CH-812, CH-869	a) fails open	Mech. binding	No impact on normal operation. Loss of isolation for seal injection line	None	Four pairs or series redundant check valves	
		b) fails closed	Mech. binding, blockage	Unable to establish seal injection flow to one RCP	Lo flow alarm from flow indicator/ controller on affected line	None	Startup delayed until valve repaired
149)	Refueling Water Tank, RWT	a) external leakage	Mfg. defect, mech. damage, corrosion	Boric acid solution lost. Reduced inventory for RCS makeup. Unable to fill refueling pool for refueling loss of inventory or for safety injection	Lo level alarms from RWT level indicators	None	Reactor would have to be shut down until RWT repaired and refilled. The fuel pool could be used to supply sufficient water for cooldown contraction and boration.

Table 9.3.4-3
(Sheet 32 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
150)	Refueling Water Tank Level Indicators (Safety Ch.); LIC-203A, LIC-203B, LIC-203C, LIC-203D	a) spurious Lo level indication or spurious Hi level indication	Elect. or mech. malfunct., setpoint drift	No direct impact on normal CVCS operation. These indicators provide input to plant protection system to generate recirculation actuation signal during safety injection. Four redundant, independent channels with two of four logic, so a single failure will not affect the PPS	Redundant level detectors	4 redundant level indicator/controllers	
151)	Level Indicator, LI-201	a) spurious Hi level alarms	Elect. or mech. malfunct., setpoint drift	No impact on normal operation. LI-201 serves no control function	Hi level alarms from LI-201 with normal level indications from other RWT level indic.	Redundant level indicators	
		b) spurious Lo level alarms	Elect. or mech. malfunct., setpoint drift	No impact on normal operation	Lo level alarm LI-201 with normal indic. from other RWT level indicators	Redundant level indicators	
152)	RWT Level Indicator/ Controller LIC-200	a) spurious Hi level alarms or indications	Elect. or mech. malfunct., setpoint drift	No direct impact on normal operation. BAMPs will not auto stop on actual Lo-Lo RWT level. Operator may terminate boric acid batching to RWT.	Hi level alarms or indic. from LI-200, with normal or Lo level indic. from other RWT level indicators.	Redundant RWT level indication and alarms. Manual control of BAMPs	
		b) spurious Lo-Lo level indications	Elect. or mech. malfunct., setpoint drift	If makeup operations are in progress, BAMPs will be stopped. Possible decrease in VCT level. Possible deboration.	Lo-Lo level alarms from LALL-200 with normal indic. from other RWT level indicators	Redundant RWT level indicators. Safety related functions can be performed using gravity-fed boration pathways.	During makeup to the VCT or charging pumps, a BAMP trip will automatically secure the make-up evolution to prevent deboration
153)	RWT Isolation Valves; CH-530, CH-531	a) fails open	Loss of power, mech. binding, valve operator failure	No impact on CVCS operation. Unable to isolate RWT during recirculation phase of safety injection	Valve position indic. in control room	None required	
		b) fails closed	Loss of power, mech. binding, valve operator failure	No impact on normal operation. Loss of safety injection inventory. Unable to fill refueling pool for refueling. For CH-530 charging pumps unable to take direct suction from RWT through one gravity feed line.	Valve position indic. in control room	100% redundant paths. Alternate path for charging pump suction	These valves are normally locked open
		c) fails to close (manual action after RAS)	Electrical malfunction, mechanical failure	Degraded performance of one train of HPSI and CS (if air is entrained)	Valve position indicator; periodic testing	Parallel redundant path for HPSI and CS from sump	Timely operator action required to close
154)	RWT Isolation Check Valves; CH-305, CH-306	a) fails open	Mech. binding	No impact on CVCS operation. Possible flow to RWT during recirculation phase of safety injection	None	CH-305 and CH-306 are qualified as "active" to preclude this failure.	
		b) fails closed	Mech. binding, blockage	Same as 153 b)	Flow indic. on approp. flow paths	Same as 153 b)	

Table 9.3.4-3
(Sheet 33 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
155)	RWT Temperature Indicator, TI-200	a) spurious Low temp. alarms	Elect. or mech. malfunction, setpoint drift	No direct impact on system operation. TI-200 has no control function	Lo temp alarm from TI-200 without alarm from TI-201	Redundant temp sensor, TI-201	
		b) false Hi or normal temp. indications	Elect. or mech. malfunction, setpoint drift	Failure to detect Lo temp condit. in RWT, possible precipitation of boric acid	Periodic test	Redundant temp sensor TI-201	
156)	RWT Temperature Sensor, TI-201	a) spurious Low temp alarms	Elect. or mech. malfunction, setpoint drift	No impact on system operation. (Local read-out only)	Lo temp. alarm from TI-201 with normal temp indic. from TI-200	Redundant temp indicator, TI-200	
		b) fails to senses Lo temp. condition	Elect. or mech. malfunction, setpoint drift	Loss of redundant temp. indication for Lo temp in RWT. Possible boric acid precipitation if Lo temp. condition goes undetected	Periodic test	Redundant temp indicator, TI-200	
157)	RWT to Charging Pump Isolation Valve; CH-327	a) fails closed	Mech. failure	No impact on normal operation. Charging pumps unable to take direct suction from RWT via one gravity feed line for HPSI check valve test or other requirements	Operator	Alternate direct suction path available	
		b) seat leakage	Contamination, mech. damage	No impact on normal operation, minor diversion of RWT inventory	None	Isolation valves at charging pump suction	
158)	RWT to Charging Pump Line, CP Suction Isolation Valves; CH-755, CH-756, CH-757	a) fails closed	Mech. binding	Unable to align affected charging pump to RWT via one gravity feed line for test of HPSI check valves or other requirements	Operator	Redundant charging pump can be used/redundant feed feed line can be used	
		b) seat leakage	Contamination, mech. damage	Minor diversion of charging flow	None	Isolation valve CH-327	
159)	RWT Isolation Valve; CH-532	a) fails open	Mech. binding, valve operator, loss of air or power	No impact on normal system operation. Unable to isolate RWT in the event of a makeup line break	Valve position indicator in control room	None	
		b) fails closed	Mech. failure, spurious signal	Loss of makeup flow to VCT or RCS. Possible cavitation damage to BAMPs	Valve position indicator in control room, Lo flow alarm from FQRC-210Y, Lo discharge pres. alarm from PI-206, 207	BAMPs will trip on Lo discharge pres makeup can continue by aligning charging pumps to RWT via valve CH-327	

Table 9.3.4-3

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
160)	Boric Acid Makeup Pump Suction Isolation Valves; CH-143, CH-145	a) fails open	Mech. binding	No impact on normal system operation. Unable to isolate BAMP for maint.	Operator	None without terminating makeup	Makeup can continue using redundant pump
		b) fails closed	Mech. failure	Unable to return BAMP to service after maint.	Operator	None	
161)	Boric Acid Makeup Pumps; BAMP 1, BAMP 2	a) fails to start	Electrical malfunction, mech. binding	Unable to start makeup flow or to recirculate RWT contents	Pump run indicator, Lo discharge pres. alarm	Redundant pump or gravity feed	
		b) stops	Elect. malfunction mech. seizure	Loss of makeup flow. Possible deboration of RCS	Lo discharge pres. alarm, Lo flow from FQRC-210Y	Redundant pump or gravity feed	During makeup to the VCT or charging pumps, a BAMP trip will automatically secure the makeup evaluation to prevent deboration
		c) fails to deliver rated flow	Excess seal leakage, mech. malfunct.	Reduced makeup flow. Possible deboration of RCS	Low discharge pres indic., Lo flow indic from FQRC-210Y	Redundant pump	
162)	BAMP Discharge Pressure Indicators; PI-206, PI-207	a) spurious Lo pres. indications or alarms	Elect. or mech. malfunction, setpoint drift	BAMP will be tripped, causing loss of makeup flow	Lo pres. alarm followed by Lo flow alarm from FQRC-210Y	Redundant BAMP can be placed in service	Same as 161) b)
		b) false Hi or normal pres. indications	Elect. or mech. malfunction	No impact on normal operation, but unable to detect Lo discharge pres. Possible pump damage	Periodic test. Lo flow alarm from FQRC-210Y if Lo pres. condit develops.	Redundant BAMP can be placed in service	Same as 161) b)
163)	BAMP Discharge Check Valve; CH-154, CH-155	a) fails open	Mech. binding	No impact on normal operation possible reverse flow through standby BAMP	None	None	
		b) fails closed	Mech. failure, blockage	Unable to establish makeup flow with affected BAMP. Possible pump damage due to dead heading	Hi discharge pres indic., Lo flow alarm from FQRC-210Y	Redundant BAMP, gravity feed	
164)	BAMP Discharge Isolation Valves; CH-152, CH-153	a) fails open	Mech. binding	No impact on normal operation unable to isolate affected pump for maint	Operator	BAMP discharge check valve provides some isolation	
		b) fails closed	Mech. binding, blockage	Unable to return affected pump to service after maint	Operator	Redundant pump, gravity feed	

Table 9.3.4-3
(Sheet 35 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
165)	BAMP Recirculation Valves; CH-192, CH-130	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate recirculation line for maint. on BAMP	Operator	Valves CH-510 and CH-647 provide adequate isolation	
		b) fails closed	Mech. failure	Unable to establish recirculation flow path for one BAMP. Possible damage to pump if it is dead headed into a closed makeup line	Operator	Redundant BAMP available	This valve would be repaired before starting affected pump. Valves closed only for pump maint
166)	BAMP Suction to Pool Cooling and Purification System (PCPS) Isolation Valve; CH-144	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to obtain borated makeup water from PCPS Unable to supply boric acid solution from RWT via one gravity feed line and from the SFP via one gravity feed line to charging pump suction header.	Operator	RWT is normal source of borated makeup water Alternate gravity feed path to individual charging pump suction lines.	
		b) seat leakage	Contamina-tion, mech. damage	BAMP will draw suction on spent fuel pool, gradually reducing its level. Reduced shielding and cooling for spent fuel	Spent fuel pool level indicators	Redundant isolation valve in PCPS	
167)	BAMP Discharge to PCPS Isolation Valve, CH-753	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to supply boric acid solution from RWT via one gravity feed line and from the SFP via one gravity feed line to charging pump suction header.	Operator	Alternate gravity feed path to individual charging pump suction ilnes.	
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of makeup flow to spent fuel pool (SFP). Gradual SFP level increase	SFP Level indicators. Possibly Lo flow indic. from FQRC-210Y	None	
168)	RWT Gravity Feed to Charging Pump Suction Isolation Valve; CH-536	a) fails closed	Mech. failure, blockage, loss of power	No impact on normal operation. Unable to supply boric acid solution from RWT via one gravity feed line to charging pump suction header	Valve position indication in control room.	Alternate gravity feed path to individual charging pump suction lines	
		b) seat leakage	Contamination mech. damage	Diversion of boric acid solution from RWT to RCS via charging pumps. Possible over boration of RCS	Sample analysis. Decreasing reactor power	None	
		c) fails open	Mech. failure	Diversion of boric acid solution from RWT to RCS via charging pumps. Possible over boration of RCS.	Sample analysis. Decreasing reactor power	None	

Table 9.3.4-3

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
169)	RWT Gravity Feed to Charging Pump Suction Header Check Valve, CH-190	a) fails closed	Mech. failure, blockage	Same as 168 a)	None	Same as 168 a)	
		b) fails open	Mech. failure, seat leakage	No impact on normal operation	None	Isolation valve, CH-536	
170)	Boric Acid Filter (BAF) Isolation Valves; CH-161, CH-166	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate BAF for element replacement	Operator	None	
		b) fails closed	Mech binding	Unable to place BAF back in service after maint.	Operator	Boric acid makeup can continue through diversion valve CH-164	
171)	BAF Diversion Valve, CH-164	a) fails closed	Mechanical binding, blockage	No impact on normal operation. Unable to divert boric acid makeup flow past BAF when BAF element replacement needed	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of boric acid makeup flow past BAF. Possible buildup of contaminants in RCS and VCT	Possibly low diff. pres. indic. from PDI-260	None	
172)	BAF Differential Pressure Indicator, PDI-260	a) spurious Hi Delta P alarms	Elect. or mech. malfunction, setpoint drift	No impact on normal operation. Possible early replacement of BAF element	Hi Delta P alarm from PDI-260, with normal indic. from FQRC-210Y, PI-206, or PI-207	None	
		b) false Lo or normal Delta P indications	Elect. or mech. malfunction	No impact on normal operation. Possible failure to detect plugged BAF element	Periodic test	FQRC-210Y and BAMP discharge pres. indic should indicate plugged element	
173)	Boric Acid Filter	a) plugged	Normal contaminant buildup	Reduced boric acid makeup flow	Hi Delta P alarm from PDI-260, Lo flow alarm from FQRC-210Y	Boric acid makeup flow can be diverted past BAF and element replaced	
		b) does not filter	Element "punch through", wrong element	Contaminant buildup in RCS and VCT	Possibly Lo Delta P indication from PDI-260	Boric acid makeup flow can be diverted past BAF and element replaced	
174)	BAF Drain Valve; CH-134	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to drain BAF for element replacement	Operator	None	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of boric acid makeup flow to recycle drain header	EDT level indic., possibly Lo flow indic. from FQRC-210Y, or Lo Delta P indic. from PDI-260	None	
175)	BAF Vent Valve; CH-132	a) fails closed	Mech. failure	No impact on normal operation. Unable to vent BAF for element replacement	Operator	None	
		b) seat leakage	Contamination mech. damage	Loss of boric acid solution, slight reduction in boric acid makeup flow	Local leak detectors possibly Lo flow indic. from FQRC-210Y	None	
176)	RWT Recircula-tion Valve; CH-510	a) fails closed	Mech. binding, valve operator malfunction, loss of air or power	No impact on normal operation. Unable to recirculate RWT contents through BAF for clean up	Valve position indic. in control room, Hi pres indic from PI-207 or PI-206	None	
		b) fails open	Mech. binding valve operator malfunct.	Boric acid makeup flow diverted back to RWT during makeup operations. Insufficient makeup flow to maintain RCS inventory also, possible deboration	Low flow alarm from FQRC-210Y, PZR LVL alarms, valve position indic. in control room	Gravity feed boric acid makeup can be instituted	A low flow alarm from FQRC-210Y will terminate automatic makeup to prevent dilution.
177)	RWT Recirculation Line Check Valve: CH-647	a) fails closed	Mech. failure blockage	Same as 176 a)	Hi pres. indic from PI-207 or PI-206	None	
		b) fails open	Mech. binding	No impact on normal operation	Operator	None	
178)	Isolation Valve Boric Acid Make-up to Holdup Tank; CH-330	a) fails closed	Mech. binding	No impact on normal operation. Unable to transfer RWT contents to hold up tank for processing or during maint. operation	Operator	None	Transfer would be made only when reactor shutdown
		b) seat leakage	Contamination mech. damage	Minor diversion of boric acid makeup flow to holdup tank during makeup operations. Possible deboration, PZR LVL decrease or VCT level decrease	Possible PZR or VCT level indic., Lo flow indic. from FQRC-210Y holdup tank level indic	None	Same as 176) b)
179)	Boric Acid Makeup Bypass Control Valve, CH-514	a) fails closed	Mech. failure, loss of power, valve operator failure	Unable to provide direct boric acid makeup to RCS on Lo-Lo VCT level. Decrease in PZR levels. Possible reactor trip on Lo PZR level	Valve posit. indic. in control room, Lo flow indic. from F-212, Lo PZR level alarms charging pump trips	Gravity feed boric acid makeup can be instituted by opening CH-536	A low-low VCT level condition is an uncommon situation during normal operation

Table 9.3.4-3
(Sheet 38 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails open	Mech. fail, spurious signal, loss of power when open	Boric acid makeup flow to VCT diverted to charging pump suction. Decrease in VCT level. Possible overboration of RCS	Lo flow indic. from FQRC-210Y, Lo VCT level indic., valve position indic. in control room. Reactor power decrease	None	A low flow alarm from FQRC-210Y will terminate automatic makeup to prevent overboration
180)	Boric Acid Makeup Flow Controller Isolation Valves; CH-653, CH-172	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate FQRC-210Y for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to restore FQRC-210Y to service. Loss of controlled boric acid makeup capability	Operator	Other boric acid makeup paths available	Valves normally open.
181)	Boric Acid Makeup Flow Controller, FQRC-210Y	a) false indication of high flow	Elect. or mech. malfunction, setpoint drift	FQRC-210Y will drive CH-210Y, closed trying to establish proper flow rate. Possible deboration of RCS	Hi flow alarms from FQRC-210Y, valve CH-210Y position indic., VCT level indic., reactor power increase	No other controlled boric acid makeup paths available, but can provide boric acid makeup via direct flow to charging pump suction.	
		b) false indication of low flow	Elect or mech. malfunction, setpoint drift	FQRC-210Y will drive CH-210Y open to maintain flow. Overboration of RCS	Lo flow alarm from FQRC-210Y, valve, CH-210Y posit. indic. VCT level indic reactor power decrease	Same as above	
182)	Boric Acid Flow Controller Outlet to Direct Boration Line Isolation Valve, CH-174	a) fails closed	Mech. binding	No impact on system operation. Unable to use FQRC-210Y as flow indicator for one direct boration flow path.	Operator	Normal direct boration path or bypass of VCT via CH-527	
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of boric acid makeup flow to VCT to charging pump suction. No change in overall boric acid concentration in RCS, but possible decrease in VCT boric acid concentration	None	None	
183)	Direct Boration Line Check Valve, CH-177	a) fails closed	Mech. binding, blockage	Same as 179 a)	Lo flow indic. from FI-212, Lo PZR level alarms, charging pump trips	Same as 179 a)	Same as 179 a)
		b) fails open	Mech. binding	Diversion of charging flow to direct boration line	None	Line isolated by valve CH-514	

Table 9.3.4-3
(Sheet 39 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
184)	Boric Acid Makeup Flow Control Valve, CH-210Y	a) fails closed	Mech. binding, valve operator failure, loss of air or power	Unable to provide controlled boric acid makeup flow to VCT or to charging pump suction, possible deboration of RCS	Valve position indicator, Lo flow alarms from FQRC-210Y reactor power increase	Same as 181 a)	Same as 176 b)
		b) fails open	Valve operator malfunction, spurious signal, mech. failure	Excess boric acid makeup flow rate to VCT or charging pump suction. Possible overboration of RCS	Hi flow alarms from FQRC-210Y, valve position indicator, VCT level indic. reactor power decrease	Same as 181 a)	A high flow alarm from FQRC-210Y will terminate automatic makeup to prevent overboration.
		c) does not respond to control signal properly	Mech. binding, valve operator	Results similar to but less dramatic than a) or b) above			
185)	Boric Acid Makeup Line Check Valve, CH-668	a) fails closed	Mech. failure, blockage	Same as 184 a)	Lo flow alarms from FQRC-210Y, reactor power increase	Same as 181 a)	
		b) fails open	Mech. binding	No impact on normal operation. Diversion of reactor makeup water to boric acid makeup line	None	Valve CH-210Y provides isolation	
186)	Reactor Makeup Water Flow Controller Isolation Valves; CH-195, CH-183	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate reactor makeup water flow controller for maint.	Operator	None	
		b) fails closed	Mech. binding	Unable to restore reactor makeup water flow controller to service. Unable to provide reactor makeup water for controlled makeup to RCS or VCT	Operator	None	No reactor makeup could take place until valve repaired
187)	Reactor Makeup Water (RMW) Flow Controller, FQRC-210X	a) senses flow rate high	Elect or mech. malfunction	FQRC-210X would drive valve CH-210X closed, reducing RMW flow. Possible overboration of RCS due to improper mix of RMW and boric acid in makeup flow	Hi flow alarms from FQRC-210X, posit. indic., decrease in VCT level, decrease in reactor power.	None	Makeup would have to be terminated until controller repaired. A high flow alarm from FQRC-210X will terminate automatic makeup to prevent over-boration.

Table 9.3.4-3
(Sheet 40 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) senses flow rate low	Elect. or mech. malfunction	FQRC-210X will drive valve CH-210X open, increasing RMW flow rate. Deboration of RCS due to excess RMW in makeup flow	Lo flow alarms from FQRC-210X, valve, CH-210X position indic., increase in reactor power.	None	Same as above for over-dilution
188)	RMW Flow Sensor FSL-250	a) fails to sense flow	Elect. or mech. malfunction, operator error	No impact on normal operation. Failure to detect RMW flow during reactor cold shutdown. Possible undetected deboration of RCS during shutdown	Periodic test	None	Flow sensor activated only when reactor is shut down
		b) spurious flow indications	Elect. or mech. malfunction	No impact on normal operation. False indication of RMW flow during reactor shutdown	Periodic test	None	
189)	RMW Makeup Flow Control Valve; CH-210X	a) fails closed	Loss of air or power, valve operator failure, spurious signal	Loss of RMW makeup flow to VCT or charging pump suction, possible over boration of RCS	Lo flow alarm from FQRC-210X, valve position indic. in control room, reactor power decrease	None	Makeup would have to be terminated until valve repaired. A low flow from FQRC-210X will terminate automatic makeup to prevent overboration.
		b) fails open	Valve operator malfunction, spurious signal, mech. binding when open	Excess RMW makeup flow to VCT or charging pump suction, possible deboration of RCS	Hi or Hi-Hi flow alarm from FQRC-210X, valve position indicator in control room, reactor power increase	None	Same as above
		c) fails to respond properly to control signal	Valve operator malfunction	Results similar to but less dramatic than a) and b) above			
190)	RMW Makeup Line Check Valve, CH-184	a) fails closed	Mech. binding, blockage	Unable to supply RMW makeup flow to VCT or charging pump suction. Possible over boration of RCS	Lo flow alarm from FQRC-210X, VCT level decrease, reactor power decrease.	None	Same as 189) a)
		b) fails open	Mech. binding	No impact on normal operation. Possible diversion of boric acid solution to RMW lines	None	Valve CH-210X provides line isolation	

Table 9.3.4-3
(Sheet 41 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
191)	Makeup Valve; CH-512	a) fails closed	Mech. binding, loss of air or power, valve operator malfunction	Unable to provide makeup to VCT. Unable to compensate for minor RCS losses, unable to conduct feed and bleed operations using normal makeup flow path.	Lo flow alarms from FQRC-210X and FQRC-210Y, VCT level indications	Makeup can be supplied directly to charging pump suction via valve CH-527	
		b) fails open	Spurious signal, valve operator malfunction mech. binding when open	Possible draining of VCT contents to makeup lines. Possible over filling and or dilution of VCT	Valve Position indic. in control level indicators	CH-210X and CH-210Y close automatically when makeup is completed except when “manual" is selected on the makeup controllers. Then CH-210X and CH-210Y provide isolation when manually closed	
192)	Makeup Line Check Valve; CH-188	a) fails closed	Mech. binding blockage	Same as 191 a)			
		b) fails open	Mech. binding	No impact on normal operation. Possible draining of VCT to makeup lines	VCT level detectors	Makeup line isolated by valve CH-512	
193)	Direct Makeup Valve; CH-527	a) fails closed	Mech. binding, valve operator malfunction, loss of air or power	Unable to supply blended makeup directly to charging pump suction. Loss of blended makeup capability if VCT isolated	Valve position indic. in control room, Lo flow alarms from FQRC-210X. FQRC-210Y. Lo PZR level alarms Lo flow indic. from FI-212	Normal makeup path is to VCT. None if VCT is isolated	
		b) fails open	Valve operator malfunction, spurious signal, mech. binding when open	Makeup flow to VCT diverted to charging pump suction	None	None	CH-527 can be closed with a handwheel for operator failures
194)	Direct Makeup Line Check Valve, CH-179	a) fails closed	Mech. binding blockage	Same as 193 a)	Lo flow alarms from FQRC-210X, and FQRC-210Y	Same as 193 a)	
		b) fails open	Mech. binding	No impact on normal operation. Minor diversion of charging suction flow to makeup lines	None	Direct makeup line isolated by CH-527	
195)	BAMP to Boric Acid Eductor Isolation Valve, CH-649	a) fails closed	Mech. binding	No impact on normal operation. Unable to initiate flow of RWT water through eductor to draw batched concentrated boric acid solution into RWT	Operator	None	

Table 9.3.4-3
(Sheet 42 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of makeup flow into the boric acid batching lines	None	Isolation valves CH-124 or CH-126	
196)	Boric Acid Batching Eductor	a) eductor doesn't draw sufficient vacuum on boric acid batching tank	nozzle plugged, wrong nozzle	Concentrated boric acid drawn from boric acid batching tank at too slow a rate. Flow to RWT has too slow a rate. Flow to RWT has too low a concentration	Lo flow indic. from FI-213	Valve CH-122 can be opened to get desired flow	Final boric acid concentration in RWT depends on total amount of boric acid added, not addition rate
		b) draws too much vacuum on BABT	Nozzle too large	Concentrated boric acid drawn into recirculation flow at too high a rate. Flow to RWT has greater than desired boron concentration. Possible precip of boric acid	Hi flow indic. from FI-213	Valve CH-122 can be closed to get desired flow rate	Same as above
197)	Boric Acid Batching Line Isolation Valve, CH-126	a) fails closed	Mech. binding, blockage	Same as 195 a)			
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Minor diversion of flow from boric acid concentrator (BAC) or PHIX to boric acid batching tank or makeup lines	None	Valves CH-122, and CH-649 provide isolation	
198)	Isolation Valve CH-124	a) fails closed	Mech. binding	Same as 195 a)			
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Possible unwanted flow from BAC or PHIX to RWT	RWT level indicators	Redundant isolation valves for BAC and PHIX	
199)	BAC to RWT Check Valve, CH-127	a) fails closed	Mech. binding, blockage	Unable to deliver concentrated boric acid bottoms from BAC to RWT. No impact on normal operation	Lo flow rate indic. from FR-295	None	
		b) fails open	Mech. binding	No impact on normal operation. Possible diversion of boric acid batching flow to BAC	None	Check valves in BAC package prevent backflow into BAC	
200)	Makeup Supply Header Isolation Valve to the BABT CH-119	a) fails closed	Mech. binding	No impact on normal operation. Unable to supply makeup water for a batch of concentrated boric acid solution	Operator	None	
		b) seat leakage	Mech. damage contamination	Possible overfilling of BABT during makeup, RMW spill	Local leak detectors	None	Causes no problem other than minor loss of RMW

Table 9.3.4-3
(Sheet 43 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
201)	Boric Acid Batching Tank BABT	a) leak	Manufacturing defect, mech. damage	No impact on normal operation. Loss of RMW when preparing a batch of concentrated boric acid	Operator, local leak detectors	None	BABT is empty during normal operation. Leak would be detected during batching operation
202)	Boric Acid Mixer	a) does not mix	Motor failure, mech. failure	Unable to properly mix concentrated boric acid batch. Possible precip. of boric acid	Operator	Manual mixing	
203)	BABT Heater	a) fails full on	Elect malfunction	Concentrated boric acid solution overheated. Possible boiling with increase in boric acid concentration	High temp. indic. from TIC-213, operator	Heater can be turned off manually	Operator is present for batching evolution.
		b) fails off	Elect or mech. malfunction	Concentrated boric acid solution not heated properly. Possible precipitation of boric acid	Lo temp. indic. from TIC-213, operator	None	BABT fluid is heated prior to adding boric acid to the tank
204)	BABT Temperature Indicator/ Controller, TIC-213	a) spurious Hi temp. readings	Elect or mech. malfunction	TIC-213 will turn off the BABT heater. Insuff. heat to boric acid solution, possible precipitation	Operator	Heater can be controlled manually	
		b) spurious Lo temp. readings	Elect. or mech. malfunction	TIC-213 will turn on the BABT heater. Boric acid solution will be overheated. Possible boiling	Operator	Heater can be manually turned off	
205)	Boric Acid Batching Drain Valves, CH-767, CH-121	a) fails closed	Mech. failure, blockage	Unable to flush and drain BABT or BAB lines after making up a batch or concentrated boric acid. No impact on normal operation	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Minor diversion of concentrated boric acid solution to recycle drain header during batching operations	Operator	None	
206)	Boric Acid Batching Valve; CH-122	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to add concentrated boric acid solution to RWT	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Diversion of RMW or boric acid solution to RWT while preparing batch of concentrated boric acid	Flow indic. from FI-213	Isolation valves CH-126 CH-649	
207)	Relief Valve CH-123	a) fails closed	Mech. binding, blockage	No impact on normal operation. Loss of overpres. protection for potentially closed line section	Periodic test	None	
		b) fails open	Spring failure, setpoint drift	No impact on operations	None	None	

Table 9.3.4-3
(Sheet 44 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
208)	Flow Indicator, FI-213	a) false Hi flow indicator	Elect. or mech. malfunction	CH-122 will be set too low, resulting in reduced boric acid mixing in RWT recirculation flow	Periodic test	None	Same as 196) a)
		b) false Lo flow indicator	Elec. or mech. malfunction	CH-122 will be set too Hi, resulting in Hi boric acid concentration in recirculation/ educting flow. Possible boric acid precipitation	Period test	None	Same as 196) a)
209)	Boric Acid Strainer	a) plugged	Normal contaminant buildup	No impact on normal operation. Unable to establish desired concentrated boric acid flow rate	Lo flow indic. from FI-213	Element can be removed and replaced before continuing boric acid addition.	
		b) doesn't strain out particles	Element "punch through," wrong element	No impact on normal operation. Possible contamination of RWT during boric acid addition	None	Makeup filters should remove contaminants before RWT inventory reaches RCS	
210)	BABT Local Sample Valve, CH-120	a) fails closed	Mech. failure, blockage	Unable to obtain sample of BABT contents for boron analysis	Operator	Sample can be obtained from top of tank	
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Local spill of boric acid solution during batch operations	Operator, local leak detectors	None	
211)	Boric Acid Lines Heat Tracing	a) fails off	Elect malfunction	No impact on normal operation. Insufficient (no) heating for lines carrying concentrated boric acid. Possible boric acid precipitation	Heat tracing status indicator	Concentrated Boric Acid solution is generally not allowed to stagnate, even in the heat traced lines. Fluid movement should prevent precip.	
212)	Makeup Supply Header to Chemical Addition Tank (CAT) Isolation Valve, CH-312	a) fails closed	Mech. failure	No impact on normal operation. Unable to supply RMW to CAT. Unable to batch chemicals for RCS 0_2 concentration and pH control.	Operator	Makeup water could be carried to tank from another source.	Normal RCS O_2 control is via H_2 blanket in VCT.
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operations. Possible overfilling of CAT with RMW during makeup operations	Local leak detectors	None	
213)	Chemical Addition Tank	leak	Mfg. defect, mech. damage	No impact on normal operation. Loss of chemical solution when preparing a batch for addition to RCS	Operator, local leak detector	None	
214)	CAT Isolation Valve, CH-171	a) fails closed	Mech. binding	No impact on normal operation. Unable to add chemical solution to RCS	Operator	None	

Table 9.3.4-3
(Sheet 45 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	No impact	None	CAT normally empty, other isolation valves downstream	
215)	Chemical Addition Strainer	a) plugged	Normal contaminant buildup	No impact on normal operation. Unable to add chemical solution to RCS	CAT not empty	Isolate strainer and replace element	
		b) fails to remove impurities	Element "punch thru", wrong element	No impact on normal operation. Potential addition of contaminants to RCS	None	Contaminants removed from primary coolant by letdown filters	
216)	CAT and Strainer Drain Valve, CH-309	a) fails closed	Mech. failure	No impact on normal operation. Unable to flush & drain CAT after adding chemical solution to RCS. Unable to drain strainer for maint.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Chemical solution diverted to waste management system. Possible increase in RCS 0_2 concentration	None	None	
217)	Chemical Metering Pump	a) fails to start	Loss of Power mech. failure	No impact on normal operation. Unable to add chemical solution to RCS	Pump run indicator	None	
		b) spurious start up	Elect. Malfunc. spurious sig. operator error	Pump damaged	Pump run indicator operator	None	Pump can only turned on by operator via hand switch, therefore this is a highly improbable incident.
218)	Chemical Addition Valve; CH-768	a) fails closed	Mech. failure	Same as 214 a)			
		b) seat leakage	Mech. damage contamination	No impact	None	Isolation valve CH-171, and CH-863.	
219)							
220)	Makeup Line Local Sample Valves; CH-648, CH-176, CH-185	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to obtain local sample at approp. locations in boric acid make up system	Operator	None	
		b) seat leakage	Contamination mech. damage	Loss of boric acid solution outside containment	Local leak detectors	None	

Table 9.3.4-3
(Sheet 46 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
221)	Resin Sluice Supply Header to Reactor Drain Tank Isolation Valve; CH-580	a) fails closed	Mech. binding, loss of air or power, valve operator malfunction	No impact on normal operation. Unable to provide RMW to fill RDT	Valve posit. indic. in control room, low flow indic. (F-249)	Alternate path via valve CH-862	
		b) fails open	Spurious signal, mech. binding or valve operator malfunc. when open	Loss of redundant containment ISOL capability for line on CIAS, possible unwanted RMW flow to RDT	Valve posit. indic. in control room, RDT level indic.	Check valve, CH-494 provides containment isolation. None for unwanted RMW flow.	
222)	Resin Sluice Supply Header Check Valve, CH-494	a) fails closed	Mech. binding, blockage	Same as 221 a)	Lo flow indic. from FI-249	Same as 221 a)	
		b) fails open	Mech. binding	Loss of redundant containment isolation capability for line. Possible drain flow to resin sluice supply header	None	Isolation valve CH-580	
223)	Resin Sluice Supply Header to RDT Manual Isolation Valve, CH-857	a) fails open	Mech. binding	No impact on normal operation, unable to isolate line for maint.	Operator	None	
		b) fails closed	Mech. failure	Same as 221 a)	Operator	Same as 221 a)	Valve is normally open
224)	PCPS to RDT Isolation Valve, CH-456	a) fails closed	Mech. failure	No impact on normal operation	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Possible diversion of drain flow to PCPS	None	None	
225)	Reactor Drain Tank; RDT	leakage	Mfg. defect, corrosion, mech. damage	Loss of primary coolant inside containment	Local leak detectors and radiation monitors, RDT level indicator LIC-268	None	
226)	RDT Level Indicator/ Controller, LIC-268	a) spurious high level alarms	Elect. or mech. malfunction, setpoint drift	No direct impact on operation. Operator may drain tank, losing steam quenching capability for PZR reliefs	Hi level alarms from LIC-268 with normal pres. indic. from PIC-268	None	
		b) spurious Lo level alarms	Same as above	No direct impact on operation. Reactor drain pumps (RDP) will be stopped. Possible level and pres. increase in RDT	Lo level indic. from LIC-268 with Hi or normal indic from PIC-268	None	

Table 9.3.4-3
(Sheet 47 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
227)	RDT Pressure Indicator/ Controller; PIC-268	a) spurious high pres. alarms	Same as above	PIC-268 will close valves CH-560 and CH-540, isolating the RDT outlet lines. Possible overfilling of RDT with a pres. increase	Hi pres. alarm from PIC-268	None	
		b) false Lo pres. indications	Elect or mech. malfunction	No impact on normal operation. Failure to detect pres. increase in RDT. Possible overpres. of gaseous waste management system (GRS) or RDPs	Periodic test	None	
228)	RDT Temp. Indicator, TI-268	Erroneous temp. indic. or alarms	Elect. or mech. malfunct. setpoint drift	No impact on operation. TI-268 has no control function	Periodic test or alarms	None	
229)	N_2 Supply Line Isolation Valve, CH-483	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate N_2 line for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to reestablish N_2 blanket in RDT. Possible combustible gas buildup in RDT	Operator	None	
230)	N_2 Control Valve; CH-484	a) fails closed	Mech. malfunct.	Loss of N_2 blanket for RDT. Possible buildup of combustible gas in RDT	N_2 usage drops, possible Lo pres indic. from PIC-268	RDT can be vented to GRS	
		b) fails open	Mech. malfunct.	Over pressurization of RDT with N_2	HI pres alarm from PIC-268	None	Rupture disc on RDT prevents rupture of tank.
231)	RDT to GRS Vent Valve, CH-540	a) fails closed	Mech. failure, loss of air or power valve operator malfunct.	No impact on normal operation. Unable to vent RDT to GRS	Valve position indic. in control room		None
		b) fails open	Spurious signal mech. binding or valve operator malfunct. when open	Unwanted venting of RDT to GRS. Possible over pres. of GRS.	Valve posit indic. in control room. Lo pres indic. from PIC-268, excess N_2 usage	None	CH-484 is set to maintain 3 psig in RDT, therefore GRS should not be overpressurized.
232)	RDT Outlet Line Containment Isolation Valves; CH-560, CH-561	a) fails open	Mech. binding, valve operator malfunct.	No impact on normal operation. Loss of redundant line isolation on CIAS. For CH-560, possible overpres. to RDP suction on Hi RDT pres	Valve posit. indic. in control room	Redundant valve for CIAS, None for Hi RDT pres. except high pressure alarm from PIC-268	

Table 9.3.4-3
(Sheet 48 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. failure, Loss of air or power, valve operator malfunct.	No impact on normal operation. Unable to drain RDT	Valve posit. indic. in control room	None	
233)	RCP Leakoff Line Check Valve, CH-487	a) fails closed	Mech. binding, blockage	Loss of flow path for leakoff from RCP vapor seals. Buildup of primary coolant on "Top" of vapor seals. Coolant may spill out over the RCP into containment.	Containment sump level alarms	None	Flow rate is approx. 1.2 GPM total
		b) fails open	Mech. binding	Possible diversion of RDT contents to RCP seal leakoff lines. Coolant may spill out over the RCP into containment.	None	None	
234)	RMWT Supply to RDT, Isolation Valve; CH-862	a) fails closed	Mech. failure	No impact on normal operation. Unable to supply RMW to RDT or to RDP suction to aid in pump down of RDT after high temp. relief valve discharge.	Operator	Alternate path via valve CH-580	
		b) seat leakage	Contamina-tion, mechan-ical damage	Unwanted RWM flow to RDT or RDP suction. RDT level increase. Possible flow of RDT contents to resin supply header	Hi level indic. from LIC-268 for flow to RDT. Lo level indic. for flow from RDT	None	
235)	Reactor Drain Pump (RDP) Isolation Valves; CH-465, CH-472, CH-466, CH-473	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate affected RDP for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to put affected RDP back in service after maint.	Operator	Redundant RDPs	
236)	RDP Discharge Pressure Indicators; PI-256, PI-255	Erroneous pressure indic.	Electrical or mech. malfunction	No direct impact on operation. PI-256 and PI-255 have no control function. Possible early maint. on RDP	Periodic test	None	
237)	Reactor Drain Pumps; RDP 1 RDP 2	a) fails to start	Electrical malfunct., mech. binding or failure	Unable to drain RDT or EDT. to PHIX, gas stripper and holdup tank	RDT or EDT level indic. pump "run" indic. pump discharge pres. indic.	Redundant pump	
		b) Running pump stops	same as above				

Table 9.3.4-3
(Sheet 49 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		c) Pump starts	Electrical malfunct., spurious signal	Unwanted draining of RDT or EDT	RDT or EDT level indic. pump "run" indic. pump discharge pres. indic	EDT or RDT isolation valves can be closed; pump power can be manually interrupted	Pumps are only started manually, therefore this is a highly improbable event.
238)	RDT Discharge Check Valves; CH-470, CH-471	a) fails closed	Mech. failure blockage	Unable to drain EDT or RDT. Possible damage to RDP due to dead heading	Hi discharge pres. indic. for RDP	Redundant RDP	
		b) fails open	Mech. binding	No impact on operation	Pressure indicator P-255 (P-256) when other RDP is running.	None	
239)	Reactor Drain Filter Isolation Valves: CH-477, CH-478	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate filter for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to return reactor drain filter to operation after maint.	Operator	Reactor drain filter can be bypassed via valve, CH-474	
240)	Reactor Drain Filter, RDF	a) plugged	Normal contaminant buildup	Unable to drain EDT or RDT through filter.	Hi Delta P alarm from PDI-258	Drain flow can be diverted by the filter while the element is replaced	
		b) doesn't filter	Element "punch thru", wrong element	Contaminants not removed from drain flow. Contam. buildup in PHIX, gas stripper or holdup tank	Low pressure indication from PDI-258.	Same as 240 a)	
241)	RDF Differential Pressure Indicator; PDI-258	a) spurious Hi Delta pressure alarm	Elect. or mech. malfunction, setpoint drift	No direct impact on operation. Possible early replacement of filter element	Hi Delta P alarms from PDI-258 with normal indic. from PI-255 or PI-256	None	
		b) erroneous Lo or normal Delta P indic.	Elect or mech. malfunct.	No impact on normal operation. Unable to detect plugged filter element	Periodic test	None	
242)	RDF Bypass Valve; CH-474	a) fails closed	Mech. failure	No impact on normal operation. Unable to bypass RDF for element replacement	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Diversion of drain flow past RDF. Contaminant buildup in PHIX, gas stripper, or holdup tank	Same as 240 b)	None	
243)	RDF Drain Valve; CH-475	a) fails closed	Mech. failure	No impact on normal operation. Unable to drain RDF for element replacement	Operator	None	

Table 9.3.4-3
(Sheet 50 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	No impact on normal operation. Portion of drain flow from RDT or EDT diverted back to EDT	EDT level indic.	None	
244)	RDF Vent Valve, CH-663	a) fails closed	Mech. failure	No impact on normal operation. Unable to vent RDF when replacing element	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Minor loss of primary coolant outside containment	Local leak detectors local radiation monitor	None	
245)	Letdown Diversion Line Isolation Valve; CH-721	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate letdown diversion valve for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to return letdown diversion line to service after maint., loss of letdown diversion capability for feed and bleed or gas stripping operations	Operator	None	
246)	Letdown Diversion Line Check Valve, CH-722	a) fails closed	Mech. binding	Loss of letdown diversion capability for feed and bleed or gas stripping operations	Lo flow indic. from FI-202	Normal letdown flow path can be maintained until valve is repaired	
		b) fails open	Mech. binding	RDT and EDT drain flow diverted to letdown diversion line	None	Letdown diversion line is closed by valve CH-500	
247)	Temperature Indicator/ Controller; TIC-264	a) spurious Hi temp. indic. and alarm	Elect. or mech. malfunction setpoint drift	EDT/RDT drain flow, or letdown diversion flow diverted from PHIX to gas stripper and/or holdup tank	Hi temp. alarm from TIC-264 with normal indic. from TI-268, TI-269, and TIC-223	None	
		b) erroneous Lo or normal temp. indic.	Elect. or mech. malfunction	No impact on normal operation. Failure to detect Hi temp flow to PHIX. Possible damage to PHIX	Periodic test	None	
248)	PHIX Flow Diversion Valve CH-565	a) fails to gas stripper	Loss of air or power, spurious signal valve operator malfunct., mech. failure	RDT/EDT drain flow or letdown flow diverted from PHIX to gas stripper. Contaminant buildup in gas stripper	Valve posit. indic. in control room, Lo Delta P indic. from PDI-265	None, except that flow will be diverted to EDT on trouble conditions in gas stripper	

Table 9.3.4-3
(Sheet 51 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails to PHIX	Spurious signal, mech. binding, valve operator malfunct.	Unable to divert Hi temp. flow past PHIX. Possible damage to PHIX. Unable to route letdown flow directly to gas stripper for continuous gas stripping	Periodic test, valve not change posit. on demand	None	
249)	PHIX Isolation Valves; CH-724, CH-490	a) fails open	Mech. failure	No impact on normal operation. Unable to isolate PHIX for maint. or resin change	Operator	None	
		b) fails closed	Mech. failure	Unable to restore PHIX to service after maint., possible contaminant buildup in gas stripper, holdup tank and/or VCT	Operator	Flow can be diverted past PHIX until valve repaired	
250)	PHIX Inlet Check Valve: CH-725	a) fails closed	Mech. binding, blockage	Unable to establish flow through PHIX. Possible contaminant buildup in gas stripper, holdup tank and/or VCT	Lo Delta P indic. from PDI-265, Lo flow indic. from FI-202 or High pres. indic. from PI-255, or PI-256	Same as 249 b)	
		b) fails open	Mech. binding	No impact on operation	None	None	
251)	PHIX Resin Fill Valve, CH-726	a) fails closed	Mech. failure	No impact on operation. Unable to add new resin to PHIX	Operator	None	
		b) seat leakage	Contamina-tion, mech damage.	Possible release of radioactive gas outside containment	Radiation monitors	Flow can be diverted past PHIX until valve is repaired	
252)	PHIX Differential Pressure Indicator; PDI-265	a) spurious Hi Delta P indic. and alarm	Elect. or mech. malfunction setpoint drift	No direct impact on operation. Possible early change out of PHIX resin	Hi Delta P alarm not clear when flow diverted to gas stripper	None	
		b) false Lo or normal Delta P indic.	Elect. or mech. malfunction	Unable to detect degradation of PHIX resin	Periodic test	None	
253)	PDI-265 Isolation Valves; CH-727, CH-492	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate PDI-265 for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to place PDI-265 back in service after maint.	Operator	For CH-727 - None for CH-492, valve CH-488 can be opened to take pres. diff. across just the PHIX	
254)	PDI-265 Isolation Valve, CH-488	a) fails closed	Mech. failure	No impact on system operation. Unable to place PDI-265 across just the PHIX rather than across PHIX and strainer	Operator	None	

Table 9.3.4-3
(Sheet 52 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Mech. damage contamination	PDI-265 will be measuring Delta P across just the PHIX when it should be measuring Delta P across PHIX and strainer. Possible failure to detect PHIX degradation or strainer degradation	None	None	
255)							
256)	PHIX Vent Valve; CH-728	a) fails closed	Mechanical failure, blockage	No impact on normal operation. Unable to vent PHIX during drain and flush operations	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Diversion of radioactive gases to GRS. No impact on operation	None	None	
257)	PHIX and PHIX Strainer Flush Valves to SRS; CH-730, CH-489	a) fails closed	Mech. binding, blockage	No impact on normal operation. Spent resin in PHIX or resin in PHIX or resin trapped in strainer, cannot be flushed to the SRS	Operator	None	
		b) seat leakage	Mech. damage, contamination	Part of flow through PHIX will be diverted to SRS	Level indicators in SRS	Isolation valves in SRS	
258)	PHIX Sluice Valve; CH-485	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to flush PHIX with RMW during resin replacement	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Part of flow through PHIX will be diverted to the sluice supply header. Possible contamination of RMW supply	None	Check valve and isolation valve on RMW supply line to sluice supply header	
259)	PHIX Drain Valve; CH-486	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to drain PHIX after flushing spent resin	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Portion of flow through PHIX diverted to EDT	Level indications, or high level alarms from LIC-251	Isolation valve CH-457 on DIDH	
260)	Pre-Holdup Ion Exchanger; PHIX	a) fails to remove contami-nation	Spent resin	Buildup of activity in holdup tank	High ΔP alarm from PDI-265	Bypass PHIX and replace resin	
		b) restricts flow	Plugged	Unable to divert letdown flow during feed and bleed operations	High Delta P alarm from PDI-265	Bypass PHIX and replace resin	

Table 9.3.4-3
(Sheet 53 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		c) external leakage	Corrosion, mfg. defect, mech. damage	Local spill of primary coolant outside containment	Local leak detectors	PHIX can be bypassed and isolated for repair	
261)	PHIX Strainer	a) fails to remove particulate matter	Element "punch through" wrong element	Buildup of contamination in holdup tank, gas stripper, or VCT	Local sample analysis.	PHIX and strainer can be bypassed and isolated for strainer repair	
		b) plugged	Normal buildup of contaminants	Reduced flow through PHIX. Reduced letdown flow during feed and bleed operations.	Hi Delta P alarm from PDI-265, Low flow indic. F-202 if diverting letdown	Same as above	
262)	PHIX Strainer Isolation Valve; CH-491	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate strainer for maint.	Operator	None	
		b) fails closed	Mech. failure, blockage	Unable to restore PHIX to service after maint. on strainer. Possible buildup of activity in holdup tank if feed and bleed or other operations requiring PHIX are in progress	Operator	PHIX can remain bypassed until valve repaired, or operations can be interrupted for valve repair	
263)	PHIX to Holdup Tank Isolation Valve; CH-655	a) fails closed	Mech failures; blockage	Unable to route letdown or RCS drain flow through PHIX directly to holdup tank. Possible forced termination of feed and bleed	Operator	Flow can be routed to HT thru gas stripper, or flow can be routed to RWT	
		b) fails open	Mech. binding when open, or seat leakage	Portion of flow to the gas stripper (GS) will be diverted to HT. Possible buildup of gases in HT	Operator (for stuck open). None for seat leakage	HT is vented to GRS	
264)	PHIX to RWT Isolation Valve; CH-495	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to route letdown or RCS drain flow to RWT after it passes through PHIX	Operator	Flow can be routed to HT, and from there to the RWT	
		b) fails open	Mech. binding when open, or seat leakage	Portion of flow to GS will be diverted to RWT. Possible buildup of gasses in RWT	Operator, RWT level indicator	Series redundant isolation valve, CH-124	
265)	PHIX to Gas Stripper Isolation Valve; CH-496	a) fails open	Mech. binding	No impact on normal operation. Portion flow from PHIX to RWT or holdup tank will be diverted to GS	Operator	Series redundant isolation valve, CH-660, can be closed	

Table 9.3.4-3
(Sheet 54 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. binding	Unable to establish continuous degasification of letdown flow. Unable to degassify PHIX discharge flow. Possible gas buildup in RWT, HT, or VCT	Operator	HT and RWT are continuously vented to GRS VCT already has H_2 blanket.	
266)	Diversion Valve, CH-566	a) fails to gas stripper	Mech. binding valve operator malfunction	No impact on normal operation. Unable to divert flow to EDT on GS trouble condition. GS efficiency reduced. Possible damage to GS	Periodic test	None	
		b) fails to EDT	Loss of air or power, spurious signal, valve operator failure	Flow to GS diverted to EDT. Loss of degasification capability. Possible overfilling of EDT	EDT level alarms, valve position indication in control room	Flow to gas stripper can be interrupted until valve repaired	
267)	Makeup supply Header to Gas Stripper, Isolation Valve; CH-654	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to flush GS with RMW prior to maint.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Primary coolant flow to gas stripper (during degasification) diverted to makeup supply header. Possible contamination of RMW supply	None	Isolation and check valves on makeup supply header	
				RMW diverted to gas stripper during makeup operations. Possible subsequent dilution of boric acid concentration in HT or VCT	None except boronmeter if dilution is significant	None	Dilution would be very minor unless continuous letdown degasification is in process, seat leakage is significant and makeup pumps are in operation
268)	Gas Stripper Isolation Valve, CH-660	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate gas stripper for maintenance.	Operator	Isolation valve CH-496 can be closed	
		b) fails closed	Mech. failure	Same as 265 b)			
269)	Gas Stripper to EDT Drain Valve, CH-662	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate GS for maint.	Operator	None	
		b) fails closed	Mech. failure	No direct impact on normal operation. Possible minor spill of primary coolant if gas stripper components have excess leakage	Operator, local leak detectors and radiation monitors	None	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
270)	Gas Stripper Sample Valve to Gas Analyzer; CH-467	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate GS for maint	Operator	None	
		b) fails closed	Mech. failure	Unable to sample GS with Gas Analyzer	Operator	None	
271)	Gas Stripper, GS	a) fails to remove gases	Loss of aux steam, loss of cooling water, mech. malfunction	Buildup of gasses in primary coolant, HT or VCT.	Local sample analysis, gas analysis	HT is vented to GRS. VCT already has H_2 blanket.	
272)	Diversion Valve CH-567	a) fails to VCT position	Mech. failure, valve operator failure	Unable to divert letdown flow to holdup tank during feed and bleed or on Hi VCT level. Possible overfilling of VCT	Hi VCT level alarms. Valve position indicator in control room	None	
		b) fails to holdup tank position	Loss of air or power, spurious signal, mech. failure, valve operator fail	Letdown flow diverted to hold-up tank during degasification of primary coolant. Decrease in VCT inventory	VCT level alarms. Hi level alarms, valve position indicator in control room	Makeup system will maintain VCT inventory	
273)	Isolation Valves; CH-656, CH-651	a) fails open	Mechanical binding	No impact on normal operation. Unable to isolate radiation monitor, or HT for maintenance	Operator	None	
		b) fails closed	Mech. failure	Unable to reestablish flow path to HT after maint. Unable to empty drain tanks to HT. Unable to conduct feed and bleed operations	Operator	None	
274)	Deleted						
275)	Hold Up Tank Level Indicator Controller, LIC-208	a) spurious low level alarms or indications	Elect. or mech. malfunct., setpoint drift	Transfer of holdup tank contents to BAC will be terminated. Possible overfilling of HT due to undetected HI level in HT	Low level alarm from LIC-208, and inspection	None	

Table 9.3.4-3
(Sheet 56 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) spurious Hi level indications or alarms	Same as above	No direct impact on normal operation. Possible undetected low level conditions in HT. Possible damage to holdup pumps if HT is drained	Hi level alarm from LIC-208, and test	None	
276)	Holdup Tank Temperature Indicator, TI-208	a) spurious low temp alarm	Elect malfunct., setpoint drift	No impact on system operation	Lo temp. alarm from TI-208 and test	None	
		b) false Hi or normal temp indications	Elect. malfunct.	No impact on normal operation. Unable to detect decreasing temp. in HT. Possible boron precipitation if temp. drops	Periodic test	None	
277)	Holdup Pump to Holdup Tank Isolation Valves CH-650	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate HT for maint	Operator	None	
		b) fails closed	Mech. failure	Unable to transfer HT contents to BAC for processing	Operator	None	
278)	Holdup Tank HT	leaks	mfg defect, mech. damage, corrosion	Loss of primary coolant quality water outside containment	HT level indicator	None	
279)	Ion Exchanger Drain Header (DIDH) Strainer Isolation Valves, CH-451, CH-454	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate DIDH strainer for maint	Operator	None	
		b) fails closed	Mech. failure	Unable to return DIDH strainer to service after maint. Unable to drain ion exchangers during resin replacement operations	Operator	None	
280)	DIDH Strainer	a) fails to remove contam-inants	Element "punch through", wrong element	Buildup of contaminants in EDT	Local sample analysis, possibly low differential pressure indication from PDI-250	None	
		b) plugged	Normal contaminant buildup	Unable to drain ion exchangers during resin replacement operations	High Delta P alarm from PDI-250	Isolate and clean strainer	
281)	DIDH Strainer Drain Valve, CH-455	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to drain and clean strainer	Operator	None	

Table 9.3.4-3
(Sheet 57 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of ion exchanger drain flow to solid waste management system	None	None	
282)	DIDH Strainer Differential Pressure Indicator, PDI-250	a) spurious Hi Delta P alarm	Elect. or mech. malfunction, setpoint drift	No adverse impact on operation. Early maint. on strainer	Hi Delta P alarm from PDI-250 and test	None	
		b) false low or normal Delta P readings	Elect. or mech. malfunction	No impact on normal operation. Failure to detect plugged strainer	Periodic test	None	
283)	DIDH Flow Sensor, F-251	Erroneous flow indications	Elect. or mech. malfunction	No impact on normal operation. Flow sensor has only local readout and has no control function	Periodic test	None	
284)	DIDH Isolation Valve; CH-457	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to drain ion exchangers during resin replacement	Operator	None	
		b) fails open	Mech. binding when open, seat leakage	Possible diversion of primary coolant from ion exchangers to EDT	Operator for mech. binding when open, otherwise none	Isolation Valves for the ion exchangers	
285)	DIDH Check Valve, CH-480	a) fails closed	Mech. failure, blockage	Same as 284 a)	No flow indic. from F-250 when CH-457 opened	None	
		b) fails open	Mech. binding, seat leakage	No impact operation	None	Isolation valve, CH-457	
286)	Equipment Drain Tank (EDT) Level Indicator/ Controller; LIC-251	a) spurious high level indications	Elect. or mech malfunct., setpoint drift	No impact on normal operation. Failure to detect Lo EDT level and stop drain pumps during EDT draining. Possible damage to drain pumps	Hi level alarm LIC-251 and test	None	
		b) spurious Lo level indication or alarm	Elect. or mech. malfunction	Unable to detect Hi level in EDT. Possible overfilling of EDT. Possible trip of RDP's when pumping down EDT	Lo level alarm from LIC-251 and test	None	
287)	EDT Temperature Indicator, TI-269	a) spurious Hi temp. indications or alarms	Elect. or mech. malfunct., setpoint drift	No impact on operation. TI-269 has no control funct.	Hi temp. alarm from TI-269 and test. Normal pres indic. from PIC-251	None	
		b) erroneous Lo or normal temp indic.	Elect. or mech. malfunct.	No impact on normal operation. Unable to detect Hi temp condition in EDT	Periodic test	PIC-251 may indic. Hi pres if EDT temp went up

FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
288)	EDT Pressure Indicator/ Controller, PIC-251	a) spurious Hi press indic. or alarm	Elect. or mech malfunct.	PIC-251 will close valves CH-563, CH-564, CH-562, effectively isolating EDT. Loss of recycle drain capability. Unable to drain EDT	Hi pres alarm from test PIC-251, and test	None	
		b) erroneous Lo or normal pres. indic.	Elect. or mech. malfunct	No impact on normal operation. Failure to isolate EDT on high pres. condition. Possible over-pressurization of GRS line and/or reactor drain pumps	Periodic test	None	
289)	EDT to GRS Isolation Valve; CH-564	a) fails open	Mech. binding, valve operator failure	No impact on normal operation. Unable to isolate lines to GRS on Hi. pres. in EDT. Possible overpres. of GRS lines	Valve posit. indic. in control room	None	
		b) fails closed	Loss of air or power, mech. failure, valve operator failure, spurious signal	Loss of ability to vent EDT to GRS. Possible pres increase in EDT.	Valve posit. indic. in control room. Pres indic. from PIC-251	None	
290)	Gas Analyzer Manual Isolation Valve, CH-458	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate Gas Analyzer for maint	Operator	CH-564 can be closed	
		b) fails closed	Mech. failure	Unable to restore one line to Gas Analyzer to service after maint	Operator	Alternate data via CH-568	
291)	EDT to GRS Line Pressure Control Valve; CH-568	a) controls back-pressure too low	Mech. malfunct., setpoint drift	Possible overpressurization of GRS lines. Decrease in EDT pres. Increased N_2 use	Lo pres. indic. from PIC-251. Increase in N_2 usage	N_2 regulator will adjust to maintain proper EDT pres.	Valve can be isolated and repaired
		b) controls back-pressure too high	Mech. malfunction, setpoint drift	Decreased venting of gases in EDT. Possible pres. increase in EDT. Decreased N_2 use	Hi press. indic from PIC-251. Decrease in N_2 in N_2 usage	N_2 Regulator will adjust to maintain proper EDT pres.	
292)	Recycle Drain Header Isolation Valve CH-562	a) fails open	Mech. binding valve operator failure	No impact on normal operation. Failure to isolate drain header from EDT on Hi pressure in EDT. Possible overpressure in drain header	Valve position indicator in control room	Check valve CH-450 will provide some protection	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) fails closed	Mech. failure, valve operator failure, loss of air, or power, spurious signal	Loss of drain capability for various leakoff lines	Valve position indication in control room	None	
293)	Recycle Drain Header Check Valve, CH-450	a) fails closed	Mech. failure, blockage	Same as 292 b)	None	None	
		b) fails open	Mech. binding	No impact on normal operation. Partial loss of isolation capability for drain header	None	Valve CH-562, will provide isolation	
294)	N_2 Supply Line Isolation Valve; CH-830	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate N_2 pres. control valve for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to restore N_2 supply after maint. Loss of proper pres. control and vent/purge capability for EDT	Operator	None	
295)	EDT N_2 Pressure Control Valve; CH-831	a) controls pressure too low	Mech. failure, setpoint drift	Decrease in EDT Vent/Purge rate. Decreased EDT pressure	Lo pres. indic from PIC-251	Vent pres. control valve will close to maintain EDT press	
		b) controls pressure too high	Mech. failure, setpoint drift	Possible overpressurization of EDT, excess N_2 usage	Hi pres. indic. from PIC-251	Vent pres. control valve will attempt to maintain EDT press. Relief valve CH-657	
296)	EDT Relief Valve, CH-657	a) fails closed	Mech. binding, blockage, setpoint drift	No impact on normal operation. Loss of overpres. protection for EDT	Periodic test	None	
		b) fails open	Spring failure, setpoint drift	Primary coolant diverted from EDT to misc radioactive sump	EDT level indic. sump level indic. Local radiation monitor	None	
297)	RSSH to EDT Check Valve; CH-858	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to cooldown EDT with this line and pump down EDT after high temperature relief discharge due to flashing in RDP suction	EDT level indic, Lo RMW flow indic. from F-249	Alternate flow path via, valve CH-562	
298)	Equipment Drain Tank, EDT	Leakage	Mfg. defect, mech. damage, corrosion	Loss of primary coolant outside containment	Lo level alarm from LIC-251, local leak detector, radiation monitor	Isolate and drain EDT for maint.

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
299)	EDT Drain Line Isolation Valve, CH-563	a) fails open	Mech. binding valve operator failure	Possible unwanted draining of EDT during draining of RDT. Possible overpressization of drain pump suction lines on high pressure in EDT	Valve position indic. in control level indic./controller LIC-251, pres. indic./controller, PIC-251	For emptying EDT, LIC-251 will stop drain pumps. Otherwise, none	
		b) fails closed	Mech. failure, valve operator malfunct. loss of air or power spurious signal	No impact on normal operation. Unable to drain EDT	Valve position indicator in control room	None	
300)	EDT Drain Line Check Valve, CH-464	a) fails closed	Mech. failure, blockage	Same as 299 b)	EDT level not decrease when attempt to pump out EDT	None	
		b) fails open	Mech. binding	No impact on normal operation. Possible flow diversion to EDT when draining RDT	None unless EDT level increases	Valve CH-563 will be closed	
301)	Local Sample Valves: CH-665, CH-723, CH-493, CH-652	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to obtain local sample	Operator	None	
		b) seat leakage	Contamination mech. damage	Local spill of primary coolant	Local leak detectors, or radiation detectors	None	
302)	EDT Local Drain Valve; CH-462	a) fails closed	Mech. binding	No impact on operations. Unable to drain EDT for maintenance	Operator	None	
		b) seat leakage	Contamination mech. damage	Possible leakage of primary coolant outside containment	Local leak detectors or radiation monitors	Drain line is blind flanged	
303)	Holdup Pump Suction Isolation Valves, CH-720, CH-734	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate one holdup pump for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to restore one holdup pump (HP) to service after maint	Operator	Redundant holdup pump	
304)	Holdup Pump; HP 1, HP 2	a) won't start	Elec. failure mech. failure	Unable to transfer contents of HT to BAC for processing. Unable to recycle contents of HT for additional cleanup	Operator, discharge pressure indicator	Redundant holdup pump	

Table 9.3.4-3
(Sheet 61 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) spurious startup	Elect. malfunction, spurious signal	High transfer rate if pumping HT contents to BAC. Possible unwanted transfer of HT contents to BAC, pump damage if isolated	HT level indicators BAC instrumentation pump run indicators	Power can be manually interrupted	Since pumps can only be started via a local HS, this is a highly improbable incident
305)	Holdup Pump Discharge Pressure Indicators; PI-270, PI-271	a) spurious High or Low pres. indic.	Elect. or mech. malfunction	No impact on normal operation. Pressure indicators have no control function. Possible unneeded maintenance on holdup pump	Periodic test	Redundant holdup pump	
306)	Holdup Pump Discharge Check Valves; CH-759, CH-735	a) fails closed	Mech. failure, blockage	Unable to transfer contents of HT to BAC, or to recirculate HT contents	High pres. indic. from HP discharge pres. indicator	Redundant holdup pump	
		b) fails open	Mech. binding	No impact on normal operation. Possible reverse flow thru standby HP	None	Suction isolation valve for standby HP is closed	
307)	Holdup Pump Discharge Isolation Valve; CH-658, CH-737	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate line to BAC for maint. or recirculation of HT contents	Operator	None for maint. Redundant HP for HT recirc.	
		b) fails closed	Mech. failure	Unable to transfer HT contents to BAC for processing after maintenance	Operator	Redundant HP can be used	
308)	Holdup Pump Recirculation Valves; CH-430, CH-446	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate holdup pump for maint.	Operator	Redundant HP can be used	
		b) fails closed	Mech. failure	Unable to restore HP recirculation line after pump maint. Possible damage to pump due to dead heading	Operator	Redundant HP can be used	
309)	HT to Reactor Drain Filter Line Check Valve, CH-685	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to recycle HT contents through reactor drain filter, PHIX or GS for additional clean up	High pres. indic. from HP discharge pres. indic.	None	
		b) fails open	Mech. binding	No impact on normal operation. Possible diversion of reactor drain tank flow directly to BAC	None	Valve CH-686 is normally closed	
310)	HT to Reactor Drain Filter (RDF) Isolation Valve, CH-686	a) fails closed	Mech. binding, blockage	Same as 309 a)	Operator	None	
		b) fails open	Mech. binding	Same as 309 b)	Operator	Check Valve CH-685

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
311)	HT to Liquid Radwaste System Isolation Valve, CH-684	a) fails closed	Mech. failure blockage	No impact on operations. Unable to transfer fluid to LRS	Operator	None	
		b) seat leakage	Contamina-tion, mech damage	Possible spill of primary coolant grade water	Local leak detectors	Line is blank flanged	
312)	BAC Bypass Line to BACIX, Isolation Valve, CH-683	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to divert HP flow to BACIX if reactor makeup water is needed when BAC out of service	Operator	None if BAC in service	
		b) seat leakage	Contamina-tion, mech. damage	Portion of HP flow diverted past BAC. Increased depletion of BACIX resin. Possibly eventual boron carry over to reactor makeup water tank (RMWT)	None	None	
313)	BAC Bypass Line to BACIX, Check Valve; CH-682	a) fails closed	Mech. failure blockage	Same as 312 a)	Hi pres. reading from HP discharge pres. indic. when CH-683 open	None if BAC in service	
		b) fails open	Mech. binding	Possible diversion of BAC purified water output back to HP discharge line	None	Isolation Valve CH-683	
314)	BAC Bypass to RWT, Isolation Valve, CH-752	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to divert HP flow to RWT if RWT inventory must be increased when BAC out of service	Operator	Operator can make up a batch of concentrated boric acid solution in BABT and add to RWT	
		b) seat leakage	Contamina-tion, mech. damage	Portion of HP flow diverted past BAC to RWT or LRS. Possible dilution of RWT	None unless RWT is diluted, then, local sample analysis	RWT concentration can be increased by adding concentrated boric acid solution from BABT	
315)	BAC Bypass Line to RWT, Check Valve, CH-718	a) fails closed	Mech. binding, blockage	Same as 314 a)	Hi pres. indication on HP discharge pres. indic. when CH-752 open	None	
		b) fails open	Mech. binding	Possible diversion of concentrated boric acid bottoms from BAC output back to HP discharge line	None	Isolation valve CH-752	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
316)	Boric Acid Concentrator BAC	a) fails to concen-trate boric acid enough	Electrical or mech. malfunction control malfunct. insufficient steam supply	Concentration of boric acid bottoms released to RWT too low. Dilution of RWT. Possible boron carryover to RMWT	Various BAC indic. and alarms, local sampling of RWT and RMWT	BACIX for boron carryover. Boric acid batching for low boron concentrate in RWT	
		b) concen-trates boric acid too much	Same as above	Concentration of boric acid bottoms released to RWT too high. RWT boron concentration increase, possible over boration of RCS	Local sampling of RWT, reactor power decrease	No safety problem	
		c) leakage	Mfg defect, corrosion, mech. damage	Release of primary coolant quality water, or concentrated boric acid solution outside containment	Local leak detectors or radiation monitors	None	
317)	BAC Isolation Valves; CH-708, CH-611, CH-732	a) fails open	Mech. failure	No impact on normal operation. Unable to isolate BAC for maint	Operator	Isolation valves on. BAC skid, and downstream	
		b) fails closed	Mech. failure, blockage	For CH-708, CH-611, unable to return BAC to service after maint. For CH-732, unable to provide RMW to flush BAC	Operator	None	
318)	BAC to RWT Isolation Valve; CH-709	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate line to RWT when transferring highly concentrated, activated bottoms to LRS	Operator	Series redundant isolation valve downstream	
		b) fails closed	Mech. failure, blockage	Unable to transfer concentrated boric acid bottoms from BAC to RWT. Unable to make up RWT inventory losses	Operator	Alternate sources for RWT inventory, including boric acid batching and spent fuel pool	
319)	BAC to LRS Isolation Valve; CH-499	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to transfer highly concentrated activated boric acid bottoms from BAC to LRS for processing	Operator	None	
		b) fails open	Mech. binding when open, seat leakage	Diversion of refueling shutdown concentration boric acid bottoms being transferred to RWT. Excess waste generation. Reduced RWT inventory makeup ability	Operator for binding, none for seat leakage	None	

Table 9.3.4-3
(Sheet 64 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
320)	Relief Valve CH-689	a) fails closed	Mech. binding, blockage, setpoint drift	No impact on normal operation. Loss of overpressure protection for potentially closed line section	Periodic test	None	
		b) fails open	Spring failure, setpoint drift	Same as 319 b)	Periodic test	None	
321)	BAC Concen-trator Concen-trate Line Heat Tracing	fails off	Electo failure	Possible precipitation of boric acid in lines, causing blockage	Heat tracing status indicator	Redundant heat tracing circuit	
322)	BACIX Bypass Line Isolation Valve; CH-619	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to bypass BACIX when BACIX needs maint.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Portion of BAC distillate bypasses BACIX. Possible boron carryover to RMWT	Local sample of RMWT	None	
323)	BACIX Isolation Valves; CH-699 CH-670	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate BACIX for maint. or resin replacement	Operator	Redundant isolation valves upstream and downstream	
		b) fails closed	Mech. failure, blockage	Unable to restore BACIX to service after maint.	Operator	BACIX can be bypassed while valve is repaired	
324)	BACIX Inlet Check Valve; CH-696	a) fails closed	Mech. binding blockage	Unable to pass BAC distillate thru BACIX to remove carryover boron	Lo flow indic. from BAC distillate flow indicator	BACIX can be bypassed while valve is repaired	
		b) fails open	Mech. binding	No impact on operation	None	None	
325)	BMWT recirc to BACIX Line Isolation Valve, CH-690	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to recirc the RMWT through the BACIX	Operator	None	Infrequent operation
		b) seat leakage	Mech. defect or damage, contamination	Minor diversion of BAC distillate to RMW header. Possible minor contamination of resin sluice supply water	None	Redundant isolation valves downstream	
326)	BACIX Resin Fill Valve, CH-679	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to add new resin to BACIX	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	No impact on operation	None	Resin fill line is blind flanged	
327)	BACIX Differential Pressure Indicator, PDI-274	a) spurious Hi Delta pres. alarm	Elect. or mech. failure, setpoint drift	Early replacement of BACIX resin	High ΔP, P-274 alarm	None	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) false low or normal Delta P indic.	Elect. or mech. malfunct.	No impact on normal operation. Failure to detect plugged BACIX	Periodic test	None	
328)	BACIX Differential Pressure Indicator Isolation Valves; CH-693, CH-677	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate PDI-274 for maint	Operator	None	
		b) fails closed	Mech. failure	Unable to restore PDI-274 to service after maint	Operator	None for CH-693, for CH-677, valve CH-678 can be opened to obtain Delta P indic. across just the BACIX	
329)	BACIX Differential Pressure Indicator Isolation Valve, CH-678	a) fails closed	Mech. failure	No impact on normal operation. Unable to set PDI-274 to indic. Delta P across just the BACIX	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	PDI-274 will read Delta P across just the BACIX. Possible failure to detect plugged BACIX strainer	None	None	
330)	BACIX Vent Isolation Valve, CH-680	a) fails closed	Mech. binding	No impact on normal operation. Unable to vent BACIX during resin replacement operations	Operator	None	
		b) seat leakage	Contamination mech. damage	Minor releases of gases to GRS during normal operation	None	None	
331)	BACIX/BACIX Strainer Sluice Valves; CH-676, CH-675	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to sluice resin and contaminants out of BACIX or the BACIX strainer	Operator	None	
		b) seat leakage	Contamina-tion mech. damage	Minor diversion of BAC distillate flow (and resin for CH-676) to LRS	None	None	
332)	BACIX Flush Valve; CH-687	a) fails closed	Mech. binding	No impact on normal operation. Unable to provide RMW to flush BACIX during resin replacement	Operator	None	

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of BAC distillate to resin sluice supply header or diversion of RMW from resin sluice supply header back to RMWT	None	Normally closed upstream valves	
333)	BACIX Drain Valve, CH-688	a) fails closed	Mech. binding	No impact on normal operation. Unable to drain BACIX for resin sluicing	Operator	None	
		b) seat leakage	Contamina-tion, mech damage	Minor diversion of BAC distillate flow to EDT	None	Normally closed downstream valve	
334)	Boric Acid Condensate Ion Exchanger, BACIX	a) fails to remove boron	Resin depleted	Possible boron carryover from BAC to RMWT	Local sample analysis	Bypass BACIX and replace resin	
		b) plugged	Buildup of contaminants	Loss of BAC distillate flow to RMWT	Hi Delta P indic from PDI-274	Same as above	
		c) external leakage	Mfg. defect. corrosion, mech. damage	Local spill of BAC distillate and resin	Local leak detectors and radiation monitors	Bypass BACIX and repair	
335)	BACIX Strainer	a) fails to remove contami-nants	Element "punch thru", wrong element	Possible buildup of contaminants in RMWT	Local sample analysis	Bypass BACIX and repair strainer	
		b) plugged	Normal contaminant buildup	Same as 334 b)	Same as 334 b)	Bypass BACIX and clean strainer	
336)	BACIX Strainer Downstream Isolation Valve: CH-671	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate BACIX strainer for maint.	Operator	Redundant isolation valve downstream	
		b) fails closed	Mech. failure	Unable to restore BACIX to service after maint. on strainer	Operator	BACIX remains bypassed until valve repaired	
337)	BACIX to LRS Isolation Valve; CH-673	a) fails closed	Mech. failure	No impact on normal operation. Unable to dump BAC distillate to LRS when BACIX is out of service	Operator	None	
		b) seat leakage	Mech. damage	Minor diversions of BAC distillate to LRS	None	None	

Table 9.3.4-3
(Sheet 67 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
338)	Isolation Valves CH-672, CH-729	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate RMWT and BACIX when dumping BAC distillate to LRS. Possible contamination of RMWT	Operator	None	
		b) fails closed	Mech. failure	Unable to restore BAC distillate flow thru BACIX to RMWT	Operator	None	
339)	RMWT Level Indicator/ Controller LIC-210	a) spurious Low-Low level indication or alarms	Elect or mech. malfunct., setpoint drift	LIC-210 will stop reactor makeup water pumps (RMWP), thereby terminating RMW flow. Possible over boration of RCS. Failure to detect overfilling of RMWT	Lo-Lo level alarms from LIC-210, periodic test	None	Makeup operations to the VCT or charging pumps will be seemed on loss of RMW pumps.
		b) spurious Hi level indications or alarms	Elect. or mech. malfunction setpoint drift	No impact on normal operation. Possible early termination of holdup tank processing through BAC. Failure to detect Lo-Lo level in RMWT and stop RMWPs. Possible cavitation damage to pumps	Hi level alarms from LIC-210, periodic test	None	
340)	RMWT Temperature Indicator TI-210	a) spurious Low temp. indic. or alarm	Elect. or mech. malfunction, setpoint drift	No direct impact on operation.	Lo temp. alarms from TI-210 and test	None	
		b) spurious Hi or normal temp. indic.	Elect. or mech. malfunction	No direct impact on operation. Unable to detect Low temp. condition in RMWT. Possible undetected freezing of RMWT	Periodic test	None	
341)	Reactor Makeup Water Tank, RMWT	a) external leakage	Mfg. defect, mech. damage	Loss of RMW inventory loss of makeup capability	Lo-Lo level alarms from LIC-210	Isolate RMWT and repair	Reactor shutdown might be required
342)	RMWT Isolation Valve; CH-771	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate RMWT for maint.	Operator	RMWP isolation valves can be closed	
		b) fails closed	Mech. failure	Unable to provide RMWT flow after maintenance	Operator	None	
343)	RMWP Isolation Valves; CH-772, CH-776, CH-773, CH-778	a) fails open	Mech. failure	No impact on normal operation. Unable to isolate RMWP for maint.	Operator	Check valves CH-775 for valve CH-776, and check valve CH-777 for valve CH-778	Two sets of isolation valves, suction and discharge, for the two RMWPs
		b) fails closed	Mech. failure	Unable to restore RMWP to service after maint	Operator	Redundant RMWP	

Table 9.3.4-3
(Sheet 68 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
344)	Reactor Makeup Water Pumps; RMWP 1, RMWP 2	a) fails to start	Loss of power, elect. failure, mech. failure	Unable to provide makeup water to VCT or to makeup water headers	Low pres. alarms from pump discharge pres. indic.	Redundant RMWP	A low flow downstream FQRC-210X will stop automatic makeup operations.
		b) operating pump stops	Same as above	Loss of RMW flow to VCT or makeup water headers	Same as above	Redundant RMWP	
		c) standby pump starts up	Spurious signal, elect. malfunct.	Sudden increase (or start) of RMW flow. Excess usage of RMW, possible deboration of RCS	Hi pres indic. from pump discharge pres. indic Hi flow indic. from RMW flow indic. Possible high VCT level alarm.	FQRC-210X will modulate valve CH-210X to maintain proper flow to VCT or RCS, operator can manually stop pump	Normally this failure in the makeup controller would cause both RMWP & BAMP's to start which would maintain proper boron concentration in VCT
345)	RMWP Discharge Pressure Indicators; PI-208, PI-209	a) spurious Lo pres. indic. or alarm	Elect. or mech. malfunct. setpoint drift	RMWP will be stopped on spurious Lo discharge pres. loss of RMW flow. Possible over boration of RCS	Lo pres alarm from pres. indic.	Redundant RMWP	Same as 339 a)
		b) false normal pres indic.	Elect. or mech.	No impact on normal operation. Failure to detect pump degradation and trip pump	Periodic test. Lo flow indic. from FQRC-210X	Operator can manually trip pump and start redundant pump	
346)	RMWP Discharge Check valves CH-775, CH-777	a) fails closed	Mech. failure blockage	Unable to initiate RMW flow. Possible damage to RMWP	High press. indic. from discharge pres. indic.	Redundant RMWP	
		b) fails open	Mech. binding	No direct impact on normal operation. Possible reverse flow thru standby pump	Possible low pressure indication/alarm from running pump	None	
347)	RMWP Recirculation Valves; CH-794, CH-140	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate RMWP for maint.	Operator	None	
		b) fails closed	Mech. failure	Loss of RMWP recirculation path. Possible pump damage if pump is deadheaded	Operator	None	
348)	Reactor Makeup Filter, RMWF	a) doesn't filter	Wrong element, "punch thru"	Possible buildup of contaminants in VCT, or makeup headers, or RCS	Local sampling, possible Lo Delta P indic. from PDI-261	Isolate and bypass filter for repair	
		b) plugged	Normal contaminant buildup	Loss of RMW flow. Possible over boration of RCS	High Delta P indic. from PDI-261. Low flow alarm FQRC-210X.	Isolate and bypass filter for maint	Automatic makeup operations will be secured on low flow from FQRC-210X

Table 9.3.4-3

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
		c) external leakage	Cracked casing, seat leak on vent valve CH-783	Local spill of RMW	Local leak detectors	Isolate and bypass filter for maint.	
349)	RMWF Isolation Valves; CH-780, CH-792	a) fails open	Mech. binding	No impact on normal operation. Unable to isolate filter for maint.	Operator	None	
		b) fails closed	Mech. failure	Unable to restore filter to service after maint	Operator	Filter can remain bypassed until valves repaired	
350)	RMWF Bypass Valve, CH-779	a) fails closed	Mech. failure, blockage	No impact on normal operation. Unable to bypass filter for maint.	Operator	None	
		b) fails open	Mech. binding when open, seat leakage	Portion of RMW flow bypasses filter. Possible buildup of contaminants in VCT or RCS	Operator for mech. binding, otherwise none	None	
351)	RMWF Differen-tial Pressure Indicator; PDI-261	a) spurious Hi Delta P alarms	Elect. or mech. malfunction setpoint drift	Early maint. on RMW filter	Hi Delta P alarm not clear when bypass filter	None	
		b) false normal Delta P indications	Elect. or mech. malfunction	No impact on normal operation. Failure to detect filter degradation	Periodic test	Filter degradation can be detected by grad increase in RMWP discharge pres. indic.	
352)	RMWF Drain Valve, CH-791	a) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to drain filter for maint.	Operator	None	
		b) seat leakage	Contamina-tion, mech. damage	Minor diversion of RMW to EDT	EDT level increases	None	
353)	RMWT Recirculation Valve, CH-511	a) fails closed	Mech. binding, loss of air or power, valve operator failure	No impact on normal operation. Unable to recirculate RMWT contents	Valve position indic. in control room	RMWP recirculation lines can be used	
		b) fails open	Mech. binding, valve operator failure	Major diversion of RMW flow while providing makeup to VCT. Possible overboration of RCS	Valve position indic. in control room. Lo flow alarms from FQRC-210X	None	Automatic makeup operations will be secured or low flow from FQRC-210X
354)	Makeup Supply Header Check Valve; CH-795	a) fails closed	Mech. binding blockage	Unable to provide RMW to makeup supply or resin sluice supply headers	Hi pres. indic. from RMWP discharge pres. indic., no flow in headers	None	
		b) fails open	Mech. binding	No impact on operation	None	None

CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
355)	Resin Sluice Supply Header Isolation Valves; CH-790, CH-799	a) fails closed	Mech. binding, blockage	Unable to provide RMW to resin sluice supply header	Operator	None	
		b) seat leakage	Contamination, mech. damage	Minor diversion of RMW from makeup supply header to resin sluice supply header	None	Resin sluice Isol. valves at individ. equip. will prevent flow	
356)	Resin Sluice Supply Header Flow Indicator, FI-249	a) indicates flow too high	Elect. or mech. malfunction	Operator will set resin sluice supply throttle valve too low, resulting in reduced RMW to air mix ratio in resin sluice supply. Possible difficulties in flushing ion exchangers	Periodic test	None	
		b) indicates flow too low	Elect or mech. malfunction	Operator will increase throttle valve setting increasing RMW to air mix ratio in resin sluice supply. Excess use of RMW, excess waste generation	Periodic test	None	
357)	Resin Sluice Supply Isolation Valve, CH-691	a) fails closed	Mech. failure	Loss of RMW supply to resin sluice supply header	Lo flow indic from FI-249	None	
358)	Resin Sluice Supply Check Valve, CH-692	a) fails closed	Mech. binding, blockage	Same as 357 a)			
		b) fails open	Mech. binding	Possible air bubble formation in RMW supply header or lines	None	Isolation valves CH-790, CH-799	
359)	Resin Sluice Supply to EDT Isolation Valve CH-762, CH-861	a) fails closed	Mech. failure, blockage	Unable to supply RMW to EDT for flushing or initial inventory or pump down EDT after high temperature relief dischg. to tank with this line.	Operator	Redundant valve and flushing line	
		b) seat leakage	Contamination mech. damage	Diversion of resin sluice supply water to EDT. EDT level increase. Possible EDT pres increase	EDT level and pres. indicators	CH-790 & 799 normally closed.	
360)	Resin Sluice Air Supply Check Valve CH-695	a) fails closed	Mech. binding blockage	Unable to supply air to mix with RMW for resin sluice supply. Excessive use of RMW when flushing ion exchangers. Excess waste generation	No flow indic. from FI-248	None	
		b) fails open	Mech. binding	No impact on normal operation. Possible leakage of RMW to air supply lines	None	Isolation/throttle valve, CH-694	

Table 9.3.4-3
(Sheet 71 of 71)
CHEMICAL AND VOLUME CONTROL SYSTEM (CVCS)
FAILURE MODE AND EFFECTS ANALYSIS

No.	Name	Failure Mode	Cause	Symptoms and Local Effects Including Dependent Failures	Method of Detection	Inherent Compensating Provision	Remarks and Other Effects
361)	Resin Sluice Air Supply Isolation/ Throttle Valve; CH-694	a) fails closed	Mech. failure	Same as 360 a)			
		b) fails to throttle properly	Mech. binding	Unable to obtain desired air supply to resin sluice supply header. Improper water to air mix ratio	Operator	RMW throttle valve can be adjusted to get proper mix ratio	
362)	Resin Sluice Air Supply Flow Indicator; FI-248	a) indicates flow too high	Elect. or mech. malfunct.	Air supply valve will be closed resulting in too little air in resin sluice supply. Excess RMW usage. Excess waste generation	Periodic test	None	
		b) indicates flow too low	Elect. or mech. malfunct	Air supply valve will be opened, resulting in high air content in resin sluice supply. Possible difficulties in flushing ion exchangers	Periodic test	None	
363)	Charging Line Check Valve (CH-639)	a) fails open	Mech. binding	No impact on normal operation. Possible diversion of High press. chemical addition flow	None	Charging pump discharge check valves will prevent signif. diversion of HI pres. chem addition flow.	
		b) fails closed	Mech. binding, blockage	Same as 120 b)	Same as 120 b)	Same as 120 b)	
364)	High Pressure Chemical Line Isolation Valves; CH-659, CH-863	a) fails open	Mech. binding, seat leakage	Possible diversion of part of charging flow to High pres. chemical addition system	None	Series redundant isolation valves	
		b) fails closed	Mech. binding, blockage	No impact on normal operation. Unable to establish HI pres chemical addition flow to RCS	Operator	None	

9.3.4.5 CESSAR Interface Requirements

Provided below are interface requirements, repeated from CESSAR Section 9.3.4.6, with the exception of the emergency power supply requirement for valve CHA-HV-524, as described in Section 9.3.4.1.A.2.c.

Below are the interface requirements that the CVCS places on certain aspects of the BOP, listed by categories. In addition, applicable General Design Criteria (GDC) and Regulatory Guides which C-E utilizes in its design of the CVCS are presented. These GDC and Regulatory Guides are listed only to show what C-E considers to be relevant, and are not imposed as interface requirements, unless specifically called out as such in a particular interface requirement.

Relevant GDC	- 1, 2, 3, 4, 26, 27, 28, 29, 30, 31, 32, 33, 54
Relevant Reg. Guides	- 1.26, 1.28, 1.29, 1.31, 1.36, 1.37, 1.44, 1.48, 1.51, 1.64, 1.68

A. Power

1. Normal Power Requirements

    a. Two independent power sources shall be available to provide electric power to the Chemical and Volume Control System equipment. Power shall be capable of being supplied from the main generator. During startup or shutdown, power shall be available from offsite.

    b. Within the plant distribution system, redundant chemical and volume control system equipment loads shall be supplied by separate buses or

motor control centers to minimize the effect of outages.

c. In the event of a failure of a bus, standby equipment connected to other buses shall be capable of being placed in operation.

2. Emergency Power Requirements

a. Charging Pumps - Each emergency power bus shall supply one pump. Additionally, the third charging pump shall be capable of receiving power from either emergency power bus. The charging pumps shall not be automatically sequenced on the emergency power buses.

b. The following are emergency power supply requirements for CVCS instrumentation:

Instrument	Control[(1)] Location	Emergency Bus
L-200 (RWT level)	A/C	A
L-201 (RWT level)	A/C	B
F-212 (Charging flow)	A/C	B
P-212 (Charging pressure)	A/C	A
L-203A (RWT RAS level)	A	A
L-203B (RWT RAS level)	A	B
L-203C (RWT RAS level)	A	C
L-203D (RWT RAS level)	A	D

c. The following are emergency power supply requirements for CVCS valves:

Valve	Emergency Bus	Control Location[1]
CH-515 (receives SIAS)	B	A/C
CH-516 (receives SIAS & CIAS)	A	A/C
CH-560 (receives CIAS)	A	A
CH-561 (receives CIAS)	B	A
CH-580 (receives CIAS)	A	A
CH-506 (receives CSAS)	A	A/C
CH-505 (receives CSAS)	B	A/C
CH-523 (receives CIAS)	B	A
CH-507	A	A/C
CH-530	B	A
CH-531	A	A
CH-203	B	A/Ct
CH-205	A	A/C
CH-255	B	A
CH-501	A[2]	A
CH-524	A	A[3]
CH-536	A[2]	A

Notes (1) Location code is as follows;
A-Control Room, B-Local,
C-Remote Shutdown Panel,
D-Location outside Control Room.

(2) Receives emergency power under LOP condition

(3) The power supply for valve CHA-HV-524 is removed by locking open its breaker at MCC PHA-M3520. Restoration of the power supply requires local operator action at the MCC before control from the main control room can be restored for the valve.

B. Protection from Natural Phenomena

1. The location, arrangement, and installation of the RWT, charging pump gravity feed piping, charging pumps, charging pump discharge piping, the letdown line between the RCS and letdown containment isolation valves, and Safety Injection Systems (SIS) trains suction piping shall be such that floods (and tsunami and seiches for applicable sites) or the effects thereof will not prevent them from performing their functions. The severity of the above natural phenomena to be considered, as well as the combination of the effects of these natural phenomena with the design conditions of ANSI N18.2-1973, shall meet the requirements of Criterion 2 of 10CFR50, Appendix A.

2. The location, arrangement and installation of the RWT, charging pump gravity feed piping, charging pumps, charging pump discharge piping, and letdown line between the RCS and letdown containment isolation valves, and SIS trains suction piping shall be such that winds and tornadoes or the effects

thereof will not prevent them from performing their functions. The severity of the winds and tornadoes to be considered, as well as the combination of the effects of these natural phenomena with the design conditions of ANSI N18.2-1973, shall meet the requirements of Criterion 2 of 10CFR50, Appendix A.

3. The location, arrangement, and installation of the RWT, charging pump gravity feed piping, charging pumps, charging pump discharge piping, and letdown line between the RCS and letdown containment isolation valves, and SIS trains suction piping shall be such that they will withstand the effects of earthquakes without loss of the capability to perform their functions. The severity of the earthquakes considered, as well as the combination of these natural phenomena with the design conditions of ANSI N18.2-1973, shall meet the requirements of Appendix A of 10CRF50, Appendix A of 10CFR100, and NRC Regulatory Guide 1.48. Failure of non-seismic systems and structures shall not cause loss of either SIS train.

C. Protection from Pipe Failure

The letdown subsystem (from the RCS coolant system), charging system (from valve CH-118 through the charging pumps to RCS to CH523), auxiliary spray, high pressure safety injection header, and drain header isolation valves (CH-329, 332, 3367) and boric acid addition system (including both of the Refueling Water Tank gravity feed connections to the charging pump suction header) the

connections from the refueling water tank to the suction of the safety injection system pumps, and the Refueling Water Tank and spent fuel pool connections to the charging pump suction header via the Boric Acid Makeup Pumps and valve CH-514 shall be protected from loss of function from the effects of pipe rupture, such as pipe whip, jet impingement, jet reaction, pressurization, or flooding.

D. Missiles

The portion of the CVCS protected from pipe failure (see 9.3.4.6.C) shall also be protected from loss of function from the effects of missiles in accordance with the missile barrier design interface requirement of Section 3.5.3.1.

E. Separation

1. Adequate physical separation shall be maintained: (1) between the normal charging line and the alternate charging line through the safety injection header; (2) between the two alternate gravity feed suction lines from the RWT to the charging pump suction header; (3) between the RWT via the boric acid makeup pumps supply direct to the charging pump suction header and the gravity feed lines from the RWT to the charging pump suction header; (4) between the charging pump control circuits, and (5) between the power circuitry to the charging pumps. A single failure due to a missile, structural damage, pipe failure, or fire shall not result in functional

impairment of more than one of these independent paths or channels.

2. The CVCS circuits which are associated with the redundant channels pertaining to boron addition, charging and letdown functions shall be physically separated to preserve redundancy and prevent interactions between channels. Associated circuit cabling from redundant channels shall either be separated, provided with isolation devices, or analyzed or tested to demonstrate that no credible single failure could adversely affect redundant channels of these circuits.

F. Independence

See electric power independence requirements in A.1. above.

G. Thermal Limitations

The ventilation system shall provide suitable ambient conditions for equipment and instrumentation: Temperature and relative humidity ranges for equipment and instrumentation shall be limited to those in Section 3.11.

H. Monitoring

Not Applicable

I. Operational/Controls

Not Applicable

J. Inspection and Testing

1. Refer to CESSAR Section 9.3.4.4 for inspection and testing requirements for the CVCS with the exception of the boric acid concentrator pumps, as noted in section 1.9.2.4.20.

K. Chemistry/Sampling

Not Applicable

L. Materials

1. Controls shall be exercised to assure that contaminants do not significantly contribute to stress corrosion of the stainless steel and welds, including welds at the CVCS boundaries.

2. Piping and components in contact with the CVCS fluid shall be fabricated of austenitic stainless steel, with the exception that the charging pump cylinder block assembly may be fabricated of martensitic stainless steel.

3. Care shall be taken to prevent sensitization and to control the delta ferrite content of (a) welds which join any system fabricated of austenitic stainless steel to the CVCS, and (b) the field welds on the CVCS.

M. System/Component Arrangement

1. The Reactor Drain Tank rupture disc shall be located beneath a concrete ceiling or foundation to help shield other components from rupture disc fragments which may result from disc rupture.

2. The CVCS shall be installed to permit access for inservice inspection in accordance with Section XI of the ASME code and testing of ASME Class 2 and 3 components.

3. Charging pump suction and discharge lines shall be designed to accommodate the pulsating flow from the reciprocating pump. Pulsations from each charging pump will occur at approximately 600 and 1200 pulses per minute. Pump suction pressure can vary by as much as 40 psi peak to peak with approximately half the pressure pulse occurring above and below the main pressure line. The pump discharge pressure can vary as much as 850 psi peak to peak; approximately 350 psi will occur above the normal operating pressure of 2485 psig and 500 psi below.

    a. The discharge piping shall be provided with restraints to minimize vibrations resulting from these pressure surges. Provisions shall be made for the installation of pump inlet and outlet pulsation dampeners in the event they are required. Suction and discharge pulsation dampeners should be directly coupled to the charging pump, no further than 5 feet away. Any piping between the pump and dampener shall be straight.

    b. Suction and discharge piping should be as straight as possible with at least 10 feet of straight pipe directly connected to the suction and discharge of the charging pump. When bends

are necessary, 45 degree elbows or long radius elbows shall be used. A bend shall not be installed directly adjacent to the pump.

c. The suction and discharge piping shall be arranged to preclude the collection of vapor or gas and inleakage of air must be prevented.

4. The location, arrangement and installation of the charging pump gravity feed piping, charging pumps, charging pump discharge piping, the letdown line between the RCS and letdown containment isolation valves, and SIS trains suction piping shall be such that internal floods or the effects thereof will not prevent them from performing their safety functions.

N. Radiological Waste

1. Tables 11.1.1-1, 11.1.1-2 and 11.1.1-3 shall be utilized in determining waste management system input from the CVCS.

O. Overpressure Protection

1. The RWT vent shall be sized to prevent pressurization of the RWT during maximum filling rate operations and to prevent vacuum formation during maximum pumpdown rate operations.

P. Related Service

1. The Refueling Water Tank shall be sized to:

a. Accommodate maximum safety injection flow (see table 6.3.3.3-1) and maintain it for at least 20 minutes before switchover to

recirculation mode, which shall occur at the 10% level in the RWT.

b. Provide sufficient volume for boric acid recycle for back to back shutdown (to 5 percent subcritical) and startup at 90 percent core life without boric acid concentrator processing.

c. Provide sufficient volume to fill the refueling pool.

d. Provisions shall be made so that particles larger than 0.09 inch diameter do not enter the Engineered Safety Feature pump suction lines.

2. The spent fuel pool shall provide an alternate source of borated water to the CVCS.

   a. A volume of 33,500 gallons shall be available to achieve cold shutdown at the end of core life (5 percent subcriticality with rods) assuming 4000 ppm boron within the fuel pool. Draining 33,500 gallons from the spent fuel pool shall not reduce the pool water level below the volume needed for minimum shielding requirements.

   b. The boric acid makeup pumps shall be able to take suction from the spent fuel pool.

3. A fire protection system shall be provided to protect the CVCS. It shall include, as a minimum, the following features:

   a. Facilities for fire detection and alarming.

b. Facilities or methods to minimize the probability of fire and its associated effects.

c. Facilities for fire extinguishment.

d. Methods of fire prevention such as use of fire resistant and non-combustible materials whenever practical, and minimizing exposure of combustible materials to fire hazards.

e. Assurance that fire protection systems do not adversely affect the functional and structural integrity of safety related structures, systems, and components.

f. Care should be exercised to ensure fire protection systems are designed to assure that their rupture or inadvertent operation does not significantly impair the capability of safety related structures, systems, and components.

g. Assurance that a fire will not cause failure in systems, structures, and components to the extent that radioactive releases to the environment will exceed the guidelines values of 10CFR100.

4. Redundant means shall be provided to maintain the RWT contents, interconnecting piping to the safety injection pump trains, instrumentation lines, and loop seal above the minimum operating temperature of 60F and below the maximum operating temperature of 120F. Ensuring that the Auxiliary Building, Annulus Building, and Containment Building ambient

temperatures remain between 60F and 120F during all normal reactor operations may be done to meet this requirement. All other RWT interconnecting piping, including the vent line, which is located outside of the auxiliary building shall be maintained at a minimum temperature of 40F to prevent freezing. Electric heaters installed in the RWT for tank heating will be used to meet this requirement.

5. Air for all CVCS pneumatic valve operators shall be clean, dry, and oil-free.

Q. Environmental

1. The CVCS shall be provided with an environmental control system such that the safety related equipment operates within the environmental design limits specified in Section 3.11.

R. Mechanical Interaction Between Components

1. Those portions of the CVCS that are part of the reactor coolant pressure boundary shall be designed to tolerate the events described in CESSAR Table 9.3-2.

S. The reactor makeup water tank (RMWT) overflow is routed to the holdup tank sump and on to the liquid radwaste system. As noted in response to NRC Question 11A.4, no provision has been made to contain the tank's contents in case of RMWT failure. The failure of RMWT is considered a low probability occurrence, which, when taken into consideration with the low radioactive contamination of the tank's contents, the existing design is acceptable.

9.3.4.6 CESSAR Interface Evaluation

The interface requirements listed in paragraph 9.3.4.1 are met by the PVNGS design as follows:

A. Power

1. Normal Power Requirements

    a. During normal operation, startup, or shutdown, power is supplied from the offsite (preferred) power supply. In the event of loss of the offsite (preferred) power supply, the charging pumps can be manually connected to the emergency diesel generator (refer to section 8.3).

    b. Within the plant distribution system, the CVCS equipment loads are supplied by separate buses or motor control centers to minimize the effect of outages with the exception of the two RWT heaters.

    The RWT heaters are powered through separate circuit breakers in a single motor control center fed from a single 480V load center. The tank contents are normally above 60F and redundant low temperature annunciation is provided in the main control room. The thick concrete tank wall construction, relatively mild Palo Verde climate, and large tank inventory combine to allow only very slow tank content temperature changes. Adequate time is available to restore heater power following

distribution equipment malfunction without concern for precipitation of tank contents.

c. In the event of a failure of a bus, standby equipment connected to other buses is placed in operation.

2. Emergency Power Requirements

a. Charging pumps - Each emergency power bus supplies one pump. Additionally, the third charging pump can receive power from either emergency power bus. The charging pumps are not automatically sequenced on the emergency power buses. However, should a pressurizer low level signal exist upon restoration of power, the standby charging pump whose breaker is set in the Auto After Stop position (designated standby charging pump) only will automatically start. If an SIAS should exist upon restoration of power, however, the automatic start will be delayed 40 seconds by a sequencer permissive signal. The requirement to preclude potential pump damage due to inadequate NPSH is met by a pressure switch which trips the pump on low suction pressure.

b. The following are emergency power supply arrangements for the CVCS instrumentation:

Instrument	Control Location[a]	Emergency Bus
CHA-LI-200 (RWT level)	A/C	A
CHA-LI-200-1 (RWT level)	A/C	A
CHB-LI-201 (RWT level)	A/C	B
CHB-LI-201-1 (RWT level)	A/C	B
CHB-FI-212 (Charging flow)	A/C	B
CHB-FI-212-1 (Charging flow)	A/C	B
CHA-PI-212 (Charging pressure)	A/C	A
CHA-PI-212-1 (Charging pressure)	A/C	A
CHA-LI-203A (RWT RAS level)	A	A
CHB-LI-203B (RWT RAS level)	A	B
CHC-LI-203C (RWT RAS level)	A	C
CHD-LI-203D (RWT RAS level)	A	D

a. Location code is as follows: A-control room, B-local, C-remote shutdown panel, D-location outside control room.

c. The following are emergency power supply requirements for CVCS valves:

Valve	Emergency Bus	Control[a] Location
CHB-UV515 (receives SIAS)	B	A/C
CHA-UV516 (receives SIAS and CIAS)	A	A/C
CHA-UV560 (receives CIAS)	A	A
CHB-UV561 (receives CIAS)	B	A
CHA-UV580 (receives CIAS)	A	A
CHA-UV506 (receives CSAS)	A	A/C
CHB-UV505 (receives CSAS)	B	A/C
CHB-UV523 (receives CIAS)	B	A

Valve	Emergency Bus	Control[a] Location
CHA-HV507	A	A/C
CHB-HV530	B	A
CHA-HV531	A	A
CHB-HV203	B	A/C
CHA-HV205	A	A/C
CH-255	B	A
CH-501	A	A
CH-524	A	A[b]
CH-536	A	A

a. Location code is as follows: A-control room, B-local, C-remote shutdown panel, D-location outside control room.

b. The power supply for valve CHA-HV-524 is removed by locking open its breaker at MCC PHA-M3520. Restoration at the power supply requires local operator action at the MCC before control from the main control room can be restored for the valve.

B. Protection from Natural Phenomena

1. Design provisions for maintaining functional capability of the RWT, the boron addition, charging, and letdown portions of the CVCS during the maximum probable flood or phenomena defined by GDC 2 are discussed in subsection 3.1.2. All of the boron addition, charging, and letdown portions are located in Seismic Category I structures. The RWT is also a Seismic Category I structure. The protection of Seismic Category I structures against natural phenomena is presented in sections 3.3, 3.4, 3.5, and 3.8.

2. The RWT is a concrete structure, seismically qualified for the PVNGS. In addition, the tank is designed to withstand the design wind and tornado forces. The rest of the CVCS system piping, valves, and equipment is located inside the auxiliary and containment buildings which are designed to withstand the wind and tornado forces as required.

3. The RWT is a Seismic Category I concrete structure, lined with an austenitic stainless steel liner. The charging, letdown, and SIS suction piping, as well as associated valves and charging pumps, are Seismic Category I pressure vessels constructed in accordance with ASME Section III, Class 2, requirements.

C. Protection from Pipe Failure

The letdown subsystem (from the RCS coolant system to CHB-UV523), charging system (from valve CHN-V118 through

the charging pumps to RCS), auxiliary spray, high-pressure safety injection headers, and charging pumps drain header isolation valves (CHA-V329, CHB-V332, CHE-V336), the RWT gravity feed connections to the charging pump suction header, the connections from the RWT to the suction of the safety injection system pumps, and the RWT and spent fuel pool connections to the charging pump suction header via the boric acid makeup pumps and valve CHN-UV514 are protected from loss of function from the effects of pipe rupture, such as pipe whip, jet impingement, jet reaction, pressurization and flooding. Refer to section 3.6.

D. Missiles

The portion of the CVCS protected from pipe failure (see paragraph 9.3.4.2, listing C) is also protected from loss of function from the effects of missiles in accordance with the missile barrier design interface requirement of paragraph 3.5.4.1.

E. Separation

1. Adequate physical separation is provided and maintained between the normal charging line and the alternate charging line through the safety injection header, between the alternate gravity fed suction lines from the RWT to the charging pumps (suction lines from the RWT via the boric acid makeup pump and the gravity fed lines from the RWT to the charging pump suction), between the charging pump control circuits, and between the power channels provided to the charging pumps. A single failure due to a

missile, structural damage, pipe failure, or fire will not impair the function of more than one of these independent paths or channels. See paragraph 8.3.1.4 for a discussion on channel separation.

2. The CVCS circuits that are associated with redundant channels pertaining to boron addition, charging, and letdown functions are physically separated to preserve redundancy and to prevent a single event from causing multiple channel malfunctions or interactions between channels. Associated circuit cabling from redundant channels is either separated, provided with isolation devices, or analyzed and/or tested to demonstrate that no credible single failure could adversely affect redundant channels of these circuits as discussed in paragraph 8.3.1.4.

F. Independence

Two independent power sources are available to provide electric power to CVCS equipment (see sublisting A.1 above).

G. Thermal Limitations

1. The ventilation systems are designed in accordance with CESSAR Section 3.11 to maintain the ambient conditions in the auxiliary building between 50 and 104F, and in the containment building between 50 and 120F, under normal operating conditions (refer to section 9.4).

2. Following a loss-of-coolant accident, including the subsequent recirculation mode of operation, the ambient air conditions of the CVCS equipment located in the auxiliary building are controlled in accordance with the requirements of section 3.11.

H. Monitoring

Not applicable

I. Operational controls

Not applicable

J. Inspection and Testing

1. Inspection and testing requirements for the CVCS are given in the Technical Requirements Manual (TRM) and comply with CESSAR Chapter 16.

K. Chemistry/Sampling

Not applicable

L. Materials

1. The insulation used on austenitic stainless steel is discussed in subsection 5.2.3. Cleaning and contamination procedures are also discussed in subsection 5.2.3. Conformance to Regulatory Guides 1.36 and 1.37 is discussed in sections 6.1 and 1.8, respectively.

2. Piping and components in contact with the CVCS fluid are fabricated of austenitic stainless steel, with the exception that the charging pump cylinder block

assembly may be fabricated of martensitic stainless steel.

3. Using the guidance of Regulatory Guides 1.44 and 1.31 as discussed in section 1.8, care is taken in preventing sensitization and in controlling the delta ferrite content of: (a) welds that join any system fabricated of austenitic stainless steel in the CVCS, and (b) field welds on the CVCS (refer to subsection 5.2.3).

M. System/Component Arrangement

1. The reactor drain tank rupture disc is located about 3.5 feet underneath a concrete ceiling. This location helps to shield other components from rupture disc fragments, which may result from disc rupture.

2. The CVCS is installed to permit access for inservice inspection in accordance with Section XI of the ASME Code and testing of ASME Class 2 and 3 components.

3. Charging pump suction and discharge lines are designed to accommodate the pulsating flow from the reciprocating positive displacement pumps, with pulsations occurring at 600 and 1200 pulses per minute.

   a. The discharge piping is provided with restraints to minimize vibrations from the pump pulsation, and from pressure surges ±50 psi, which are the resultant pressure surges with installed pulsation dampeners. The suction and discharge

pulsation dampeners are installed in the immediate vicinity of the charging pumps, with only short, straight pieces of pipes enabling inservice inspection of the welds and facilitating pipe supports.

b. The suction and discharge piping is installed as straight as possible. The plant layout does not allow installation of 10 straight feet of suction and discharge pipes. To compensate for this, pipe bends in the suction piping are 5d bends and elbows in the discharge piping are long radius elbows.

c. Charging pump suction and discharge piping is arranged to preclude collection of vapor or gas in the piping. Should any air be present in the pump suction piping, it would collect in the suction pulsation dampener, from whence it can be periodically purged. In addition, all piping is provided with high-point vents to facilitate purging the system after prolonged shutdowns.

4. Protection is provided from internally generated flooding that could prevent performance of safety-related functions. Refer also to section 3.6 and subsection 9.3.3.

N. Radiological Waste

1. CESSAR Tables 11.1.1-1, 11.1.1-2, and 11.1.1-3 are utilized in determining waste management system input from the CVCS.

O. Overpressure Protection

1. The RWT vent is sized to prevent pressurization of the tank during maximum filling rate operations and to prevent vacuum formation during maximum pumpdown rate operations.

P. Related Services

1. The RWT is sized to:

   a. Ensure that a sufficient volume of borated water will be available to sustain two trains of ECCS and CSS pump flow for the duration of the injection period as assumed in the safety analyses.

   b. Provide sufficient volume for boric acid recycle for back-to-back shutdown (to 5% subcritical) and subsequent startup at 90% core life without boric acid concentrator processing.

   c. The RWT provides sufficient volume to fill the refueling pool.

   d. The engineered safety feature pump suction lines are provided with strainers that prevent particles larger than 0.09-inch diameter from entering the engineered safety feature pumps.

   e. The RWT suction is designed to prevent vortexing by the use of an appropriately designed suction strainer.

2. The spent fuel pool provides an alternate source of borated water to the CVCS.

    a. A minimum of 33,500 gallons is available. The associated reduction in spent fuel pool water level (less than 4 feet) will not appreciably reduce shielding of stored fuel.

    b. The boric acid makeup pump can be realigned to take suction from the spent fuel pool.

3. The fire protection system for the CVCS is discussed in subsection 9.5.1.

    a. Facilities for fire detection and alarming are provided in the auxiliary building where CVCS components are located.

    b. The probability of a disabling fire is minimized by compartmentation, which confines the fire and its associated effect to a limited area.

    c. The plant is equipped with multiple facilities for fire extinguishment. For details, refer to subsection 9.5.1.

    d. The probability of fire is minimized by selection of fire-resistant materials and by minimizing the quantities of combustibles.

    e. The fire protection system and piping have been designed to assure adequate separation from the safety-related components. The building/room draining capability assures that the flood water level, due to a single active failure of the

fire protection lines, would not impair the functioning of the safety-related components.

f. In addition to design features explained in sublisting P.3.e above, the drain systems are designed to mitigate the consequences of inadvertent activation of the fire protection systems.

g. A fire will not cause failure in systems, structures, and components to the extent that radioactive releases to the environment would exceed the guideline values of 10CFR100.

4. The RWT interconnecting piping to the safety injection pump trains, the gravity feed line to the charging pumps, instrumentation lines, and loop seal will be maintained at a minimum temperature of 60F by redundant heat tracing, powered from two redundant power sources. Redundant electric heaters installed inside the tank, powered from a common MCC, assure the minimum tank water temperature of 60F. As noted in the response to Question 6A.51, vent lines from the RWT are not heat-traced since the vent is located in the uppermost portion of the tank. The vent pipes are routed without piping pockets that could cause the accumulation of moisture. As the design winter ambient temperature at PVNGS is 25F for 24 hours, plugging of the RWT vent is considered very improbable.

Q. Environmental

1. The CVCS is provided with an environmental control system such that the safety-related equipment operates within the environmental qualification parameters specified in Appendix A of the Equipment Qualification Program Manual, as discussed in section 9.4.

R. Mechanical Interaction Between Components.

1. The portions of the CVCS that are part of the reactor coolant pressure boundary are designed to tolerate the events described in CESSAR Table 9.3-2.

9.3.5 STANDBY LIQUID CONTROL SYSTEM (BWRs)

This section is not applicable to PVNGS.

9.3.6 COMPRESSED GAS STORAGE SYSTEMS

Compressed gas storage is provided for nitrogen (N_2), hydrogen (H_2), carbon dioxide (CO_2), air, and Halon 1301. Refer to subsection 9.5.1 for the description, safety design bases, and safety evaluation of the CO_2 and Halon 1301 storage subsystems. Subsection 10.3.2 provides a description of the N_2 accumulators for the atmospheric dump valves and safety design bases and evaluations. Compressed air system descriptions, safety design basis, and safety evaluations are provided in subsections 9.3.1 and 9.5.6. Also refer to the PVNGS response to NRC Question 15A.55 contained within appendix 15A.

9.3.6.1 Safety Design Bases

The following safety design bases are applicable to the N_2 and H_2 storage:

A. Safety Design Basis One

The N_2 and H_2 storage subsystems shall be designed and located such that a tank rupture will not adversely affect any system, component, or structure required for safe shutdown.

9.3.6.2 Compressed Gas Storage System Description

9.3.6.2.1 Nitrogen Storage Subsystem

The nitrogen storage subsystem provides nitrogen for use as a pressurized gas blanket in various plant components and systems, as shown in the system P&IDs 01, 02, 03-M-GAP-001 and -002. Design parameters of the subsystem are provided in table 9.3-11.

9.3.6.2.2 Hydrogen Storage Subsystem

The hydrogen storage subsystem provides hydrogen for use as part of an oxygen-free gas blanket in various plant components and systems, as shown in engineering drawings 01, 02, 03-M-GAP-001, -002 and 01, 02, 03-M-GHP-001. Design parameters of the subsystem are provided in table 9.3-11.

The following protective measures are considered in the design to prevent fires and explosion during operation:

- The bulk storage system is located outdoors, away from any ignition sources. The distribution piping is of all-welded construction, and verified leaktight.

- To avoid producing an explosive mixture in the turbine-generator casing during the hydrogen fill or removal evaluation, carbon dioxide is used to purge air or hydrogen, respectively.

9.3.6.3 Safety Evaluation

The following safety evaluation is applicable to N_2 and H_2 storage:

A. Safety Evaluation One

The N_2 and H_2 storage subsystems are located north of the turbine building, outside of any plant structure.

Due to their location, the tank rupture energy release, noted in table 9.3-11, is not sufficient to adversely affect any system, component, or structure required for safe shutdown.

9.3.6.4 Tests and Inspections

No regularly scheduled periodic testing is done on this system. Containment penetration piping and isolation valves are examined for inservice inspection as described in section 6.6.

Table 9.3-11
COMPRESSED GAS STORAGE

Gas	Quantity of Vessels	Applicable Codes	Location in Plant	Pressures (psig)			Energy Release (Max) per vessel	Deviation From Codes
				Design	Operating	Maximum		
N_2	8 cylinders per unit, each 8350 std	ASME, OSHA, DOT	Outside	2450	2400	**2400**	$4.84 \times 10^7 \frac{\text{ft} - \text{lbf}}{\tan k}$	None
N_2	1 liquid N_2 tank, 3200 gal, per unit	ASME OSHA, DOT	Outside	245	245	**245**	$3.77 \times 10^7 \frac{\text{ft - lbf}}{\text{tank}}$	None
N_2[(a)]	6 cylinders per unit, each 1.7std ft^3	ASME, OSHA, DOT	Outside	2450	2400	**2400**	$1.13 \times 10^6 \frac{\text{ft - lbf}}{\text{tank}}$	None
H_2	14 vessels per unit 8932 std ft^3 vessels	ASME, OSHA, DOT,	Outside	2450	2400	**2400**	$4.72 \times 10^7 \frac{\text{ft - lbf}}{\text{tank}}$	None

Plant design can accommodate the failure of any of the above vessels or parts of vessels without jeopardizing nuclear safety.

(a) These nitrogen cylinders are now functionally retired because the ADV acculultor tanks capacity have been increased.

This page intentionally left blank

9.4 AIR CONDITIONING, HEATING, COOLING AND VENTILATION SYSTEMS

Heating, ventilation, and air conditioning (HVAC) systems are provided as required throughout each unit for personnel comfort, personnel safety protection, and equipment functional protection.

The HVAC systems provided for each building or room are designed for the specific functional requirements of that individual building or room.

For those buildings and rooms required for functional use during all plant operating modes (normal, shutdown, emergency), two separate HVAC systems are provided (although some essential ducting is shared):

- Individual system for normal operation
- Individual system for emergency (essential) operation

For the essential system, redundant Seismic Category I trains are provided.

The meteorological conditions used as a basis for the design of the HVAC systems are listed in table 9.4-1 and in section 2.3. The design temperatures for each building, room, or area are provided in table 9.4-2. These temperatures are designated as "enveloping" because the maximum and minimum allowable temperatures are listed in the table. For areas serviced by normal and essential cooling systems, the enveloping temperatures cover the entire range of allowable temperatures with either cooling system in operation. For the containment building, the enveloping temperatures cover all modes of

operation with the normal cooling system in service. Essential containment cooling and heat removal are discussed in Section 6. In certain rooms, a transient temperature higher than the enveloping temperature is allowed for brief periods. A summary of the individual HVAC systems' equipment performance data and design details is tabulated in table 9.4-3.

This Section, 9.4, should be used in conjunction with Appendix A of the Equipment Qualification Program Manual. Appendix A of the Equipment Qualification Program Manual provides additional design information that must be considered when discussing HVAC performance and design parameters.

Table 9.4-1
OUTSIDE DESIGN CONDITIONS

Item	Parameter
Duration of design temperature, yearly percent	0.5% & 0.6%[a]
Summer design temperature[a] normal HVAC systems	113F (db) and 76F (wb)
Winter design temperature[a]	28F db
Winter minimum temperature	11F db
Elevation	950 ft msl
Average wind velocity	7 mi/h

a. Outside design temperatures are based on 0.5% summer design temperature (43.8 h/yr) and 0.6% winter design temperature (52.5 h/yr) for all HVAC systems, normal and essential. From ASHRAE Recommended Outdoor Design Temperatures for Buckeye, Arizona, 1972.

AIR CONDITIONING, HEATING, COOLING,
AND VENTILATION SYSTEMS

9.4.1 CONTROL BUILDING

The control building HVAC systems include an essential HVAC system and a normal HVAC system. Both HVAC systems, essential and normal, are provided for the following two areas:

- Control room, computer room, and associated rooms at elevation 140 feet
- Engineered safety features (ESF) switchgear, ESF equipment rooms, and battery rooms

Without ventilation, temperatures in the ESF air handling units' room will be less than 96F. Essential equipment in these areas is qualified to this limit.

The HVAC system for the upper and lower cable spreading rooms operates in the normal mode only, and is included as a part of the normal HVAC system of the ESF switchgear, ESF equipment rooms, and battery rooms. Without ventilation, temperatures in the upper and lower cable spreading rooms will be less than 105F. Essential equipment in these areas is qualified to this limit.

9.4.1.1 Essential HVAC System -- Control, Computer, and Associated Rooms

The essential (safety-related) HVAC system, as well as the habitability systems for the control room, are discussed in section 6.4.

Table 9.4-2
ENVELOPING DESIGN TEMPERATURES[c]

HVAC System	Interior Temperatures Maximum (F)	Interior Temperatures Minimum (F)
Control room	80[a][d]	70
Computer area	80[a][d]	70
ESF switchgear	104	40
ESF equipment rooms	104	60
Battery rooms	85	60
Cable spreading	122	40
Auxiliary building (excluding ESF equipment room and access control area)	104[b]	50
Access control area	80	70
ESF pump rooms	104	50
Containment building	120	50
Fuel building	104	50
Radwaste building	104	50
Turbine building		
Below operating deck	122	50
Above operating deck	122	40
Diesel generator building		
Diesel generator room	140	50
Diesel generator control room	122	39
Essential spray pond pump house	122	32

a. Relative humidity 40% to 60%

b. During a normal plant shutdown, the shutdown heat exchanger rooms and adjacent valve galleries shall be maintained at a maximum temperature of 122F

c. Refer to Appendix A of the Equipment Qualification Program Manual for additional information regarding the areas, rooms and buildings that are listed in this Table. Some of the HVAC systems that are listed, such as the ESF pump rooms and ESF equipment rooms, may have specific areas within that particular system's boundary that have design values which are more restrictive than the design values that are listed in this Table.

d. Maximum temperature for Rooms J-307, J-308, J-313/314, J-315/J-316, and J-318 (non-essential occupancy rooms within Control Room envelope) is 90°F

a. The equipment performance data listed in this table is kept for historical purpose. For latest values, see applicable HVAC calculations.

b. These values are equipment manufacturer's rated performance. The equipment capacity of the essential cooling units is capable of maintaining the temperature in the ECW, LPSI, CS, HPSI, AFW pump rooms and the ESF electrical penetration rooms within their design basis temperature values.

9.4.1.2 Normal HVAC System -- Control, Computer, and Associated Rooms

The control room complex is located on elevation 140 feet 0 inch. The normal HVAC system provided for the control and computer room includes cooling by an air washer (evaporative) for the outside air supply which is common for the total control building and by a recirculating air conditioning system with cooling coils served by the normal chilled water system described in section 9.2.

Heating is provided by the use of electric zone heaters located in the supply air ducts.

9.4.1.2.1 Design Bases

9.4.1.2.1.1 Safety Design Bases. The normal HVAC system provided for the control and computer room has no safety design bases. Protection of the operator from radioactivity and poisonous gases is described in section 6.4. The isolation is treated as a part of the essential control room HVAC system.

The vital area in the control building is the control room (elevation 140 feet). This is the only area subject to ESF grade charcoal/HEPA filtration. Contamination of this area is prevented by pressurization (using filtered makeup air) to ¼-inch water gauge.

Dose rates due to noble gases in other areas of the control building will be approximately the same as in the control room, ignoring local shielding effects. Accordingly, access by operators into other areas of the control building will not be

unduly restricted by airborne dose, provided respiratory and facial protection is used. (Whole-body exposure to operators due to iodine is 1.3 rem over 30 days.)

Equipment qualification design bases considered the radiation dose from airborne activity in the building, as well as direct dose from the outside cloud and adjacent buildings.

Accordingly, a proper environment for operation of essential equipment has been provided.

9.4.1.2.1.2 Power Generation Design Bases. The normal HVAC system provided for the control and computer room complex has one power generation design basis:

A. Power Generation Design Basis One

The normal HVAC system shall supply conditioned air to the control and computer room during normal plant operating conditions to provide personnel comfort and to maintain a suitable operating environment for equipment.

9.4.1.2.1.3 Codes and Standards. The normal HVAC system provided for the control and computer room is designed in accordance with codes and standards set forth in table 3.2-1.

9.4.1.2.2 System Description

The control room normal HVAC system is shown schematically in engineering drawings 01, 02, 03-M-HJP-001,-002 and 02-M-HJP-003. Major components of the system include one air

conditioning unit, ductwork with associated controls, and dampers for supply, return, and outside air, one smoke exhaust fan, one kitchen exhaust, and one toilet exhaust fan.

The outside air preconditioning unit is shared with the normal air conditioning system for the remaining parts of the control building.

There are two outside air intakes located at opposite ends of the control building. The outside air passes through an air washer, which cools the air adiabatically and cleans it. The preconditioned outside air flows into the mixing box of the draw-through type air conditioning unit where it mixes with the return air from the control and computer room. This air conditioning unit contains a high efficiency filter, chilled water cooling coil, and fan which discharge the conditioned air into the supply air ductwork connecting the unit with the control and computer room air distribution system. Part of the supply air is returned from the control and computer room while the balance is exhausted to the atmosphere by the kitchen and toilet rooms exhaust fans.

In case of a local fire incident, smoke can be removed by use of portable smoke removal equipment. The existing smoke removal system in the control room building can be used to remove the smoke. Only portable equipment, however, is relied on for smoke removal capability.

9.4.1.2.2.1 System Components. The normal HVAC system is comprised of the following components:

A. Air Washer

The air washer utilizes finely sprayed water to provide for the adiabatic cooling of the outside air being supplied to the building. The air washer consists of a metal enclosure, banks of spray nozzles, moisture eliminators, sump, and pump. A moisture eliminator downstream of the spray chamber is used to remove entrained moisture particles from the air. Water for the air washer is supplied from the domestic water system as discussed in subsection 9.2.4.

B. High Efficiency Filter

High efficiency filter elements precede the chilled water cooling coils of the air handling unit to maintain a clean cooling coil surface for the air being processed. The filters measure 24 by 24 inches and the fiberglass filter medium is encased in stainless steel or coated carbon steel. The airflow capacity is 500 cubic feet per minute per filter element.

C. Water Cooling Coil

The cooling coils are of nonferrous construction with aluminum plate fins mechanically bonded to seamless copper tubing. Coils are arranged for counterflow, using chilled water. The tube bundle is enclosed in a steel frame. Coils are arranged for horizontal airflow

and include vent and drain connections. The chilled water system is discussed in subsection 9.2.9.

D. Fans

Fans are capable of delivering the design flowrate with all filters at their maximum anticipated pressure drop. Fans were chosen with a steeply rising pressure-flow characteristic to maintain a reasonably constant airflow over the full filter train life.

E. Kitchen and Toilet Exhaust Fans

Exhaust fans are axial type.

F. Heaters

Electric heating elements (installed in the ducts) are used to heat the room supply air.

9.4.1.2.2.2 System Operation. The normal air conditioning system operates during normal modes of operation. Outside air is mixed with recirculating air and filtered through a high efficiency filter, cooled to the required design temperature, and discharged into a duct system which distributes the air to the computer rooms, control room, cabinet areas, offices, conference room, instrument repair room, kitchen, and halls.

Zone electric duct heaters, controlled by zone thermostats, regulate the temperature of each zone.

Outside air is supplied to make up for air exhausted from the kitchen and toilet areas. In case of a major fire in the control or computer room, the operation will be transferred to

the remote shutdown panel from where the reactor may be shut down. Firefighting will be initiated and the portable smoke removal equipment will be used to remove the products of combustion and noxious fumes produced and exhaust them to the outside once the fire is under control. The existing smoke removal system can also be used to exhaust smoke. Only portable equipment, however, is relied on for smoke removal capability.

In the event of a fire in the computer room, the smoke detectors close the ventilating ducts to isolate the computer room and contain the smoke. Also, an alarm sounds in the main control room.

The exhaust air from the kitchen, men's and women's toilets, and janitor's room is exhausted through normal exhaust fans to the atmosphere.

The system is started manually and can be stopped manually. In case of emergency conditions, the normal HVAC system is automatically stopped and isolated at the same time that the essential HVAC system is activated.

9.4.1.2.3 Safety Evaluation

Since the control and computer room normal HVAC system has no safety design bases, no safety evaluation is provided.

9.4.1.2.4 Inspection and Testing Requirements

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

9.4.1.3 Essential HVAC System -- ESF Switchgear, ESF Equipment Rooms, and Battery Rooms

9.4.1.3.1 Design Bases

9.4.1.3.1.1 Safety Design Bases. Safety design bases pertinent to the essential HVAC system supplying the ESF switchgear, ESF equipment rooms, and battery rooms are as follows:

A. Safety Design Basis One

The essential HVAC system, consisting of a separate HVAC train for each redundant train of the ESF switch-gear, ESF equipment rooms, and the battery rooms shall be designed to maintain the room temperature requirements listed in table 9.4-2, and to provide for the required ventilation and exhaust for the ESF battery rooms when operating during accident conditions.

B. Safety Design Basis Two

Failure of an active component of the essential HVAC system serving one train of the ESF switchgear, ESF equipment rooms, and battery rooms, simultaneously with a loss of offsite power, shall not result in the complete loss of any ESF system function.

C. Safety Design Basis Three

The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms shall be designed to operate during and after a safe shutdown earthquake (SSE).

9.4.1.3.1.2 Power Generation Design Bases. The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms has no power generation design bases.

9.4.1.3.1.3 Codes and Standards. The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms is designed to the codes and standards identified in table 3.2-1.

9.4.1.3.2 System Description

The ESF switchgear rooms and battery rooms are located at elevation 100 feet 0 inch. The essential HVAC units are located on the 74-foot 0 inch and 100-foot 0 inch elevations of the control building.

The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms is shown in engineering drawings 01, 02, 03-M-HJP-001, -002 and 02-M-HJP-003.

Two redundant, physically separated, air conditioning systems are provided, one for each ESF equipment train.

Each train includes two air handling units. One unit is composed of a high efficiency filter, a chilled water cooling coil, fans, supply and return air ductwork, and the other unit is composed of a chilled water cooling coil, fans, and supply air duct work. All units will start with either a safety injection actuation signal (SIAS) or loss of offsite power.

The outside air supplied during emergency operation may carry airborne dust. The outside air intake filters are designed for

an average dust loading of 1.78 mg/m^3 with an average maximum dust concentration period of 30 days. This dust loading is based on reference 2.

The essential HVAC system is inactive during normal operation and thus is not exposed to the atmospheric dust.

Separate 100% capacity exhaust fans are provided for each battery room. The fans exhaust to the atmosphere in order to prevent any hydrogen buildup in the battery room.

There are four battery rooms and one essential exhaust fan for each room. There is a backdraft damper in each exhaust duct.

The battery room air is supplied through a transfer grille with a fire damper. The exhaust fans exhaust the air directly to the atmosphere.

9.4.1.3.2.1 Component Description. System components are described briefly as follows:

A. Air Handling Unit Housings

   The air handling unit housings are Seismic Category I and are of all-welded carbon steel construction.

B. High Efficiency Filters

   High efficiency filter elements precede the chilled water cooling coils in one unit in order to maintain the cooling efficiency of the coils. Filters are 24 by 24 by 12 inches in size, and the filter medium is encased in a fire-retardant frame. The airflow velocity is 250 feet per minute, nominal. The minimum

average efficiency is 85% based on the ASHRAE 52-68 test method.

C. Cooling Coil

The cooling coils are of seamless copper tubing with copper plate fins mechanically bonded to them. Coils are arranged for counterflow using chilled water. The tube bundle is enclosed in a steel frame. Coils are arranged for horizontal airflow and include vent and drain connections. The chilled water cooling coils are served by the essential chilled water system discussed in subsection 9.2.9.

D. Fans

Fans are Seismic Category I and are capable of delivering the design flowrate with all filters at their maximum anticipated pressure drop. Fans are chosen with a steeply rising pressure-flow characteristic to maintain a reasonably constant airflow over the full filter train life. Fan and motor materials are suitable for operation under the environmental conditions associated with the postulated design basis loss-of-coolant accident.

E. Ductwork

The system ductwork and dampers are Seismic Category I. Accessibility and adequate working space for maintenance and testing operations are provided in the design and layout of the system equipment.

F. Battery Room Essential Exhaust Fans

The battery room exhaust fans are of nonsparking, explosion-proof construction and are designed for the specific service intended. The fans are designed to Seismic Category I requirements.

9.4.1.3.2.2 System Operation. Upon receipt of an ESF system actuation signal, the essential ESF switchgear, ESF equipment, and battery room HVAC system is automatically put into operation. The normal HVAC system is isolated and ceases operation.

Transfer to the essential system may also be initiated manually from the control room. The following actions take place automatically when transferring to the essential system:

- Closing the isolation dampers
- Stopping the normal air handling unit
- Stopping each battery room's normal exhaust fan
- Stopping the normal outside air supply air washer
- Stopping the normal chilled water system
- Activation of both essential HVAC trains and their associated essential chilled water systems
- Starting the essential exhaust fans in the battery rooms

After automatic activation of both safety trains, one train may be taken out of service manually, if the ESF equipment train which it serves is not required to remain functional.

The recirculation fans draw air through prefilters, high efficiency filters, and the chilled water coils and discharge the air into the ESF switchgear rooms and the battery rooms. The essential exhaust fans exhaust the battery room air to the atmosphere.

The ESF equipment room air (obtained by circulation from the ESF switchgear rooms) is recirculated through the essential cooling trains. Outside air is brought in to make up for the battery room air exhausted to the atmosphere.

9.4.1.3.3 Safety Evaluations

Safety evaluations are numbered to correspond to the safety design bases in paragraph 9.4.1.3.1.1.

A. Safety Evaluation One

   The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms is capable of filtering and cooling the air supplied to the rooms under accident conditions, of maintaining the room air temperatures within the specified limits, and of providing ventilation and exhaust for the ESF battery rooms.

B. Safety Evaluation Two

A single active failure in one train of the essential HVAC system or in its supporting systems, including a loss of offsite power, does not cause a complete loss of ESF system function. The system single failure analysis is presented in table 9.4-4.

C. Safety Evaluation Three

The essential HVAC system for the ESF switchgear, ESF equipment rooms, and battery room is designed to Seismic Category I requirements.

9.4.1.3.4 Inspection and Testing Requirements

The systems and components used in the ESF switchgear, ESF equipment, and battery room essential HVAC system are designed to permit testing and inspection to assure the integrity and capability of the system. Such tests and inspections can be made during normal plant operation.

9.4.1.4 Normal HVAC System -- ESF Switchgear, ESF Equipment Rooms, Battery Rooms, Upper and Lower Cable Spreading Rooms

9.4.1.4.1 Design Bases

9.4.1.4.1.1 Safety Design Bases. The normal HVAC system provided for the ESF switchgear, ESF equipment rooms, battery rooms, and upper and lower cable spreading rooms has no safety design bases.

Table 9.4-4
ESSENTIAL HVAC SYSTEM SINGLE FAILURE ANALYSIS ESF SWITCHGEAR, ESF EQUIPMENT AND BATTERY ROOMS

Component	Failure Mode/ Cause	Effects on System	Method of Detection	Inherent Compensating Provision
Outside air damper	Fails closed makeup air side/ corrosion	Loss of makeup air to rooms	Position indicating lights in control rooms	Each of the two redundant ESF equipment and battery rooms is conditioned by separate air conditioning systems
Air handling unit	Fails to operate/ mechanical or electrical failure	Loss of cooling to one ESF train	Low fan differential pressure alarm in control room	Each of the two redundant ESF equipment and battery rooms is conditioned by separate air conditioning systems
Battery room exhaust fan	Fails to operate/ mechanical or electrical failure	Hydrogen level rises in battery room	Low fan differential pressure alarm in control room	Each of the two redundant ESF equipment and battery rooms is conditioned by separate air conditioning systems
ESF switchgear and battery room supply damper	Fails to operate/ mechanical or electrical failure	Loss of cooling to one ESF train or battery room	Position indicating lights in control rooms	Each of the two redundant ESF equipment and battery rooms is conditioned by separate air conditioning systems
Non-ESF dampers and ducts	Fails to operate/ mechanical or electrical failure	None	Operator patrol	Two independent ESF HVAC systems provided

9.4.1.4.1.2 Power Generation Design Bases. The normal HVAC system provided for the ESF switchgear, ESF equipment rooms, battery rooms, and upper and lower cable spreading rooms has the following power generation design bases:

A. Power Generation Design Basis One

The normal HVAC system provided for the ESF switchgear, ESF equipment rooms, battery rooms, and upper and lower cable spreading rooms shall supply conditioned air to the rooms and areas served during normal plant operating conditions to maintain the required temperatures for equipment, and to provide the required ventilation and exhaust for the battery rooms.

B. Power Generation Design Basis Two

Portable smoke removal equipment shall be provided to remove smoke from the control building.

9.4.1.4.1.3 Codes and Standards. The normal HVAC system provided for the ESF switchgear, ESF equipment rooms, battery rooms, and upper and lower cable spreading rooms is designed in accordance with codes and standards set forth in table 3.2-1.

9.4.1.4.2 System Description

The normal HVAC system provided for the ESF switchgear, ESF equipment rooms, battery rooms, and upper and lower cable spreading rooms is shown in engineering drawings 01, 02,

03-M-HJP-001, -002 and 02-M-HJP-003. This system is located on elevation 74 feet 0 inch. Major components are two air handling units, supply and return ductwork, and exhaust fans. The outside air preconditioning unit is shared with the normal control room system, shown in engineering drawings 01, 02, 03-M-HJP-001, -002 and 02-M-HJP-003. The treated outside air flows into the mixing box at the entrance of the draw-through type air handling unit where it is mixed with air returning from the ESF switchgear, ESF equipment, and the cable spreading rooms. The mixed air is drawn through a high efficiency filter before it is cooled by the chilled water coil. The chilled water coil is supplied with chilled water from the chilled water system discussed in subsection 9.2.9. The fan discharges the air into the supply ductwork through which it flows to the ESF switchgear rooms, and, from there, to the ESF equipment and battery rooms. The supply ductwork also furnishes air to the upper and lower cable spreading rooms.

The battery room ventilation system is designed to maintain the combustible gas concentration in the battery rooms below the lower flammability limit of hydrogen. To accomplish this, air in the battery rooms is exhausted to the outside atmosphere in order to continuously sweep combustible gases out of the battery rooms. After receipt of an alarm indicating that the normal exhaust fan is not operating, the operator may remote manually start the emergency exhaust fan. Failure of the emergency exhaust fan to either start or continue to run will be detected by either a light on the control room panel, failure of the alarm to clear, or by the reactivation of the

alarm. The battery room essential exhaust fan will automatically start upon loss of offsite power or SIAS with simultaneous shutoff of the normal exhaust fan.

Air from the ESF equipment rooms and the cable spreading rooms is recirculated by returning the air through the return duct to the air handling unit where it is mixed with outside air and circulated into the system.

The system is started manually and can be stopped manually. It is automatically stopped and isolated in case conditions require operation of the essential HVAC system.

In the event of fire, area fire detectors will sound an alarm in the control room and the supply fan may be deactivated manually, if required. Smoke removal is then manually initiated by use of portable smoke removal equipment. The existing smoke removal system can also be used to remove smoke. Only portable equipment, however, is relied on for smoke removal capability.

9.4.1.4.2.1 System Components. System components are described as follows:

A. Air Washer

The air washer is shared with the control room HVAC system, and is described in paragraph 9.4.1.2.2.1.

B. Air Handling Unit

The high efficiency filter, cooling coil, and fan are identical to those described in paragraph 9.4.1.2.2.1.

C. Exhaust Fan

The battery room exhaust fans (one fan per room) are of nonsparking, explosion-proof construction.

D. Smoke Exhaust Fan

The smoke exhaust fan is a centrifugal fan capable of providing 300 cubic feet per minute exhaust per 200 square feet of floor space for any given floor at one time. Portable smoke removal equipment will be used to remove smoke from the control building. Only portable equipment, however, is relied on for smoke removal capability.

9.4.1.4.3 System Operation

During normal plant operation, recirculated air from upper and lower cable spreading rooms, ESF switchgear, and ESF equipment rooms is mixed with outside air and is distributed through the rooms. Outside air is used to make up for the air exhausted from the battery rooms.

9.4.1.4.4 Safety Evaluation

Since the normal HVAC system for the ESF switchgear, ESF equipment rooms, and battery rooms has no safety design bases, no safety evaluation is provided.

9.4.1.4.5 Inspection and Testing Requirements

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

9.4.2 AUXILIARY BUILDING

Both essential and normal HVAC systems are provided for the auxiliary building. The equipment rooms, access control areas, the mechanical and electrical penetration areas, areas below the 100-foot 0 inch elevation of the main steam support structure (MSSS), and the remainder of the auxiliary building are served by a normal HVAC system. The ESF equipment rooms and the safety-related auxiliary feedwater pump rooms are served by an essential HVAC system during emergency operation. The essential system in the auxiliary building consists of individual essential cooling units for each ESF equipment room.

9.4.2.1 Normal HVAC System -- Equipment Rooms, Access Control Area, Penetration Area, and ESF Pump Rooms

The auxiliary building normal HVAC system is designed to maintain an environmental condition suitable for personnel comfort and safety and for performance of the equipment.

9.4.2.1.1 Design Bases

9.4.2.1.1.1 Safety Design Bases.

A. Safety Design Basis One

   The ductwork at all levels of the auxiliary building below level 140 feet 0 inch shall be designed to retain structural integrity, but is not required to function during and after a safe shutdown earthquake.

9.4.2.1.1.2 Power Generation Design Bases.

A. Power Generation Basis One

The normal auxiliary building HVAC system shall be designed to maintain the required temperatures and ventilation for the various areas of the building.

B. Power Generation Basis Two

The normal auxiliary building HVAC system shall be designed to prevent uncontrolled release of airborne radioactivity. This shall be accomplished by exhausting more air than is supplied and by exhausting through charcoal filtration trains.

9.4.2.1.1.3 Codes and Standards. The normal auxiliary building HVAC system is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.2.1.2 System Description

The auxiliary building HVAC system, shown schematically in engineering drawings 01, 02, 03-M-HAP-001, -002, -003 and -004 consists of two outside air supply units, multizone air handling units for the access control area, a local recirculating air handling unit for the control element drive mechanism (CEDM) control system, motor generator set rooms, and, for the charging pump rooms, two exhaust filter units, exhaust fans for the laboratories, and associated ductwork, dampers, registers, and control.

9.4.2.1.2.1 Component Description. System components are described as follows:

A. Outside Air Handling Units

Each air handling unit consists of a dust filter, a cooling coil, and a supply fan. Electric duct heaters are installed downstream of each air handling unit.

B. Multizone Air Handling Unit

The air handling unit consists of a cooling coil, an electric heating coil, control dampers, and a fan.

C. Recirculating Air Handling Unit

Each recirculating air handling unit consists of a cooling coil and a fan.

D. Exhaust Filter Units

Each set of exhaust filters consists of a high efficiency filter, high efficiency particulate air (HEPA) filter, carbon adsorber, downstream HEPA filter, and an exhaust fan.

E. Laboratory Exhaust Fans

The fans exhaust from the fume hoods in the laboratories to the exhaust system upstream of the exhaust filter units.

9.4.2.1.2.2 System Operation. During normal plant operation, treated outside air is distributed through the building on a once-through basis. Only the air in the CEDM control system area, the motor generator set rooms, and the

charging pump rooms is recirculated through a local handling unit. The air flows from corridors to rooms to prevent spread of potential airborne radioactivity, and, from there, it is exhausted continuously through the exhaust filter units to the plant vent.

Air supplied to the access control area is cooled or heated to provide the closer temperature control required for personnel comfort.

Air supplied to radiation protection and locker rooms is taken from the outside air supply unit, then heated or cooled in a double duct system with zone mixing boxes, which distribute the air.

The air supplied to the radio-chemical laboratory and sampling room is exhausted through fume hoods by transfer fans to the continuous exhaust system.

Exhaust air from the decontamination room, storage area, counting room, and men's and women's toilets is discharged to the continuous exhaust system.

In the event of fire in the auxiliary building, fire and smoke detectors will alarm in the control room.

Smoke removal will be accomplished as follows:

The firefighters will remove the smoke from the fire area to the outside by means of portable smoke removal equipment. If normal HVAC system is available, smoke may be exhausted to outside by use of portable smoke removal equipment and existing exhaust filtration units.

In case the portable smoke removal equipment in conjunction with exhaust filtration units is used, the two HEPA filters in each of the two banks of the two exhaust filtration units will be removed and the exhaust system will be restarted. The HEPA filters would be removed to prevent HEPA clogging by the smoke particles.

The auxiliary building exhaust air system is continuously monitored for radiation levels. Isolation of this system from the ESF pump rooms during emergency conditions is discussed in paragraph 9.4.2.2.

The two 50% capacity air filtration units located on the roof of the auxiliary building exhaust to the plant vent stack.

The auxiliary building is kept under a slight negative pressure, except when any of the access doors are open, to ensure that leakage is into the building.

9.4.2.1.3 Safety Evaluation

The ducts below elevation 140 feet 0 inch are supported by Seismic Category I supports, and the ducts are designed to retain their structural integrity during and after an SSE.

9.4.2.1.4 Inspections and Testing Requirements

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

9.4.2.2 Essential HVAC System -- ESF Equipment Rooms and Essential Exhaust

The auxiliary building HVAC system described in this section includes those systems that function post-LOCA within the ESF pump room, and the exhaust system, that maintains the auxiliary building below elevation 100 feet 0 inch at a negative pressure post-LOCA to prevent unfiltered release of possible airborne radioactivity to the surroundings.

9.4.2.2.1 Design Bases

9.4.2.2.1.1 Safety Design Bases. Safety design bases pertinent to the ESF equipment room essential cooling system and essential exhaust system are as follows:

A. Safety Design Basis One

The ESF pump room and safety-related auxiliary feedwater pump room coolers shall be designed to maintain the required room temperatures to ensure the operability of the ESF pumps and motors during accident conditions.

B. Safety Design Basis Two

The ESF essential cooling and exhaust system shall be designed to withstand the effects of an SSE.

C. Safety Design Basis Three

Following a LOCA, the ESF equipment and safety-related auxiliary feedwater pump rooms are automatically isolated (at approximately the 100-foot elevation) from

the auxiliary building normal HVAC system on receipt of an SIAS signal.

D. Safety Design Basis Four

Areas with safety injection piping and equipment shall be kept under measurable negative pressure in relation to ambient during emergency conditions by exhausting through ESF filtration systems.

E. Safety Design Basis Five

The auxiliary building essential HVAC system shall be designed so that a single failure of any active component, assuming loss of offsite power, cannot result in complete loss of an ESF system function.

Protection of the auxiliary building essential HVAC system from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with the postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

9.4.2.2.1.2 Power Generation Design Basis. The essential HVAC system has no power generation design basis.

9.4.2.2.1.3 Codes and Standards. The essential HVAC system is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.2.2.2 System Description

The ESF equipment room essential air coolers, shown schematically in engineering drawings 01, 02, 03-M-HAP-001, -002, -003 and -004, consist of a recirculating air handling unit, including a cooling coil, in each pump room. There are no outside air connections.

The essential exhaust filtration system consists of two essential exhaust filtration units shared with the fuel building, and a connecting tunnel and plenum.

9.4.2.2.2.1 Component Description. Each ESF equipment room air handling unit consists of a fan and a cooling coil.

Electric and chilled water service for the unit is provided by the same trains which provide these services to the pump in the room. Water is distributed to the ESF equipment room cooling coils from the essential chilled water system as described in section 9.2.

The essential filtration units are described in paragraph 9.4.5.2.2.

9.4.2.2.2.2 System Operation. Following a LOCA, the ESF equipment and safety-related auxiliary feedwater pump rooms are automatically isolated (at approximately the 100-foot elevation) from the auxiliary building normal HVAC system on receipt of an SIAS signal. The building pressure is reduced to a measurable negative pressure relative to below ambient by the fuel building essential exhaust fans for the space below

elevation 100 feet 0 inch in the auxiliary building. Air exhausted from the ESF equipment rooms is filtered by the fuel building essential filter units. The essential exhaust filter units are automatically actuated by starting the fans and opening the dampers to the units in response to ESF pump start signal.

The essential air coolers are automatically started to maintain the equipment room design temperature. Each equipment room has its own air cooling unit.

High room temperature conditions in each ESF pump room are alarmed remotely in the control room.

9.4.2.2.3 Safety Evaluation

Safety evaluations pertinent to the ESF pump room essential cooling system are numbered to correspond to the safety design bases and are as follows:

A. Safety Evaluation One

   The essential cooling system is designed to maintain the temperature inside the ESF equipment rooms within the temperature range listed in table 9.4-2.

B. Safety Evaluation Two

   The fan, coils, piping, and valves associated with the ESF equipment room coolers are designed in accordance with Seismic Category I criteria.

C. Safety Evaluation Three

Two Seismic Category I isolation dampers and fire dampers are provided in the supply and return ducts penetrating the 100-foot elevation to isolate the normal exhaust and supply system.

D. Safety Evaluation Four

Two independent essential exhaust filter units are connected to the auxiliary building through Seismic Category I plenum and tunnel to the fuel building essential exhaust trains to provide exhaust filtration of the ESF equipment rooms, and maintain the pressure of the space below the 100-foot 0 inch elevation at a measurable negative pressure relative to the outside.

E. Safety Evaluation Five

The equipment for the auxiliary building essential HVAC system is provided with redundant trains A and B powered by separate buses A and B such that a failure of a single active component of the HVAC system cannot result in a complete loss of any ESF system function.

An ESF equipment and safety-related auxiliary feedwater pump room essential cooling system single failure analysis is presented in table 9.4-5.

9.4.2.2.4 Inspection and Testing Requirements

Preoperational testing is performed as described in section 14.2.

Table 9.4-5
ENGINEERED SAFETY FEATURES EQUIPMENT AND SAFETY-RELATED AUXILIARY FEEDWATER PUMP ROOM ESSENTIAL COOLING SYSTEM SINGLE FAILURE ANALYSIS (Sheet 1 of 2)

Component	Failure Mode/ Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Valves to essential chilled water supply	Fails closed/ operator failure	ESF equipment or safety-related auxiliary feedwater pump room overheats	High temperature alarm in control room	Redundant ESF and safety-related auxiliary feedwater pump and associated HVAC train available	
	Fails open/ operator failure	None	Position indicator in control room	None	Valve normally open
Air cooling unit	Cooling water coil leakage	ESF equipment or safety-related auxiliary feedwater pump room overheats	High temperature alarm in control room	Redundant ESF and safety-related auxiliary feedwater pump and associated HVAC train available	

Table 9.4-5
ENGINEERED SAFETY FEATURES EQUIPMENT AND SAFETY-RELATED AUXILIARY FEEDWATER PUMP ROOM ESSENTIAL COOLING SYSTEM SINGLE FAILURE ANALYSIS (Sheet 2 of 2)

Component	Failure Mode/ Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
	Fan motor fails/ mechanical or electrical failure	ESF equipment or safety-related auxiliary feedwater pump room overheats	High room temperature alarm in control room	Redundant ESF and safety-related auxiliary feedwater pump and associated HVAC train available	
Isolation damper	Fails open	None	Position indicator in control room	Redundant damper in duct available which also receives closing signal	

9.4.3 RADWASTE BUILDING

The function of the radwaste building HVAC system is to maintain ventilation in the process equipment areas, to provide personnel safety in access areas, and to restrict the spreading of airborne radioactivity. The radwaste building HVAC system is required to function during normal plant operation. This system is a once-through air system. There is no recirculation of air in the building, except in the control room where there is no source of potential airborne radiation.

9.4.3.1 Design Bases

9.4.3.1.1 Safety Design Bases

The radwaste building HVAC system has no safety design basis.

9.4.3.1.2 Power Generation Design Bases

The radwaste building HVAC system is designed to maintain the required temperatures to ensure the operability of the radwaste building equipment, to maintain suitable personnel working conditions, and to prevent exfiltration of untreated air containing airborne radioactivity. Airflow is from low activity to higher radioactivity areas.

9.4.3.1.3 Codes and Standards

The radwaste building HVAC system is designed to the applicable codes and standards listed in table 3.2-1.

9.4.3.2 System Description

The radwaste building HVAC system, shown schematically in engineering drawings 01, 02, 03-M-HRP-001, consists of a supply air system, exhaust filter system, and associated ductwork, dampers, registers, and controls.

9.4.3.2.1 Component Description

System components are described as follows:

A. Supply Air Handling Units

The two 50% air handling units each consist of an intake louver, a filter, evaporative cooling pad, pump, and a supply fan. Duct heaters are installed downstream of the supply air handling unit.

B. Exhaust Filter Unit

The two 50% exhaust filter units each consist of a high efficiency filter, a HEPA filter, and an exhaust fan.

C. Radwaste Building Control Room Air Handling Unit

The recirculating air handling unit consists of a moderate efficiency filter, a cooling coil, and a fan. The cooling coil is serviced from the normal chilled water system described in section 9.2. A duct heater is installed downstream of the air handling unit.

9.4.3.2.2 System Operation

The outside air supply is cooled adiabatically by the air handling units and is distributed to the radwaste building. The

air flows to the various rooms and from corridors to rooms to prevent uncontrolled flow of potential airborne radioactivity. The air is exhausted through the radwaste building exhaust filter unit to the plant vent. The radwaste building is maintained at a negative pressure to ensure that leakage is into the radwaste building. The negative pressure is maintained by exhausting more air from the building than is being supplied.

The system includes two 50% air supply units and two 50% exhaust filter units, to preclude total system loss in case of a fan (or exhaust filter) failure.

A recirculating local air handling unit is provided in the radwaste equipment control room, where there is a high local heat load but no source of potential airborne radioactivity. In order to provide fresh air and pressurization, the recirculated air is mixed with air from the radwaste building removal supply unit at the inlet to the local unit.

9.4.3.3 Inspection and Testing Requirements

Acceptance testing of this system is performed to demonstrate proper system and equipment functioning.

9.4.4 TURBINE BUILDING

The turbine building HVAC system described in this section operates during normal plant operation and during the shutdown period, depending upon heat removal requirements. The turbine building HVAC system includes the following subsystems: turbine building general area ventilation subsystem, switchgear room and

battery room ventilation subsystem, and lube oil room ventilation subsystem. The condenser air removal system is discussed in section 10.4.

9.4.4.1 Design Bases

9.4.4.1.1 Safety Design Bases

The turbine building HVAC system has no safety design bases.

9.4.4.1.2 Power Generation Design Bases

A. Power Generation Design Basis One

   The turbine building HVAC system shall be designed to maintain the required temperatures specified in table 9.4-2 to ensure equipment operation.

B. Power Generation Design Basis Two

   The system shall prevent combustible concentration of hydrogen gas from accumulating within the battery room.

C. Power Generation Design Basis Three

   The system shall provide adequate ventilation by exhaust for the lube oil room.

D. Power Generation Design Basis Four

   The system shall provide adequate ventilation by exhaust for the demineralizer area.

9.4.4.1.3 Codes and Standards

The turbine building HVAC system is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.4.2 System Description

The turbine building HVAC system shown schematically in engineering drawings 01, 02, 03-M-HTP-001 consists of supply air handling units, duct heating coils associated ductwork, dampers, registers, controls, and exhaust fans. The air is supplied at all levels, transferred to the higher levels. Approximately 80% is exhausted through the roof exhaust fans, and the remaining 20% is exfiltered through wall openings and other exhaust fans.

9.4.4.2.1 Component Description

A. Supply Air Handling Units

Six air handling units, are provided. Three of the units are located at elevation 100 feet 0 inch (ground level) outside the building and on one side. The other three are located at elevation 176 feet 0 inch (turbine deck level) outside and on the opposite side of the building.

B. Roof Exhaust Fans

Four roof exhaust fans are provided. These are axial fans with vertical axes and weather heads.

C. Exhaust Fans

Four axial fans of the nonsparking explosion-proof type are provided for special exhaust from the battery room and from the lube oil room.

D. One vane-axial fan is provided for special exhaust from the demineralizer area.

E. One centrifugal fan is provided to exhaust the fumes from the secondary chemistry chemical addition tanks.

9.4.4.2.2 System Operation

The outside air is cooled adiabatically by the air handling units. From the supply fans, the air is ducted to the three levels along both sides of the building. In the summer and during power operation, all the air is exhausted via the exhaust fans and exfiltration.

During winter plant shutdown, part of the air is recirculated.

The supply air is distributed through ducts to the building.

The ventilation supply air unit distributes the air through ducts to the switchgear room and the battery room. During winter operation, the battery room space thermostat controls the electric duct heater located in the supply air duct and maintains 75F space temperature. The electric duct heater is turned off automatically to prevent burnout if the airflow switch, located in the battery room supply air duct, detects no airflow.

The switchgear room air is exhausted to atmosphere through backdraft dampers. Battery room air is exhausted to the atmosphere through an exhaust fan.

Ventilation supply air from the turbine building is distributed through the lube oil room. The air is exhausted to atmosphere by duct-mounted exhaust fans.

The exhaust ducts of the chemical addition tanks are maintained at a negative pressure within the turbine building. This minimizes any leakage of the tank fumes within the turbine building.

9.4.4.3 Safety Evaluation

Since the turbine building HVAC system has no safety design bases, no safety evaluation is provided.

9.4.4.4 Inspection and Testing Requirements

The turbine building HVAC system is designed to permit periodic inspection of system components to assure the capability of the system.

9.4.5 FUEL BUILDING

Two separate HVAC systems are provided for the fuel building. The normal system functions during normal plant operation only. The essential system functions only in the event of a fuel handling accident or LOCA. The fuel handling accident is evaluated in section 15.7. The LOCA is discussed in

section 15.6. The normal HVAC system is a once-through air system. The essential system is a filtered exhaust system.

9.4.5.1 Normal Fuel Building HVAC System

9.4.5.1.1 Design Bases

9.4.5.1.1.1 Safety Design Bases. The fuel building normal HVAC system has no safety design bases.

9.4.5.1.1.2 Power Generation Design Bases.

A. Power Generation Design Basis One

The fuel building HVAC system shall be designed to maintain the required temperature to ensure the operability of fuel building equipment, and to provide the required ventilation to maintain the level of airborne radioactivity below permissible limits.

9.4.5.1.1.2 Codes and Standards. The fuel building HVAC system is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.5.1.2 System Description

The normal fuel building HVAC system, shown schematically in engineering drawings 01, 02, 03-M-HFP-001, consists of two 50% capacity supply air handling units, two 50% normal exhaust units, associated ductwork, dampers, registers, and controls. The equipment performance data of the fuel building HVAC systems are listed in table 9.4-3. Figure 9.4-1 shows the

ventilation flow distribution and general physical layout of the HVAC systems over the spent fuel pool. The ventilation rate for each set of units, one supply and one exhaust, is sufficient to meet the requirements of 10CFR20.1-20.601 for 40 hours per week of occupational exposure when operating alone.

The normal units are located on the roof of the building, and are arranged for ease of access, control, and monitoring. The exhaust fan removes more air than is supplied. The extra air is made up by infiltration from the outside and from adjoining areas of the auxiliary building, thus minimizing the possibility of exfiltration.

The fuel handling building doors are provided with self-closers to prevent an open door from disrupting fuel handling building ventilation.

9.4.5.1.2.1 Component Description. System components are described briefly as follows:

A. Supply Air Handling Unit

Each air handling unit consists of an oil impingement dust filter (not currently used)(1), evaporative cooler, and a supply fan.

B. Normal Exhaust Unit

Each exhaust unit consists of an exhaust fan.

(1) The oil impingement filter has been removed for trains where DMWO 3144423 has been implemented.

C. Heating Coil

Electrical heating coils are located in the ductwork to maintain the minimum design temperature.

9.4.5.1.2.2 System Operation. During normal operation, the fuel building is ventilated by distributing tempered, outside air throughout the building. The air is cooled adiabatically by the evaporative cooler which uses domestic water. The air is exhausted continuously to the fuel building vent. The fuel building is maintained under a negative pressure to ensure that all leakage is into the building.

Design temperatures for the fuel building are listed in table 9.4-2.

9.4.5.1.3 Safety Evaluation

Since the fuel building normal HVAC system has no safety design bases, no safety evaluation is provided.

9.4.5.1.4 Inspection and Testing Requirements

Acceptance testing of the system is performed to demonstrate proper system and equipment functioning.

9.4.5.2 Fuel Building Essential HVAC System

9.4.5.2.1 Design Bases

9.4.5.2.1.1 Safety Design Bases.

A. Safety Design Basis One

The fuel building essential HVAC system is designed to limit the potential release of radioactive iodine in the event of a fuel handling accident or a design basis LOCA (refer to paragraph 9.4.2.2).

B. Safety Design Basis Two

The fuel building essential HVAC system is designed to function during and after an SSE.

C. Safety Design Basis Three

Any single failure in the fuel building essential HVAC system will not impair the system's ability to comply with safety design bases one and two.

9.4.5.2.1.2 Power Generation Design Bases. The fuel building essential HVAC system has no power generation design bases.

9.4.5.2.1.3 Codes and Standards. Applicable codes and standards for the fuel building essential HVAC system are given in table 3.2-1.

9.4.5.2.2 System Description

The fuel building essential HVAC system consists of two 100% capacity exhaust charcoal filtration units. Each unit exhausts air from the fuel building to the fuel building vent to prevent release of airborne radioactivity to the surroundings in case of a fuel handling accident.

The essential exhaust trains are also connected through a Seismic Category I plenum and tunnel to the auxiliary building ESF equipment rooms. Separate dampers are provided for this service. These units would be utilized to create low pressure in the auxiliary building and thus prevent release of unfiltered air from the auxiliary building due to ESF system leakages post-LOCA. Refer to paragraph 9.4.2.2.

9.4.5.2.2.1 System Components. System components are described as follows:

A. Filter Unit Housings

The filter unit housings are Seismic Category I and are made of carbon steel. Each housing is provided with a service access door, explosion-proof light, filter test connections, connections for pressure gauges, and floor drains. The housings are of all welded construction. Filter unit housings are designed in accordance with Regulatory Guide 1.52 as noted in section 1.8.

B. High Efficiency Filters

The high efficiency elements are of pleated, fine fiber sheet media with a separator. The elements measure 24 by 24 by 12 inches and are capable of handling a nominal flowrate of 1000 cubic feet per minute each. The filter element is sealed in a fire-retardant frame. The minimum average efficiency of the filter, using atmospheric dust, is 85% by ASHRAE Standard 52 test methods. Prefilters are designed and qualified in accordance with Regulatory Guide 1.52 as noted in section 1.8.

C. High Efficiency Particulate Air Filters

Filter elements of the HEPA filters are pleated fiberglass with asbestos insert design, measure 24 by 24 by 11.5 inches, and are capable of handling a nominal flowrate of 1000 cubic feet per minute each. The filter medium is encased in stainless steel, is equipped with face guards on both sides, and is water- and fire-resistant. The filter element minimum acceptance criterion is removal of 99.97% of 0.3 micron thermally generated monodisperse DOP particles. These filter elements are designed and qualified in accordance with Regulatory Guide 1.52.

D. Carbon Adsorber

The adsorber sections contain impregnated activated carbon that meets the requirements of Regulatory Guide 1.52, with the exception taken in section 1.8,

with an assigned decontamination efficiency of 95% for elemental iodide and organic iodide. Each adsorber is designed for a maximum loading of radioiodine well below the recommendations of Regulatory Guide 1.52.

E. Fans

Essential air filtration unit fans are capable of delivering the design flowrate with all filters at their maximum anticipated pressure drop. Fans are chosen with a steeply rising pressure-flow characteristic to maintain a reasonably constant airflow over the full filter train life. Fan and motor materials are suitable for operation under the environmental conditions associated with the postulated design basis accident (DBA), in conformance with Position C.3.1 of Regulatory Guide 1.52, as noted in section 1.8. Essential air filtration unit fans are Seismic Category I.

F. Ductwork

The essential system ductwork is Seismic Category I, designed in accordance with Position C.3.m of Regulatory Guide 1.52. Ductwork is redundant where required to provide functional support to active components in meeting the single active failure criteria. Leaktight ductwork and isolation dampers are provided where required to prevent release of unfiltered air to the surroundings. In general conformance with Position C.4 of Regulatory Guide 1.52,

accessibility and adequate working space for maintenance and testing operations are provided in the design and layout of the air purification system equipment.

G. Isolation Dampers

Eight isolation dampers are provided in the normal ventilation supply and exhaust subsystem at the following locations:

- Two pairs of isolation dampers are located in the normal ventilation supply air duct at elevation 140 feet 0 inch of the fuel building. Each pair of dampers is in series. The two separate pairs of dampers are located in parallel with one another.
- Two pairs of isolation dampers in series are located in the normal ventilation exhaust air subsystem at elevation 140 feet 0 inch of the fuel building. Each pair of dampers is in series. The two separate pairs of dampers are located in parallel with one another.

Four isolation dampers are provided in each essential air filtration unit to control the appropriate service, either for the fuel building in case of a fuel handling accident, or for the auxiliary building post-LOCA.

H. Instrumentation

Details of the radiation monitors used to provide the signal placing the fuel building essential HVAC system in operation are given in section 11.5. Information, including detector locations, type of radiation, detector type, range, and sensitivity, is given in table 11.5-1.

Differential pressure indication is provided across filters and carbon adsorbers.

The instrumentation is designed to Seismic Category I requirements. A description of initiating circuits, logic, interlocks, and redundancy of instrumentation relating to fuel building essential HVAC system is discussed in section 7.3.

9.4.5.2.2.2 System Operation. In the event of a fuel handling accident, the fuel building is isolated automatically by the closure of the isolation dampers in the normal ductwork upon sensing a high level radiation signal either from the radiation monitor in the normal exhaust ductwork or from the fuel pool area monitor. There are eight Seismic Category I dampers, four in the normal supply and four in the normal exhaust ducts. At the same time the two exhaust filter units are actuated by the same high level radiation signal. Air infiltration into the fuel building is used for makeup in this mode of cleanup operation. A negative pressure in the fuel

building is maintained by exhausting of this filtered air to the atmosphere.

Refer to paragraph 9.4.2.2 for a discussion of the essential filtration operation following a LOCA.

The isolation and initiation of the units can be done manually from the control room. Also, refer to paragraph 9.4.2.2.2.2 for a discussion of the operation of the ESF equipment room exhaust to the fuel building essential HVAC system.

9.4.5.2.3 Safety Evaluation

Safety evaluations are numbered to correspond to the safety design bases.

A. Safety Evaluation One

   The fuel building essential HVAC system is designed to limit the offsite dose following a fuel handling accident or LOCA within the guidelines of 10CFR100. Radiological consequences of a LOCA are discussed in section 15.6. Radiological consequences of a fuel handling accident are discussed in section 15.7.

B. Safety Evaluation Two

   The fuel building essential HVAC system is designed to Seismic Category I requirements.

C. Safety Evaluation Three

   A single failure in any component of the fuel building essential HVAC system will not impair the system's ability

to fulfill the requirements of safety design bases one and two. A single failure analysis is given in table 9.4-6.

9.4.5.2.4 Testing and Inspection

Preoperational testing is performed as described in section 14.2.

9.4.6 CONTAINMENT BUILDING

The containment building HVAC systems described in this section include those systems that function during normal plant operation, containment preaccess period, or during extended shutdown. These systems are not required to operate during any design basis accident.

The containment hydrogen control system is discussed in subsection 6.2.5.

The normal operation systems shown in engineering drawings 01, 02, 03-M-HCP-001, -002, -003 and 01, 02, 03-M-CPP-001 are described in this section and include:

- Normal cooling system
- Normal cleanup system
- Normal purge system
- Control element drive mechanism cooling system
- Cavity cooling system
- Tendon gallery system

Table 9.4-6
SINGLE FAILURE ANALYSIS FUEL BUILDING ESSENTIAL HVAC SYSTEM
FUEL HANDLING ACCIDENT MODE (Sheet 1 of 2)

Component	Failure Mode	Effect	Comment
Fan	Failure	Loss of one exhaust filter	Redundant exhaust filter provided
Filter	Plugged	Loss of one exhaust filter	Redundant exhaust filter provided
Fuel building inlet damper	Fails to open	Loss of one exhaust filter	Redundant exhaust filter provided
Auxiliary building inlet damper	Fails to close	Degraded performance of one exhaust filter	Redundant exhaust filter provided
Fuel building normal ventilation isolation damper	Failure to close	None	Redundant isolation damper provided in series
Radiation monitor	Failure	None	Redundant monitor provided

Table 9.4-6
SINGLE FAILURE ANALYSIS FUEL BUILDING ESSENTIAL HVAC SYSTEM
LOCA MODE (Sheet 2 of 2)

Component	Failure Mode	Effect	Comment
Fan	Failure	Loss of one exhaust filter	Redundant exhaust filter provided
Filter	Plugged	Loss of one exhaust filter	Redundant exhaust filter provided
Auxiliary building inlet damper	Fails to open	Loss of one exhaust filter	Redundant exhaust filter provided
Fuel building inlet damper	Fails to close	Degraded performance of one exhaust filter	Redundant exhaust filter provided
Auxiliary building normal ventilation isolation damper	Failure to close	None	Redundant isolation damper provided in series

The containment requires normal air conditioning, heating, and ventilating to maintain the required temperature to ensure equipment operability, and to provide the required ventilation and control of airborne radioactivity for personnel access.

9.4.6.1 Design Bases

9.4.6.1.1 Safety Design Bases

A. Safety Design Basis One

   The HVAC equipment and ductwork within the containment and the MSSS shall be designed to retain the structural integrity, but is not required to function during and after a safe shutdown earthquake.

B. Safety Design Basis Two

   Those portions of containment HVAC systems that penetrate the containment boundary shall be designed as Seismic Category I insofar as they are required to function to maintain containment isolation capability.

9.4.6.1.2 Power Generation Design Bases

A. Power Generation Design Basis One

   The containment HVAC systems are designed to maintain a containment ambient air temperature between 50F and 120F during normal plant operation to permit continuous operation of all equipment within the containment. The system is also designed to prevent concrete structures within the containment from exceeding the maximum design temperature of 150F except for the concrete

under the reactor vessel column baseplates which have a maximum design temperature of 200F.

B. Power Generation Design Basis Two

The containment normal cooling system is designed to provide adequate internal recirculation to ensure thorough mixing of air throughout the containment, with the containment closed to the outside atmosphere and pressurized to design pressure, so that periodic containment integrated leakage rate tests can be conducted in accordance with 10CFR50, Appendix A, General Design Criterion 52 and 10CFR50, Appendix J.

C. Power Generation Design Basis Three

The containment purge system is designed to purge the containment atmosphere to the plant vent stack while introducing filtered and treated makeup air from the outside to provide adequate ventilation for personnel comfort when the plant is shut down during refueling operations and maintenance, and for limited periods during power operation to allow operator access.

D. Power Generation Design Basis Four

The recirculation cleanup units are designed to reduce the concentration of airborne radioactivity in the containment atmosphere prior to routine personnel access during operation, or in advance of a scheduled plant shutdown.

E. Power Generation Design Basis Five

Cooling air is provided to the CEDMs under normal plant operation with one air handling unit (AHU) and two vane-axial fans which produce a minimum flow rate of 700 standard cubic feet per minute (scfm) per CEDM at a temperature range of 80F to 120F. However, the cooling system can also operate with one single fan, when the other fan is inoperable and its discharge is closed with the backdraft damper, at a reduced flow rate such that it can satisfy the environmental conditions for the operation of the CEDMs. The environmental temperature conditions of the CEDM coils, RSPTs and cable under the reduced flow rate were evaluated in reference 3 and found to be acceptable. This change increases availability of the operating system without having to rely on the redundant standby AHU with its respective two fans in the CEDM cooling system.

F. Power Generation Design Basis Six

The reactor cavity cooling system is designed to maintain an average air temperature of 120F or below inside the reactor cavity. The region below the permanent reactor cavity/refueling pool seal and above the neutron shield plug in the annulus may reach a maximum of 150F.

G. Power Generation Design Basis Seven

The MSSS HVAC system is designed to provide cooling above the 100-foot 0 inch elevation and in the main steam and feedwater line penetration areas.

H. Power Generation Design Basis Eight

Nonsafety-related containment HVAC systems are designed to withstand the DBE to the extent that they will not collapse during the seismic event and damage safety-related systems and components.

9.4.6.1.3 Codes and Standards

The containment building HVAC system is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.6.2 System Description

The containment HVAC systems are shown in engineering drawings 01, 02, 03-M-HCP-001, -002, -003 and 01, 02, 03-M-CPP-001. Data pertinent to the containment normal HVAC system are as follows:

A. The normal cooling system for the containment building consists of four air cooling units of 50% capacity each located at elevation 120 feet 0 inch that are cooled by chilled water. Electrical heating coils are provided in the discharge ducts.

B. The normal cleanup system for the containment building consists of two filtering units of 50% capacity located

at elevation 140 feet 0 inch that clean the containment atmosphere prior to personnel access.

C. The normal purge system for the containment consists of a refueling purge and a power access purge. The refueling purge train is used for high flowrate purge during refueling and is closed during normal power generation. It consists of a supply air handling unit and an exhaust fan.

   The power access purge is used for low flowrate purge prior to and during power access periods. It consists of a supply air handling unit and charcoal exhaust filtration unit. The purge supply and exhaust units are located on the roof of the auxiliary building.

   Containment supply and exhaust penetrations and isolation valves for refueling purge are 42-inch diameter, and for power access purge they are 8-inch diameter.

D. Two 100% capacity air handling units located on the missile shield above the reactor constitute the cooling system for the control element drive mechanisms.

E. Four 50% capacity fan assemblies located at elevation 80 feet 0 inch are used to ventilate the containment cavity.

F. The containment tendon gallery is ventilated by supply and exhaust fans.

G. The normal ventilation system for the MSSS consists of two 100% capacity supply air units. These units are located at elevation 166 feet 11 inches and provide cooling for the MSSS and main steam and feedwater containment penetration areas. One 100% capacity normal exhaust fan for each side of the MSSS, located at elevation 139 feet 0 inch, provides ventilation air for the main steam and feedwater penetration areas to the turbine building.

9.4.6.2.1 System Components

The system components are described as follows:

A. Each normal containment air cooling unit consists of a steel housing, chilled water cooling coils on three sides, a vane-axial fan, associated ductwork, and damper. Heating coils are installed in the ductwork downstream of the air cooling unit.

B. Each normal cleanup filtration unit consists of a housing with a prefilter (high efficiency filter), a HEPA filter, a charcoal adsorber with activated charcoal followed by a HEPA filter and a fan.

C. The supply unit for the containment refueling purge consists of a steel housing with a dust separator (oil impingement filter), a cooling coil, and two fans at 15,000 cubic feet per minute each. Heating coils are installed in the ductwork downstream of the supply air unit.

The supply unit for containment power access purge consists of a housing, a moderate efficiency filter, a high efficiency filter, a cooling coil, a heating coil, and a fan of 2000 cubic feet per minute capacity.

The exhaust for the refueling purge consists of two 16,500 cubic feet per minute fans in parallel. For the power access purge, the exhaust consists of a filtration unit with prefilter, a HEPA filter, a charcoal adsorber, a HEPA filter, and a 2200 cubic feet per minute fan.

D. Each one of the two control element drive mechanism cooling units consists of a steel housing with a cooling coil served by component cooling water and two, two-stage, vane-axial fans.

E. The units for the cavity cooling system each consist of a vane-axial fan and a two-position motorized damper on the discharge side of the fan.

F. The units for the tendon gallery system consist of a vane-axial supply fan and a vane-axial exhaust fan.

G. Each supply air unit for the MSSS consists of an oil impingement filtration unit and a vane-axial fan.

9.4.6.2.2 System Operation

The containment HVAC system normal mode of operation is described as follows:

A. The normal cooling system for the containment is designed to maintain the temperature and reduce the humidity below 90% within the limits specified in table 9.4-2. The containment air cooling can be maintained by two of the four units. The units are controlled from the control room. In the event of a loss of offsite power, the containment air cooling can be maintained. All four units are connected to the ESF buses. They are not energized post-LOCA. Temperature indicators for each level in the containment building are provided in the control room.

B. The normal cleanup system, together with the normal purge system discussed below, is designed to control the airborne radioactivity below the level required for personnel access for inspection, maintenance, and refueling operations. The recirculation cleanup system will clean up the internal air without providing new air makeup.

C. The refueling purge is designed to maintain the airborne radioactivity below the level that permits sustained personnel occupancy during refueling. The power access purge is designed to maintain the airborne radioactivity below the level that permits short-term personnel occupancy during reactor power operation. This system and the normal cleanup system reduce airborne radioactivity concentrations during the entire period of containment building occupancy.

The purging operation is initiated manually from the control room prior to personnel entry to the containment building. The containment is maintained at a negative pressure relative to the atmosphere during the purge cycle.

In the event that the concentration in the containment of either airborne particulates or iodine activity is higher than desired levels, air cleaning is accomplished by activating the recirculation filtration unit. This unit is equipped with charcoal and HEPA filters to reduce containment airborne radioactivity to acceptable levels. The operation of this unit is initiated from the control room by manually energizing the fan.

The containment penetrations of the refueling purge supply and exhaust are equipped with motor-operated isolation valves inside the containment and motor-operated isolation valves outside the containment. The refueling purge penetrations may be isolated using blind flanges in plant operating modes 1-4 as described in section 6.2.4. The containment penetrations of the power access purge supply and exhaust are provided with air-operated isolation valves inside and outside containment. The containment penetrations, including the isolation valves and appropriate seismic restraints, are designed in accordance with Seismic Category I, Quality Class Q, requirements as defined in section 3.2. The valves are controlled automatically by the containment

isolation system (discussed in subsection 6.2.4 and section 7.3), which overrides all manual signals.

D. The cooling system for the CEDM is designed to satisfy the environmental conditions for equipment operation. Both cooling units are connected to the ESF buses, but not energized post-LOCA, so that air cooling can be maintained in the event of a loss of offsite power. The system functions by induction of containment air through the control element drive mechanism. The air pulled through is returned to the containment atmosphere at a temperature less than or equal to 125°F.

The CEDM cooling units function continuously during normal plant operation and may be running during plant shutdown periods, depending upon the heat loads. The units are manually operated from the control room. Normally, one cooling unit is operating and the other unit is on standby. The operating cooling unit, under normal plant operation, provides cooling air to the CEDMs with two 50% capacity vane-axial fans; however, the cooling system can also operate with a single fan running when the other fan is inoperable and its discharge is closed to prevent short circuit of the air. Manual backdraft dampers are installed in the discharge side of the fans to stop air flow from containment on the fan unit that is not operating. The standby cooling unit is automatically energized when the power to the operating unit is lost. A low-differential pressure switch detects the loss of operation of any cooling unit, and transmits

an alarm signal for annunciation in the control room. Motorized dampers are located in the ductwork leading from the CEDM shroud to the units. These dampers are interlocked with the fans. These units are powered by a bus energized by the diesel generator upon loss of offsite power but not energized post-LOCA.

The containment air enters from below the CEDMs and hot air is exhausted from the top of the CEDM shroud. CEDM shroud access and shield doors are locked and administratively controlled in their required positions to support the CEDM cooling functions. Component cooling water is supplied to the cooling coils of these units when the fan is energized.

E. The reactor cavity cooling system operates in conjunction with the containment normal cooling units and provides cooling of the primary shield and reactor cavity to maintain the concrete temperature limit of 150F maximum. The system functions continuously during normal plant operation. Portions of the system may be running during plant shutdown periods, depending on the heat loads.

The system includes four 50% capacity fan units. Normally, two units are operating and the other two units are on standby. The units are manually operated from the control room. The two standby units can be manually energized when the reactor cavity temperature reaches the allowable maximum. Four cavity high-temperature alarm channels are annunciated in the control room.

Motorized dampers, which are located in the discharge of the fans, are electrically interlocked with the fan drive motors. The dampers will close upon fan shutdown. These units are powered from a bus energized by the diesel generator upon loss of offsite power, but not post-LOCA.

F. Tendon Gallery Ventilation System

The system provides ventilation with 100% outside air by one supply fan and one exhaust fan and provides a habitable environment in the tendon gallery area.

The fans are operated manually from local switches and activated during the preaccess period.

G. MSSS Normal Ventilation System

The MSSS normal ventilation system provides once-through ventilation with 100% filtered outside air for the MSSS. The supply air units are activated from a local control panel located in the MSSS. The main steam and feedwater penetration areas to the turbine building are cooled by exhaust air from the MSSS and turbine building. The air is exhausted to the atmosphere by 100% capacity fans for each side of the MSSS. The exhaust fans are activated from a local control panel in the MSSS.

9.4.6.3 Safety Evaluation

A. Safety Evaluation One

The ducts are supported by Seismic Category I supports and HVAC equipment and ducts in the containment are designed to preclude their damaging Seismic Category I components or structures.

B. Safety Evaluation Two

Those portions of containment HVAC systems which penetrate the containment boundary have been designed to Seismic Category I requirements as detailed in section 3.2 and subsection 6.2.4.

9.4.6.4 Inspections and Testing Requirements

Acceptance testing for this system is described in section 14.2.

9.4.7 DIESEL GENERATOR BUILDING -- HVAC SYSTEM

The diesel generator building HVAC system is designed to remove heat during diesel operation and to maintain the temperature within the required limits for personnel occupancy to perform maintenance and repair.

9.4.7.1 Design Bases

9.4.7.1.1 Safety Design Bases

Safety design bases pertinent to the diesel generator building HVAC system are as follows:

A. Safety Design Basis One

The diesel generator building HVAC system shall be designed to maintain the temperatures within the limits required to ensure the operability of the equipment during emergency conditions.

B. Safety Design Basis Two

A single failure in the diesel generator building HVAC system shall not cause the complete loss of both diesel generators.

C. Safety Design Basis Three

The diesel generator building HVAC system is designed to function during and after an SSE.

9.4.7.1.2 Power Generation Design Bases

The diesel generator building HVAC system maintains the temperatures suitable for personnel performing maintenance and repair, and for the starting of the diesel engines, if required, within the diesel startup time frame.

9.4.7.1.3 Codes and Standards

The HVAC system for the diesel generator building is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.7.2 System Description

The diesel generator HVAC system is designed to ventilate the diesel generator and the diesel generator control rooms. A separate HVAC system is provided for each compartment. Each system is powered from its respective ESF bus. The diesel generator HVAC system is shown schematically in engineering drawings 01, 02, 03-M-HDP-001.

The diesel generator room is ventilated using one 100% essential exhaust fan to maintain the temperature within the specified limits during operation of the diesel engine. When the exhaust fan is in operation, air is drawn from the outside ventilation air intake located at the opposite end of the diesel compartment from the fan.

During normal plant operation, the room is ventilated by a normal exhaust fan.

Two 50% capacity unit heaters are provided to heat the diesel generator room during normal plant operation during cold weather to maintain a minimum room temperature of 50F. The heaters are controlled by room thermostats.

During essential operation of the diesel generators the diesel generator equipment control room is ventilated by essential air handling unit and during normal plant operation by the normal air handling unit. The air is exhausted from the control room into the diesel generator room.

Each diesel fuel oil day tank room is ventilated by two redundant 100% capacity normal exhaust fans. One fan normally

operates, while the other is in standby. Air is supplied from the diesel generator room.

9.4.7.2.1 Component Description

Components of the diesel generator HVAC system are as follows:

A. Essential Exhaust Fans

   The exhaust fans are heavy duty, direct-driven, vane-axial fans.

B. Outside Air Intake

   The outside air intake is through a building opening.

C. Normal Ventilation Fans

   The normal exhaust fan is a vane-axial fan.

D. Spray Nozzles

   Spray nozzles are no longer in use; abandoned in place.

E. Unit Heaters

   The unit heaters consist of an electric resistance heater element and a fan combined in a metal housing.

F. Diesel Generator Equipment Control Room Essential Air Handling Unit

   The essential outside air supply unit for the diesel generator control room consists of a high efficiency filter and a supply fan.

G. Diesel Generator Equipment Control Room Normal Air Handling Unit

The normal air handling unit consists of a high efficiency filter and a supply fan.

9.4.7.2.2 System Operation

During essential operation, the exhaust fan will induce the flow of outside air through the outside air intake over the heat-producing equipment to pick up the heat load, and exhaust the heated air to the atmosphere. A room thermostat controls operation of the exhaust fan which limits the room air temperature to 140F maximum.

During normal plant operation, the room is ventilated by the normal ventilation fans to limit the air temperature to 122F.

The unit heater pulls air over electric resistance heater elements to heat the room air during cold weather. Room thermostats control the input to the heaters to maintain a minimum air temperature of 50F. The unit heater fan is used to provide circulation of air during maintenance and repair operations, if required.

The essential outside air supply unit will provide ventilation to the diesel generator control room to limit the temperature of this room to 122F. The filters for this unit have a dust holding capacity which exceeds the required design basis capacity.

The outside air supplied during emergency operation may carry airborne dust. The filters for the essential air handling

units are designed for an average dust loading of 1.78 mg/m^3 with an average maximum dust concentration period of 30 days. This dust loading is based on reference 2. The filter in this unit has the capacity to hold the amount of dust that is anticipated for the period of essential operation. The air will flow from the diesel generator control room to the diesel generator room.

9.4.7.3 Safety Evaluation

Safety evaluations pertinent to the heating and ventilation system are numbered to correspond to the safety design bases and are as follows:

A. Safety Evaluation One

The diesel generator building is provided with an HVAC system designed to distribute air over the diesel generator, its components, and the control equipment to maintain the maximum air temperature at or below the maximum design temperature specified in table 9.4-2. A normal unit heating system, designed to distribute tempered air in the diesel generator building, maintains the minimum temperature at or above the minimum design temperature and the maximum temperature at or below the maximum design temperature specified in table 9.4-2.

B. Safety Evaluation Two

No single failure of any component in the diesel generator building HVAC system can prevent the system from complying

with safety design basis one. A single failure analysis is provided in table 9.4-7.

C. Safety Evaluation Three

The diesel generator HVAC system fans and dampers are designed to Seismic Category I criteria.

9.4.7.4 Inspection and Testing Requirements

Preoperational testing is performed as described in section 14.2.

9.4.8 ESSENTIAL SPRAY POND PUMPHOUSE

The essential spray pond (ESP) pumphouse HVAC subsystem consists of two essential safety exhaust fans, one each for train A and train B. The function of this subsystem is to provide ventilation in the two ESP pumphouses.

Outside air (20,000 cubic feet per minute for each train) is drawn through existing missileproof entrance openings by exhaust fans HSA-J01 and HSB-J01 and exhausted through missileproof grating. Ventilation air will maintain the room design temperature of 120F based on an outside air temperature of 113F. The room temperature will also be maintained at or below the pump qualification temperature, which is 122F, based on an outdoor temperature excursion to 116F. The exhaust fan is interlocked with the pump motor so that the fan and pump run simultaneously. The fan motors are Class 1E-powered from independent Class 1E power supplies.

Table 9.4-7

HVAC SYSTEM SINGLE FAILURE ANALYSIS FOR DIESEL GENERATOR BUILDING

Component	Failure Mode/ Cause	Effects on System	Method of Detection	Inherent Compensating Provision
Diesel generator room ventilation exhaust fan	Fails to operate/ mechanical or electrical failure	Partial loss of ventilation	Temperature rise in room	Redundant diesel generator available
Room thermostat	Fails to operate	Partial loss of ventilation	Temperature rise in room	Redundant diesel generator available
Diesel generator control equipment room ventilation supply fan	Fails to operate/ mechanical or electrical failure	Loss of ventilation	Temperature rise in room	Redundant diesel generator available

9.4.8.1 Design Bases

9.4.8.1.1 Safety Design Bases

Safety design bases applicable to the ESP pumphouse HVAC subsystem are as follows:

A. Safety Design Basis One

   The essential spray pond pumphouse HVAC subsystem is designed to assure ventilation of the ESP pumphouses with outside air to maintain the temperatures within the limits required to ensure the operability of the equipment within the pumphouses during emergency or post-accident operation of the essential spray pond system (ESPS).

B. Safety Design Basis Two

   The exhaust fans are Quality Class Q, are provided with missile protection, and are designed to function during and after an SSE.

9.4.8.1.2 Power Generation Design Basis

The ESP pumphouse HVAC subsystem is designed to ventilate the pumphouses with outside air to maintain the temperatures within the limits required to ensure operability of the equipment within the pumphouses during normal plant shutdown ESPS operation.

9.4.8.1.3 Codes and Standards

The essential spray pond pumphouse HVAC subsystem is designed to conform to the applicable codes and standards listed in table 3.2-1.

9.4.8.2 System Description

The ESP pumphouse HVAC subsystem ventilates each ESP pumphouse using a single fan for each pumphouse. The A and B train pumphouses are each provided with corresponding train-related fans. The subsystem also includes necessary ductwork.

9.4.8.2.1 Component Description

The ESP pumphouses each contain one essential Quality Class Q, missile-protected exhaust fan and ductwork as described in tables 9.4-3 and 3.2-1.

9.4.8.2.2 System Operation

The essential ventilation fans for the ESP pumphouses operate whenever the ESP pumps are running. The exhaust fans induce a flow of outside air over the ESP pump motors and exhaust the heated air to the outside atmosphere. Conditions inside the pumphouses will approach outside air temperatures and normally be within the range identified in table 9.4-2.

9.4.8.3 Safety Evaluation

Safety evaluations applicable to the ESP pumphouse HVAC subsystem are numbered to correspond to the safety design bases and are as follows:

A. Safety Evaluation One

   The ESP pumphouses are provided with an HVAC subsystem designed to circulate and exhaust outside air through each pumphouse to maintain air temperatures within operability limits for the equipment within the pumphouses.

B. Safety Evaluation Two

   The ESP pumphouse HVAC essential exhaust fans and structural supports are missile-protected and designed to Seismic Category I criteria. The exhaust fans are Quality Class C.

9 4.8.4 Inspection and Testing Requirements

Preoperational testing is performed as described in section 14.2.

9.5 OTHER AUXILIARY SYSTEMS

9.5.1 FIRE PROTECTION SYSTEM

The fire protection system (FPS) is designed to detect, contain, and extinguish fires in the plant.

The fire protection water supply and pumping equipment is shared by all units. Other fire protection equipment described below is provided for each unit individually.

Where referred to in this section, the FPS includes fire detection and extinguishing systems and equipment. It is exclusive of such design elements as physical separation, barrier separation, and burning characteristics of combustibles, which limit the propagation of fire, but do not actively extinguish it.

Appendix 9B, Fire Protection Evaluation Report, describes and discusses the effects that various postulated fires may have on areas of the plant which contain safety-related structures, systems, and components.

Carpeting or resilient floor covering is utilized in the PVNGS control room for noise and dust control, to reduce operator fatigue, and to enhance the man-machine interface. The floor covering is listed by a nationally recognized testing laboratory as having a critical radiant flux minimum of 0.45 watts per square centimeter as determined by the NFPA 253 or ASTM E 648 test method.

9.5.1.1 Design Bases

9.5.1.1.1 Safety Design Bases

Safety design bases pertinent to the FPS are as follows:

A. Safety Design Basis One

The fire protection system shall be designed to minimize, consistent with other safety requirements, the effects of fires on structures, systems, and components important to safety, in accordance with 10CFR50, Appendix A, General Design Criterion 3, Fire Protection, Appendix R, Part III, Sections G, J, and 0, and Appendix A to BTP APCSB 9.5-1.

B. Safety Design Basis Two

Fire protection systems shall be designed so that their rupture or inadvertent operation does not significantly impair the function of plant structures, systems, and components important to safety, in compliance with 10CFR50, Appendix A, General Design Criterion 3, Fire Protection.

C. Safety Design Basis Three

Fire protection system components shall be designed to preclude their structure failure due to seismic loading which could cause loss of function to safety-related systems or components, in compliance with 10CFR50, General Design Criterion 3, Fire Protection.

D. Safety Design Basis Four

American Nuclear Insurer's (ANI) recommendations shall be used as guidance such that fire hazards and potentials are reduced during construction of multiple-unit plants when one or more units are in operation.

E. Safety Design Basis Five

Structures, systems, and components important to safety shall be designed and located to minimize the fire hazards consistent with other plant safety requirements. This requirement is in compliance with 10CFR50 General Design Criterion 3, Fire Protection. Noncombustible and heat-resistant materials shall be used wherever practicable throughout the plant.

The basis fire protection for engineered safety features (ESF) shall be achieved through separation of systems serving the same safety function, by fire barriers between such installations or by providing alternate means of assuring safe shutdown. Plant fire barriers, walls, and enclosures shall be rated and located as set forth in appendix 9B.

F. Safety Design Basis Six

The fire protection system shall be designed to minimize the effects of fires and to provide the capability to control and extinguish fires encountered in the plant. Areas housing equipment necessary to achieve safe shutdown that are protected by manual fire protection shall be accessible with respect to heat, smoke, toxic combustion products, and radiation.

The firefighting component shall be located as close as practical to the area it is to serve.

G. Safety Design Basis Seven

The plant fire protection water supply system shall be capable of supplying the required flow with any one of the three fire pumps out of service. The fire protection water supply system shall be rated to supply the hydraulically calculated demand for the largest fire sprinkler or deluge system plus 500 gallons per minute for manual hose stream.

To minimize cycling of the main fire pumps, a fire water jockey pump shall be provided to maintain system pressure.

The fire water/well water reserve tanks shall be separated by a distance so as to preclude washout of one tank by failure of the other.

H. Safety Design Basis Eight

Only one of the three fire pumps shall be motor-driven, with the remaining two pumps driven by diesel engines. The motor-driven pump shall have two sources of power.

I. Safety Design Basis Nine

The fire protection water supply yard main shall be arranged so that each branch line from the yard main to the various areas in each unit's facilities may be supplied with water by alternate flow paths. Two-way supplied fire hydrants, controlled by individual curb box valves, shall be installed at approximately 250-foot

intervals within the power block area, and as required near other hazards and near other remote buildings.

J. Safety Design Basis Ten

Hydraulically balanced automatic preaction and wet pipe sprinkler systems and hydraulically designed automatic water spray systems shall be installed in areas with a high fire potential. Criteria for determining the need for these systems shall be in substantial compliance with the following guidelines:

- ANI guidelines, Basic Fire Protection for Nuclear Power Plants, April 1976.
- Appendix A to Branch Technical Position APCSB 9.5-1, Guidelines for Fire Protection for Nuclear Power Plants Docketed Prior to July 1, 1976 (revised February 24, 1977).

K. Safety Design Basis Eleven

Automatic low-pressure carbon dioxide flooding systems shall be provided for normally unoccupied electrical equipment and battery rooms that are safety-related. Hand hose lines supplied with low-pressure carbon dioxide from a central storage unit shall be provided for use in areas near nonsafety-related switchgear and motor starter panels.

L. Safety Design Basis Twelve

For equipment located in the remote shutdown rooms, computer room, the inverter room, and the communications equipment room, Halon 1301 flooding systems shall be

provided. In the occupied areas of the control room complex, portable water and carbon dioxide fire extinguishers shall be installed. Portable CO_2 extinguishers in the control room for manual firefighting shall not result in an uninhabitable condition within the room if the extinguishers are discharged since adequate ventilation is provided.

M. Safety Design Basis Thirteen

Fire hose stations shall be provided for all buildings and all floors, and spacing shall be such that normally accessible areas can be covered by 75- or 100-foot hoses where practical. Isolated cases may allow the use of 125- or 150-foot hose lengths if necessary.

N. Safety Design Basis Fourteen

Portable fire extinguishers shall be provided throughout normally accessible areas of the plant using the guidelines of NFPA 10 (1975) as referenced in table 9B.3-1.

O. Safety Design Basis Fifteen

Alarms shall be provided in the control room to function upon activation of automatic fire protection systems. Fire detection systems shall be installed in areas where a potential for fire exists. These detection systems shall alarm locally and in the control room.

P. Safety Design Basis Sixteen

Fire protective clothing and respiratory apparatus for use by plant firefighting personnel shall be provided

for use in fires which could produce an adverse environment and thus preclude manual fire suppression or could inhibit manual firefighting operations.

Q. Safety Design Basis Seventeen

Fire dampers shall be provided in those ventilation ducts penetrating rated fire barriers and penetration seals shall be provided for pipe, electrical raceways, or similar openings and shall provide fire protection equal to or greater than the rating of the fire barrier penetrated. Fire doors or the equivalent shall be installed in door openings through rated barriers.

R. Safety Design Basis Eighteen

Emergency lighting systems shall be provided in accordance with the guidance provided in Appendix A to NRC Branch Technical Position APCSB 9.5-1 (revised February 24, 1977) and 10CFR50, Appendix R, Section III.J (issued September 1, 1982), in areas needed for the local manual operation of safe shutdown equipment and in access and egress routes thereto in the event of a fire.

The emergency lighting fixtures shall be selected to be applicable to the areas in which they are installed and shall not necessarily include or exclude sealed beam units. Selection of fixtures and bulbs shall allow normal movement during emergency conditions.

Batteries for emergency lighting shall be rated for a minimum of 8 hours in areas needed for the operation of

safe shutdown equipment and in access and egress routes to these areas

The emergency lighting fixtures may or may not normally be lighted but shall automatically energize upon loss of essential ac, in areas where essential lighting is provided, or upon loss of normal ac, in areas where essential lighting is not provided.

The emergency lighting system is described in subsection 9.5.3.

Applicable codes and regulations of the State of Arizona, the National Fire Codes of the National Fire Protection Association (NFPA), and applicable sections of Title 29, Chapter XVII, Part 1910, Occupational Safety and Health Standards of the Code of Federal Regulations, as set forth in the Federal Register, Volume 37, Number 202, dated October 18, 1972, have been used as guidance in developing the plant fire protection system design.

9.5.1.2 System Description

The water and gaseous portions of the fire protection systems are shown schematically in engineering drawings 01, 02, 03-M-FPP-002, -003, -004, -006, A0-M-FPP-001 and A0-M-FFP-005.

Table 9.5-1 provides a tabulation of the types of fire protection and fire detection and actuating devices provided for each specific area in the plant.

Each unit's fire protection system is comprised of diversified monitoring, detection, alarm, suppression, and extinguishment

facilities particularly selected to protect the area or equipment from damage by fire. The system includes the following major features:

- Fire protection water supplies, yard mains, and hydrants
- Wet pipe sprinkler systems (hydraulically designed)
- Deluge water spray systems (hydraulically designed)
- Automatic preaction systems (hydraulically designed)
- Low-pressure carbon dioxide systems
- Halon 1301 systems
- Standpipes and fire hose stations
- Portable CO_2 and dry chemical (ABC powder) fire extinguishers
- Fire and smoke monitoring, detection, and alarm systems
- Fire walls and barriers

9.5.1.2.1 Component Description

Components of the plant fire protection system are selected to provide comprehensive protection against fire hazards throughout the plant.

A. Fire Protection Water Supplies

The primary water source for the fire water system is two 500,000 gallon carbon steel tanks located near the water reclamation facility boundary. These tanks are designated as the fire water/well water reserve tanks. Of the 500,000 gallons stored within each tank,

300,000 gallons are dedicated for fire protection. The remaining 200,000 gallons are available for fire protection and other uses by means of suction piping that penetrates each tank above the 300,000-gallon level. Makeup water for the fire water/well water reserve tanks is supplied by either of two site wells known as (B-1-6) 34abb and (B-1-6) 27dd (Arizona well numbering system).

	I	Ionization detector (invisible smoke)
	L	Line-type heat detector
	UV	Ultraviolet detector (flame or spark)
	PE	Photoelectric smoke detector
Accessibility:	O	No special protective device required
	P	Protective device required

B. Fire Pumps and Distribution System

Fire water is supplied by three 50% horizontal centrifugal fire pumps, two of which are driven by diesel engines and the third by an electric motor. The fire pumps take suction from either or both of the fire water/well water reserve tanks and distribution to the power block loop is accomplished by two redundant discharge lines.

To minimize unnecessary starting of the fire pumps, a motor-driven jockey pump is provided to maintain fire water header pressure when there is little or no flow requirement. When flow to the fire water system is required, the fire pumps are designed to start sequentially to decreasingly lower pressures in the fire main.

C. Yard Mains, Hydrants, and Valves

The fire protection water main consists primarily of a closed 12-inch underground loop encompassing all units, the service and administration buildings, and site construction buildings. The underground piping throughout the yard area is either cement mortar-lined (ductile) cast iron, Class 150, with Tyton joints or reinforced fiberglass, ASTM D2996, with adhesive-bonded bell and spigot joints.

The yard main is provided with post-indicator valves for sectional control. Post-indicator valves are also located such that the yard loop for any individual power block can be isolated from the yard loops of the

remaining units. Manually-operated water supply gate valves, installed in the automatic preaction sprinkler, wet pipe sprinkler, and deluge water spray systems, are used during plant construction to isolate the parts of the fire protection system that are functional from those parts of the system still under construction.

Outside hydrants are provided at approximately 250-foot intervals within the power block area and as required near other hazards and near other remote buildings. Hydrants are equipped with 2-1/2-inch hose connections.

In the unlikely event that the plant fire pumps cannot furnish an adequate water supply to the distribution system, the yard main includes pump connections for obtaining water from the circulating water system cooling tower basin by using portable pumping units.

D. Wet Pipe Sprinkler Systems

Wet pipe sprinklers, hydraulically designed using NFPA Pamphlet No. 13 (1976) as guidance, are provided to protect the areas so indicated in table 9.5-1. Each wet pipe system provides fusible-link sprinkler heads arranged such that water flow densities meet the requirements of ANI, and also NFPA Pamphlet No.13 (1976).

E. Deluge Water Spray Systems

Deluge water spray systems, hydraulically designed using NFPA Pamphlet No. 15 (1973) as guidance, are provided to protect the equipment so indicated in table 9.5-1. Each deluge water spray system provides

open head spray nozzles arranged and directed such that water flow densities meet the guidelines of ANI, and also NFPA Pamphlet No. 15 (1973).

F. Automatic Preaction Sprinkler Systems

Automatic preaction sprinklers, hydraulically designed using NFPA Pamphlet No. 13 (1976) as guidance, are provided to protect the areas so indicated in table 9.5-1. Each automatic preaction system contains piping supervised by service air and fusible link sprinkler heads arranged such that flow densities meet the guidelines of ANI, and also NFPA Pamphlet No. 13 (1976).

G. Low-Pressure Carbon Dioxide Systems

Low-pressure carbon dioxide systems, designed using NPFA Pamphlet No. 12 (1973) as guidance, are provided for total flooding and local hand hose application in those areas so indicated in table 9.5-1. Each CO_2 flooding system, when activated, provides a 50% concentration of CO_2 by volume in the hazard area. Discharge nozzles are oriented such that direct impingement of CO_2 liquid/vapor upon equipment is avoided.

H. Halon 1301 Systems

Halon 1301 fire suppression flooding systems, designed using NFPA Pamphlet No. 12A (1973) as guidance, are provided to protect the areas so indicated in table 9.5-1. All system components are Underwriters

Laboratories (UL)-listed or Factory Mutual (FM)-approved. Each Halon system, when activated, provides a minimum (maximum) Halon concentration of 5% (7%) by volume in occupied hazard areas, and 5% (10%) by volume in unoccupied areas or areas evacuable within 1 minute as provided by NFPA Pamphlet 12A (1973), Section 2-1.1.3.

I. Standpipes and Hoses

Wet standpipes for fire hoses are designed using NFPA Pamphlet No. 14 (1976) as guidance. Standpipes are provided for all buildings and all floors. Four-inch standpipes are provided for multiple hose connections and 2-1/2-inch standpipes are provided for single hose connections. The standpipe hose connections are equipped with 1-1/2-inch hose valves and either 75 or 100 feet (or in isolated cases 125 or 150 feet) of 1-1/2-inch woven jacket lined hose. Adjustable spray nozzles are used for areas where nonelectrical fires might occur, and approved fog nozzles (Class C) are used in areas where electrical fires might occur.

J. Dry Chemical Systems

Dry chemical extinguishing systems consist of a 350-pound dry chemical powder tank and gas cylinder mounted on a mobile chassis. The unit is equipped with 50 feet of 3/4-inch hose and a nozzle designed for local application of dry chemical powder.

K. Portable Fire Extinguishers

Portable fire extinguishers for manual extinguishment of fires are provided throughout normally accessible areas of the plant and in occupied areas of the control room utilizing the guidelines of NFPA 10 (1975) as referenced in table 9B.3-1. Portable extinguishers of the multipurpose type for use on Classes A, B, and C fires have a capacity of 20 pounds of dry chemical (ABC powder) and are rated by UL as 10-A:40-B:C. The units are UL-labeled. Portable extinguishers for Classes B and C fires have a capacity of 20 pounds of carbon dioxide, have a minimum UL rating of 10-B:C, and are UL-labeled.

L. Fire Barriers

Fire barrier walls and floors, and walls within 50 feet of oil-filled transformers, are located and rated in accordance with ANI guidelines, Basic Fire Protection for Nuclear Power Plants, April 1976. All fire barriers applicable to safety-related areas are shown and discussed in appendix 9B. Where ventilation systems penetrate these barriers, fire dampers providing fire protection equal to or greater than the penetrated wall ratings are provided. All cable tray, conduit, HVAC duct, and piping penetrations through fire barriers are sealed using seal designs of equal or greater rating than the rating of the penetrated barriers. Penetration seals meet the acceptance

criteria of ASTM Standard E119 (1976) or IEEE-634 (1978).

Where door openings penetrate rated barriers, the openings are protected by door assemblies providing fire protection equal to or greater than the rating of the penetrated barrier. All fire doors shall be purchased as UL- or FM-labeled doors except as noted in the appendix 9A response to Question 9A.106.

M. Fire and Smoke Monitoring, Detection, and Alarm System

Fire and smoke monitoring, detection, and alarm is accomplished by ionization (I), photoelectric (PE), and ultraviolet (UV) detectors, and by heat responsive or heat-actuated devices (HAD) in areas as indicated in table 9.5-1.

Selection, placement, and spacing of fire monitoring, detection, and alarm devices are based on consideration of design, configuration, and employment of the area together with draft conditions due to natural or mechanical ventilation.

The fire and smoke monitoring, detection, and alarm system includes a supervisory circuit that indicates the failure of individual circuits and detectors. Both monitoring and supervisory alarm signals register locally and in the control room. In the control room, incoming FPS alarms activate audible and visual annunciators individually or in groups.

A computerized visual display is provided in the control room for the appraisal and trend evaluation of

incoming FPS alarms. The display alarm messages indicate the area of the plant that initiated the alarm and if an automatic or fixed manual fire extinguishing system is in operation. Fire protection system alarms are also indicated on local fire zone indicating panels.

9.5.1.2.2 System Operation

Operation of the FPS is described briefly as follows:

A. Fire Protection Water Supplies

Water for the fire water/well water reserve tanks is supplied by the site deep-well pumps. Both fire water/well water reserve tanks are normally filled simultaneously through either a two-inch or an eight-inch makeup control valve. Although the tanks are normally filled simultaneously, each tank may be filled individually by closing the appropriate isolation valves. During normal filling operations (tank levels above 400,000 gallons), the fire water/well water reserve tanks are filled through the two-inch control valve. For tank levels below 400,000 gallons, makeup is provided through the eight-inch control valve. Both deep-well pumps automatically start whenever either fire water/well water reserve tank level decreases below 388,000 gallons. Each deep-well pump is rated at approximately 1,400 gallons per minute. One pump is capable of completely filling one tank in less than eight hours.

Suction pipes for other water uses are located in such a manner as to avoid tapping the lower 300,000-gallon portion of each storage tank for that is dedicated for fire protection purposes.

The fire water/well water reserve tanks have provisions for chemical addition from a nearby chemical addition skid. Chemical addition to the fire water/well water reserve tanks and the fire protection water system is required for corrosion control.

The two fire water/well water reserve tanks are interconnected through normally open valves, both on the FPS water suction pipe side and on the makeup water supply side. Water level in the tanks is controlled by dual level controllers and the makeup control valves located in the common water supply line to the two tanks. Each tank is provided with a level controller, a local level indicator, and high and low level alarm switches. High and low level alarms are annunciated in the control room.

B. Fire Pumps and Distribution System

During normal operation, the fire protection water system is kept continuously full and pressurized by the jockey pump.

When significant flow (more than 40 gallons per minute) is required to the fire water system, the fire pumps are designed to start sequentially on decreasingly lower pressures in the fire main. Normally, the first fire pump to start would be the motor-driven fire pump

when the pressure in the fire main header drops to 95 psig. If the fire main pressure drops below 90 psig and remains below that point for at least 20 seconds, the first diesel-driven fire pump cycles on. The second diesel-driven fire pump will cycle on if the pressure in the fire main header drops below 85 psig and remains below that pressure for at least 30 seconds. These time delays for the diesel-driven pumps preclude excessive cycling when there is a sudden drop of fire main pressure through all three setpoints and when a single 1500 gallons per minute pump can fulfill the system demand. The diesel fire pumps continue to run until shut off manually by the operator.

In accordance with NFPA No. 20 (1976), remote alarms and indications are provided in the main control room for the following conditions:

- Diesel malfunction (common alarm includes items such as low lube oil pressure, high jacket water temperature, engine failure to start automatically, engine overspeed trip, loss of battery charger, battery failure, and fuel oil day tank low level)
- Controller main switch not in automatic
- Diesel pump running

To run performance tests, discharge of each fire pump can be routed back to the fire water/well water reserve

tanks through a flow element and through normally closed valves.

C. Yard Mains, Hydrants, and Valves

During normal operation, the yard main piping is kept continuously full and pressurized to 110 psig. If portions of the fire main need to be taken out of service for maintenance, appropriate post-indicator valves are manually closed to facilitate these repairs. The jockey pump maintains the yard main piping pressurized. Any failure of the yard main piping due to excessive leakage, greater than jockey pump capability, or rupture is detected by main fire pump operation without a fire alarm.

Post-indicator valves are positioned on the fire main such that no more than four side branches from the main are affected by the closing of two valves in one vicinity. Post-indicator valves are also located in each branch line from the main so that these lines can be isolated if necessary. Post-indicator valves are cast iron, with a nonrising stem with a 2-inch square operating nut. Valves are opened by turning the nut counterclockwise. Most post-indicator valves have post-indicators that extend a minimum distance of 3 feet above the ground. The post-indicator valves that do not have above grade post-indicators, are provided with position indicators located below grade and access covers to allow verification of valve position.

Operation of outside fire hydrants is intended for use only by trained firefighting personnel. Hydrants are of the dry-barrel type with a 6-inch flanged joint inlet, two 2-1/2-inch hose nozzles, and one 4-1/2-inch steamer nozzle, all with National Standard threads. The PVNGS fire department has emergency response vehicle(s) which carry an assortment of hoses, nozzles, and auxiliary equipment in lieu of hose houses.

D. Wet Pipe Sprinkler Systems

Wet pipe sprinkler system operation is initiated on a rise in ambient temperature to the melting point of fusible links on sealed sprinkler heads, thus permitting the spray heads to open. Flow of water through the alarm check valve energizes local alarms and registers an alarm condition in the control room. Once initiated, wet sprinkler system operation is terminated manually by shutting a local gate valve adjacent to the system alarm check valve or by shutting the appropriate post-indicator valve in the yard.

E. Deluge Water Spray Systems

Deluge water spray system operation (except those systems protecting electrical cable trays) is initiated by an electric thermostat-type heat responsive device that senses either a rapid rise in ambient temperature or attainment of a high fixed-temperature, and releases a tripping device that opens the deluge valve supplying water under pressure to open deluge nozzles. Actuation of the heat-responsive device also initiates a local

alarm and registers the alarm condition in the control room independently of water flow in the system. Manual release of the deluge valve tripping device also initiates local and remote alarms. System operation is terminated by manually shutting a local gate valve adjacent to the system deluge valve.

Deluge water spray system operation for those systems protecting electrical cable trays is initiated by a combination of line-type heat detectors and product-of-combustion detectors that sense heat and smoke respectively and release a tripping device that opens the deluge valve. Actuation of either of these detection devices without the other will initiate local and remote alarms but will not release the deluge valve.

F. Automatic Preaction Sprinkler Systems

Automatic preaction sprinkler system operation (except those systems protecting electrical cable trays and the turbine driven auxiliary feedwater pump room) is initiated by the product-of-combustion detectors. When a detector senses the products of combustion, it releases a tripping device which opens the deluge valve and pressurizes the system with water.

Automatic preaction sprinkler system operation for the turbine driven auxiliary feedwater pump room is initiated by cross-zoned, product-of-combustion detectors. When two of these detectors (one from each zone) sense the products of combustion, they release a

tripping device that opens the deluge valve and pressurizes the system with water.

Automatic preaction sprinkler system operation for those systems protecting electrical cable trays is initiated by either line-type heat detectors or product-of-combustion detectors. When either the line-type heat detectors sense heat or the product-of-combustion detectors sense smoke, they release a tripping device that opens the deluge valve and pressurizes the system with water.

Actuation of the detectors also initiates a local alarm and registers the alarm condition in the control room. Actual flow of water upon the hazard area does not occur until the rise in ambient temperature reaches the melting point of fusible links of sealed sprinkler heads, thereby permitting flow through the head. Once water flow is initiated, system operation can be terminated by manually shutting a local gate valve adjacent to the system deluge valve.

G. Low-Pressure Carbon Dioxide Systems

Operation of the automatic low-pressure carbon dioxide total flooding system is activated by fire detection devices located within the hazard areas using NFPA No. 72E-1978, Standard on Automatic Fire Detectors, as guidance. The fire detection devices are arranged in a cross-zone logic configuration to provide early warning and minimize the potential of inadvertent carbon dioxide (CO_2) discharges. The system can be activated

either automatically by the fire detection devices or manually. A timed predischarge alarm is provided to allow occupants in the hazard area to exit safely prior to CO_2 discharge. Operation status of the system is monitored in the control room as described in paragraph 9.5.1.2.1, listing M.

The following sequence of events takes place during activation of the CO_2 system:

1. Activation of one or more fire detection devices on a single zone circuit.

   a. Local alarm bell activates to warn personnel of a fire and potential CO_2 discharge.

   b. Alarm condition is registered in the control room.

2. Activation of one or more fire detection devices on two zone circuits.

   a. Predischarge alarm circuit energizes and local siren activates for personnel evacuation.

   b. A CO_2 system activation condition is registered in the control room.

   c. Fans and dampers are placed in a configuration to isolate the hazard area.

   d. Following the predischarge alarm, the CO_2 discharge circuit is energized for the required master valve and selector valve operation.

e. The selector valve for the hazard area opens and releases CO_2 for a predetermined discharge interval.

f. Upon completion of the discharge cycle, the discharge circuit is deenergized and flow of CO_2 is stopped.

The alarm condition is maintained until the system is reset manually.

Conveniently located pushbutton stations are provided for each hazard area for manual operation. These stations enable personnel to place the system in operation in the event that fire is observed before a detector has been actuated. The pushbutton systems have a guard or other design feature to prevent accidental actuation.

An electro-manual pilot cabinet is included for each master valve. These valves are normally energized so that the master valves open automatically in case of electric power interruption and pressure the discharge headers up to the selector valves. An operating lever also enables personnel to operate the master pilot valve manually, thereby opening the master valve.

An electro-manual pilot cabinet normally deenergized with a supervised 1/4-inch, lever-operated shutoff valve is also included for each hazard area. These serve to pilot the automatic selector valves on normal system operation. An operating lever enables personnel to operate the system manually in the event of electric

power interruption. The shutoff valve precludes the discharge of CO_2 into the hazard area while occupied by personnel.

Operation of CO_2 hose reels for local application is initiated by manually removing the playpipe from its support bracket, thereby causing the master valve at the storage tank to open and charge the piping up to the nozzle. Discharge of CO_2 is controlled by utilizing the squeeze-type valve at the nozzle. Replacement of the playpipe on its support closes the master valve.

H. Halon 1301 Systems

Halon 1301 system operation is prealarmed by the product of combustion and actuated by thermal detectors in the remote shutdown rooms, and by product-of-combustion detectors that are cross-zoned in the computer, communication, and inverter rooms. Actuation of the first circuit (or loop) on the cross-zoned systems accomplishes the following function:

- Energizes an audible and visual alarm

The actuation of second circuit (or loop) on the cross-zoned system shall accomplish the following functions:

- Audible and visual alarm energized. Predischarge alarm circuit energizes and local alarm sounds for personnel evacuation.
- HVAC dampers closed

- Magnetic door holders released, if applicable (i.e., if the doors are not normally closed)
- Halon discharged

Manual pull stations are provided for system actuation. The detection system trips the release valve assembly on the agent storage cylinder to discharge the total capacity of the agent storage cylinder. In this manner, a minimum (maximum) Halon 1301 concentration of 5% (7%) by volume is achieved in the occupied hazard areas, and 5% (10%) by volume in unoccupied areas or areas evacuable within 1 minute as provided by NFPA Pamphlet 12A (1973), Section 2-1.1.3. Alarms are also provided in the control room for Halon discharge and Halon system malfunctions. A concentration level of up to 7% Halon 1301 in the computer room may be inhaled by personnel for 4 or 5 minutes without risk of serious effects. The control room will remain habitable at all times.

I. Standpipes and Hoses

Inside hose stations are intended to be operated by plant personnel for the manual control of small fires. Adjustable spray nozzles are used for areas where non-electrical fires might occur, and approved fog nozzles (Class C) are used in areas where electrical fires might occur.

J. Dry Chemical Systems

The 350-pound dry chemical extinguisher is wheeled to the vicinity of Class A (ordinary combustible materials), Class B (flammable liquids, gases, and greases), or Class C (energized electrical equipment) fires. After it is wheeled to the appropriate fire area, the dry chemical extinguisher is operated manually by plant personnel.

K. Portable Fire Extinguishers

Appropriate portable extinguishers can be carried to the vicinity of Classes A, B, or C fires and can be manually operated by plant personnel for the control of small fires.

L. Fire Barriers

Fire barriers are generally passive fixtures and require no operation. Exceptions are HVAC dampers that pass through fire-rated walls and floors. Normally, the HVAC fire dampers are open, and their closure occurs only when heat causes their fusible links to melt or when activated by automatic gas extinguishing systems.

M. Fire and Smoke Monitoring, Detection, and Alarm Devices

Fire and smoke monitoring, detection, and alarm devices are activated by several different stages of a fire. Ionization detectors alarm at the presence of invisible combustion gases during the incipient stage of fire. Photoelectric detectors operate on a light principle

where smoke entering a light beam either obscures the beam's path or reflects light into a photocell. Flame detectors respond directly to the ultraviolet radiation emanating from a flickering flame sustained for at least 3 seconds in areas where fire developed rapidly with a minimum or absent incipient stage. Thermal detectors react to the attainment of a high fixed-temperature or rapid rise in ambient temperature, in excess of 15F per minute, and provide alarm service as well as release service for certain automatic systems as discussed above.

Failure of a single fire detection device is annunciated by the circuit's supervisory alarm. Such an indication prompts inspection and replacement or repair of the failed component. During the period when the failed fire detector is out of service, a detection capability continues to exist since more than one detector is installed in each area.

9.5.1.3 Safety Evaluation

The primary evaluation of the compliance of the PVNGS design with applicable regulatory and industry standards has been presented in appendix 9B, Fire Protection Evaluation Report. This report has been extensively referenced in the safety design bases evaluations of this section.

A. Safety Evaluation One

Fire protection has been achieved, consistent with 10CFR50, Appendix A, General Design Criterion 3,

Appendix R, Part III, Sections G, J, and O, and Appendix A to BTP APSCB 9.5-1 by the integrated consideration of fire prevention and fire suppression. Fire prevention measures have been incorporated in the plant design by physically separating ESF trains, reducing available combustible materials, installing fire barriers, and ensuring that adequate space and environmental controls have been provided to facilitate manual firefighting. Fire suppression methods incorporated in the design have been reported in appendix 9B. Additional consideration has been given to the effects of fire suppression activities and equipment on plant systems and structures. Water-resistant electrical equipment has been utilized where feasible and the measures described in evaluations B and C have been implemented.

B. Safety Evaluation Two

The consequences of failure or inadvertent operation of fire suppression systems have been minimized by ESF train separation, use of preaction systems, adequate floor drains to remove excess water, and use of fire suppression measures such as CO_2 or Halon 1301 in sensitive electrical and/or personnel areas. Appendix 9B contains additional, location specific, information regarding the potential failure of suppression systems.

C. Safety Evaluation Three

Fire suppression system components are seismically supported in plant areas where a nonseismically supported component could cause loss of function to safety-related systems or components as a result of an SSE.

D. Safety Evaluation Four

Site fire suppression systems or components that are required to be available by an operating unit during the construction of other units will be isolated from the effects of construction. Power block fire suppression systems are duplicated for each unit. These measures provide protection recommended by the ANI guidelines referred to in the design basis.

E. Safety Evaluation Five

Separation of structures, systems, and components important to safety is provided as noted in appendix 9B.

F. Safety Evaluation Six

The fire protection system provides the capability to fight fire throughout the plant, as noted in appendix 9B. The effects of fires are minimized as noted in evaluation A. Areas housing equipment necessary to achieve safe shutdown are accessible with respect to heat, smoke, toxic combustion products, and radiation as noted in appendix 9B. The location and intended use of firefighting components are as described in appendix 9B.

G. Safety Evaluation Seven

The plant fire protection water supply system is capable of supplying rated flow, even with equipment failures, to the extent noted in table 9.5-2.

A fire water jockey pump is provided.

H. Safety Evaluation Eight

Two fire pumps are diesel-driven. One is motor-driven from either of two sources of power.

I. Safety Evaluation Nine

Each branch fire protection water line to the turbine, auxiliary, control, containment, and diesel generator buildings may be supplied with water by an alternate flow path. Fire protection water to the fuel and radwaste buildings is provided through single paths due to the limited fire potentials in these buildings as noted in appendix 9B. Two-way-supplied fire hydrants, controlled by individual curb box valves, are installed at approximately 250-foot intervals within the power block area, and as required near other hazards and near other remote buildings.

J. Safety Evaluation Ten

Wet pipe sprinkler, automatic preaction sprinkler, and water spray systems are installed in the plant as described in appendix 9B.

K. Safety Evaluation Eleven

Low-pressure carbon dioxide flooding systems are installed in the plant as described in appendix 9B.

L. Safety Evaluation Twelve

Halon 1301 flooding fire suppression is provided in the control building as described in appendix 9B. Portable carbon dioxide extinguishers are provided in the control room as noted in appendix 9B. Design of these systems is such that their use will not result in an uninhabitable condition within the control room.

M. Safety Evaluation Thirteen

Fire hose stations are provided as described in appendix 9B.

N. Safety Evaluation Fourteen

Portable fire extinguishers are provided in accessible areas of the plant using the guidelines of NFPA 10 (1975) as referenced in table 9B.3-1.

Table 9.5-2
SINGLE FAILURE ANALYSIS IN FIRE PROTECTION SYSTEM
(Sheet 1 of 3)

Component	Normal Function	Failure Mode	Effects on Fire Protection System	Method of Detection
Fire water/ well water reserve tank	Contains half the primary source of fire protection water.	Leak or rupture	None. A second fire water/well water reserve tank is available with a volume of 300,000 gal.	Level alarms
Fire water jockey pump	Maintains system pressure when there is little or no flow requirement.	Fails to start due to loss of power or motor failure.	None. The electric motor-driven fire pump is available to maintain system Pressure.	Alarm in control room that electric motor-driven fire pump is running.
Electric motor-driven fire pump	Supplies up to 1500 gal/min to system.	Fails to start due to loss of power or motor failure.	None. Two diesel-driven fire pumps are available to provide full system demand of 3000 gal/min.	Alarm in control room that pump failed to start
Diesel-Driven fire pump	Supplies up to 1500 gal/min to system.	Fails to start due to engine malfunction or loss of battery.	None. One other diesel-driven pump and an electric motor-driven pump are available to provide full system demand of 3000 gal/min.	Alarm in control room that pump failed to start or trouble alarm

Table 9.5-2
SINGLE FAILURE ANALYSIS IN FIRE PROTECTION SYSTEM
(Sheet 2 of 3)

Component	Normal Function	Failure Mode	Effects on Fire Protection System	Method of Detection
Underground supply line to yard loops	Connects fire pump discharge header with yard loops.	Leak or rupture	None. Redundant supply line available to handle full system flow demand.	Flow to system with fire pump operating and absence of any fire alarm or fire hose usage
Underground yard loop in area of turbine, auxiliary, control, containment, and diesel generator buildings	Supplies fire protection water to each building noted.	Leak or rupture	None. Any single failure in this portion of the loop can be isolated by PIV valves such that redundant supply lines to these buildings are fed from the operating portions of the yard loop.	Flow to system with fire pump operating and absence of any fire alarm or fire hose usage
Underground yard loop in area of radwaste and fuel buildings	Supplies fire protection water to each building noted.	Leak or rupture	Loss of fire water to fixed sprinkler systems and inside hose stations for any one of the two buildings noted.	Flow to system with fire pump operating and absence of any fire alarm or fire hose usage

TABLE 9.5-2
SINGLE FAILURE ANALYSIS IN FIRE PROTECTION SYSTEM
(Sheet 3 of 3)

Component	Normal Function	Failure Mode	Effects on Fire Protection System	Method of Detection
Preaction sprinkler system	Spray water on areas containing ESF equipment if fire develops.	Pipe crack	None. Piping within the hazard area is normally dry.	Alarm in control room indicating loss of piping air pressure.
		Deluge valve failure	None. Piping within the hazard area would be pressurized, but closed-head sprinklers would prevent inadvertent water spray on ESF equipment.	Alarm in control room that deluge valve had opened.

O. Safety Evaluation Fifteen

Activation of automatic fire protection systems will generate an alarm in the control room. Fire and smoke monitoring and associated alarms are provided as described in appendix 9B.

P. Safety Evaluation Sixteen

Protective clothing and respirator equipment are available for fire department use in areas in which fire can produce an adverse environment.

Q. Safety Evaluation Seventeen

Fire dampers are provided in ventilation ducts that penetrate rated fire barriers. These dampers provide fire protection equal to or greater than the rating of the fire barrier penetrated.

R. Safety Evaluation Eighteen

Emergency lighting is provided as described in subsection 9.5.3. Emergency lighting provides for normal movement under emergency conditions. Applicable codes and regulations of the State of Arizona, the National Fire Codes of the National Fire Protection Association, and applicable sections of Title 29, Chapter XVII, Part 1910, Occupational Safety and Health Standards of the Code of Federal Regulations as set forth in the Federal Register Volume 37, Number 202, dated October 18, 1972, have been used as guidance in developing the plant fire protection system design.

9.5.1.4 Inspection and Testing Requirements

A. Preoperational Testing

Testing of the system is performed as described in section 14.2.

B. Post-Operational Testing

The PVNGS fire protection systems and equipment are tested and inspected at regular intervals. The NFPA codes, standards, and recommended practices are used as guidance in determining content and frequency of the periodic tests and inspections, as specifically committed to in other sections of this document.

The following fire protection features are subjected to periodic tests and/or inspections:

- Fire suppression water system
- Spray and sprinkler systems
- Carbon dioxide systems
- Fire hose stations
- Yard fire hydrants
- Halon systems
- Fire barriers (walls, fire doors, penetration seals, fire dampers)
- Fire detection instrumentation
- Fire pumps
- Emergency lighting

- RCP lube oil collection system
- Lightning protection
- Selected manual fire protection equipment
- Selected communications equipment

The fire protection test program is the responsibility of the Fire Protection Department Leader.

Equipment out of service including fire suppression, detection, and barriers is controlled through the administrative program and appropriate remedial actions taken. As conditions warrant, remedial actions include compensatory measures to ensure an equivalent level of fire protection in addition to timely efforts to make repairs and restore equipment to service.

No changes are made to the test and inspection procedures without ensuring compliance with the provisions of the facility operating license condition.

9.5.1.5 PVNGS Fire Protection Program

9.5.1.5.1 Overall Requirements of the PVNGS Fire Protection Program

The fire protection program at PVNGS has been established to protect the safety of personnel, to minimize property loss, to assure, in the event of a fire, the capability to safely shutdown the reactor and maintain it in a safe shutdown condition, and to minimize radioactive releases to the environment in the event of a fire. The fire protection program at PVNGS is an integrated effort involving design

features, trained personnel, equipment, and procedures to provide defense-in-depth protection of the public health and safety and to minimize the loss of property. The program consists of the following elements:

- Engineering design, procurement, and configuration management of safe shutdown capability and fire protection features
- Fire prevention including:
  - Control of transient combustible material
  - Control of ignition sources
  - Fire watch program
  - Periodic inspections
- Maintenance and testing of fire protection features
- Impairment and system status of fire protection features
- Training
- Fire response
- Quality assurance
- Licensing
- Risk management

The procedures, equipment, and personnel for implementing the fire protection program for buildings storing new fuel elements and for adjacent fire zones which could affect the fuel storage zone were operational before fuel was received at the site.

The program was fully operational prior to initial fuel loading.

9.5.1.5.2 Fire Protection Program Responsibilities

The Senior Vice President, Site Operations has overall management responsibility for the PVNGS Fire Protection Program.

The Vice President, Nuclear Engineering is responsible for the engineering design and configuration management of the Fire Protection Program Design Basis. These responsibilities have been delegated to the appropriate individuals within the Nuclear Engineering Organization.

The Vice President, Operations Support, is responsible for the overall direction, administration and supervision of the Fire Protection Program and for the procedures, equipment, and staffing necessary for implementing the day-to-day fire protection operations of the program. These responsibilities are delegated to leaders in Fire Protection.

The PVNGS Fire Department, which is comprised of the onshift emergency response personnel, is an organizational element of Fire Protection.

The Vice President, Operations Support is also responsible for ensuring programmatic implementation of the following: Fire Prevention activities, the performance of maintenance and testing, fire protection features impairment and system status, training, and fire response activities. These responsibilities have been delegated to the appropriate individuals within Fire Protection.

9.5.1.5.3 Fire Protection Administrative Controls

Administrative controls to maintain the performance of the fire protection systems and personnel at PVNGS are provided. These controls include:

A. Procedures designating plant staff positions responsible for the elements of the fire protection program.

B. Procedures to evaluate proposed plant modifications for their impact on the fire protection design basis.

C. Procedures to control transient combustible material and ignition sources in areas containing or representing a hazard to safety related areas; to provide fire watches; and to conduct periodic inspections to ensure continued compliance with these administrative controls.

D. Procedures to test fire protection features to demonstrate conformance with design and system readiness requirements; to delineate responsibilities for procedure development, performance, and evaluation of test results; and to identify frequency.

E. Methods to address the level of fire protection provided when a particular fire protection feature is impaired or during periods of maintenance.

F. Measures to provide identification of impairment and system status of fire protection features.

G. Training programs for fire protection/prevention and fire response activities as described in section 13.2.

H. Actions to be taken by plant personnel for fire emergency notification and response.

I. Strategies for fighting fires in all safety related areas and areas presenting hazards to safety related equipment.

J. Actions to mitigate the effect of a fire on the ability to safely shut down the reactor for alternative shutdown areas.

K. The fire protection QA Program to ensure the critical aspects of design, procurement, administrative controls, maintenance, and testing are applied to ensure that fire protection features are available and functional.

9.5.1.5.4 Fire Protection Program Qualifications

9.5.1.5.4.1 Fire Protection Engineer. Staff personnel include at least one fire protection engineer who provides review and technical assistance with the design, selection of equipment, inspection, tests, and overall review of the program. This individual meets the qualifications for member grade of the Society of Fire Protection Engineers.

9.5.1.5.4.2 Fire Department Personnel Qualifications. PVNGS maintains a full-time industrial fire department. Each fire department shift is comprised of a minimum of five professional firefighters at all times.

All fire department personnel are a minimum of 21 years of age and have a high school diploma or equivalent. All fire department members meet the medical and physical fitness requirements established by the PVNGS site physician and the Vice President Operations Support.

All personnel assigned to full-time firefighting activities have a minimum of 3 years of full-time firefighting, inspection, fire prevention, or nuclear plant experience. Volunteer firefighting experience is counted at a ratio of 2 to 1.

Each shift has an individual designated as the shift fire captain who is responsible for assessing the severity of a fire, for fire department response, and for directing the firefighting activities and strategies. The fire department has a minimum composition as described in section 13.1.2.6.

A licensed nuclear operator, designated as fire team advisor, who is trained and qualified in assessing the potential safety consequences of fire and fire suppressants on safe shutdown capabilities supports the fire department during fire emergencies in the power block. Fire Team Advisor qualifications are identified in the Fire Team Advisor Training Program Description.

9.5.2 COMMUNICATION SYSTEMS

The PVNGS communication system, comprised of internal (intraplant) and external (plant-to-offsite) communications, is designed to provide convenient and effective operational communications between various plant locations, and between the plant and offsite locations. The elements of the communication systems credited to address postulated fires are described in table 9B.3-1.

9.5.2.1 Design Bases

Various communication systems are provided in the plant to ensure reliable communication during plant startup, operation, shutdown, and maintenance under normal and emergency conditions. The design bases of these systems are:

A. An electronic private automatic branch exchange (EPABX) telephone system, a sound powered telephone system, a plant two-way radio system, an Emergency Evacuation Alarm System, and a public address system are provided to accomplish onsite communication between the control room and various plant locations.

B. Public and private telephone systems, the plant two-way radio system, the APS corporate two-way radio system, and telephone land lines for the Local Law Enforcement Agency (LLEA) are provided to permit plant-to-offsite communication on a continuous basis. Details of available, diverse, communication systems are provided in the PVNGS Emergency Plan. Details of the LLEA communication system are provided in the Security Plan.

C. The plant has a private ringdown telephone communication link via the fiber optics (sonet ring) system to the APS energy control center (ECC). Alternate links are provided by dial telephones via the plant EPABX.

D. An emergency evacuation alarm system is designed to warn personnel to evacuate the exclusion area in the event of a design basis accident (DBA).

E. Communication systems are provided with reliable backup power supplies for each subsystem as noted in table 9.5-3.

F. The communication systems comply with applicable local codes, standards, ordinances, and Federal Communications Commission (FCC) regulations.

G. Required communication systems will be capable of performing under conditions of maximum plant noise levels being generated during the various operating conditions including accident conditions. (Refer to table 9.5-4).

H. In high noise areas (greater than 95 dB), public address or unit evacuation systems are clearly audible or visible throughout the exclusion area. In areas where audible or visible evacuation signals cannot be assured, administrative measures will be provided.

Table 9.5-3
COMMUNICATION SYSTEMS POWER SUPPLIES

System	Power Supply
EPABX telephone system	UPS (battery[f] and charger)
PA system	Battery[a] and charger
Fiber Optics (sonet ring)	UPS (battery[a] and charger) associated with APS fiber optics equipment
Sound-powered telephone	None required[d]
Plant two-way radio system	UPS (battery[e] and charger)[d]
Two-way radio (mobile units)	Vehicle battery
Emergency evacuation alarm system (unit)	UPS (battery[b] and charger)
Emergency evacuation alarm system (area)	Solar panels with battery[c] Backup

a. 8-hour operation

b. 2-hour operation

c. 30-minute operation

d. Communication systems relied on to address postulated fires as described in table 9B.3-1.

e. Each plant two-way radio system uninterruptible power supply (UPS) can power its loads for at least four hours from the associated backup batteries before restoration of an ac power supply becomes necessary. Upon loss of the normal ac power supply, a backup ac power supply can be selected by means of a manual bus transfer switch. In the event of a station blackout, the system also has the capability of being supplied by the alternate ac station blackout generators.

f. 2-hour (targeted value) operation to support Emergency Plan.

9.5.2.2 System Description

The locations of permanent plant telephones and public address speakers within the power block are shown on station lighting and communication plan drawings. Design and configuration requirements for communications system (QF) components are based on regulatory commitments and the importance of a component's function in operating the plant in a safe manner. Design control is maintained in accordance with Installation Specification 13-JN-0999, which divides communication circuits into four types (Plant, EN-700, Extended, and Convenience) in order to maintain proper controls based on component function.

A complete list of available communication system links for intraplant and offsite emergency communications is provided in Table 3 of the PVNGS Emergency Plan.

9.5.2.2.1 Intraplant Communication Systems

9.5.2.2.1.1 EPABX Telephone System. The EPABX system is one of the principle means of communication within the plant, but is not credited for addressing postulated fires. The system provides lines of communications between site EPABX telephones including the unit control rooms and interfaces with the external public telephone system and the public address (PA) system. A backup power system is provided to supply emergency power to the EPABX telephone switches for 8 hours, which exceeds the 2 hour requirement from Table 9.5-3, to support the Emergency Plan. Notification is provided to the Unit 1 Control Room in the event that plant operations will be impacted by a failure of the backup power supply for the EPABX exchange located in the Service Building.

As a key communication system at PVNGS, the EPABX telephone system has been evaluated for communications during normal and emergency operation. Refer to the PVNGS Emergency Plan and the Security Plan for more information.

Table 9.5-4
SUMMARY OF ONSITE COMMUNICATIONS SYSTEM CAPABILITIES AND NOISE CONSIDERATIONS DURING TRANSIENTS AND/OR ACCIDENTS

Station	Maximum Anticipated Sound Levels (dBA)	Communication Systems Available and Maximum Background Noise for Effective Communication[a]				
		EPABX Telephone (dBA)	EPABX Telephone Jack (dBA)	Emergency Evacuation/ Public Address[b] (dBA)	Sound Power Phones[c,d] (dBA)	Portable 800 MHz Radio (dBA)[d]
Control room	70	92	-	-	118	95
Remote shutdown panel	75	92	-	102	118	95
Safety injection pump rooms	111	92	118	102	-	95
Shutdown heat exchanger rooms	90	92	118	102	-	95
ESF switchgear rooms	75	92	118	102	-	95
Piping penetration rooms	100	92	118	102	-	95
Radwaste building	102	92	118	102	-	95
Auxiliary feedwater pump rooms	110	92	118	102	-	95

a. Reference 1
b. Based on data supplied by vendors
c. Headset
d. Credited for mitigation of postulated fires as described in table 9B.3-1

9.5.2.2.1.2 Public Address System. The Public Address System consists of a master control cabinet, remote central amplifier, and speakers located throughout the plant in the areas that they serve. A backup power system is provided to supply emergency power for 8 hours. Emergency Evacuation Alarm System consoles are used to send announcements to the PA system. Telephones located inside and outside the power block may also send announcements to the PA system using dedicated access numbers. Operators may override the PA system from each control room EVAC System console and from control room telephones. The PA system has been evaluated for communications during normal and emergency operation. Refer to the PVNGS Emergency Plan for more information.

9.5.2.2.1.3 Emergency Evacuation Alarm System. An Emergency Evacuation Alarm System consisting of pole-mounted electronic outdoor warning sirens, powered by solar powered batteries, located outside each power block is provided to alert all personnel within the security boundaries of PVNGS. All sirens (both unit and area) are initiated from the siren command module in each unit’s main control room. A microphone is provided to permit announcements over the Emergency Evacuation Alarm System. Each unit emergency evacuation alarm system is provided with batteries with a 2-hour capacity. Evacuation/accountability is assured in high noise work areas (greater than 95 dB) by the use of audible alarms, flashing lights, and/or administrative measures. This communication system is not relied on for addressing postulated fires as described in Table 9B.3-1; however the Evacuation Alarm System has been evaluated for communications during normal and

emergency operation. Refer to the PVNGS Emergency Plan for more information.

9.5.2.2.1.4 Sound Powered Telephone System. A private, direct-line, sound powered telephone system is provided between the fuel building and the main control panel in the control room for each unit. A second independent system is provided between the main control room and maintenance control points throughout the unit. The systems can be connected together by a merge switch located in the control building, 140-foot elevation. This system is credited for addressing postulated fires as described in UFSAR table 9B.3-1.

As a primary communication system used by PVNGS fire department, the sound powered telephone system has been fully evaluated to ensure communication for normal and emergency operation. Refer to the PVNGS Emergency Plan, Security Plan, and UFSAR Table 9B.3-1 for more information.

9.5.2.2.1.5 Deleted

9.5.2.2.1.6 Plant Two-Way Radio System. The plant two-way radio system provides voice radio communications throughout the PVNGS site and the surrounding emergency planning zone (EPZ). It also provides a two-way radio communications link to the LLEA and, in conjunction with the APS corporate two-way radio system, a backup to the Notification and Alert Network (NAN) state and county emergency response organizations in the Phoenix metropolitan area. The PVNGS operations, security, and fire departments as well as numerous other site support groups utilize the radio system for their normal emergency radio

communications. The plant two-way system operates in a licensed frequency band.

Radio system user groups access the system with portable, mobile, and fixed radio transceivers which have been programmed and configured to be part of the system. The system uses a process known as trunking to time-share the available repeater frequencies. The system is designed to mitigate equipment failures through automatic reassignment of control functions in and the capability for direct portable-to-portable communication.

To enhance its reliability, the plant two-way radio system has redundant ac power feeds and battery-backed uninterruptible power supplies (UPSs). As described in UFSAR Table 9.5-3, the battery bank of each radio system UPS has been sized to power the associated radio system loads for a minimum of four hours before restoration of an ac power supply becomes necessary. In the event of a station blackout, the system also has the capability of being supplied by the alternate ac station blackout generators to support communications for safe shutdown activities. Refer to UFSAR section 8.3.1.1.10.

The plant two-way radio system, in conjunction with the sound powered telephone system, is relied upon to address postulated fires as described in UFSAR Table 9B.3-1. All of the portable radios that are part of the system have rechargeable batteries. A number of portable radios have been stored in recharger units in selected locations throughout the plant to provide ready access to the system for communications during fires and other emergencies.

As a primary communication system used by PVNGS operations, security, and fire departments, the plant two-way radio system and its failure modes have been fully evaluated to ensure communication during for normal for normal and emergency operation. Refer to the PVNGS Emergency Plan, Security Plan, and UFSAR Table 9B.3-1 for more information.

9.5.2.2.2 Plant-to-Offsite Communication Systems

9.5.2.2.2.1 Public Offsite Communications System. The EPABX interconnects with the Public Switch Network Provider, to provide communications with the local area PTNS from EPABX extensions in the plant, and ancillary buildings, including EOF and TSC. This provides direct dialing to locations outside the plant. Additional ringdown telephones in emergency centers are provided for emergency communications (paragraph 9.5.2.2.2.4).

The security centers have land lines directly connected to the public telephone system for the LLEA as a backup to the EPABX connected trunks. Refer to PVNGS Security Plan for details of this communication interface.

9.5.2.2.2.2 Private Offsite Communications System. The private offsite communications system provides communications via APS owned radio systems and microwave system and SRP-owned microwave systems. An 800 MHz control station has been integrated into the PVNGS plant two-way radio system to provide a direct radio link from the site security centers to the LLEA (Maricopa County Sheriff's Office) radio system. The APS corporate two-way radio system, in conjunction with the PVNGS plant two-way radio system, provides radio links to the five

Notification and Alert Network (NAN) state and county emergency response organizations in the Phoenix metropolitan area. Fiber optics ringdown telephone links provide communications with the APS ECC.

9.5.2.2.2.3 Security Force Communications. The plant two-way radio system is the primary means for security force communications. Refer to paragraphs 9.5.2.2.1.6 and 9.5.2.2.2.2 for a description of the system. The radio system uses multiple repeaters, redundant site central controllers, redundant ac power supplies, and battery-backed uninterruptible power supplies (UPSs) to meet the requirements for security force radio communications as specified in 10CFR73.55. Additionally, in the unlikely event of a total system failure, the security force portable radios are capable of direct portable-to-portable communications.

Refer to the PVNGS Security Plan for detail of PVNGS Security Force Communication.

9.5.2.2.2.4 Emergency Communication System. Diverse systems are provided to ensure means of intraplant-to-offsite communications under emergency operating conditions. Interfaces with these systems are located in the unit control rooms, TSC, EOF, and various emergency facilities. Refer to the PVNGS Emergency Plan (Section 7) to determine availability of PVNGS emergency response facility communications.

9.5.2.2.3 System Operation

Diverse systems are provided to ensure means of intraplant-to-offsite communications under normal and emergency operating conditions. The sound-powered telephone system and plant two-way radio system address postulated fires as described in table 9B.3-1. Intraplant communication systems have adequate flexibility to keep plant personnel informed of plant operational status. Refer to the PVNGS Emergency Plan (Section 7) to determine availability of PVNGS to offsite emergency response facility communications.

9.5.2.3 Inspection and Testing Requirements

The communications systems are conventional and have a history of successful operation at existing plants. Most of these systems are in routine use and this will ensure their availability. Those systems not frequently in use will be tested at periodic intervals to ensure functionality when required.

Plant operating procedures will provide for periodic preventive maintenance and surveillance testing to assure the functionality of the onsite communication system. Communication systems relied on to address postulated fires are included in the fire protection test program. Maintenance and testing will consist of, as a minimum, a yearly inspection of each telephone in the control room area, shutdown panel, and working stations. The telephone system in the control room area, shutdown panel, and working stations are routinely used by station personnel during normal station operation. Any telephone which does not

function properly will be reported to the testboard for immediate repair.

Those systems not frequently in use will be tested at periodic intervals to assure functionality when required.

9.5.3 LIGHTING SYSTEMS

This subsection discusses the unit and station lighting systems.

9.5.3.1 Design Bases

The lighting, including essential and emergency subsystems, associated with safety-related equipment is protected from winds, floods, missiles, and pipe ruptures to the extent that protection provided for specific ESF equipment also provides protection for the lighting system. Protection from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against the dynamic effects associated with the postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

9.5.3.1.1 Safety Design Bases

Safety design bases applicable to the lighting system are as follows:

A. Safety Design Basis One

Structures supporting the components of essential lighting and emergency lighting systems, which serve

the main control room and the remote shutdown room, shall be designed to retain structural integrity during and after a safe shutdown earthquake.

B. Safety Design Basis Two

The lighting system, comprised of normal, emergency, and essential subsystems, shall be designed so that a single failure of any subsystem or electrical component of a subsystem, assuming loss of offsite power, cannot terminate the system's ability to illuminate areas occupied during a reactor shutdown or emergency.

9.5.3.1.2 Power Generation Design Bases

Power generation design bases applicable to the lighting system are as follows:

A. Power Generation Design Basis One

Area lighting intensities provide the illumination required for comfort and worker efficiency in the performance of the visual activities required in that area. Outdoor lighting complies with the security provisions of ANSI N18.17-1973.

B. Power Generation Design Basis Two

Mercury-vapor fixtures and mercury switches are not used inside the containment building and fuel building. Sodium vapor lights are utilized in the containment and fuel building for illumination. These lights contain a trace amount of mercury. This has been evaluated as being acceptable.

C. Power Generation Design Basis Three

Lighting fixtures containing aluminum or aluminum alloys are not used inside the containment building.

9.5.3.1.3 Codes and Standards

Design and installation of the plant lighting systems use the guidance provided by the National Electrical Code (NFPA No. 70-1975/ANSI C1-75) and the Handbook of the Illuminating Engineering Society with the exception that Palo Verde uses a plant drawing system rather than detailed field markings to identify the loads being serviced by each branch circuit disconnect (NEC 110-22).

9.5.3.2 System Description

9.5.3.2.1 General Description

Unit lighting is divided into three subsystems: normal, essential, and emergency. The normal system is supplied from non-Class 1E ac buses. The essential system is connected to Class 1E ac buses. The emergency lighting system, consisting of batteries, battery chargers, and lamps, is fed from the same supply as the essential lighting system, where essential lighting is provided, or the normal lighting system, where no essential lighting is provided, and function on loss of the ac power source. Safe shutdown emergency lighting fixtures in an area/room are fed from the same circuits as the essential lighting fixtures for the same area/room. The safe shutdown lighting drawings (01, 02, 03-E-ZPL-001, 002, 003, 004) indicate all essential/emergency lighting which includes emergency battery lighting units which is required for the

local manual operation of safe shutdown equipment and access/egress routes thereto in the event of a fire.

9.5.3.2.2 Component Description

The three lighting categories are described briefly in the following paragraphs.

9.5.3.2.2.1 Normal Lighting. The normal lighting system is the system that provides the primary source of illumination for the entire station and is supplemented by essential lighting during normal plant operating modes. In each unit, the lighting load is distributed equally between two non-Class 1E lighting load centers, each consisting of 1000 kVA, 13,800-480/277-volt, dry-type transformers with 208/120 and 480/277-volt distribution subsystems. Areas remote from the lighting load center are fed from the local power sources. Lighting transformers for the system are solidly grounded at neutrals.

9.5.3.2.2.2 Essential Lighting. The essential lighting system supplements the normal lighting and provides sufficient illumination to allow personnel safe access/egress throughout each unit in the event of a failure of the normal lighting system. In addition, essential lighting is also designed to provide sufficient illumination necessary for the local manual operation of safe shutdown equipment in the event of a fire. The essential lighting system supplies the lighting in the main control room and the remote shutdown room. Redundancy is provided in the essential lighting system in the control room and remote shutdown panel room, to shut down and maintain the unit in a hot shutdown condition. The essential lighting

system serving the control room and remote shutdown panel area is fed from Class 1E motor control centers (MCCs), via Class 1E regulating transformers, and is not tripped on safety injection actuation signal (SIAS). The remainder of the essential lighting feeders for the plant area are tripped on SIAS and can be manually reconnected after diesel generator sequencing. The essential lighting system is normally energized and is supplied from two redundant Class 1E load centers.

9.5.3.2.2.3 Emergency Lighting. Emergency lighting has two different intended functions depending on the area where it is located.

In areas where operator local manual actions are required for safe shutdown in the event of fire, emergency lighting is provided in accordance with Appendix R to 10CFR Part 50, Section III.J. In these areas emergency lighting is designed to provide sufficient illumination for the operator to perform the required safe shutdown actions in the event of a loss of essential power. Appendix R emergency lighting is provided by either individual dc units, centralized dc/ac UPS systems, or in some limited cases portable lanterns. Both of the fixed systems (i.e., dc units and UPS) have a minimum 8-hour battery power supply.

Sealed beam battery-powered portable lanterns will also be readily available to the operators for the following: when access/egress or manual actions are required in the yard area (i.e., condensate storage tank pumphouse, reactor make-up watertank, alternate entrances to the diesel generator building) (this deviation to 10CFR50, Appendix R,

Section III.J, is discussed in Section 9B.2.0.E); and when actions are necessary beyond 8 hours or to serve as a compensatory measure for nonfunctional emergency lights. Some Appendix R designated emergency lighting also serves as station blackout lighting.

In other areas, where no safe shutdown action is required, emergency lighting is provided to support the safe access/egress of personnel as necessary. This emergency lighting uses batteries capable of providing a minimum of 1.5 hours of illumination in the event of a loss of essential power or normal power if no essential lighting is provided in the area. The individual dc emergency lighting units consist of a battery, lamps, and charger all included in a single fixture. The units provide illumination automatically on a loss of the ac power source. Areas without routine human habitation may not be equipped with emergency lighting (Reference NFPA 101, 1976).

The centralized dc/ac UPS systems consists of a battery source, charger, inverter, transfer switch, and a series of ac lighting fixtures (either fluorescent or incandescent). This system automatically transfers from the ac source to the battery source on a loss of ac power.

9.5.3.2.2.4 Portable Lighting

During maintenance activities or when equipment is not in-service, portable fluorescent drop lights can be utilized even though fluorescent lights contain trace amounts of mercury. The portable lights are to be removed after maintenance or prior to the equipment being placed in service.

If a fluorescent light is needed to illuminate an in-service plant component for remote monitoring, an evaluation will be performed to demonstrate that breakage of the light will not adversely impact plant equipment.

9.5.3.3 Safety Evaluation

The safety evaluations are numbered to correspond to the safety design bases and are as follows:

A. Safety Evaluation One

The batteries, UPS unit, and lighting fixtures of the control room horseshoe suspended ceiling in the control building are capable of withstanding the safe shutdown earthquake (SSE), and are seismically qualified by analysis and/or testing in accordance with IEEE Standard 344-1975. In accordance with Position C.2 of Regulatory Guide 1.29, MPS units and associated lighting fixtures, and self-contained, battery-powered emergency lighting units above safety-related equipment are installed in such a manner that during and after a SSE, their failure will not incapacitate the operator nor cause crippling damage to needed safety-related equipment. The MPS units and associated lighting fixtures, and the self-contained, battery-powered emergency lighting units serving plant areas outside of the control room horseshoe area are not required to function during or after a seismic event.

B. Safety Evaluation Two

Reliable lighting is provided to permit the operators to shut down the unit safely and to maintain it in a safe shutdown condition at any time. The lighting system is designed to provide lighting in those areas used during a reactor shutdown or emergency.

Essential lighting in the control room, remote shutdown panel room, and associated local control stations are fed from Class 1E buses. The essential lighting in the control room and at the remote shutdown panels is arranged so that alternate fixtures are fed by redundant buses to maximize the coverage of remaining fixtures in the event of a loss of one Class 1E bus. Physical separation by fire zone is provided to maintain independence of the redundant essential lighting circuits feeding the control room horseshoe area and the remote shutdown panel.

If the offsite (preferred) power supply to a Class 1E bus fails, the associated emergency diesel generator is started automatically. Prior to restoration of essential power, the emergency lighting system provides illumination. Lighting in the control room and remote shutdown area is automatically restored during emergency diesel generator sequencing. For a detailed description of the emergency lighting system refer to section 9.5.3.2.2.3.

A single failure analysis is provided in table 9.5-6.

9.5.3.4 Inspection and Testing Requirements

Normal and essential ac lighting circuits are normally energized and require no periodic testing. The emergency lighting system is inspected and tested periodically to ensure functionality of the system.

Table 9.5-6

LIGHTING SYSTEM SINGLE FAILURE ANALYSIS

Name	Failure/Malfunction	Effect On		
		Normal Lighting	Essential Lighting	Emergency Lighting
Onsite power	Auxiliary transformer short circuit	Complete loss--automatic transfer to startup source	None	None
13.8 kV balance of plant bus	Short circuit	Half lost	None	None
Offsite power	Total loss	None	Total loss—restored after diesels are started and loaded	Automatic energization of emergency lighting, deenergized after diesels started and loaded
4.16 kV engineered safety features bus	Short circuit	None	Half lost	Automatic energization of half of dc lighting
480V engineered safety features bus	Short circuit	None	Half lost	Automatic energization of half of dc lighting
480V essential lighting transformer	Short circuit	None	Half lost	Automatic energization of half of dc lighting
480V essential lighting bus	Short circuit	None	Half lost	Automatic energization of half of dc lighting
125V-dc Class 1E bus	Short circuit	None	None	None-self-contained battery units energized

9.5.4 DIESEL GENERATOR FUEL OIL STORAGE AND TRANSFER SYSTEM

Two fully redundant diesel generator fuel oil storage (DGFOS) and transfer facilities are provided for each of the three plant power generating units. This system provides onsite storage and delivery of fuel oil for operation of the two diesel generators provided as a part of the ESFS for each unit and which are required as a consequence of a loss of offsite power.

9.5.4.1 Design Bases

9.5.4.1.1 Safety Design Bases

A. Safety Design Basis One

   The DGFOS shall provide onsite storage of fuel oil for at least 7 days of continuous, concurrent operation of both diesel generators when operating at the maximum load of the onsite power system, as specified in section 8.3.

B. Safety Design Basis Two

   The DGFOS shall remain functional during and after the SSE.

C. Safety Design Basis Three

   A single failure of any active component shall not impair the DGFOS ability to mitigate the consequences of an accident or affect its ability to support a safe reactor shutdown.

D. Safety Design Basis Four

The DGFOS shall be capable of being operated and monitored from both the control room and from the local diesel generator control panel.

E. Safety Design Basis Five

The DGFOS shall supply the required fuel for the routine scheduled operational testing and inspection of the diesel generators without compromising system ability to meet its minimum operational requirements.

F. Safety Design Basis Six

The DGFOS shall have provisions for truck refill of each diesel generator fuel oil tank and each diesel generator day tank.

G. Safety Design Basis Seven

The DGFOS shall provide for flame arrestors on all storage tank vents.

H. Safety Design Basis Eight

Diesel fuel oil shall be maintained at a temperature above the cloud point: i.e., above the low temperature at which the separation of wax becomes visible.

I. Safety Design Basis Nine

The DGFOS shall be protected against missiles generated from other equipment failures or due to extreme natural phenomena effects, as discussed in sections 3.2, 3.3, 3.4, 3.5, and 3.6.

J. Safety Design Basis Ten

Fuel day tanks and the diesel generator building shall be fire-protected.

K. Safety Design Basis Eleven

The DGFOS shall be capable of being fully tested during normal unit operations.

9.5.4.1.2 Power Generation Design Bases

A. Power Generation Design Basis One

The DGFOS will not interfere with normal unit power generation activities during system tests and maintenance activities.

9.5.4.1.3 Codes and Standards

The DGFOS conforms to applicable portions of the following codes and standards:

- IEEE 308-1971, Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations
- IEEE 387-1972, Trial Use Criteria for Diesel Generator Units Applied as Standby Power Supplies for Nuclear Power Generating Stations
- IEEE 323-1974, General Guide for Qualifying Class 1 Electrical Equipment for Nuclear Power Generating Stations
- IEEE 344-1975, IEEE Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

- ASME Boiler and Pressure Vessel, Section III, Class 3
- National Fire Protection Association
- American Nuclear Insurers
- Underwriter's Laboratories
- National Association of Corrosion Engineers
- The PVNGS design complies with ANSI N195-1976 with exceptions as listed in section 1.8, under the response for Regulatory Guide 1.137.

9.5.4.2 System Description

The DGFOS is shown schematically in engineering drawings 01, 02, 03-M-DFP-001 and figure 9.5-5.

Two fully redundant DGFOSs are provided for each unit. Each DGFOS consists of one diesel fuel oil storage tank, one diesel fuel oil transfer pump, and one diesel fuel oil day tank per diesel generator along with the associated piping, valves, and instrumentation. Indications, alarms, and sensors are listed in table 9.5-7. Components are described in subsequent sections. Table 9.5-8 lists the major components in the DGFOS and their design specifications. The DGFOS is designed in accordance with the codes and standards specified in table 3.2-1. The DGFOS is designed to comply with Position C.2 of Regulatory Guide 1.137 as discussed in section 1.8.

In addition, cross-connection is provided between the fuel storage tanks which allows the diesel engines to be supplied with fuel from either tank. This configuration is not credited in the safety analysis for several reasons (1) Cross-connecting

the diesel fuel oil storage tanks during normal operations (in Modes 1, 2, 3, or 4) violates the independence and redundancy design criteria. (2) There is only one fuel transfer pump per storage tank which is powered by its associated divisional bus, i.e., there is not a redundant fuel transfer pump. (3) Aligning the operable transfer pump to the opposite diesel will cause its normally associated diesel to be considered inoperable. (4) Due to accessibility, aligning the manual cross connect valves will take a long time (on the order of hours).

Refer to PVNGS Technical Specifications for fuel oil sampling requirements. Should the day tank oil be found unacceptable, it is drained into drums for nonsafety-related uses. Should the storage tank oil be found unacceptable, storage tank and day tank contents may be processed to return the fuel oil to within specification requirements. If such processing is not feasible or successful, then all oil, including the day tank oil, will be removed and replaced with fresh oil.

Newly delivered oil will be sampled per Regulatory Guide 1.137 before the oil is placed in the storage tank.

Table 9.5-7

DIESEL GENERATOR FUEL OIL AND TRANSFER -- INDICATIONS, ALARMS, AND SENSORS
(Sheet 1 of 2)

Parameter	Local Indication	Local Diesel Generator Panel	Control Room	Comments
Fuel oil storage tank	• Gauge (level)	• Alarm (low level)	• Common trouble alarm	
Transfer pump dis-charge pressure	• Gauge (pressure)	• Alarm (low pressure)	• Alarm (low pressure)	Transfer pump starts auto-matically on low level in fuel oil day tank. Manual operation of transfer pump available locally at DG control panel
Transfer pump strainer D/P		• Alarm (high D/P)	• Common trouble alarm	
Fuel oil day tank level	• Gauge (level)	• Alarm (high or low level)	• Alarm (low level) • Common trouble alarm (high level)	Level con-troller con-trols transfer pump in replenishing day tank

Table 9.5-7

DIESEL GENERATOR FUEL OIL AND TRANSFER -- INDICATIONS, ALARMS, AND SENSORS

(Sheet 2 of 2)

Parameter	Local Indication	Local Diesel Generator Panel	Control Room	Comments
Fuel oil filter D/P	• Gauge (D/P)	• Alarm (high D/P)		Alarm indicates dirty fuel filters. Twin filters are provided for replacement during operation (a)
Fuel oil supply header pressure	• Gauge (pressure)	• Alarm (low pressure)		

a. This system has no automatic interlocks for filter change out - operator action required.

Table 9.5-8
DIESEL GENERATOR FUEL OIL STORAGE AND
TRANSFER SYSTEM DESIGN SPECIFICATIONS

Equipment or Parameter[a]	Quantity Per Station Generating Unit	Type or Capacity
Fuel oil storage tank	2 (one per diesel)	83,000[b] gal
Fuel oil storage transfer pump	2 (one per diesel)	15 gal/min
Fuel oil day tank	2 (one per diesel)	1,100[b] gal

a. All equipment Safety Class 3 and Seismic Category I.

b. Nominal Capacity

Diesel fuel oil will normally be supplied from Phoenix, Arizona, 34 miles to the east. Many major and independent oil companies have sufficient supply facilities in West Phoenix at the Southern Pacific Pipe Lines Terminal (tank farm). Companies such as Union Oil Company, Shell Oil Company, Chevron, and ARCO, among others, operate out of this Phoenix terminal. The Southern Pacific pipeline pumps fuel to the Phoenix terminal from Los Angeles, California, or El Paso, Texas. An additional storage terminal is located in Tucson, Arizona, approximately 100 miles from Phoenix. An interstate highway runs east and west between Phoenix and Blythe, California, approximately 110 miles west of the site, where fuel is also available. The highway is approximately 6 miles north of the site over an all-weather road.

As discussed in section 2.4 and paragraph 2.4.1.1, the plant site is above maximum probable flood level. Therefore, as a minimum, access to the site by helicopter is not affected by flooding in the highly unlikely event that an accident occurs concurrent with flooding throughout the Arizona desert such that all rail and roads are unusable for 7 days or more.

9.5.4.2.1 Diesel Generator Fuel Oil Storage Tanks

Each diesel generator fuel oil storage tank is buried underground and has a nominal capacity of 83,000 gallons, which provides for the following: (1) 7 days of continuous diesel operation at full load, (2) an unrecoverable fuel volume for sediment, which is already accounted for in the unavailable volume below the suction nozzle, and (3) sufficient fuel for required periodic testing of the diesel generators. The fuel oil storage tanks are protected from corrosion in accordance with Recommended Practice, Control of External Corrosion on Underground or Submerged Metallic Piping Systems, RP-01-69, as published by the National Association of Corrosion Engineers (NACE).

The diesel fuel oil storage tank internal corrosion is minimized as follows:

A. Testing of fuel oil when delivered, per ASTM requirements, will ensure oil of the proper quality is admitted to the storage tanks.

B. Periodic testing of oil samples for water and sediment will detect potential or actual corrosion problems.

C. The fuel oil transfer pumps take suction above the tank bottom and will not pull up any water or sediment.

D. Duplex strainers with differential pressure alarms filter the oil before introduction into the fuel oil day tank and can be cleaned.

E. The supply pipe from the day tank to the engine is above the tank bottom and will not withdraw sediment.

F. A duplex strainer with differential pressure alarms is provided on the inlet of the engine-driven fuel oil booster pump. A duplex filter with differential pressure alarm is provided on the discharge of the engine-driven fuel oil booster pump. Both can be cleaned or have elements replaced as required.

G. Low rainfall at the site (refer to section 2.3) will preclude water accumulation and subsequent corrosion.

H. APS diesel fuel storage tanks, throughout the many years of operation of other fossil plants, have experienced no history of corrosion problems.

I. The tank interior was sandblasted to remove scale and mill slag to minimize the potential for accumulation of corrosion and sediment during the tank life.

The external surface of the diesel fuel oil storage tank was cleaned in accordance with Steel Structures Painting Council (SSPC)-SP10-63. A 30 mil coat (dry film thickness) of Koppers Bituplastic 33 was applied in accordance with the manufacturer's directions. No internal coating is provided.

The PVNGS Technical Specifications require that any accumulated water in the storage tank is removed on a quarterly basis, and that the fuel is analyzed in accordance with the Diesel Fuel Oil Testing Program. Periodic water removal will preclude algae growth and periodic fuel oil quality testing will preclude the use of degraded fuel.

In the unlikely event that a storage tank must be cleaned, the requirements of ANSI N195 will be met. The tank will be emptied, cleaned, and refilled with fuel meeting the specifications described in Regulatory Guide 1.137, Position C.2.

The fuel oil storage tank fill lines are located outdoors, and terminate approximately 2-3/4 feet above ground level and 2 feet above a concrete surface. The fill line has a threaded cap. The vent has a turned down opening. Both openings are above the flood level discussed in section 2.4.

The tanks are installed in accordance with Occupational Safety and Health Administration OSHA 29CFR1910, Subpart H, Hazardous Materials, Section 1910.106. Appropriate instrument connections are installed. Tank vents are equipped with flame arrestors. Other fittings permit fuel oil replenishment by truck and water removal from the tank as required.

A vault built above each diesel fuel oil storage tank provides tornado and missile protection for the submersible transfer pump in the tank, connections on the tank, and transfer pump associated valving. The foundation of the vault is independent of the tank to avoid any load transfer to the tank shell. The vault is of water-proof design. The vault is considered to be

“water-proof” in that the walls extend above the site PMP flood water-surface elevation. In addition, the entire vault is located above the maximum predicted groundwater elevation. As such, the vault provides protection for the diesel generator fuel oil transfer system instrumentation and electrical equipment. The likelihood of significant water seepage through the vault structure is remote.

The vent lines are routed inside the vault and project through the top slab. The vent line has a flange connection inside the vault. This vent line can easily be replaced at the flange connection should the projection of this line become damaged by a tornado-generated missile. The diesel generator fuel oil storage tanks are located underground about 35 feet from the diesel generator building. In the unlikely event that either or both the truck fill line and the tank vent are damaged and cannot be removed at the tank flange connections, there are two unused flanged connections. These connections are located inside the vault on the tank as shown in engineering drawings 01, 02, 03-M-DFP-001. These connections could be used as temporary vent or fill connections.

A cathodic protection system is provided for the fuel oil storage tanks and piping. The plant cathodic protection system consists of a number of rectifiers and deep bed anodes producing a direct current flow through the ground to the metallic objects buried in the soil which require corrosion protection.

The cathodic protection rectifiers are distributed throughout the site with power supplied from non-Class 1E, 480V MCCs. The

rectifier positive output is impressed upon the deep well anodes. The ground grid interconnects the rectifier negative and the metal to be protected. The deep anode bed holes are drilled to various depths (approximately 20-200 feet below grade) and are 12 inches in diameter. The anodes are spaced approximately 10-35 feet apart in the hole.

Test stations with reference electrodes and test coupons are installed along buried pipes to monitor protection levels. Shunts are installed in each anode circuit to make current measurements. Trimming resistors are installed, where required in each anode circuit, to balance anode output current circuits.

9.5.4.2.2 Diesel Generator Fuel Oil Transfer Pumps

One fuel oil transfer pump is provided for each diesel generator. Each pump has a capacity of more than the consumption rate of a diesel generator at full power. Each pump is capable of nominally pumping 15 gallons per minute. Discharge valves are locked open. Strainers are provided in the fuel transfer line to the day tank of each train. The fuel oil transfer pumps are powered from the 480V, Class 1E power system as shown in table 8.3-1. In case of loss of offsite power, each pump is powered from its corresponding diesel generator.

9.5.4.2.3 Diesel Generator Fuel Oil Day Tanks

Each diesel generator fuel oil day tank has a usable nominal capacity of 1100 gallons. Tank fittings provide for tank fill, tank overflow, water removal, and recirculation. Each tank is

provided with appropriate instrumentation. Tank vents are equipped with flame arrestors. The tank level is controlled by high and low level switches. At the high position there is approximately 2.7 hours of fuel available at 100% engine rated power. At the low position, approximately 1.9 hours of fuel is available in the tank. This exceeds the one hour minimum fuel plus 10% required by ANSI N195-1976. The tank is located in a vault approximately 30 feet above the diesel engine, thereby ensuring a positive suction head for the diesel generator fuel oil feed pumps.

9.5.4.2.4 Piping Surfaces

Exterior surfaces of the diesel generator fuel oil underground piping are protected in accordance with American Water Works Association (AWWA) Standards.

9.5.4.3 System Operation

The diesel fuel oil transfer pump takes suction from the diesel generator fuel oil storage tank and discharges into the diesel generator fuel oil day tank.

Diesel fuel oil is supplied to the diesel generator fuel oil feed pumps from the day tanks by gravity feed.

The diesel generator fuel oil transfer pump is automatically started and stopped by a signal from the level controls in the diesel generator day tank. This pump is started at the low level regardless of whether the diesel engine is running or not. If the pump fails to start, a low-pressure condition in the pump discharge is annunciated in the main control room.

The operator can then manually start the transfer pump from a switch in the main control room. If the transfer pump still fails to operate, a low level day tank alarm is actuated to alert the operator to take corrective action. Fuel can then be supplied from the redundant train by opening valves on an interconnecting line and the diesel generator may be allowed to continue running. As stated at Section 9.5.4.2 this capability is not credited in the safety analysis.

The automatic pump in the system also may be actuated manually by the operator from the control room or from the diesel generator room local control panel.

9.5.4.4 Safety Evaluation

Safety evaluations are numbered to correspond to the safety design bases and include the following:

A. Safety Evaluation One

The capacity of each of the underground diesel generator fuel oil storage tanks is sufficient for 7-day operation plus an allocation for periodic testing of each of the diesel generators using diesel fuel oil which meets the specifications of ASTM D975, Table 1, having an API gravity of within 0.3 degree at 60F or a specific gravity of within 0.0016 at 60/60F, when compared to the supplier's certificate or an absolute specific gravity at 60/60F of greater than or equal to 0.83 but less than or equal to 0.89 or an API gravity at 60F of greater than or equal to 27 degrees but less than or equal to 39 degrees, at the largest actual

operating load indicated in section 8.3. Cross-connect lines with double-locked closed valves are provided so that either transfer pump can discharge to the fuel oil day tank serving the redundant diesel generator. The cross-connect piping and valves are designed as Seismic Category I. As stated at Section 9.5.4.2 this capability is not credited in the safety analysis. Additional fuel can be delivered to the plant site by truck, rails, or helicopter within 7 days of concurrent operation of both diesel generators as required by section 9.5.4.1.1.A.

B. Safety Evaluation Two

The DGFOS, including cross-connect piping and valves, is designed to Seismic Category I requirements using the methods of section 3.9.

C. Safety Evaluation Three

The diesel generator fuel oil storage tanks, fuel oil day tanks, fuel oil transfer pumps, and the piping and valves between storage tanks, day tanks, and diesel generator engines are designed and constructed in compliance with ASME Boiler and Pressure Vessel Code, Section III, Class 3. Fuel oil tanks are sized, enclosed, and built in conformance with NFPA, ANI, NACE, API, and UL requirements.

A single failure analysis is provided in table 9.5-9.

Complete physical redundancy of mechanically active components is provided in the DGFOS. One fuel oil transfer pump is provided for each diesel generator.

The pump is powered from the bus to which the diesel generator it serves is connected. Failure of one pump or one diesel generator does not affect the operability of any component in another train. The two operating DGFOSs provided for each generating unit are physically separated from each other to prevent interaction from one unit to the other. While cross-connect capability exists for use when a failure has occurred in one of the DGFOS or transfer systems, cross-connecting the diesel fuel oil storage tanks during normal operations in Modes 1, 2, 3, or 4 would violate the independence and redundancy design criteria. The cross-connect is isolated by double isolation valves which are kept normally locked.

D. Safety Evaluation Four

The transfer pump can be operated from either the main control room or the local diesel control panel. Alarms and indications of day tank levels and transfer pump status are displayed in the main control room and at the local diesel control panel.

E. Safety Evaluation Five

Fuel reserve for testing is ensured by sizing the diesel generator fuel oil storage tanks to contain a sufficient allocation of fuel capacity above that required for 7-day full load operation.

F. Safety Evaluation Six

Each individual diesel generator's fuel oil storage tank and day tank is equipped with a fill pipe fitted with standard connections for refill from tank trucks.

Table 9.5-9

DIESEL GENERATOR FUEL OIL SYSTEM SINGLE FAILURE ANALYSIS

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Fuel oil transfer pump	Inoperable/mechanical or electrical failure	Low level in fuel oil day tank	Low level alarm in day tank	Pump in redundant train can be aligned to supply day tank[a]	Two full-capacity pumps per unit power supply from different MCCs in same load group There are two redundant diesel generators, each with its own fuel tank. There is one full-capacity fuel oil transfer pump in each fuel tank. Manual cross- connect to other pump is available.[a]
Transfer pump check valve	Fails open/ material failure	Piping drains to storage tank		Day tank will not drain. Flow path to tank will remain open	Fill line enters top of day tank. Manual cross-connect to other pump is available[a]
Duplex strainer	Clogged/dirty oil	Low level in fuel oil day tank	High-pressure differential alarm	Flow is diverted to redundant strainer	Strainer can be manually bypassed
Transfer piping	Line break/ corrosion or mechanical damage	Low header pressure	Low-pressure alarm	Redundant diesel remains in service Diesel can run 2.5 hours without replenishment	
Level control in fuel oil day tank	Failure to function/material failure or mechanical bind or electrical failure	Low level in oil day tank	Redundant low level alarm on day tank	Low level alarm	Operator starts pump
Cross-connect line shutoff valve	Fails open/ material failure	No effect on system performance	Handle position	Redundant valve in series	Valve is normally locked closed

a. As stated in Section 9.5.4.2 the cross-connect capability is not credited in the safety analysis.

G. Safety Evaluation Seven

System tank vents are equipped with flame arrestors as shown in engineering drawings 01, 02, 03-M-DFP-001.

H. Safety Evaluation Eight

Maintenance of the diesel fuel oil above the cloud point; i.e., above the low temperature at which the separation of wax becomes visible, is achieved by enclosing the equipment in heated buildings, and installation below the frost line.

I. Safety Evaluation Nine

The DGFOS components are of Seismic Category I design and are installed underground or in buildings that include no other system's components.

J. Safety Evaluation Ten

The fire protection system provides a preaction sprinkler system for each compartment of the diesel generator building as described in subsection 9.5.1.

K. Safety Evaluation Eleven

All components of the DGFOS are capable of being fully tested during normal unit operation.

9.5.4.5 Inspection and Testing Requirements

The diesel generator fuel oil storage tank for each diesel generator is tested by nondestructive methods in accordance with ASME Boiler and Pressure Vessel Code, Section III, Class 3, and is subjected to routine tests and inspections during construction and installation.

Refer to the Technical Specifications for operational tests and inspections.

9.5.4.6 Instrumentation Applications

A pressure switch, installed on the transfer pump discharge, initiates an alarm in the control room and local diesel generator control panel if the day tank level is low and low pressure exists in this header. The alarm indicates that fuel oil is not being pumped to the day tank.

Level switches on each day tank start or stop the transfer pump at preset level points. Level switches also initiate low-low day tank level alarms in the control room and diesel generator panel in the generator room. Refer to section 7.4 for the DGFOS fuel oil transfer logic.

9.5.5 DIESEL GENERATOR COOLING WATER SYSTEM

The diesel generator cooling water system (DGCWS) removes waste heat of combustion from the diesel generator engine. The DGCWS then transfers this heat to the essential spray pond system through the jacket water heat exchanger. The DGCWS initially preheats the combustion air during diesel generator engine starts by providing warm water through the combustion air heaters. Each diesel generator engine is provided with an identical and independent DGCWS. The DGCWS is described in the following subsections.

9.5.5.1 Design Bases

9.5.5.1.1 Safety Design Bases

The DGCWS is designed to the following design bases:

A. Safety Design Basis One

The DGCWS shall remove rejected heat from each diesel engine at rated design load of the diesel generator.

B. Safety Design Basis Two

The DGCWS shall be designed such that a single failure of any component cannot cause loss of system ability to mitigate the consequences of an accident or to safely shut down the reactor.

C. Safety Design Basis Three

The DGCWS shall be designed to remain functional in the event of an SSE.

D. Safety Design Basis Four

In normal standby status, the DGCWS shall be maintained in a warmed condition in order for the diesel generator to start within the required load acceptance time frame.

9.5.5.1.2 Power Generation Design Bases

A. Power Generation Design Basis One Active components of the DGCWS are capable of being tested during plant operation in accordance with 10CFR50, General Design Criterion 46.

B. Power Generation Design Basis Two

The DGCWS is treated to minimize corrosion.

Protection of the DGCWS from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

Codes and standards applicable to the DGCWS are listed in table 3.2-1.

9.5.5.2 System Description

The arrangement of the diesel generators and components of the DGCWS is shown in engineering drawings 13-P-ZGL-701, 13-P-ZGL-702 and 01, 02, 03-M-DGP-001.

The DGCWS is procured as an integral part of the diesel generator system. Nominal operating parameters of the jacket water, combustion air, lube oil and fuel oil coolers[a] are listed in table 9.5-10.

(a). In units where DEC-00649 has been implemented, the diesel generator fuel oil coolers cooling function has been permanently retired.

Table 9.5-10
DIESEL GENERATOR COOLING WATER SYSTEM
NOMINAL OPERATING PARAMETERS

Component	Q (Btu/hr)	Cooling Water Flow, lbm/hr	Cooling Water ΔT, °F
Combustion Air Cooler	4,400,000	148,005	29.8
Jacket Water Cooler	5,520,000	289,575	19.1
Lube Oil Cooler	2,440,000	198,459	12.3
Fuel Oil Cooler[(a)]	51,000	5,944	11

NOTE: The listed heat loads are design loads from vendor submittals. The mass flow rates shown are actual flow measurements except for the fuel oil cooler which is a calculated value. No flow data was obtained for this cooler because it is not required for engine operation[(a)]. Therefore, the fuel oil coolers of all six emergency diesel generators have been functionally abandoned. The cooling water ΔT values shown are calculated based on the indicated heat loads and cooling water mass flow rates. This table shows nominal operating parameters. The minimum flow rates required, however, are based on the spray pond inlet temperature and the tube plugging/blockage criterion established for each cooler.

The DGCWS consists of a combustion air (intake) cooler, a closed loop jacket cooling system consisting of an engine-driven cooling water pump, a water-cooled jacket water heat exchanger, a surge tank (jacket water stand pipe), valves, instrumentation, and controls. The engine turbocharger is also cooled by the DGCWS. A small motor-driven recirculation jacket water pump, a heater, and a thermostat are included in the system to maintain the jacket water in a warm standby condition. Each diesel engine has its own independent DGCWS.

(a). In units where DEC-00649 has been implemented, the diesel generator fuel oil coolers cooling function has been permanently retired.

Cooling water from the essential spray pond system (ESPS) is used as the coolant in the jacket water heat exchanger.

Cooling water flow is from the water pump discharge through the jacket water heat exchanger, then through the engine, turbocharger, combustion air coolers, and governor oil cooler, then through the surge tank to the pump inlet. Adequate design margin for the diesel generator cooling water system is provided by the diesel manufacturer.

An automatic temperature regulating valve controls flow in the jacket water heat exchanger bypass line to maintain proper water temperature.

DGCWS makeup to the system surge tank is accomplished manually as needed from the demineralized water system. In addition, makeup can be provided from the Seismic Category I, Safety Class 3, safety-related condensate storage and transfer system. See Section 9.2.6 for details. A local gauge glass is provided for the surge tank. The DGCWS is treated for corrosion control; the cooling water chemistry control program is the same as that described in Section 9.2.2.1.4 for the essential cooling water system.

A 40 kW electric immersion heater in the DGCWS provides standby heating for the DGCWS. Water is circulated by a small warmup pump. Heater power and pump operation are controlled by a thermostat, to maintain water temperature within the manufacturer's recommended range.

Only vertical and horizontal piping runs are provided in order to eliminate air pockets. The height of the surge tank ensures that the pump suction piping and most of the remaining system

is initially filled with water. During startup, air trapped in the engine will be displaced by the pump discharge. The design, due to the height of the surge tank, ensures that the DGCWS remains filled with water.

9.5.5.2.1 Component Description

9.5.5.2.1.1 Jacket Water Heat Exchanger. The jacket water heat exchanger is a horizontal shell and tube type. The exchanger, which carries the jacket cooling water on the shell side, is designed to remove 5,520,000 Btu/hr, with the jacket water cooled from 170F to 160F. Jacket water cooling is accomplished by transferring heat to the essential spray pond system water, which flows through the heat exchanger tubes.

9.5.5.2.1.2 Jacket Water Pump. The jacket water pump is a centrifugal pump that is engine-driven by a chain drive, and is mounted on the front of the engine. Lubrication is automatic, from the engine oil supply. The pump operates at 1750 rpm, and is rated at 1350 gallons per minute at 70 feet (TDH).

9.5.5.2.1.3 Jacket Water Warmup (Circulating) Pump. The jacket water warmup pump is a centrifugal type, electric motor-driven pump and is mounted on the diesel engine auxiliary skid. It has a 5 hp driver, three phase, 460V, 60 Hz, and is rated at 175 gallons per minute at 40 feet (TDH). The heater is rated at 40 kW, 480V, three-phase, 60 Hz. Power is supplied from a 480V, Class 1E motor control center. With the pump control switch in the AUTO/STOP position and the heater control switch

in the AUTO position, the jacket water warmup pump and the jacket water warmup heater automatically start when the engine temperature is below the manufacturer's recommended lower setpoint. This setup ensures that the heater will be deenergized when the warmup pump is deenergized. The pump and heater continue to operate until the engine temperature rises above the manufacturer's recommended upper setpoint, which stops the operation of the pump and heater. There are no interlocks with other systems.

9.5.5.2.1.4 Temperature Control Valve. This is a self-contained, temperature-actuated, three-way valve that responds to the jacket water pump discharge temperature. The entire cooling water flow passes through the jacket water cooler when the jacket water temperature at the inlet to the valve exceeds approximately 175F.

9.5.5.2.1.5 Combustion Air Cooler/Heater. These coolers are of radiator-type design. Each cooler has two water sides, one side for ESPS cooling water to cool the combustion air after engine warmup, and one side for jacket cooling water to preheat the combustion air when the air is below 100F. The jacket water flow is bypassed around the cooler when the combustion air reaches 100F.

9.5.5.2.1.6 Surge Tank. The DGCWS surge tank is an atmospheric vessel which accommodates coolant expansion due to temperature changes and provides net positive suction head (NPSH) to the water pumps. The surge tank provides an adequate reserve to compensate for any minor leaks in the DGCWS. The

surge tank is equipped with a sight glass. Makeup is manually initiated via a manual valve. The tank volume is approximately 258 gallons.

9.5.5.2.1.7 Electric Immersion Heater. The electric immersion heater is rated at 40 kW, three-phase, 480V, and 60 Hz. Power is supplied from a 480V, Class 1E motor control center.

9.5.5.2.2 System Operation

When the diesel generator is not in operation, the DGCWS is heated by an electric immersion heater and circulated by a jacket water warmup pump. The heater and motor are controlled by a thermostat to keep the DGCWS within the manufacturer's recommended temperature range.

When the diesel engine starts, the engine-driven jacket water pump circulates the cooling water through the DGCWS, bypassing the jacket water heat exchanger. When the cooling water entering the temperature control valve reaches approximately 165F, the three-way thermostatic valve automatically modulates water to the jacket water heat exchanger to maintain approximately 170F cooling water out of the engine. When the cooling water entering the temperature control valve is approximately 175F, all water is directed to the jacket water heat exchanger. In this manner, the cooling water is maintained at the proper temperature for maximum engine efficiency.

During emergency operation, operator action is required to prevent engine damage in event of overheating. Alarm response

procedures described in paragraph 13.5.2.1, listing E, are prepared for alarms associated with this system, incorporate information from the troubleshooting guide, and provide operator guidance in alarm response.

The DGCWS is a closed system and is independent of any other plant cooling water system.

9.5.5.2.3 Unloaded Operation

See Section 8.3.1.1.4.12

9.5.5.3 Safety Evaluation

A. Safety Evaluation One

The DGCWS is sized to cool the diesel generator while operating at design load when the ESPS water is at a maximum temperature.

B. Safety Evaluation Two

Refer to table 9.5-11 for a single failure analysis of the DGCWS.

The DGCWS is independent of other plant cooling water systems; therefore, a single failure in any other cooling water system will not affect the DGCWS. A failure of the essential spray pond system, however, will result in a loss of essential spray pond system to the jacket water heat exchanger, which will result in an increase in temperature of the DGCWS and eventual engine shutdown. However, since there are independent redundant trains of the essential spray pond water system and independent, redundant diesel generator

systems, this type of failure cannot affect the redundant diesel generator system and prevent safe shutdown. Similarly, a single failure in the DGCWS cannot affect the associated ESPS train or the redundant diesel generator and prevent safe shutdown.

Table 9.5-11
DIESEL GENERATOR COOLING WATER SYSTEM
SINGLE FAILURE ANALYSIS (Sheet 1 of 2)

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Essential spray ponds system	Leak or rupture in supply line/ corrosion	Loss of cooling of combustion air, jacket circ. water loop and lube oil circ. loop	High temperature indication and alarm on jacket water circulating loop and lube oil circulating loop	Redundant diesel generator remains in service	
Circulating water temper-ature control valve	Fails to throttle flow to cooler/ valve sticks open	Continuous flow through cooler causing low temper-ature in system. Diesel runs cold, less efficient	Low temperature indication on jacket water circulating loop	Redundant diesel generator remains in service	Operator may throttle cooling water flow
	Fails to throttle flow to bypass/ heat ex-changer/valve sticks closed	Loss of cooling of jacket water circu-lating loop excessive temperature	High temperature indication and alarm on jacket water circu-lating loop	Redundant diesel generator remains in service	
Engine-driven circulating water pump	Inoperable/ mechanical failure	Low header pres-sure	Low-pressure alarm	Redundant diesel generator remains in service	
Surge tank	Leaks/corrosion	Low water level	Gauge	Makeup water re-places losses	

Table 9.5-11
DIESEL GENERATOR COOLING WATER SYSTEM
SINGLE FAILURE ANALYSIS (Sheet 2 of 2)

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Jacket water heat exchanger	Leaks/corrosion ruptures	Low level in surge tank	Gauge	Redundant diesel generator remains in service	
Standby electric jacketwater heater	Open circuit/ circuitry fault	Drop in circulating water temperature. Diesel generator not at optimum temperature to start	Low temperature indication and alarm on jacket water circulating loop	Redundant diesel generator remains in service	Diesel generator will start but may not do so within TS required time frame
Standby jacket water circulation pump	Inoperable/mechanical or electrical failure	Drop in jacket water temperature. Diesel generator not at optimum temperature to start	Low temperature indication and alarm on jacket water circulating loop	Redundant diesel generator remains in service	Diesel generator will start but may not do so within TS required time frame
Jacket water circulating water piping	Line break or major leak/vibration	Low level in surge tank. Diesel generator not operative	Gauge	Redundant diesel generator remains in service	

Table 9.5-12
DIESEL GENERATOR COOLING WATER SYSTEM - INDICATIONS, ALARMS, AND SENSORS
(Sheet 1 of 2)

Parameter	Local Indication	Local Engine Control Panel	Control Room	Comments
Engine jacket water heat exchanger temperature	• Gauge[a]			
Engine jacket water heat exchanger pressure	• Gauge (inlet and outlet)			
Circulating pump pressure	• Gauge (inlet and outlet)			Indicators are present for both standby circulating and engine-driven pumps
Engine supply pressure	• Gauge	• Alarm (low-pressure) • Gauge inlet and outlet	• Common trouble alarm	
Engine jacket water heat exchanger temperature	• Gauge (inlet and outlet)			

a. All instruments are checked during monthly testing of engine.

DIESEL GENERATOR COOLING WATER SYSTEM - INDICATIONS, ALARMS, AND SENSORS
(Sheet 2 of 2)

Parameter	Local Indication	Local Engine Control Panel	Control Room	Comments
Engine return jacket water temperature	• Gauge	• Gauge • Alarm (high or low)	• Common trouble alarm	High temperature shuts down diesel in test mode only
Jacket water level control	• Gauge			

C. Safety Evaluation Three

The DGCWS is a supporting system to the diesel generator systems, and is designed to Seismic Category I requirements to assure that the system will remain functional during or after an SSE.

D. Safety Evaluation Four

The DGCWS immersion heater and warmup pump are Seismic Category I, and are powered from a Class 1E power supply in order to assure a warm engine and fast start and load acceptance. Low jacket water temperature will be alarmed at the local control panel and in the main control room.

9.5.5.4 Inspections and Testing Requirements

Testing of the diesel generator system is discussed in sections 8.3 and 14.2.

In lieu of thermal performance testing as required by Generic Letter 89-13, the Diesel Generator support system heat exchangers will be cleaned and inspected every other refueling outage.

9.5.6 DIESEL GENERATOR STARTING SYSTEM

Each diesel generator unit is composed of one diesel engine, one generator, and their associated controls. Therefore, the following discussion is limited to a diesel generator starting system (DGSS) for only one diesel engine.

A compressed air starting capability is provided for each diesel generator and is shown schematically in engineering

drawings 01, 02, 03-M-DGP-001 (Sheets 6 and 9). Equipment location is shown in engineering drawings 13-P-ZGL-701 and 702.

9.5.6.1 Design Bases

The DGSS has no power generation design bases. The following safety design bases establish the DGSS requirements:

A. Safety Design Basis One

   The DGSS shall provide a stored compressed air supply sufficient for accomplishing a diesel generator start in less than or equal to 10 seconds. As guidance for the receiver capacity, each air receiver shall be sized to accomplish five consecutive starts from the receiver design working pressure without being refilled.

B. Safety Design Basis Two

   The DGSS shall remain functional during and after an SSE.

C. Safety Design Basis Three

   The DGSS shall ensure that a single failure of any component cannot cause loss of the system capability to mitigate the consequences of an accident or to safely shut down the reactor.

D. Safety Design Basis Four

   The DGSS shall be capable of being monitored and controlled from either the control room or the local diesel generator control panel.

Protection from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4.

Missile protection is discussed in section 3.5. Protection against dynamic effects associated with postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

Codes and standards applicable to the DGSS are listed in table 3.2-1.

9.5.6.2 System Description

The DGSS, as shown schematically in engineering drawings 01, 02, 03-M-DGP-001, Sheets 6 and 9 consists of two independent and redundant networks of compressed air, each consisting of a motor-driven air compressor, air dryer, air receiver, pneumatic control valve and two solenoid pilot valves. To support maintenance activities, one of the two compressed air networks may be removed from service during plant operations for short periods of time. Each compressor is powered from a separate station service bus. Table 9.5-13 lists the major components in the DGSS and their design specifications.

Each air receiver is designed to provide sufficient air capacity to start the diesel generator in less than or equal to ten seconds. The startup time is defined as the total elapsed time between receipt of an automatic start signal and closure of the diesel generator circuit breaker in the safety-related ac power distribution system. Each air receiver is maintained in a ready-to-use state at a maximum pressure of approximately 250 psig. The tanks are provided with a pressure switch to start and stop the compressors as required. The low pressure alarm is set at a level to ensure that engine start time requirements are met. Low-pressure is alarmed locally and as a

common trouble alarm to the main control room. High pressure safety relief valves are provided. The compressors are not required during the starting operation or during diesel engine operation. The position of the air receiver outlet valve is monitored in the control room to ensure air availability. No operator action is required to prevent damage to the diesel engine upon low starting air pressure.

9.5.6.3 System Operation

Normally, each air compressor serves one air receiver. A piping cross connect is provided so, if one compressor or air dryer is unavailable, the functional compressor and air dryer may be used to charge both air receivers. The compressors start when the air storage tank pressure drops to approximately 240 psig and stop when the pressure reaches approximately

Table 9.5-13
DIESEL GENERATOR STARTING SYSTEM
DESIGN SPECIFICATIONS

Equipment or Parameter	Quantity Per Unit	Type or Capacity
AC motor air start compressor	4 (2 per diesel)	38 standard ft^3/min at 250 psig
Air dryer	4 (2 per diesel)	75 standard ft^3/min at 250 psig
Air storage tank (receivers)	4 (2 per diesel)	83 ft^3 at 250 psig

250 psig. Each compressor is capable of pressurizing a receiver from 100 psig to 250 psig in approximately 30 minutes. The compressors are powered from a 480V, non-Class 1E motor control center. The compressor motors are 15 hp, 460V, three-phase, 60 Hz at 1800 revolutions per minute. The air dryer, a combination radiator and refrigeration unit, reduces the compressed air dewpoint at the air receivers to less than 50F in a 70F ambient environment or at least 10F less than the lowest expected ambient temperature. Air samples may be taken at the air receivers to verify the dewpoint. A check valve between the air dryer and storage tank ensures that a broken line will not result in a sudden loss of air. Air from each of the storage tanks discharges into the diesel generator through a pneumatic admission valve, which is activated by solenoid pilot valves on receipt of a diesel generator start signal. The air piping interconnects downstream of the pneumatic admission valves. The admission system delivers air simultaneously to the time and pilot air distributor and to the individual air-start valves in each cylinder. Pilot air, delivered by the distributor, opens the air-start valves in proper sequence. Starting air is then admitted directly into the cylinders for fast, reliable cranking and starting.

9.5.6.4 Safety Evaluation

Evaluation of the safety design bases listed in paragraph 9.5.6.1 are described as follows:

A. Safety Evaluation One

   Sufficient storage capacity is provided in each compressed air tank to accomplish a diesel generator

start in less than or equal to 10 seconds. Sufficient storage capacity exists in each air receiver at its design working pressure to accomplish five consecutive engine starts without recharging the receiver.

B. Safety Evaluation Two

The DGSS, excluding the compressors and dryers, is designed to Seismic Category I requirements using the techniques of section 3.9.

C. Safety Evaluation Three

The DGSS, exclusive of the air compressors and air dryers, is designed in accordance with Seismic Category I requirements as specified in section 3.2. Any system, equipment, or structure which is not Seismic Category I and whose collapse could result in loss of a required function of the DGSS through either impact or flooding is analytically checked to determine that it will not collapse when subjected to seismic loading.

Diesel generator train redundancy and independency design provisions ensure that a single failure of any component cannot cause loss of system ability to mitigate the consequences of an accident or to safely shut down the reactor.

D. Safety Evaluation Four

Monitoring of the DGSS is provided at both the control room and the local diesel generator control panel.

9.5.6.5 Inspection and Testing Requirements

Testing of diesel generator systems is discussed in sections 8.3 and 14.2.

9.5.6.6 Instrumentation Applications

Each compressed air storage tank is provided with a pressure sensing device that initiates operation of the air compressors along with a pressure sensing device that actuates an alarm in the control room and at the local diesel generator control panel when the air pressure drops below a preset value. Other features are covered in paragraph 9.5.6.2.

Instruments are checked during monthly testing of the engine. Calibrations are routinely performed according to the PVNGS Preventative Maintenance Program, and alarms are verified operable.

9.5.7 DIESEL GENERATOR LUBRICATION SYSTEM

The diesel generator lubrication system (DGLS) provides clean, temperature-controlled, lubricating oil to the diesel engine for standby and operating modes. Each engine is provided with an independent system.

9.5.7.1 Design Bases

The following safety design bases list the requirements that must be met by the DGLS. The DGLS has no power generation design bases.

A. Safety Design Basis One

The DGLS shall provide adequate lubrication at a controlled temperature to the diesel generator.

B. Safety Design Basis Two

The DGLS shall ensure that a failure of any component cannot cause the loss of system ability to mitigate the consequences of an accident or to safely shut down the reactor.

C. Safety Design Basis Three

The DGLS shall remain functional during and after the SSE.

D. Safety Design Basis Four

The DGLS shall be maintained at an operating temperature that ensures the engine lubricates properly under all normal operating conditions. The DGLS shall maintain the lube oil at a normal keep warm temperature during standby that can assist the diesel engine in starting within the required load acceptance time frame.

Protection from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

Codes and standards applicable to the DGLS are listed in table 3.2-1.

9.5.7.2 System Description

The DGLS for each engine consists of one integral engine-driven circulating lubricating oil pump, one standby lube oil circulating (keeps warm and lubricated) pump, two standby oil heaters, one filter, basket strainers, one water-cooled lube oil cooler, valves, and instrumentation. Table 9.5-15 lists the major components in the lubrication system and their design specifications.

The manufacturer's recommendations are followed to analyze and replace the engine oil. The oil is sampled at a minimum of quarterly during engine operation and then analyzed for viscosity, foreign material (dirt and wear metals), water, acidity and Total Base Number (TBN). The oil will be replaced based on oil analysis as required.

The full flow lube oil filter contains 146 elements of wound viscose yarn of 16 micron rating. A built-in bypass is provided to ensure lubrication if the filter becomes clogged. The pressure differential across the lube oil filter is indicated through a differential pressure indicating device that is monitored by the operators. Two basket strainers are provided to prevent debris from a ruptured filter element from entering the engine.

In the unlikely event of system leakage, a low level switch in the engine crankcase provides an alarm at the diesel control board. Oil would flow into the floor drain system, which is separate for each engine.

Cooling water from the ESPS is used as the cooling medium in the lube oil cooler to control the lubrication oil temperature.

When the lube oil temperature is low, the lubrication oil is automatically diverted around the oil cooler by a threeway thermostat controlled bypass valve to elevate the lube oil temperature to the operating range. The lube oil cooler cools 670 gallons per minute of oil on the shell side with 401 gallons per minute of ESPS water on the tube side at 2,440,000 Btu/h.

The lube oil circulating pump and heaters are powered from a 480V, Class 1E motor control center.

Table 9.5-15
DIESEL GENERATOR LUBRICATION SYSTEM
DESIGN SPECIFICATIONS

Equipment or Parameter	Quantity	Type or Capacity
Engine-driven lube oil pump	1	670 gal/min
Lube oil filter	1	Full flow, replaceable element type
Lube oil cooler	1	Shell and tube type
Standby circulating lube oil pumps	1	112 gal/min at 50 psig
Electric resistance standby heaters	1	19 kW, 480V, 3 phase, 60 hz
	1	4 kW, 480V, 3 phase, 60 hz

Crankcase explosion relief valves are located at 12 of the 20 openings in the sides of the engine center frame, or block. These valves relieve pressure buildup from a primary explosion.

9.5.7.3 Safety Evaluation

A. Safety Evaluation One

The diesel engine-driven pump provides oil to the engine critical components during engine operation. Oil is kept at a constant pressure and temperature by use of regulating valves, recirculation lines, and a lube oil cooler. During periods of standby status, the motor-driven pump and electric oil heaters keep the critical components lubricated and warmed.

B. Safety Evaluation Two

The lubricating oil supply is sized to provide adequate diesel generator lubrication. The lubrication subsystem is capable of supplying lube oil without augmentation from other sources. The engine driven lube oil pump is chain driven. A single failure may be assessed as a failure of the diesel generator with which it is associated; in such a circumstance, safe shutdown is attained and maintained by the appropriate redundant diesel generator installation. A single failure analysis is presented in table 9.5-16.

C. Safety Evaluation Three

The DGLS is designed in accordance with Seismic Category I requirements as specified in section 3.2. The components (and supporting structures) of any system, equipment, or structure which is not Seismic Category I, and whose failure could result in loss of a required function of the DGLS through either impact or

flooding, are analytically determined to not fail when subjected to seismic loading.

D. Safety Evaluation Four

The DGLS is provided with a standby electric pump that circulates lube oil through the DGLS. Oil is heated by electric heaters when the engine is not operating. High lube oil viscosities that accompany low lube oil temperatures are thus prevented. This assists in quick engine starting and increases component life through proper lubrication during quick starts.

Diesel generator alarms associated with the DGLS are described in section 8.3. DGLS indications and alarms are summarized in table 9.5-17.

Pressure relief valves are provided on the discharge of each oil pump and on the engine supply header. A pressure regulator regulates oil pressure to the turbocharger. Oil flow is not monitored.

The recirculation oil pump and heaters are interlocked such that they operate only when the engine speed is less than 280 revolutions per minute. Except for shutdown functions, no other interlocks are provided.

Operator action is not required to prevent damage to the engine upon low oil pressure if EDG control air is available, as the engine will be automatically shut down. If EDG control air is not available, the EDG can be tripped manually to shut off the fuel racks by activating a lever on the side of the engine. During emergency operation, as discussed above, turbocharger protective functions are bypassed and operator action is

required. Oil filters and strainers may be manually bypassed for cleaning during operation. Oil may be added to the crankcase during operation at the indicated fill point. Alarm response procedures are available in each D.G. control room for alarms associated with this system. These procedures instruct the operator on appropriate action for each alarm.

Table 9.5-16
DIESEL GENERATOR LUBRICATION SYSTEM SINGLE FAILURE ANALYSIS

Component	Failure Mode/Cause	Effects on System	Method of Detection	Inherent Compensating Provision	Remarks
Engine-driven oil pump	Inoperable/mechanical failure	Loss of adequate lubrication on critical sliding components	Low-pressure alarm and trip	Redundant diesel generator remains in service.	
Oil filter	Clogged/dirty oil	Oil flow is reduced	High-pressure differential alarm	Redundant diesel remains in service	Operator may bypass filter housing and change filter elements
Temperature control valve	Fails to throttle flow to cooler/ material failure	Oil flows through oil cooler causing low temperature in system	Low-temperature alarm	Diesel continues to run. Temperature may be maintained by reducing cooling water flow as required.	Operator may control cooling water flow manually.
	Fails to throttle flow to bypass/ material failure	Oil bypasses cooler causing high temperature in system	High-temperature alarm	Redundant diesel generator remains in service.	
Heat exchanger	Tube leaks or blockage/corrosion	Oil flow to engine is reduced	Low-pressure alarm in lube oil system or high-temperature alarm	Redundant diesel generator remains in service.	
Electric standby heater	Open circuit/ electrical failure	Oil temperature too low. Diesel generator not at optimum temperature to start	Low-temperature alarm	Redundant diesel generator in service.	Diesel generator starts but may not do so in the Tech Spec required time frame.
Standby oil circulating pump	Inoperable/mechanical or electrical failure	Oil temperature too low. Reduced lubrication to sliding surfaces at startup.	Low-temperature alarm	Redundant diesel generator in service.	Diesel generator starts but may not do so in the Tech Spec required time frame.
Lube oil piping	Line breaks or major leaks/corrosion or mechanical damage	No lube oil flow.	Low pressure alarm trip	Redundant diesel generator remains in service.	

Table 9.5-17
DIESEL GENERATOR LUBE OIL INDICATIONS AND ALARMS

Parameter	Local	Engine Control Panel (Local)	Control -Room	Comments
Lube oil pressure	• Gauge (engine pump disch. and motor driven pump disch.)			
	• Gauge (inlet and outlet of lube oil heat exch.)			
	• Gauge (inlet pressure to engine)	• Gauge (inlet pres. to engine) Alarm (inlet pres. to engine)	• High priority trouble alarm	• Low pressure will shut down diesel in test and emergency mode
	• Gauge (inlet pres. to turbocharger)	• Gauge (inlet pres. to turbocharger • Alarm (inlet pres. to turbocharger)	• High priority trouble alarm	• Low pressure will shut down diesel in test mode only
	• Gauge (LO filter differential pressure)	• Alarm (high D/P)	• High priority trouble alarm	• Diesel continues to run
Crankcase pressure	• Gauge (crankcase pressure)	• Alarm (high pressure)	• High priority trouble alarm	• High pressure will shut down diesel in test mode only
Lube oil temperature	• Gauge (lube oil cooler inlet temperature)	• Gauge (lube oil temperature) • Alarm (high oil temperature	• Low priority trouble alarm	• Diesel continues to run
	• Gauge (lube oil cooler outlet temperature			
	• Gauge (LO engine inlet temperature)	• Gauge (lube oil temperature • Alarm (low oil temperature	• Low priority trouble alarm	• Engine available for starting, but may not make Tech spec required time
Lube oil level	• Level gauge (engine crankcase)	• Alarm (low level)	• Low priority trouble alarm	• Diesel continues to run

Instruments are read at least monthly during engine testing. Calibrations are routinely performed according to the PVNGS calibration program and alarms verified operable.

9.5.7.4 Inspection and Testing Requirements

Testing of the diesel generator system is discussed in sections 8.3 and 14.2.

9.5.8 DIESEL GENERATOR COMBUSTION AIR INTAKE AND EXHAUST SYSTEM

This section discusses the mechanical features of the diesel generator combustion air intake and exhaust system. The diesel generator building ventilation system is discussed in subsection 9.4.7.

9.5.8.1 Design Bases

9.5.8.1.1 Safety Design Bases

The diesel generator combustion air intake and exhaust system is designed to meet the following safety design bases:

A. Safety Design Basis One

   The diesel generator combustion air intake and exhaust systems shall be capable of supplying adequate combustion air and disposing of resultant exhaust products to permit continuous short-term operation of the diesel generator at 110% of nameplate rating.

B. Safety Design Basis Two

The diesel generator combustion air intake and exhaust system shall be designed to remain functional during and after a safe shutdown earthquake.

C. Safety Design Basis Three

The diesel generator combustion air intake and exhaust system shall be designed so that a single failure of any component, assuming a loss of offsite power, cannot result in complete loss of the diesel generation function.

9.5.8.1.2 Power Generation Design Bases

The diesel generator combustion air intake and exhaust system is capable of being tested during plant operation in accordance with 10CFR50, General Design Criterion 10.

Protection of the diesel generator combustion air intake and exhaust system from wind and tornado effects is discussed in section 3.3. Flood design is discussed in section 3.4. Missile protection is discussed in section 3.5. Protection against dynamic effects associated with postulated rupture of piping is discussed in section 3.6. Environmental design is discussed in section 3.11.

Codes and standards applicable to the diesel generator combustion air intake and exhaust system are listed in table 3.2-1.

9.5.8.2 System Description

9.5.8.2.1 General Description

Each diesel engine is provided with an air intake and exhaust system. The major components of the system include an air intake filter, intake silencer, an exhaust silencer, combustion air cooler/heaters and associated piping and flexible connections, shown in engineering drawings 13-P-ZGL-701, -702 and 01, 02, 03-M-DGP-001.

9.5.8.2.2 System Operation

There are no active components within the diesel generator combustion air intake and exhaust system.

Combustion air flow or exhaust flow is not monitored, as there are no levels to be monitored.

Each power cylinder is equipped with a thermocouple to provide exhaust temperature indication at the local engine control panel. The exhaust temperature at the turbocharger inlet and outlet is provided from thermocouples. Indication is at the local engine control panel. Combustion air temperature is indicated locally, and thermocouples provide indication at the local engine control panel.

The turbocharger discharge pressure and the intake manifold pressures are indicated locally and at the local engine control panel.

A differential pressure switch on the combustion air piping downstream of the combustion air filter registers the pressure drop across the air filter locally.

There are no system interlocks.

Upon initiation of a diesel generator start signal, combustion air is drawn into the air intake filter, through the intake silencer, and delivered to the engine. The air intake filter, intake silencer, and the combustion air piping are sized to supply an adequate supply of air to the engine for short-term periods while operating at 110% of nameplate rating. The short-term rating is based upon 2 hours of operation every 24 hours. The air filter is an oil-impingement type with a low-pressure drop. The air filter is sized to provide adequate combustion air during dust storm conditions.

After the exhaust gas passes through the turbocharger, the exhaust gas enters the exhaust pipe, then passes through the exhaust silencer, and is piped out of the building. The exhaust piping and silencer are sized to prevent excess back-pressure on the engine for the short-term period when operating at 110% of nameplate rating.

During standby, warm jacket water cooling water flows through the heater section of the combustion air cooler/heaters.

Jacket water flow continues when the engine starts and operates until the combustion air reaches 100F to ensure smooth acceleration and load acceptance. When the combustion air reaches 100F due to turbocharger compression, the jacket water is shut off. Cooling water from the essential spray ponds flows in the cooler section upon a diesel generator start signal, and continues to flow to prevent excessively high combustion temperatures.

No operator action is required to prevent potential damage caused by the combustion air inlet and exhaust system to the engine. No local or remote alarms are required.

Instruments are checked during monthly testing of the engine. Calibrations are routinely performed according to the PVNGS M&TE, and alarms are verified operable.

9.5.8.3 Safety Evaluation

A. Safety Evaluation One

The diesel generator combustion air intake and exhaust system is capable of supplying an adequate quantity of filtered combustion air to the engine and of disposing of the resultant exhaust gases without creating an excessive backpressure on the engine.

The combustion air intake filter is located in a separate enclosure on the second floor of the diesel generator building and is protected against tornado missiles. The intake silencer is located inside the missile-proof diesel generator building.

The combustion air intake is located on the sidewall of the second floor of the diesel generator building below the roof level, approximately 40 feet above grade. The 59,920 cubic feet per minute engine exhaust and 105,000 cubic feet per minute ventilation exhaust discharge is in an upward direction from the diesel generator building roof through a rectangular chimney. The exhaust is carried in an exhaust pipe inside the chimney. The exhaust is directed vertically upward.

The top of the exhaust pipe and the chimney exit are approximately 90 feet above grade and about 50 feet above the air intake. These design features will preclude the recirculation of exhaust gases into the air intake.

The engine exhaust, which is approximately 35% of the building air flow, would be sufficiently mixed prior to reaching the combustion air intake filter. The above mixed intake air would not affect engine performance.

The combustion air intercooler cooler section utilizes spray pond water. The intercooler heater section carries jacketwater. Both the intercooler cooler and heater sections are fabricated from copper-nickel tubing. These corrosion-resistant materials minimize the possibility of tube leaks.

The diesel generator buildings are not equipped with gaseous fire protection systems, nor are they located near the gas storage facilities. The carbon dioxide storage tank is located at a distance of 220 feet, the hydrogen storage facility is 600 feet away, and the nitrogen storage system is 500 feet away. These distances are adequate to ensure that accidental releases of these gases will not degrade diesel performance.

The meteorological data presented in paragraphs 2.3.1.1.5 and 2.3.1.2.5 indicate that snow, hail, or freezing rain are extremely rare and very light. It is not probable that either the intake or

exhaust could be plugged by snow or ice. The intake and air filter are sized to adequately provide combustion air during dust storm conditions.

B. Safety Evaluation Two

The diesel generator combustion air intake and exhaust system is designed to Seismic Category I requirements as specified in section 3.2. The components (and supporting structures) of any system, equipment, or structure that are not Seismic Category I and whose failure could result in loss of a required function of the diesel generator combustion air intake and exhaust system through either impact or flooding are analyzed to determine that they will not fail when subjected to seismic loading.

C. Safety Evaluation Three

The diesel generator combustion air intake and exhaust system does not contain any active components. A single failure of any component cannot result in a complete loss of the diesel generator. A single failure is considered as a failure of the diesel generator with which the component is associated. In such a circumstance, safe shutdown is attained and maintained by the appropriate redundant diesel generator.

9.5.8.4 Inspection and Testing Requirements

Testing of the diesel generator system is discussed in subsection 8.3.1 and section 14.2.

9.5.9 STATION BLACKOUT EVALUATION

9.5.9.1 General

10 CFR Part 50.63 requires that each light water-cooled nuclear power plant be able to withstand and recover from a station blackout (SBO) of a specified duration.

The station blackout (SBO) coping requirements of 10 CFR 50.63, Loss of All Alternating Current Power, were previously met for the Palo Verde Nuclear Generating Station (PVNGS) by having the capability to cope with an SBO for up to four hours. Based on NUMARC 87-00, Revision 1 criteria, the June 14, 2004 loss of offsite power event at PVNGS resulted in a reclassification of PVNGS to a 16 hour SBO copying plant.

The SBO 16 hour copying evaluation was submitted to the NRC in APS letter 102-05370, dated October 28, 2005. Supplemental information was provided in APS letter 102-05465, dated April 19, 2006. The NRC approved the 16-hour SBO coping evaluation in a Safety Evaluation Report dated October 31, 2006.

The 16 hour coping strategy analysis assumes that Alternate AC (AAC) is started and loaded during the first hour. The operators will start a cool-down to shutdown cooling conditions. The Atmospheric Dump Valves (ADVs) will be used for heat removal, as required by station procedures.

9.5.9.2 16 Hour Coping Assessment

The ability of PVNGS to cope with an SBO was assessed, with the following results.

9.5.9.2.1 Condensate Inventory for Decay Heat Removal

The 16 hour coping duration evaluation, using the CENTS Code, requires approximately 242,000 gallons of condensate to make-up for decay heat, sensible heat, and the heat from SG inventory which is well within the design basis for the condensate storage tank.

9.5.9.2.2 Assessing the Class 1E Battery Capacity

There is no effect on the Class 1E batteries caused by the 16 hour coping period. The battery chargers are loaded onto at least one Station Blackout Generator (SBOG) at 1 hour. The batteries have more than adequate capacity to supply the required loads during the first hour of an SBO event.

9.5.9.2.3 Alternate AC Power Source

Two SBOGs designated as Alternate AC (AAC) power sources are available at 1 hour of the onset of the SBO event. Each SBOG has sufficient capacity and capability to operate those systems necessary for coping with an SBO for the required duration of 16 hours to bring the plant to and maintain the plant in a safe shutdown condition.

Additional information concerning the AAC power system is provided in Section 8.3.1.1.10.

9.5.9.2.4 Compressed Air

The SG ADVs are the primary means of heat removal during an SBO. The ADVs are air operated valves with a backup nitrogen accumulator. In addition, to ensure availability of control

air to support ADV operation for a 16 hour SBO, a backup supplemental compressed gas connection has been provided for use during an SBO condition. However, this backup supplemental compressed gas system is now functionally retired because the ADV accumulator tanks capacity have been increased.

9.5.9.2.5 Effects of Loss of Ventilation

a. Inside Containment

No design basis accidents (DBAs) (i.e., loss of coolant accidents (LOCAs) or steam line breaks) or beyond DBAs (i.e., resulting in core damage) are assumed coincident with an limited to (1) loss of cooling water, (2) loss of ventilation systems, and (3) limited reactor coolant pump (RCP) seal leakage. SBO results in a slow heatup of containment due to loss of ventilation and RCP leakage and temperatures in a 16 hour SBO are bounded by thermal profiles considered for DBA-LOCA event as presented in Section 6.2 of the UFSAR.

The design basis accident model is adjusted for SBO. The containment temperature and pressure response to a 16 hour SBO has been calculated considering both the sensible and the latent heat addition to the containment. The sensible heat is from the component hot surfaces including the primary and secondary system. The latent heat addition is from the RCS and the RCP seal leakage of 111 gpm (25 gpm/RCP plus 11 gpm TS 3.4.14 leakage) in addition to RCS discharge from pressurizer vent valves. The analysis credits a conservative heat transfer for passive heat sinks in the containment,

however no active cooling by sprays or air coolers is assumed. Selection of the heat transfer coefficient is based on leakage from RCP seals to containment environment that will produce a saturated atmosphere and the dominant means of heat transfer will be by condensation. Consistent with previous analyses of the long-term containment responses, the Uchida condensing heat transfer correlation is used. Additionally, one third of the total containment area was excluded in the model to provide acceptable conservatism in the theoretical model.

The peak temperature and pressure remain well below the LOCA and MSLB DBA for the duration of the 16 hour SBO. Therefore, equipment within the containment will perform their intended function for the duration of the event. The current equipment qualification (EQ, 10 CFR 50.49) bounds the SBO environment.

b. Outside Containment

For all rooms with essential equipment, the essential air handling unit (AHU) will be available after AAC is available (at 1 hour). Table 9.5-18 provides a list of rooms evaluated for the 16 hour SBO coping duration plant specific geometries and heat sources. Additionally a heat sink (floor) was included where the rooms were located in plant areas with no contact to soil. Additional heat source steam leakage was added to the AFW steam driven pump room evaluation to assure a bounding analysis.

Required SBO support equipment in the rooms were evaluated to ensure a basis existed to provide an adequate assurance of operation in accordance with NUMARC 87-00.

Table 9.5-18

Assessment of Equipment Operability Outside the Containment During SBO

In all cases essential heating ventilation and air conditioning (HVAC) will be available after AAC is available (at 1 hour)

Room	Room Classification NUMARC 87-00, 2.7.1(2)
Control Room	Condition 1
DC Equipment Rooms	Condition 2
Emergency Switchgear Rooms	Condition 1
Battery Rooms	Condition 1
Charging Pump Rooms	Condition 2
ESF Pump Rooms	Condition 1
AFW-Steam Driven Pump Room	Condition 3 (1)

[1]This room is Classified as Condition 3 based on its analyzed steady state temperature as modeled per NUREG 87-00 Revision 1(2.7.1(2) and 7.2.4, Appendices F and H). All components within this room are evaluated for the environmental conditions, with the Terry Turbine Control Panel being the limiting component.

9.5.9.2.6 Containment Isolation

A review of plant containment isolation valves was performed to ensure that containment integrity is provided during the SBO event. NUMARC 87-00, Section 7.2.5 defines “containment integrity” as the capability for valve position indication and closure of containment isolation valves independent of the preferred class 1E power supplies. The containment isolation valves requiring this capability are valves that may be in the open position at the onset of an SBO. Acceptable means of position indication include local mechanical indication, DC-powered indication and AAC-powered indication. All station containment isolation valves were identified by performing a review of the plant design bases. Based on this review, it is concluded that under SBO conditions, containment integrity is accomplished.

9.5.9.2.7 Reactor Coolant Inventory Loss

Sources of expected reactor coolant inventory loss during the SBO event include RCS leakage (11 gpm per TS 3.4.14) and losses due to RCP seal leakage (25 gpm/RCP per NUMARC 87-00). Analysis of the RCS during SBO indicates that expected rates of reactor coolant inventory loss do not result in the core uncovering in the first hour or the subsequent 15 hours of coping using AAC power source. Analysis further indicates that RCS makeup systems beyond those currently unavailable under DBEs are not required. Sufficient head exists to maintain core cooling under natural circulation.

The limiting SBO scenarios conditions were simulated using only qualified 1E components with the CENTS code. The analysis supports a determination of the plant's capability to cope for up to 16 hours under SBO conditions. The analysis is initiated from hot full power conditions (3990 MWt) with the maximum allowed RCS leakage of 11 gpm. Onset of SBO conditions are assumed to immediately cause RCP, turbine, and reactor trips, and failure of the RCP seals resulting in an additional total leakage of 100 gpm.

No operator action for RCS inventory loss is assumed within the first hour of the event. The following operator actions are assumed after actuation of the AAC power source at one hour:

a) Control of cooldown using ADVs.

b) The AFW system is adjusted to maintain SG level.

c) The HPSI flow is delivered to maintain RCS inventory, subcooling, and natural circulation.

d) At 4 hours – operators adjust ADVs for approximately a 30°F/hr cooldown and maintain pressure in the RCS using the pressurizer vent valve.

It is concluded that the ability to maintain adequate RCS inventory to ensure that the core can be cooled is achieved using the existing safety systems for 16 hours. The rates of coolant inventory loss under SBO conditions do not result in core uncovery and the station can cope with a 16 hour duration SBO event.

9.5.9.2.8 Emergency Lighting

The emergency lighting system with eight hour battery-backed power supplies provides illuminating requirements where local manual operation is required within the power block. This lighting illuminates automatically upon a loss of AC power. After 1 hour, the A train essential lighting is powered by the SBOGs.

9.5.9.2.9 Communications

The primary modes of communication during an SBO are the telephone system, the plant 2-way radio system, and the sound powered phone system. The telephone system has at least a 2 hour battery capability. The 2-way radio system has a 4 hour battery system and will be transferred to the SBOGs. The sound powered phone system requires no external power source to operate.

9.5.9.2.10 Station Procedures

Specific operator actions were considered as part of performing the design analyses supporting the 16 hour SBO coping period. As previously stated, these actions used the ADVs for RCS cooldown and the AFW system for SG level control. Based on design Reactor Coolant Pump seal leakage rates, RCS inventory control uses the HPSI system.

The governing Station operation procedures provide operator flexibility with respect to mitigating the effects of SBO due to variations in RCS leakage rates. For SBO conditions with limited RCS leakage, the charging system will be used for RCS inventory control. The pressurizer vent or auxiliary spray may also be used for RCS pressure control as station conditions and equipment availability allow.

APPENDIX 9A

<u>QUESTION 9A.1</u> (NRC Question 430.4) (9.5.2)

The information regarding the onsite communications system (subsection 9.5.2) does not adequately cover the system capabilities during transients and accidents. Provide the following information:

(a) Identify all work stations on the plant site where it may be necessary for plant personnel to communicate with the control room or the emergency shutdown panel during and/or following transients and/or accidents (including fires) in order to mitigate the consequences of the event and to attain a safe cold plant shutdown.

(b) Indicate the maximum sound levels that could exist at each of the above identified working stations for all transients and accident conditions.

(c) Indicate the types of communication systems available at each of the above identified working stations.

(d) Indicate the maximum background noise level that could exist at each working station and yet reliably expect effective communication with the control room using:

  (1) the page party communications systems, and

  (2) any other additional communication system provided that working station.

(e) Describe the performance requirements and tests that the above onsite working stations communication systems will be required to pass in order to be assured that effective communication with the control room or emergency shutdown panel is possible under all conditions.

(f) Identify and describe the power source(s) provided for each of the communications systems.

(g) Discuss the protective measures taken to assure a functionally operable onsite communication system. The discussion should include the considerations given to component failures, loss of power, and the severing of a communication line or trunk as a result of an accident or fire.

RESPONSE:

(a) The onsite communications system is not required to prevent or mitigate the consequences of UFSAR chapter 15 design basis events nor to attain a safe cold plant shutdown. Nevertheless, paragraph 9.5.2.1.G and table 9.5-4 identify all working stations on the plant site where it may be necessary for plant personnel to communicate with the control room or the emergency shutdown panel during and/or following transients and/or accidents, including fires, and with the control room under conditions of normal operation.

(b) Table 9.5-4 has been added to show maximum sound levels anticipated at each station identified, communication systems available at each station identified, and the maximum background noise that could exist at each working station and yet reliably expect effective communication.

(c) Refer to listing (b) above.

(d) (1) PVNGS does not have a page party system.

(2) Refer to listing (b) above.

(e) The response is given in paragraph 9.5.2.3.

(f) Power sources to communication systems are described in table 9.5-3.

(g) Paragraph 9.5.2.3 discusses communication systems' availability. Calculation 13-MC-FP-316 provides the technical basis for the availability of the communications systems which address postulated fires.

Refer to subsection 9.5.2 for a discussion on the uninterruptable power systems and two-way portable radios.

UFSAR table 9B.3-1 describes the communication systems which are credited for addressing postulated fires.

QUESTION 9A.2 (NRC Question 430.5) (9.5.3)

Identify the vital areas and hazardous areas where emergency lighting is needed for safe shutdown of the reactor and the evacuation of personnel in the event of an accident. Tabulate the lighting system provided in your design to accommodate those areas so identified. Include the degree of compliance to Standard Review Plan 9.5.1 regarding emergency lighting requirements in the event of a fire.

RESPONSE: The lighting needed for the safe shutdown of the reactor and the evacuation of personnel in the event

of an accident is the essential lighting subsystem and the emergency lighting subsystem.

The safe shutdown lighting drawings 01, 02, 03- E-ZPL-001, E-ZPL-002, E-ZPL-003, E-ZPL-004 identify areas where lighting is needed to accomplish safe shutdown of the reactor and evacuation of personnel in the event of a fire. Paragraph 9.5.3.2 describes the power supplies for the essential and emergency lighting subsystems.

PVNGS compliance with Appendix A of NRC Branch Technical Position APCSB 9.5-1 is identified in FSAR section 9B.3, table 9B.3-1, item D.5.

QUESTION 9A.3 (NRC Question 430.6) (9.5.4)

Describe the instruments, controls, sensors and alarms provided for monitoring the diesel engine fuel oil storage and transfer system and describe their function. Discuss the testing necessary to maintain and assure a highly reliable instrumentation, control, sensors and alarm system and where the alarms are annunciated. Identify the temperature, pressure, and level sensors which alert the operator when these parameters exceed the ranges recommended by the engine manufacturer and describe what operator actions are required during alarm conditions to prevent harmful effects to the diesel engine. Discuss the system interlocks provided. (SRP 9.5.4, Part III, Item 1).

RESPONSE: The description of instruments and controls for the diesel generator fuel oil storage and transfer system are shown in amended paragraph 9.5.4.2 and engineering

drawings 01, 02, 03-M-DFP-001. Calibration and testing is performed in accordance with the PVNGS preventative maintenance program.

QUESTION 9A.4 (NRC Question 430.7) (9.5.4)

The diesel generator structures are designed to seismic and tornado criteria and are isolated from one another by a reinforced concrete wall barrier. Describe the barrier (including openings) in more detail and its capability to withstand the effects of internally generated missiles resulting from a crankcase explosion, failure of one or all of the starting air receivers, or failure of any high or moderate energy line and initial flooding from the cooling system so that the assumed effects will not result in loss of an additional generator. (SRP 9.5.4, Part III, Item 2).

RESPONSE: The diesel generators are separated by a 1-foot 9-inch thick, penetration-free, concrete wall. The wall is able to withstand the effects of internally-generated missiles resulting from a crankcase explosion.

The diesel crankcase is provided with relief covers (see response to NRC Question 430.27). The starting air receivers and associated piping, constitute the only high energy lines in the building. They are separated from the redundant tanks of the other diesel engine by concrete walls 1 foot 9 inches thick with no openings.

In event of a moderate energy fluid piping crack, the redundant diesels are separated so that neither spray nor flooding can affect the other generator. The operator is

alerted by operation of sump pumps in the affected diesel engine compartment.

QUESTION 9A.5 (NRC Question 430.8) (9.5.4)

Describe your design provisions made to protect the fuel oil storage tank fill and vent lines from damage by tornado missiles. (SRP 9.5.4, Part II).

RESPONSE: The response is given in amended paragraph 9.5.4.2.1.

QUESTION 9A.6 (NRC Question 430.9) (9.5.4)

Discuss the means for detecting or preventing growth of algae in the diesel fuel storage tank. If it were detected, describe the methods to be provided for cleaning the affected storage tank. (SRP 9.5.4, Part III, Item 4).

RESPONSE: The response is given in paragraph 9.5.4.2.1.

QUESTION 9A.7 (NRC Question 430.10) (9.5.4)

In paragraph 9.5.4.2.1 you state that the diesel fuel oil storage tanks are protected from corrosion in accordance with recommended practice "Control or External Corrosion on Underground or Submerged Piping Systems," RP-01-69 as published by the National Association of Corrosion Engineers. This statement is incomplete; it does not discuss the buried piping or internal corrosion of the storage tanks due to water in the fuel oil. Expand the FSAR to include a more explicit description of proposed protection of underground piping.

Where corrosion protective coatings are being considered (piping and tanks) include additional industry standards which will be used in their application. Also discuss what provisions will be made in the design of the fuel oil storage and transfer system in the use of a impressed current type cathodic protection system, in addition to waterproof protective coatings, to minimize corrosion of buried piping or equipment. If cathodic protection is not being considered, provide your justification. (SRP 9.5.4, Part II, and Part III, Item 4).

RESPONSE: The response is given in amended paragraphs 9.5.4.2.1 and 9.5.4.2.4.

QUESTION 9A.8 (NRC Question 430.11)(3.2, 9.5.4 through 9.5.8)

The FSAR text and table 3.2-1 states that the components and piping systems for the diesel generator auxiliaries (fuel oil system, cooling water, lubrication, air starting, and intake and combustion system) that are mounted on the auxiliary skids are designed Seismic Category I and are ASME Section III Class 3 quality. The engine mounted components and piping are designed and manufactured to DEMA standards, and are Seismic Category I. This is not in accordance with Regulatory Guide 1.26 which requires the entire diesel generator auxiliary systems be designed to ASME Section III Class 3 or Quality Group C. Provide the industry standards that were used in the design, manufacture, and inspection of the engine mounted piping and components. Also show on the appropriate P&IDs where the quality group classification changes from Quality Group C.

RESPONSE: The engine-mounted piping for auxiliary systems is designed and manufactured by the engine manufacturer. The engine and engine-mounted auxiliaries (called the engine package) are designed and sold as standby units for nuclear service. The standard design of the engine package does not include ASME III items. The design specification specifically exempted the engine package from ASME Section III. Engineering drawings 01, 02, 03-M-DGP-001 shows quality group classification changes. The design specification requires the use of ANSI B16.5 flanges and B31.1 piping. The engine package is seismically analyzed to withstand a safe shutdown earthquake.

QUESTION 9A.9 (NRC Question 430.12) (9.5.4)

Paragraph 9.5.4.2 emergency diesel engine fuel oil storage and transfer system (EDEFSS) does not specifically reference Regulatory Guide 1.137 and ANSI Standard N195 "Fuel Oil Systems for Standby Diesel Generators." Indicate if you intend to comply with this regulatory guide and standard in your design of the EDEFSS; otherwise, provide justification for noncompliance. (SRP 9.5.4, Rev. 1, Part II, Item 12).

RESPONSE: The diesel generator fuel oil storage and transfer system is designed to comply with Position C.2 of Regulatory Guide 1.137 as discussed in Section 1.8.

Refer to paragraph 9.5.4.1.3 for PVNGS compliance with ANSI N195-1976.

QUESTION 9A.10 (NRC Question 430.13) (9.5.4)

Discuss what precautions have been taken in the design of the fuel oil system in locating the fuel oil day tank and connecting fuel oil piping in the diesel generator room with regard to possible exposure to ignition sources such as open flames and hot surfaces. (SRP 9.5.4, Part III, Item 6).

RESPONSE: The fuel oil day tank is located in a separate room from the diesel engine. Fuel oil piping is routed along the ceiling and building walls to avoid possible ignition sources. The fuel lines do not cross over the engine or pass near the exhaust piping.

QUESTION 9A.11 (NRC Question 430.14) (9.5.4)

Discuss the precautionary measures that will be taken to assure the quality and reliability of the fuel oil supply for emergency diesel generator operation. Include the type of fuel oil, impurity and quality limitations as well as diesel index number or its equivalent, cloud point, entrained moisture, sulfur, particulates, and other deleterious insoluble substances; procedure for testing newly delivered fuel, periodic sampling and testing of onsite fuel oil (including interval between tests), interval of time between periodic removal of condensate from fuel tanks and periodic system inspection. In your discussion include reference to industry (or other) standard which will be followed to assure a reliable fuel oil supply to the emergency generators. (SRP 9.5.4, Part III, Items 3 and 4).

RESPONSE: Refer to amended paragraph 9.5.4.2.

Fuel oil will meet the requirements of Position C.2 of Regulatory Guide 1.137 as discussed in section 1.8.

QUESTION 9A.12 (NRC Question 430.15) (9.5.4)

Provide additional justification to support your statement in paragraph 9.5.4.4 that sufficient additional fuel can be delivered to the plant site by truck, rail, or helicopter. In your discussion include sources where diesel quality fuel oil is available and distances traveled from the source to the plant. Also discuss how fuel oil will be delivered onsite under extremely unfavorable environmental conditions, including probable maximum flood conditions.

RESPONSE: The response is given in amended paragraph 9.5.4.2.

QUESTION 9A.13 (NRC Question 430.16) (9.5.4)

You state in paragraph 9.5.4.2 that the diesel generator fuel oil storage tank is provided with an individual fill and vent line. Indicate where these lines are located (indoor or outdoor) and the height these lines are terminated above finished ground grade. If these lines are located outdoors, discuss the provisions made in your design to prevent entrance of water into the storage tank during adverse environmental conditions.

RESPONSE: The response is given in amended paragraph 9.5.4.2.1.

QUESTION 9A.14 (NRC Question 430.17) (9.5.5)

Subsection 9.5.5 indicates that the function of the diesel generator cooling water system is to dissipate the heat transferred through the: 1) engine water jacket, 2) combustion air (intake) cooler, and 3) engine turbo charger. Provide information on the individual component heat removal rates (Btu/hr), flow (lbs/hr) and temperature differential (°F) and the total heat removal rate required. Also provide the design margin (excess heat removal capacity) included in the design of major components and subsystems. (SRP 9.5.5, Part III, Item 1).

RESPONSE: The response is given in amended paragraph 9.5.5.2 and table 9.5-10.

QUESTION 9A.15 (NRC Question 430.18) (9.5.5)

Provide the results of a failure mode and effects analysis to show that failure of a piping connection between subsystems (engine water jacket, lube oil cooler, service water system, combustion air (intake) cooler, and engine turbocharger cooler) does not cause total degradation of the diesel generator cooling water system. (SRP 9.5.5, Part III, Item 1a).

RESPONSE: Each engine is provided with a separate diesel generator cooling water system as discussed in subsection 9.5.5. No single failure can affect both diesel generator cooling water systems.

QUESTION 9A.16 (NRC Question 430.19) (9.5.5)

You state in paragraph 9.5.5.1 the diesel engine cooling water is treated as appropriate to minimize corrosion. Provide additional details of your proposed diesel engine cooling water system chemical treatment with regards to corrosion and organic fouling, and discuss how your proposed treatment complies with the engine manufacturers recommendations. (SRP 9.5.5, Part III, Item 1c).

RESPONSE: The closed loop jacket cooling water system, is discussed in section 9.5.5.2. The essential spray pond system, is treated with sulfuric acid for pH control and sodium hypochlorite for organic fouling. The supplier has been provided with the essential spray pond water analysis, and appropriate materials of construction have been selected.

QUESTION 9A.17 (NRC Question 430.20) (9.5.5)

Describe the instrumentation, controls, sensors and alarms provided for monitoring of the diesel engine cooling water system and describe their function. Discuss the testing necessary to maintain and assure a highly reliable instrumentation, controls, sensors, and alarm system, and where the alarms are annunciated. Identify the temperature, pressure, level, and flow (where applicable) sensors which alert the operator when these parameters exceed the ranges recommended by the engine manufacturer and describe what operator actions are required during alarm conditions to

prevent harmful effects to the diesel engine. Discuss the systems interlocks provided. (SRP 9.5.6, Part III, Item 1c).

RESPONSE: The response is given in amended paragraph 9.5.5.2 and table 9.5-12.

QUESTION 9A.18 (NRC Question 430.21) (9.5.5)

The diesel generators are required to start automatically on loss of all onsite power and in the event of a LOCA. The diesel generator sets should be capable of operation at less than full load for extended periods without degradation of performance or reliability. Should a LOCA occur with availability of offsite power, discuss the design provisions and other parameters that have been considered in the selection of the diesel generators to enable them to run unloaded (on standby) for extended periods without degradation of engine performance or reliability. Expand your PSAR/FSAR to include and explicitly define the capability of your design with regard to this requirement. (SRP 9.5.5, Part III, Item 7).

RESPONSE: The response is given in amended section 8.3.1.1.4.12, 3rd paragraph.

QUESTION 9A.19 (NRC Question 430.22) (9.5.5)

You state in paragraph 9.5.5.2 each diesel engine cooling water system is provided with a surge tank to provide for system expansion and for venting air from the system. In addition to the items mentioned, the surge tank is to provide for minor system leaks at pump shafts seals, valve stems and other components, and to maintain required NPSH on the system

circulating pump. Provide the size of the expansion tank and location. Demonstrate by analysis that the expansion tank size will be adequate to maintain required pump NPSH and makeup water for 7 days continuous operation of the diesel engine at full rated load without makeup, or provide a Seismic Category I, Safety Class 3 makeup water supply to the expansion tank.

RESPONSE: The cooling water system expansion tank is located on the auxiliary skid. Makeup is provided from the condensate storage tank. Refer to amended paragraph 9.5.5.2 for additional discussion.

QUESTION 9A.20 (NRC Question 430.23) (9.5.5)

Provide the source of power for the diesel engine motor-driven recirculation jacket water pump and electric jacket water heater. Provide the motor and electric heater characteristics, i.e., motor hp, operating voltage, phase(s), frequency and kW output as applicable. Also include the pump capacity and discharge head. Revise the FSAR accordingly.

RESPONSE: The response is given in paragraphs 9.5.5.2.1.3 and 9.5.5.2.1.7.

QUESTION 9A.21 (NRC Question 430.24) (9.5.6)

Provide a discussion of the measures that have been taken in the design of the standby diesel generator air starting system to preclude the fouling of the air start valve or filter with moisture and contaminants such as oil carryover and rust. (SRP 9.5.6, Part III, Item 1).

RESPONSE: The starting air system is designed by the diesel engine manufacturer. The air compressors and other starting air equipment are provided as a package. As discussed in paragraph 9.5.6.3, a refrigerated air drier is supplied to preclude corrosion in the starting air system. All air piping will be cleaned and blown out prior to engine operation to remove contaminants.

<u>QUESTION 9A.22</u> (NRC Question 430.25) (9.5.6)

Describe the instrumentation, controls, sensors, and alarms provided for monitoring the diesel engine air starting system, and describe their function. Describe the testing necessary to maintain a highly reliable instrumentation, control, sensors, and alarm system and where the alarms are annunciated. Identify the temperature, pressure, and level sensors which alert the operator when these parameters exceed the ranges recommended by the engine manufacturer and describe any operator actions required during alarm conditions to prevent harmful effects to the diesel engine. Discuss system interlocks provided. Revise your FSAR accordingly. (SRP 9.5.6, Part III, Item 1).

RESPONSE: The response is given in amended paragraphs 9.5.6.2 and 9.5.6.6.

<u>QUESTION 9A.23</u> (NRC Question 430.26) (9.5.6)

Provide the source of power for the diesel engine air starting system compressors and motor characteristics, i.e., motor hp,

operating voltage, phase(s), and frequency. Revise your FSAR accordingly.

RESPONSE: The response is given in revised paragraph 9.5.6.3.

QUESTION 9A.24 (NRC Question 430.27) (9.5.7)

For the diesel engine lubrication system in subsection 9.5.7, provide the following information: 1) define the temperature differentials, flowrate, and heat removal rate of the interface cooling system external to the engine and verify that these are in accordance with recommendations of the engine manufacturer; 2) discuss the measures that will be taken to maintain the required quality of the oil, including the inspection and replacement when oil quality is degraded; 3) describe the protective features (such as blowout panels) provided to prevent unacceptable crankcase explosion and to mitigate the consequences of such an event; and 4) describe the capability for detection and control of system leakage. (SRP 9.5.7, Part II, Items 8a, 8b, 8c, Part III, Item 1.)

RESPONSE: The response is given in amended table 9.5-10 and paragraphs 9.5.5.2 and 9.5.7.2.

QUESTION 9A.25 (NRC Question 430.28) (9.5.7)

What measures have been taken to prevent entry of deleterious materials into the engine lubrication oil system due to operator error during recharging of lubricating oil or normal operation? (SRP 9.5.7, Part III, Item 1c).

RESPONSE: The engine lubrication oil system has only one fill connection, which is clearly labeled on the diesel skid. There are no interconnections with other systems, therefore, operator-induced valving errors can be excluded as sources of foreign materials in the lubrication oil system. Additionally, the instruction manual includes a brief description of oil fill procedures.

QUESTION 9A.26 (NRC Question 430.29) (9.5.7)

Describe the instrumentation, controls, sensors, and alarms provided for monitoring the diesel engine lubrication oil system and describe their function. Describe the testing necessary to maintain a highly reliable instrumentation, control, sensors, and alarm system and where the alarms are annunciated. Identify the temperature, pressure, and level sensors which alert the operator when these parameters exceed the ranges recommended by the engine manufacturer and describe any operator action required during alarm conditions to prevent harmful effects to the diesel engine. Discuss systems interlocks provided. Revise your FSAR accordingly. (SRP 9.5.7, Part III, Item 1e).

RESPONSE: The response is given in amended paragraph 9.5.7.3, listing D, and table 9.5-17.

QUESTION 9A.27 (NRC Question 430.30) (9.5.7)

Provide the source of power for the diesel engine prelube oil pump, and lube oil circulation heater and used lube oil tank transfer pump, and motor characteristics, i.e., motor hp,

operating voltage, phase(s), and frequency. Also provide the pump capacity and discharge head. Revise your FSAR accordingly.

RESPONSE: The response is given in amended subsection 9.5.7 and table 9.5-15. No used lube oil transfer pump is provided.

QUESTION 9A.28 (NRC Question 430.31) (9.5.7)

Several fires have occurred at some operating plants in the area of the diesel engine exhaust manifold and inside the turbocharger housing which have resulted in equipment unavailability. The fires were started from lube oil leaking and accumulating on the engine exhaust manifold and accumulating and igniting inside the turbocharger housing. Accumulation of lube oil in these areas, on some engines, is apparently caused from an excessively long prelube period, generally longer than 5 minutes, prior to manual starting of a diesel generator. This condition does not occur on an emergency start since the prelube period is minimal.

When manually starting the diesel generators for any reason, to minimize the potential fire hazard and to improve equipment availability, the prelube period should be limited to a maximum of 3 to 5 minutes unless otherwise recommended by the diesel engine manufacturer. Confirm your compliance with this requirement or provide your justification for requiring a longer prelube time interval prior to manual starting of the diesel generators. Provide the prelube time interval your diesel engine will be exposed to prior to manual start.

RESPONSE: The engine manufacturer has designed the engine prelube system to operate continuously to all engine parts, including the turbocharger.

QUESTION 9A.29 (NRC Question 430.32) (9.5.8)

Describe the instrumentation, controls, sensors, and alarms provided in the design of the diesel engine combustion air intake and exhaust system which alert the operator when parameters exceed ranges recommended by the engine manufacturer and describe any operator action required during alarm conditions to prevent harmful effects to the diesel engine. Discuss systems interlocks provided. Revise your FSAR accordingly. (SRP 9.5.8, Part III, Items 1 and 4).

RESPONSE: The response is given in revised paragraph 9.5.8.2.2.

QUESTION 9A.30 (NRC Question 430.33) (9.5.8)

Provide the results of an analysis that demonstrates that the function of your diesel engine air intake and exhaust system design will not be degraded to an extent which prevents developing full engine rated power or cause engine shutdown as a consequence of any meteorological or accident condition. Include in your discussion the potential and effect of fire extinguishing (gaseous) medium, recirculation of diesel combustion products, or other gases that may intentionally or accidentally be released onsite, on the performance of the diesel generator. (SRP 9.5.8, Part III, Item 3).

RESPONSE: The response is given in paragraph 9.5.8.3, listing A.

QUESTION 9A.31 (NRC Question 430.34) (9.5.8)

Discuss the provisions made in your design of the diesel engine combustion air intake and exhaust system to prevent possible clogging, during standby and in operation, from abnormal climatic conditions (heavy rain, freezing rain, dust storms, ice and snow) that could prevent operation of the diesel generator on demand. (SRP 9.5.8, Part III, Item 5).

RESPONSE: The response is given in amended paragraph 9.5.8.3, listing A.

QUESTION 9A.32 (NRC Question 430.35) (9.5.8)

Show by analysis that a potential fire in the diesel generator building together with a single failure of the fire protection system will not degrade the quality of the diesel combustion air so that the remaining diesel will be able to provide full rated power.

RESPONSE: Each engine has a separate intake and exhaust. Each intake occurs on the same side of the building as its diesel. Each engine is enclosed in a 3-hour resistant fire wall. Assuming a fire in one engine during operation of both engines, the combustion smoke would be discharged out the exhaust vent. Paragraph 9.5.8.3, listing A, states that this exhaust mixture could be directly sucked into the intake and not degrade engine performance. To

prevent suction of exhaust gases, the exhaust is directed vertically upward and released 50 feet above the intake.

QUESTION 9A.33 (NRC Question 430.36) (9.5.8)

Experience at some operating plants has shown that diesel engines have failed to start due to accumulation of dust and other deleterious material on electrical equipment associated with starting of the diesel generators (e.g., auxiliary relay contacts, control switches, etc.). Describe the provisions that have been made in your diesel generator building design, electrical starting system, and combustion air and ventilation air intake design(s) to preclude this condition to assure availability of the diesel generator on demand.

Also describe under normal plant operation what procedure(s) will be used to minimize accumulation of dust in the diesel generator room; specifically, address concrete dust control. In your response also consider the condition when Unit 1 is in operation and Unit 2 is under construction (abnormal generation of dust).

RESPONSE: The diesel engine control panels are located in rooms separated from their respective engine, and are ventilated with filtered air. Any electrical boxes located in the engine room are dust tight. Additionally, the floor of the diesel generator building is treated with a hardener for dust control.

Procedures governing housekeeping that implement the recommendations of Regulatory Guide 1.39 as modified in section 1.8 will be available onsite for NRC review

60 days prior to fuel load. These procedures control the accumulation of dust in the diesel generator rooms and, together with the design features described above, adequately assure the availability of the diesel generators on demand, including when Unit 1 is in operation and Unit 2 is under construction.

Section 4.5.3.1 of the PVNGS Environmental Report Operating License Stage (PVNGS ER-OL) describes the construction dust control program that, when combined with the physical distance between Units 1 and 2, will minimize construction related dust.

QUESTION 9A.34 (NRC Question 281.2) (9.1.3)

For the fuel pool cleanup system, indicate that chemical analyses at least weekly and continuous radiological monitoring will be made for measuring the efficiency of the filters and ion exchange resins to remove impurities and radioactive materials from the pool water. State what criteria (chemical parameters, decontamination factors, etc.) will be used to determine replacement of the filters and ion exchange resins.

RESPONSE: The response is given in amended paragraph 9.1.3.4.

Continuous radiological in-line monitoring is not a requirement for the system as outlined in Regulatory Guide 1.45 (also, see subsection 11.5.1 and table 9.3-3).

<u>QUESTION 9A.35</u> (NRC Question 281.3) (9.3.2)

Describe the provisions to meet the requirements of post-accident sampling of the primary coolant and containment atmosphere. The description should address all the requirements outlined in Section II.B.3 of Enclosure 3 in NUREG-0737 (Clarification of TMI Action Plan Requirements) and should include the appropriate P&IDs. In addition, if gas chromatography is used for reactor coolant analysis, special provisions (e.g., pressure relief and purging) should be provided to prevent high-pressure carrier gas from entering the reactor coolant. With respect to clarification (4) in Section II.B.3 of NUREG-0737, if the chloride concentration in the reactor coolant samples exceeds the limit in the Technical Specification, oxygen analysis will be mandatory. Provide also either (a) a summary description of procedures for sample collection, sample transfer or transport, and sample analysis, or (b) copies of procedures for sample collection, sample transfer or transport, and sample analysis.

RESPONSE: The response is given in amended subsection 9.3.2.

<u>QUESTION 9A.36</u> (NRC Question 460.4) (9.2)

Describe provisions for ensuring that the limits for radioactive concentrations are not exceeded in the demineralized water system and condensate storage facilities.

RESPONSE: Demineralized Water System: This system is nonradioactive and there is no radioactive input to the system. Refer to amended subsection 9.2.3.

Condensate Storage Facilities: This is a nonradioactive system. Refer to amended subsections 9.2.6 and 11.2.2.

QUESTION 9A.37 (NRC Question 460.5) (9.3 and 11.5)

a) Provide continuous process monitoring capability for the spent fuel pool and refueling pool treatment systems.

b) Clarify whether discrete sample analyses provisions are available for both the high and low TDS holdup and monitor tanks.

c) Describe the provisions for monitoring concentrate monitor tank activities.

d) Describe the process sampling provisions for grab sampling iodine in fuel storage area vent system, radwaste area vent system, and the evaporator vent system (these are required by Standard Review Plan, Section 11.5, Rev. 2, "Process and Effluent Radiological Monitoring and Sample Systems," See Table 1A).

RESPONSE:

a) Refer to amended paragraph 9.1.3.2.1.2.

b) Discrete sample capabilities are listed in table 9.3-3 (sheet 10 of 12). Refer to amended paragraph 11.2.2.3.

c) Sample capabilities are described in paragraph 11.2.2.3, and listed in table 9.3-3 (sheet 10 of 12).

d) Continuous iodine collection using a charcoal cartridge will be provided for the fuel building.

The radwaste area and evaporator vent are designed to be grab sampled from the grab sample connection on radiation monitor XJ-SQN-RU-14. Prior to release, the plant vent radiation monitors (XJ-SQN-RU-143 and XJ-SQN-RU-144) continuously collect an iodine sample using a charcoal cartridge. Additionally, areas in the radwaste building may be grab sampled for iodine using a movable airborne monitor.

QUESTION 9A.38 (NRC Question 460.6) (9.4 and 11.3)

Provide a table comparing the design features and radioactivity removal capability of each normal ventilation filter system to each position detailed in Regulatory Guide 1.140, Rev. 1 (October 1979), "Design, Testing and Maintenance Criteria for Normal Ventilation Exhaust System Air Filtration and Adsorption Units of Light-Water-Cooled Nuclear Power Plants." For each item for which an exception is taken, the applicability of the proposed exception should be justified.

RESPONSE: The response is provided in table 1.8-3.

QUESTION 9A.39 (NRC Question 282.1) (9.1.2.3)

Provide fabrication details of the Boral tube inserts to be used in the spent fuel storage pool. Provide details of the kind and thickness of the cladding of the Boral. Explain how exposed Boral matrix (Boron carbide) is protected from the

borated pool water. Describe corrosion protection of the Boral tube.

RESPONSE: The response is given in amended paragraph 9.1.2.2.2.

<u>QUESTION 9A.40</u> (NRC Question 490.4) (9.3.4.5)

A. The process radiation monitor (PRM) is said to be a "trending device to warn the operator of possible fuel failure." Regardless of whether the amount of failed fuel is greater or less than 1%, is the PRM capable of providing an indication of the number of failed rods (e.g., 1 or 2 rods vs. 10 or 50 rods)? Is the reading continuous and direct so that the operator can readily note any potential rapid escalation of failing fuel?

B. The alarm setpoints are adjustable. To what equivalent percent failed fuel or number of failed rods are the setpoints intended to correspond? What action is triggered by the alarms?

C. If the PRM readings indicate the presence of leaking fuel rods during a given cycle, what surveillance will be performed during the next refueling outage to identify the leakers and nature of the damage?

RESPONSE: The response is given in amended section 11.5.

QUESTION 9A.41 (NRC Question 410.7) (9.3.1)

Concerning the compressed air system, provide the following additional information:

a) Describe the means provided to verify that proper instrument air quality will be maintained over the plant life to assure the safety function of the system (i.e., air-operated valves will fail in their safe position on loss of instrument air supply). Include the air quality limits which should not be exceeded in order to assure the above safety function.

b) Verify that a single failure of any air-operated valve to assume its fail safe position will not prevent the function of a safety-related system or compromise the ability to safely shut down.

RESPONSE:

a) The response is given in amended paragraph 9.3.1.5.

b) As there are two independent, 100% capacity trains of safety-related equipment available to perform ESF functions, a single failure in either train will not prevent the function of the other train.

QUESTION 9A.42 (NRC Question 410.8) (9.3.3)

You state in FSAR paragraph 9.3.3.2.1.1.2 that maximum abnormal leakage each ESF sump is estimated to be 50 gallons per minute. What is the basis for this assumption? It is our position that you verify that adequate protection has been provided for safety-related equipment assuming a total pipe rupture for all

nonseismic piping system (such as the fire protection system and nuclear cooling water system) and components (such as tanks) located in safety-related areas. This protection cannot assume credit for non-Seismic Category I sump pumps. Your response should include the time required for operator action if necessary to provide protection of essential equipment once indication from the Class 1E level switches is given.

RESPONSE:

The abnormal leakage of 50 gallons per minute conservatively bounds the total leakage from all ESF components, such as pumps, valves, etc. The auxiliary building is sized to accept 400,000 gallons of non-ESF leakage before any leakage would affect ESF components. For flooding considerations, all nonseismic piping was assumed to have failed. The water volume released will not exceed the design 400,000-gallon capacity. The auxiliary building rooms, including the ESF pump rooms on elevation 40, were analyzed for flooding due to rupture of the largest nonsafety-related piping for a duration of 30 minutes. Flooding was also analyzed based on operation of fire protection systems, such as hoses and sprinklers, for 15 minutes without operator action or without operation of the sump pumps.

<u>QUESTION 9A.43</u> (NRC Question 410.9) (9.3.3)

Engineering drawings 01, 02, 03-M-RDP-002 shows locked closed manual valves on the drain lines from both essential auxiliary feedwater system (AFS) pump rooms in the main steam support

structure. Describe the purpose of the valves and the means provided to prevent loss of function of the essential AFS pumps as a result of internal flooding.

RESPONSE: Refer to engineering drawings 01, 02, 03-M-RDP-002.

<u>QUESTION 9A.44</u> (NRC Question 410.10) (9.4)

Verify that the CESSAR interfaces for environmental conditions for equipment within the C-E scope of supply have been satisfied by the Palo Verde HVAC system designs.

RESPONSE: The CESSAR interfaces have been met by the HVAC system.

<u>QUESTION 9A.45</u> (NRC Question 410.11) (9.4)

FSAR table 9.4-1 identifies the weather conditions within the site area which serve as the design basis for HVAC system sizing based on ASHRAE data to 1972. Verify that weather conditions since 1972 have not resulted in the need to modify HVAC system designs in order to meet the environmental qualification limits for plant areas containing safety-related equipment.

RESPONSE: The design basis for HVAC systems used to meet environmental qualification envelope parameters is that the limits be met under outside air conditions of 113F dry bulb, 76F wet bulb. Comparison of actual site and Phoenix data since 1972, as shown in tables 2.3-8 and 2.3-9 with data obtained prior to 1972 (refer to table 2.3-11),

indicates that weather conditions have not become more severe.

QUESTION 9A.46 (NRC Question 410.12) (9.4)

Describe the measures provided for detecting and correcting dust accumulation on safety-related equipment in order to assure their availability on demand.

RESPONSE: PVNGS has developed a housekeeping program on equipment throughout the plant. Safety-related equipment is included in this program. The program provides for the periodic inspection and cleaning of equipment and will be a part of the preventative maintenance program.

QUESTION 9A.47 (NRC Question 410.13) (9.4)

Describe the affect on the safety function of the essential HVAC systems in the event of a single failure in a fire damper in the ventilation system ducts. It is our position that such a failure not compromise the safety function of the HVAC system.

RESPONSE: A single fire damper failure (actuation) in one ESF ventilation train will render that train inoperable. As another redundant 100% capacity ESF ventilation train is provided, there will be no adverse effect upon the safety function of essential ventilation. Also see engineering drawings 01, 02, 03-M-HJP-001, -002, and 01, 02, 03-M-HFP-001.

QUESTION 9A.48 (NRC Question 410.14) (9.4.1)

FSAR subsection 9.4.1 indicates that emergency ventilation is not provided for the upper and lower cable spreading room. Verify that safe operating conditions for essential equipment are maintained in these rooms during all accident modes (including long term plant cooldown). If this cannot be demonstrated, provide a safety grade means of indication of the conditions in these rooms with sufficient time for operator action to provide the necessary temporary cooling, or provide a safety-related emergency cooling system for these rooms.

RESPONSE: The response is given in amended subsection 9.4.1.

QUESTION 9A.49 (NRC Question 410.15) (9.4.1)

In the event of indication of radioactive contamination of the normal control room intake, the normal ventilation system is shut off and isolated as the essential control room system is started. However, the control building normal air handling unit or essential ESF switchgear room air handling unit (if operating) would continue to function and circulate potentially contaminated air to other areas of the control building. Describe the measures provided to prevent contamination of vital areas of the control building and still assure a proper environment for operation of essential equipment.

RESPONSE: The response is given in amended paragraph 9.4.1.2.1.1.

QUESTION 9A.50 (NRC Question 410.16) (9.4.1)

Expand table 9.4-4, "Single Failure Analysis for the Essential ESF Switchgear, ESF Equipment and Battery Rooms" to include the consequences of failure of any system component. This analysis should verify that a single failure in any safety-related damper or total failure of all nonsafety-related dampers and ducts in the ESF switchgear, ESF equipment and battery rooms HVAC system will not prevent at least one train of the essential ESF switchgear room HVAC system from performing its safety function.

RESPONSE: The response is provided in amended table 9.4-4.

QUESTION 9A.51 (NRC Question 410.17) (9.4.1)

Describe the measures for assuring a proper operating environment for essential control room and ESF switchgear room air handling units when the normal control building HVAC system is not available in emergency conditions.

RESPONSE: The response is given in amended subsection 9.4.1.

QUESTION 9A.52 (NRC Question 410.18) (9.4.1)

Verify that the control room HVAC air intake chlorine and radiation monitors are Seismic Category I.

RESPONSE: Control room HVAC air intake chlorine and radiation monitors are Seismic Category I.

<u>QUESTION 9A.53</u> (NRC Question 410.19) (9.4.1)

The essential fuel building and auxiliary building exhaust units serve only those auxiliary building equipment areas located below elevation 100 feet 0 inch. The charging pumps, letdown heat exchangers, and other CVCS equipment which contain radioactive fluid are located above the 100 foot 0 inch elevation. Describe the means provided for detecting potential radioactivity in these rooms under emergency conditions when the normal HVAC system is not available, and isolating them prior to release of unacceptable airborne contamination to the environment.

RESPONSE: There are three methods available to detect potential airborne radioactivity in the upper levels (above elevation 100 feet 0 inch) of the auxiliary building when normal HVAC is not operable:

- Noble gas monitor 13-J-SQN-RU-9 (see section 11.5)
- Fixed and portable area radiation monitors.

There is, however, little likelihood that airborne contamination due to leakage from the CVCS could be released at unacceptable levels. The use of the CVCS under post-accident conditions is not required. Before it could be used, non-Class 1E power or manual actions would have to be available. As two normal HVAC filtration units are provided on different non-Class 1E buses, it is reasonable to expect that at least one train of filtration could be placed in operation prior to use of the CVCS. Under this alignment, the auxiliary building upper level

(13-J-SQN-RU-10), auxiliary building ventilation exhaust inlet (13-J-SQN-RU-8), and plant vent (13-J-SQN-RU-143 and 13-J-SQN-RU-144) radiation monitors can also be used to monitor exhaust concentrations.

Without the HVAC system in operation, there would be no driving force for release, and, therefore, exfiltration rates would be low. If use of the CVCS is required without the availability of HVAC filtration, radiation monitoring will be required to ensure and confirm that unacceptable releases do not occur.

QUESTION 9A.54 (NRC Question 410.20) (9.4.2)

Describe the means provided for assuring the proper operating environment under normal and emergency conditions for the essential spray pond pumps in order to assure the availability of the ultimate heat sink.

RESPONSE: The spray pond pumphouse (both train A and train B) are cooled by ventilation air. Refer to amended subsection 9.4.8.

QUESTION 9A.55 (NRC Question 410.21) (9.4.2 and 9.4.5)

Describe the interaction in the essential fuel building and auxiliary building exhaust air handling units operation when they are being utilized for emergency operation for processing fuel building air and auxiliary building air before release to the environment. Specifically:

(a) Does continued operation of the normal fuel handling building ventilation system in the event of a safety

injection actuation result in potential contamination of the fuel building environment when the essential exhaust unit is processing contaminated auxiliary building air?

(b) Does contaminated fuel building air enter the auxiliary building through the interconnecting tunnel in the event of a fuel handling accident?

RESPONSE:

(a) No, the systems are separated up to the exhaust plenum.

(b) No, dampers HFA-M06 and HFB-M06 close on fuel building essential ventilation actuation signal (FBEVAS).

QUESTION 9A.56 (NRC Question 410.22) (9.4.3)

Describe the means provided for isolating the radwaste building ventilation system following a design basis event (such as a SSE) in order to prevent the release of potentially radioactive airborne contaminants through building openings.

RESPONSE: The radwaste building ventilation system will be automatically tripped following loss of offsite power. It can be manually tripped after any other design basis event. As noted in paragraph 15.7.3.5, dose consequences from the instantaneous unfiltered release of the contents of one waste gas decay tank will be less than 1% of 10CFR100 limits. Accordingly, isolation of radwaste building ventilation is not required.

APPENDIX 9A

QUESTION 9A.57 (NRC Question 410.23) (9.4.5)

Describe the means provided for assuring the proper operating environment for the spent fuel pool cooling pumps and thereby assure the safety of the spent fuel pool, when the normal fuel building HVAC system is isolated in a fuel handling accident, or not available due to a loss of offsite power.

RESPONSE: Infiltration of air to replace that being exhausted by the essential system will provide adequate cooling. The essential system is available during a fuel handling accident or a loss of offsite power.

QUESTION 9A.58 (NRC Question 410.24) (9.4.6)

Verify that loss of the normal main steam and feedwater penetration HVAC supply and exhaust system in the main steam support structure in an emergency situation will not result in an environment detrimental to essential equipment in the MSSS.

RESPONSE: MSSS does not require forced ventilation to maintain the equipment qualification profile noted in Appendix A of the Equipment Qualification Program Manual.

QUESTION 9A.59 (NRC Question 281.7) (9.1.3)

Your response to our previous Question 281.2 did not indicate any chemical or radionuclide limits for initiating replacement of filters and ion exchange resins. It is our position that chemical and radionuclide limits in the spent fuel pool water, such as conductivity, gross gamma and iodine activity, demineralizer differential pressure, pH, and crud level, are

needed for initiating corrective action to enable safe operating conditions in the pool. Verify that you will meet this position and provide the above information.

RESPONSE: The response is given in the amended response to Question 9A.34 (NRC Question 281.2).

QUESTION 9A.60 (NRC Question 281.8) (9.3.2 and 18.II.B.3)

Provide information that satisfies the attached proposed license conditions for post-accident sampling.

NUREG-0737, II.B.3 - Post-Accident Sampling Capability

REQUIREMENT

Provide a capability to obtain and quantitatively analyze reactor coolant and containment atmosphere samples, without radiation exposure to any individual exceeding 5 rem to the whole body or 75 rem to the extremities (GDC 19) during and following an accident in which there is core degradation. Materials to be analyzed and quantified include certain radionuclides that are indicators of severity of core damage (e.g., noble gases, iodines, cesiums, and nonvolatile isotopes), hydrogen in the containment atmosphere and total dissolved gases or hydrogen, boron and chloride in reactor coolant samples in accordance with the requirements of NUREG-0737.

To satisfy the requirements, the applicant should (1) review and modify his sampling, chemical analysis, and radionuclide determination capabilities as necessary to comply with NUREG-0737, II.B.3, and (2) provide the staff with information

pertaining to system design, analytical capabilities, and procedures in sufficient detail to demonstrate that the requirements have been met.

EVALUATION AND FINDINGS

The applicant has committed to a post-accident sampling system that meets the requirements of NUREG-0737, Item II.B.3 in Amendment, but has not provided the technical information required by NUREG-0737 for our evaluation.

Implementation of the requirement is not necessary prior to low power operation because only small quantities of radionuclide inventory will exist in the reactor coolant system and, therefore, will not affect the health and safety of the public. Prior to exceeding 5% power operation, the applicant must demonstrate the capability to promptly obtain reactor coolant samples in the event of an accident in which there is core damage consistent with the conditions stated below:

1. Demonstrate compliance with all requirements of NUREG-0737, II.B.3, for sampling, chemical and radionuclide analysis capability, under accident conditions.

2. Provide sufficient shielding to meet the requirements of GDC 19, assuming Regulatory Guide 1.4 source terms.

3. Commit to meet the sampling and analysis requirements of Regulatory Guide 1.97, Rev. 2.

4. Verify that all electrically powered components associated with post-accident sampling are capable of

being supplied with power and operated, within 30 minutes of an accident in which there is core degradation, assuming loss of offsite power.

5. Verify that valves which are not accessible for repair after an accident are environmentally qualified for the conditions in which they must operate.

6. Provide a procedure for relating radionuclide gaseous and ionic species to estimated core damage.

7. State the design or operational provisions to prevent high pressure carrier gas from entering the reactor coolant system from online gas analysis equipment, if it is used.

8. Provide a method for verifying that reactor coolant dissolved oxygen is at <0.1 ppm if reactor coolant chlorides are determined to be ≥ 0.15 ppm.

9. Provide information on (a) testing frequency and type of testing to ensure long term operability of the post-accident sampling system, and (b) operator training requirements for post-accident sampling.

In addition to the above licensing conditions, the staff is conducting a generic review of accuracy and sensitivity for analytical procedures and online instrumentation to be used for post-accident analysis. We will require that the applicant submit data supporting the applicability of each selected analytical chemistry procedure or online instrument along with documentation demonstrating compliance with the licensing conditions 4 months prior to exceeding 5% power operation, but

review and approval of these procedures will not be a condition for full-power operation. In the event our generic review determines a specific procedure is unacceptable, we will require the applicant to make modifications as determined by our generic review.

RESPONSE: See amended paragraph 9.3.2.2, tables 9.3-3, 9.3-4, and response to 18.II.B.3.

QUESTION 9A.61 (NRC Question 440.85) (18.II.K.3.25)

Your response to Item II.K.3.25 of NUREG-0737 states that the reactor coolant pump normal cooling water system (nonsafety grade nuclear cooling water system) is backed up by the essential cooling water system during loss of offsite ac power. Describe the manual action involved and the manual action time required for transferring the cooling water supplies. Also, state that your operating procedure allows enough time to restore the cooling water supplies to the RCP seals before you trip the RCPs. After the RCP trip, you may still need essential cooling water supply to the RCP seals.

RESPONSE: The response is given in subsection 18.II.K.3.25.

QUESTION 9A.62 (FPER Question 1) (9B.2)

Certain assumptions used in your fire hazard analysis are unacceptable. It is our position that reliance on the following items in your fire hazard analysis is not justifiable or applicable, namely:

(a) The use of Table 6-8A from the NFPA, Fire Protection Handbook, 14th Edition, as a basis for the duration of a fire as a function of combustible loading for various types of combustibles, and

(b) The assumption that the fire duration in all areas can be based on oxygen depletion, since a single failure of a fire damper or in the ventilation system could negate this assumption.

Revise your fire hazard analysis and conclusions based on deleting these assumptions from the original analysis.

RESPONSE:

(a) Appendix 9B states that "presently there is no test or analytical data to completely explain the combustion of plastic or oil in a typical nuclear power plant compartment." Appendix 9B only uses National Fire Protection Association (NFPA) Handbook curves (Table 6-8A) and T. Z. Harmathy curves as a state-of-the-art guide and description of one of many possible sets of fire events.

The fire evaluation for any given compartment considers the ability of the fire barriers to withstand the maximum heat release of a "flashover" fire with respect to the American Society of Testing Materials (ASTM) Standard E119 (1976) time-temperature fire curve and the various influences that are related to this particular fire. The report uses several of these rough yardsticks, as they

relate to the time-temperature curve, without completely depending on any one of them.

(b) The analysis regarding oxygen depletion is not used to determine the rating of fire barriers. Refer to the revised fire hazards analysis of appendix 9B.

QUESTION 9A.63 (FPER Question 2) (9B.2)

On Page II-3[a] under Item A.1.e.(3)[a], "Fire Suppression Systems/Safety Equipment Protection,"[a] as well as in other areas of the fire hazard analysis, you state that "there will be no inadvertent operation, careless operation, or rupture of extinguishing equipment." This statement does not comply with Appendix A, BTP 9.5-1, Section A.5, which states that "failure or inadvertent operation of the fire suppression system should not incapacitate safety-related systems or components." State that you will comply with this position.

RESPONSE: The statement has been deleted from the amended fire hazards analysis; the consequences of inadvertent operation of, or a crack in, a moderate energy line in the fire suppression system will meet the guidelines of BTP ASB 3-1 as indicated in the amended section 9B.3 response to BTP APCSB 9.5-1, Appendix A, Section A.5.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.64 (FPER Question 3) (9B.2)

On Pages II-90[a], II-93[a], and in other areas of the fire hazard analysis, you do not list the cables as a combustible. Complete the fire hazard analysis in those areas to include cables as a combustible.

RESPONSE: Cable that is not enclosed in conduit is considered as a combustible in the revised fire hazards analysis.

QUESTION 9A.65 (FPER Question 4) (9B.3)

Appendix A of BTP 9.5-1, Section E.3(d), states that for interior firefighting, at least one hose stream with a maximum hose length of 75 feet should be capable to reach the fire location. State that your design complies with this position.

RESPONSE: The PVNGS design complies except as noted in the response to Question 9A.115.

QUESTION 9A.66 (FPER Question 5a) (9B.3)

Page III-3[a], Item A.4: Describe the provisions that will be provided to prevent lightning from initiating fires which could damage safety-related equipment or fire protection equipment.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: The design of lightning protection for the structures is in accordance with the Underwriter's Laboratory Standard UL96A, 1964. All startup transformers and main transformers and 13.8 kV switchgear are protected with appropriate lightning arrestors. This protection eliminates or drastically reduces the surges from entering the protective equipment.

<u>QUESTION 9A.67</u> (FPER Question 5b) (9B.3)

Page III-3[a], Item A.4: Meet the position of Appendix A, Section A.5, which states that with only one of the fire pumps operating, the maximum water demand of any water spray or sprinkler system plus a demand of 750 gal/min for hand hose use is met.

RESPONSE: Refer to the response provided in amended table 9B.3-1, Sections E.2.(c) and E.2.(e).

<u>QUESTION 9A.68</u> (FPER Question 6) (9B.3)

Page III-12[a], Item D: For the following listed items, substantiate their fire resistance capabilities as they pertain to safety-related areas or high hazard areas by verifying that their construction will be in accordance with a particular fire-tested design. Identify the design, test method, and acceptance criteria.

a. Rated fire barriers including floor, ceiling, wall systems, structural members, and doors. Indicate the type

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

of protective material used and the design number in reference to ASTM Standard E119.

b. Fire dampers and fire doors, including the installation of the same in ventilating ducts penetrating fire barriers of safety-related areas; fire door dampers are required in a 3-hour rated fire barrier penetrations.

c. Fire barrier penetration seals around ducts, pipes, cables, cable trays, and conduit or any other openings. Verify that the seals will be the 3-hour requirements for ASTM E119 or other acceptable tests. Verify that the in-plant cable tray supports are similar to the ones used in the fire tests and that, in case of collapse of the trays, the resultant unsupported load and torque on the penetration seal will not affect the integrity of the seal.

d. Item D.1(e): Identify any safety-related area where noncombustible metal deck roof will be used and indicate how the 3-hour fire rating will be met to comply with Appendix A, BTP 9.5-1.

RESPONSE: The design, construction, test method, and acceptance criteria for the above items are as follows:

a. Fire-Rated Barriers

Structural concrete walls and floor thicknesses exceed the fire barrier requirements and, where applicable, are identified as fire barriers in order to ensure that penetrations are of equal rating.

Structural steel members, where required, are protected by spray-on fireproofing systems listed in the Underwriter's Laboratories Fire Resistance Directory (ULFRD) for the appropriate hourly ratings for beams and columns. Other structural steel members, where required, are protected by water suppression systems. (Refer also to the responses to Questions 9A.107, 9A.108, and 9A.110).

Acoustical or plaster ceilings and plaster walls are constructed in accordance with the appropriate design system listed in the ULFRD.

Depending on the manufacturer's product used, the following ULFRD designs or equivalents are used:

(1) Plaster partitions

UBC Table 43B No. 61 - 3 hours
U-409 - 1 hour

(2) Plaster ceilings

G519 - 1 hour where required

(3) Acoustical ceilings

G036 - 1 hour concealed suspension system
G204 - 1 hour exposed suspension system

(4) Fireproofing

X701 for columns
N706 for beams

(5) Doors and frames will bear the appropriate UL or FM fire rating label.

(6) Floors and roof slabs exceed minimum required thicknesses for structural reasons. No UL design is applicable.

(7) Gypsum board partitions

U-411 (UBC Table 43B No. 71) - 2 hours

(Refer to the response to Question 9A.109).

b. Fire Dampers and Fire Doors

Test method and acceptance criteria for dampers are in accordance with UL 555-79. Typically, the devices carry the UL label and are installed in sleeves which are attached to the duct work and supported by the walls. The devices are positioned between the two wall surfaces. A failure of the duct on either side will not violate the fire barrier. There are a few cases where the damper is not installed in the tested configuration. The dampers are mounted off the centerline of the wall or on the surface of the wall and are supported in part or totally by structural steel attached to the fire wall. Following is a fire protection evaluation of the areas where surface-mounted dampers are installed:

(1) Control Building

(a) Dampers installed on the interior wall of the HVAC shafts (2-hour shaft with 1-1/2-hour dampers) are exposed to no combustible load.

(b) Dampers installed on the exterior wall of the HVAC shafts are in fire zones with detection and automatic suppression systems (CO_2 or water). This would mitigate the effects of fire and limit the heat exposure. The duct supports are seismically designed and, therefore, are of substantial steel construction. They would withstand a design basis fire with automatic suppression.

(c) There is one surface-mounted damper at the 74-foot level (essential chiller room) of the control building in the 3-hour rated central wall. The total combustible (fire) loading in this fire zone (No. 1) is low and consists primarily of charcoal filters located about 40 feet away. This calculated fire severity is very conservative because it contains an allowance for transient charcoal sufficient to completely fill the filter. Smoke detection is installed in the room for early warning. This installation provides reasonable assurance that a fire will not propagate through the wall. On the other side of the damper is a 2-hour rated concrete soffit containing no combustibles. There is no direct communication with the adjacent fire area.

(2) Auxiliary Building

(a) Zone 37A corridor, 70-foot level. There is one surface-mounted damper in a 1-hour rated portion of a concrete wall. The total combustible (fire) loading is low and there is smoke detection installed in the zone for early warning. Spatial separation on either side of the wall between redundant safe shutdown equipment is approximately 60 feet total, with no intervening combustibles. This installation provides adequate separation and protection of safe shutdown equipment.

(b) Zone 52A corridor, 120-foot level. There is one surface mounted damper in a 1-hour rated portion of a concrete wall. The total combustible (fire) loading is moderate and consists primarily of cable trays protected by an automatic detection and water suppression system. Redundant safe shutdown equipment is also separated by approximately 80 feet to that located in zone 52D. This installation provides adequate separation and protection of safe shutdown equipment.

Based upon the above analysis of fire hazards, equipment separation, and fire suppression systems available, the surface mounted dampers in these areas

will provide adequate protection without fireproofing.

Typically, 3-hour dampers are used in 3-hour walls and 1-1/2-hour dampers are used in 2-hour and 1-hour walls. The fire dampers purchased for PVNGS are all of identical material and constructed to 3-hour standards. Where exact replication of a tested configuration cannot be achieved, the installation will meet the following criteria:

1. The continuity of the fire barrier material shall be maintained.
2. The thickness of the barrier shall be maintained.
3. The nature of the support assembly shall be unchanged from the tested configuration.
4. The application or "end use" of the fire barrier shall be unchanged from the tested configuration.
5. The configuration shall be reviewed by a qualified fire protection engineer and found to provide an equivalent level of protection.

(Refer to the response to Question 9A.108).

Class A doors are used in 3-hour fire walls, Class B doors are used in 2-hour fire walls, and Class C doors are used in 1-hour fire walls. (Refer to the response to Questions 9A.106).

c. Fire Barrier Penetration Seals

Testing and acceptance criteria are as specified in ASTM Standard E119 (1976) or IEEE-634 (1978). Seals are typically installed in the same manner as tested. Where exact replication of a tested configuration cannot be achieved, the installation will meet the following criteria:

1. The continuity of the fire barrier material shall be maintained.

2. The thickness of the barrier shall be maintained.

3. The nature of the support assembly shall be unchanged from the tested configuration.

4. The application or "end use" of the fire barrier shall be unchanged from the tested configuration.

5. The configuration shall be reviewed by a fire protection engineer and found to provide an equivalent level of protection.

Quality assurance, quality control, and other measures are made to ensure that the actual installation conforms to the specified requirements. The cable trays are supported by tray supports located close to the wall penetration to increase the reliability and integrity of the raceway system in case of fire. Consequently, the penetration seals will not be affected due to unsupported load. (Refer to the response to Question 9A.110.)

d. Metal Deck Roof

All roof slabs in safety-related areas are of structural concrete. Structural thickness exceeds the 3-hour fire separation requirements.

<u>QUESTION 9A.69</u> (FPER Question 7) (9B.3)

Page III-15[a], Item D.1.(i): Verify that the floor drains are of adequate size to handle any run-off from any water type fire protection and hand hose system. In areas without drains, analyze the effects of standing water and water seepage through any openings in the floors onto safety-related equipment.

Describe protection to be provided for any equipment susceptible to water damage.

RESPONSE: Refer to the response provided in amended table 9B.3-1, Section D.1.(i).

<u>QUESTION 9A.70</u> (FPER Question 8) (9B.3)

Page III-20[a], Item D.4.(a): Appendix A states that the products of combustion should be removed from the fire area and the removal should be controlled, monitored, and directed outside. Describe for your plant how heat, smoke, and toxic fumes will be removed from safety-related fire areas using either fixed or portable air handling units. Describe how exhaust and makeup air would be provided to achieve adequate air movement. Where portable air handling equipment is used, describe the route that would be used to reach the exterior,

---

a. Page references are no longer applicable due to FPER reformatting for FSAR amendment 13.

considering the reduction of rated fan capacity due to duct length, time requirement in placing units into operation, and the ability to handle fire temperature gases. For areas where the ventilation system will be used, describe the access to and location of controls.

RESPONSE: The products of combustion, smoke, and gases will be removed from the safety-related zones and areas by means of portable smoke removal equipment.

In general, a fire floor or area will be exhausted to the outside, utilizing portable smoke removal equipment.

A. Auxiliary and Radwaste Buildings

The smoke will, in case of fire, be removed from the fire area by use of portable smoke removal equipment.

1. The fire department, with self-contained breathing apparatus and the smoke ejectors, will go to the fire area or room. The ejector along with flexible ducts will be placed so as to exhaust the smoke from the fire area to the outside.

   The smoke can be exhausted to outside through stairwells and opening on top of the stairwells.

The portable smoke ejectors are designed to withstand smoke and temperatures encountered for fire department operation.

The makeup air would partly be supplied by opening the appropriate outside doors.

B. Control Building

Smoke in the control building will be removed by the portable smoke removal equipment. The smoke will be vented to the outside either directly, or through HVAC chase or through stairwells. The fresh air is obtained by opening missile doors or stairwell doors or through corridor building.

C. Fuel Building

The fuel building is a large, open structure, where the smoke and hot air will seek to the ceiling or the space under the roof and the smoke will be exhausted by use of normal HVAC system, when it is available. Smoke from selected enclosed compartments will be exhausted by use of portable smoke removal equipment.

<u>QUESTION 9A.71</u> (FPER Question 9) (9B.3)

Page III-23[a]:

a. Item C.1: Verify that the complete fire alarm system, valve supervision and waterflow indication will conform to the following established standards: NFPA 72D (Class A systems), and NFPA (Class I circuits) including standby power.

b. Item C.2: Provide a plot plan showing the underground water supply, tanks, reservoirs, hydrant locations, and sectional control valves. Also, provide diagrammatic plans showing the water supply throughout the plant

a. Page references are no longer applicable due to FPER reformatting for FSAR amendment 13.

showing all valves, hose stations, headers, standpipes, sprinkler systems, and the location of fire pumps and piping.

RESPONSE:

a. The PVNGS design for the fire alarm system uses NFPA 72D (1975) (Class A systems) and NFPA 70 (1975) (Class I circuits as guidance in the containment building only and Class B systems in other buildings.

   The PVNGS design for fire alarm systems is as follows:

   1. Detection Systems

      a. Detectors to panel (Class A)

      b. Panels to concentrator (Class B)

      c. Secondary power supplies in safety-related areas are designed in accordance with NFPA 72D (1975), Paragraph 2223, except for panel 1JQKNE10D which serves the 140-foot elevation of the auxiliary building. The 140-foot elevation of the auxiliary building is normally occupied, and portable fire extinguishers and manual hose reels are provided.

   2. Detection Systems Actuating Water Suppression Systems

      a. Detector to panel (Class B) two independent detection circuits, protectowire, and smoke

detectors are provided in safety-related areas except containment spray (CS), high-pressure safety injection (HPSI), and low-pressure safety injection (LPSI) pump rooms. These rooms are separated from the remainder of the auxiliary building by 3-hour rated fire barriers.

b. Panels to concentrator (Class A) for safety-related areas except containment spray, HPSI, and LPSI pump rooms.

c. Secondary power to meet NPFA 72D (1975) Paragraph 2223

d. Panels to concentrator (Class B) for nonsafety-related areas.

b. See figure 9B-7 (formerly FPER Figure 30), which shows the underground water supply, tanks, reservoirs, hydrant locations, and sectional control valves. The PVNGS fire protection P&IDs 01, 02, 03-M-FPP-002, -003, -004, -006 and A0-M-FPP-001 and -005 showing all valves, hose stations, headers, standpipes, and sprinkler systems.

QUESTION 9A.72 (FPER Question 10) (9B.3)

Page III-25[a], Fire Pump Rooms: Item C.2.(c): State that you comply with the position in Appendix A which requires the fire pumps be separated from each other and adjacent areas by a 3-hour rated barrier, and the installation of automatic sprinklers over the diesel fire pumps be in accordance with NFPA 20. Also, verify that individual alarms are provided for each pump.

RESPONSE: The fire pump arrangement at PVNGS is designed such that each of the three fire pump units are isolated from each other by 2-hour fire walls, and each diesel pump room is protected per NFPA 20 (1976) by a wet pipe sprinkler system installed per the guidance of NFPA 13 (1976).

Further separation of the diesel-driven units is accomplished by "spatial separation," in that the motor-driven fire pump is located between the rooms containing the diesel units.

No significant combustible loading is located within the motor-driven pump room. The diesel fuel oil storage tanks are located outside the diesel pump rooms at opposite sides of the building.

Individual alarms are provided for each pump as described in the PVNGS position to BTP APCSB 9.5-1, Appendix A, Section E.2.(c).

a. Page references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.73 (FPER Question 11) (9B.3)

Page III-15[a], Item D.1.(j): Certain areas, such as zones 37A and 37B (formerly zone 37A), 42C, 48, 52, 54 and 74A and 74B (formerly zone 74), housing redundant systems, deviate from the guidelines in BTP 9.5-1, Appendix A, which provide for fire barriers with a minimum 3-hour rating for protection of safety-related equipment. Therefore, in areas where redundant safety-related systems are exposed to a single fire hazard, describe the fire barrier, including fire resistance rating with reference to ASTM E119 test data, which will be provided for the protection of the redundant systems or cables.

RESPONSE: Components are protected with a noncombustible radiant energy shield or protective coating for the purpose of meeting the separation requirements of 10CFR50, Appendix R, Section III.G. Refer to the revised fire hazards analysis of section 9B.2 and the responses to Questions 9A.92, 9A.94, and 9A.95.

QUESTION 9A.74 (FPER Question 12) (9B.1)

Provide drawings showing the routing of cables serving the essential safe shutdown systems and equipment. Identify their function and show the routing to each piece of equipment from power source, control room, and remote shutdown panel. The drawings should show the minimum physical separation distance and/or barriers between redundant electrical circuitry and cable routings for each applicable system and/or component.

---

a. Page references are no longer applicable due to FPER reformatting for FSAR amendment 13.

Control instrumentation, and motive power cable routings, should be included.

Verify that there are no significant electrical differences between the Unit 1 systems and/or components essential to achieve and maintain a safe shutdown to those of Units 2 and 3, or explicitly define and justify those differences.

RESPONSE: The following drawings of nuclear safety-related conduit and cable tray routings have been submitted separately:

A. Control Building

   1. 13-E-ZJC-001 through -004

   2. 13-E-ZJC-033 and -034

B. Auxiliary Building

   1. 13-E-ZAC-001 through -008

   2. 13-E-ZAC-010 through -013

   3. 13-E-ZAC-015 through -018

   4. 13-E-ZAC-065 and -066

C. Containment Building

   1. 13-E-ZCC-007 through -012

   2. 13-E-ZCC-041, -042, and -045

D. Fuel Handling Building

   1. 13-E-ZFC-001 and -002

E. Legend Sheet

1. 13-E-ZAC-050

These drawings show the routing of Channels A, B, C, and D raceways.

The safety-related aspects of Units 1, 2, and 3 are functionally identical, and differ only in minor field installation details. (Refer also to the response to Question 9A.92).

<u>QUESTION 9A.75</u> (FPER Question 13) (9B.1)

Identify any safety-related systems which are disabled by initiation of a fire protection system, either by a direct interlock or as a result of the application of extinguishing agents.

RESPONSE: There are no interlocks between fire suppression system and safety-related systems. Application of extinguishing agents cannot disable more than one train of a safety-related system.

<u>QUESTION 9A.76</u> (FPER Question 14) (9.5.1)

Describe the communication used between the plant fire brigade and the control room during a fire situation.

RESPONSE: There are many available, generally independent means of communication provided to the control room for communication with the fire department, including the plant two-way radio system, the plant telephone, sound powered phone system, face to face, and public address

systems. All of these may be used for communication between the plant fire department and the control room during a fire situation, if they are available. However, only the two communication systems listed below are necessary to allow all required communication between the plant fire department and the control room during a fire situation.

A. The plant two-way radio system, which establishes communication between the fixed and portable radios carried by plant personnel and fire department members outside the control room.

B. Sound-powered phone system

QUESTION 9A.77 (FPER Question 15) (9B.1 and 9B.2)

Identify those Class 1E electric systems and components required for achieving cold shutdown, including circuits emanating from independent power divisions which are spacially separated to satisfy independence criteria. In each case either demonstrate the capability of the design to withstand a single fire event, including exposure fire without loss of function, or modify the design accordingly. Also demonstrate that the plant can be brought to a safe cold shutdown in the event of loss of offsite power.

Supplement the information which has been provided to include all systems and components such as instruments and controls which are essential to achieve and/or maintain cold shutdown (safe shutdown). Also, identify any of these systems and/or components whose electrical circuitry and/or cables are not redundant.

RESPONSE: 10CFR50, Appendix R, has substantially clarified the scope of this question. For discussion of this issue, refer to sections 9B.1 and 9B.2.

QUESTION 9A.78 (FPER Question 16a) (9B.2)

Control Building

Page II-3[a], Item A.1.c.(2)[a] and Page II-7[a], Item A.2.c.(2)[a]: You state that two Class B and one Class A rated doors are in the rated fire barriers. Engineering drawing 13-A-ZYD-029 (formerly FPER Figure 1) shows three unlabeled doors in fire zone 1 and fire zone 2. Verify that the Class A rated fire door is installed in the 3-hour fire barrier between the essential chiller rooms, zones 1 and 2.

RESPONSE: Refer to the revised fire hazards analysis presented in section 9B.2.

QUESTION 9A.79 (FPER Question 16b) (9B.2)

Control Building

Page II-3[a], Item A.1.f[a] and Page II-3[a], Item A.2.f[a]:

(1) For the 3-hour rated outside air supply plenum shown in engineering drawing 13-A-ZYD-029 (formerly FPER Figure 1), describe how the outside air is supplied to chillers in zones 1 and 2, and verify that the soffit at elevation 91 feet 0 inch has a 3-hour rating.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

(2) Verify that the controls for manual smoke exhaust systems for fire zones 1 and 2 will be located outside the fire zones.

(3) Verify that you comply with the guidelines of Appendix A, BTP 9.5-1, Section D.1.(j), which require that the ventilation openings from the plenum and soffit as well as the ventilation openings at the floor and ceiling are cut off by 3-hour fire doors or dampers throughout the control building. Justify any deviation in your design from the guidelines of Appendix A.

RESPONSE:

(1) Outside air is supplied through the vertical chase to the 2-hour rated soffit plenum located at elevation 91 feet 0 inch in zone 2. The 3-hour rated horizontal concrete duct directs the outside air supply to the train A HVAC equipment located in fire zone 1. A 3-hour fire damper is provided at the concrete duct penetration into fire zone 1 at the column line JC wall. Sheet metal HVAC ducting directs the outside air supply from the plenum to the train B HVAC equipment located in fire zone 2 and to the normal HVAC equipment located in fire zones 1 and 2. These HVAC ducting connections to the soffit plenum are provided with 1-1/2-hour rated fire dampers and the outside air supply to the normal HVAC equipment ducting is also provided with 3-hour fire dampers at the column line JC wall penetrations.

(2) The smoke from fire zone 1, train A essential chiller room, and fire zone 2, train B, essential chiller room, will be removed by use of portable smoke removal equipment. Hence the controls for portable smoke removal equipment will be outside the fire zones 1 and 2. In case the existing fixed smoke removal system is available and could be used for smoke removal, it is controlled from the control room at elevation 140 feet and thus from a location outside the space. Only portable equipment, however, is relied on for smoke removal capability.

(3) Three-hour rated fire dampers and fire doors are provided to separate the train A and B equipment located in zones 1 and 2, respectively. The outside air supply chase is not safe shutdown related. The fire area boundary is located at the column line JC wall (zone 1 to zone 2 boundary) and does not include the outside air shaft.

QUESTION 9A.80 (FPER Question 16c) (9B.2)

Control Building

Page II-13[a], Item A.3.f[a]: You state that there is no ventilation provided in the cable shafts for train A and train B (fire zones 3A and 3B [formerly zone 3] in engineering drawing 13-A-ZYD-029 [formerly FPER Figure 1]). Indicate how smoke will be removed in the cable shaft (fire zones 3A and 3B [formerly zone 3]) during a fire.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: The "cable shafts" are actually rooms at each elevation of the control building, with cable penetrations in the floors and ceilings. Smoke detection is provided for each "cable shaft" room.

The smoke venting from cable shafts will be performed by opening the doors between cable shafts and fire zones 1 and 2 (train A and B, essential chiller rooms) and then venting smoke from fire zones 1 and 2 via portable smoke removal equipment.

QUESTION 9A.81 (FPER Question 16d) (9B.2)

Control Building

Page II-32[a], Item B.5.a[a]: Verify that the emergency exhaust fans in the battery rooms, zones 8A and 8B (formerly zone 8), are supervised and upon failure indicate a trouble condition in the control room as stated in Regulatory Guide 1.120, Section C.6.g.

RESPONSE: The emergency exhaust fans in the battery rooms, zones 8A, 8B, 9A, and 9B (formerly zones 8 and 9) are supervised. Loss of emergency exhaust will alarm in the control room.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.82 (FPER Question 16e) (9B.2)

Control Building

Page II-70[a], Item D.3[a]:

(1) Indicate the functions and quantity of safety-related cables above suspended ceilings and provide a list of such locations. Describe the fire protection systems for these locations.

(2) It is our position that smoke detectors should be installed in the control room cabinets and consoles, if redundant trains are in the same cabinet. Verify that you comply with this position. Also, describe the additional fire protection measures which will be provided.

(3) Verify that all rooms (kitchen, pantry, storeroom) shown engineering drawing 13-A-ZYD-029 (formerly FPER Figure 4) within the periphery of the 3-hour barriers of fire zone 17, excluding the computer room, have at least 1-hour cut-offs from the control room and have an automatic sprinkler protection.

RESPONSE:

(1) There are no safety-related cable trays located above suspended ceilings within the PVNGS power blocks. There are enclosed vertical raceways (8- by 8-inch metal gutters) which penetrate the corners of the suspended ceiling in the control room and the floor of the upper cable spreading room. However, these

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

raceways can be seen from the control room (ref. table 9B.3-1, item D.1.f). Portable fire extinguishers are provided in the vicinity and the area is manned 24 hours per day. There are train A safety-related conduits above the suspended ceilings of zones 57I, 57J, and 57N (elevation 140 feet 0 inch of the auxiliary building). A portion of the 140 foot 0 inch elevation floor is a fire area boundary providing separation from the redundant train B circuits.

(2) Smoke detectors are provided in the ventilation stream outside of each control room cabinet with redundant channels. In the event of a fire in a cabinet, early warning detection and the proximity of operating personnel and portable fire extinguishers will prevent damage to redundant safe shutdown channels.

(3) All rooms are separated from the control room proper by a 1-hour fire wall. No automatic sprinkler protection is provided. Smoke detectors are provided in each of these rooms. The rooms are of light hazard with no permanent cooking facilities (rangetop stove/oven). A portable microwave and small appliances (such as coffee pot and toaster oven) are located in the kitchen area. Portable fire extinguishers are available. (Refer to the response to Question 9A.118)

QUESTION 9A.83 (FPER Question 16f) (9B.3)

Control Building

Page III-40[a] Item D.5: You state that fixed CO_2 hose reels will be used as fire protection for cables passing through the switchgear room. CO_2 hose reels do not provide adequate protection to the cables. It is our position, stated in Appendix A, that automatic suppression systems be provided for cables passing through the switchgear room. State that you will comply with this position.

RESPONSE: Refer to the revised fire hazards analysis presented in section 9B.2.

QUESTION 9A.84 (FPER Question 16g) (9B.3)

Page III-15[a], Item D.1.(j) and Page III-18[a], Item D.3.(e): It is our position that 3-hour barriers should be provided around cable shafts in the control building. You state that for uncovered cable trays no fire breaks will be provided. Fire breaks should be installed as per Regulatory Guide 1.120, Section C.4.c(4), at a maximum distance of 20 feet for horizontal trays, and at each floor/ceiling level for vertical trays in areas that are not protected by automatic water systems. Between levels or in vertical cable chases fire stops should be installed at the midheight if the vertical run is 20 feet or more but less than 30 feet, or at 15-foot intervals in vertical runs of 30 feet or more. Also, indicate how an

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

internal fire will be detected and extinguished in a closed cable tray.

RESPONSE: Three-hour barriers enclose all cable shafts in the control building. In vertical cable trays, fire stops (penetration seals) are installed in each rated fire barrier. PVNGS design provides fire stops in horizontal trays penetrating fire rated walls and walls with sealed penetrations. The fire stops at the fire rated walls and floors will confine the fire to that zone without affecting the adjacent zones.

Where PVNGS used IEEE 383 cable rated at 210,000 BTU/hr during construction, its regulatory commitment to cable fire retardancy is IEEE 383 at 70,000 BTU/hr. As such, PVNGS now procures power block cable to IEEE 383 fire retardancy requirements, other nationally recognized standards (e.g., UL 1581 Vertical Tray Flame Test, UL 910, or UL 1666) which have been evaluated to meet or exceed IEEE 383 fire retardancy requirements, or other criteria (e.g., new standards) evaluated by Design (Electrical) Engineering for fire retardant equivalency. There are 27 cables installed at PVNGS that do not meet the IEEE 383 flame test. These 27 cables have been evaluated, for both electrical and fire protection properties, and "Accepted-As-Is" by Material Engineering Evaluation (MEE) 02480. Safety-related areas outside containment which have significant concentrations of cable are provided with automatic water suppression systems. The above active and passive protection features will minimize the spread of

fire in cable trays within a fire zone. No additional "fire breaks" are deemed necessary by the Fire Hazards Analysis nor by current NRC guidelines.

Cable tray covers are used in plant areas where the separation guidelines of Regulatory Guide 1.75 cannot be met. In these areas, the cable trays are protected by line-type thermal detectors or ionization detectors for early warning and/or suppression system actuation. Most of these cable trays are also protected by automatic preaction or deluge sprinkler systems. The cable trays not protected with automatic suppression systems are located inside containment, and manual firefighting with local hose stations or portable extinguishers would be used to extinguish the fire.

<u>QUESTION 9A.85</u> (FPER QUESTION 16h) (9B.2)

Page II-41[a], Item B.7[a]: You state in Section 7.4.1.10 of the PSAR, "Emergency Shutdown from Outside the Control Room," that you have the design capability to achieve and maintain a safe hot shutdown and a potential capability for subsequent cold shutdown of the reactor in the event the control room becomes inaccessible or inhabitable. In this regard, provide the responses to items below;

(1) Provide a list of essential safe shutdown equipment with a description of how remote instrumentation and control would be accomplished. Identify each safe shutdown equipment and its associated instrumentation and control

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

equipment for which electrical energy is essential for its proper operation.

(2) Assuming that the offsite power grid is not available, provide supporting information which may be used to conclude that electrical power, instrumentation, or control required for safe shutdown equipment will not be lost in the event a fire occurs in the main control room or cable spreading room.

(3) Identify and describe any changes in the original electrical design as a result of the incorporation of this emergency alternate method for achieving and maintaining a safe shutdown.

RESPONSE:

(1) Section 7.1 provides a list of essential safe shutdown equipment. Section 7.4 provides a description of the equipment. Additionally, the 10CFR50 Appendix R, III.G/III.L compliance assessment is presented in APS calculation 13-MC-FP-318. (See Section 9B.1.4.2.2)

(2) Safe shutdown can be achieved using only Class 1E powered equipment and limited, local-manual, operator action. As two cable spreading rooms are provided (one for each train), fire in one cable spreading room will not cause loss of function in the other cable spreading room and its associated train. Therefore, fire in a cable spreading room will not cause loss of function in more than one train and

will not prevent reaching safe shutdown from the control room.

A fire in the control room is prevented from affecting both safe shutdown trains by the use of transfer switches in the B train of safe shutdown equipment. Control can be maintained at the remote shutdown panel and local control stations utilizing equipment and components identified in safe shutdown equipment.

(3) Smoke detectors are provided in the control room to minimize the effect of a control room fire. Class 1E controls and Seismic Category I air supply are provided for the control of the main steam atmospheric dump valves, disconnect switches have been added for train B equipment and the control nests have been moved outside of the control room. Additional remote shutdown panel indication, and emergency lighting and sound-powered communication capabilities have been provided.

QUESTION 9A.86 (FPER Question 17) (9B.2)

Diesel Generator Building

(a) Engineering drawing 13-A-ZYD-031 (formerly FPER Figures 6 and 7);

(1) It appears in engineering drawing 13-A-ZYD-031 (formerly FPER Figures 6 and 7) that safety-related equipment is not separated in all areas of the diesel generator building by 3-hour rated construction, in

particular, the equipment located in fire zones 25A and 25B (formerly fire zone 25) as well as fire zones 21A, 21B, 22A, and 22B (formerly fire zones 21 and 22) which are connected by a pipe trench. Meet the Appendix A guidelines of 3-hour fire barriers.

(2) Provide the locations of all manual hose stations in the building.

(b) Page II-85[a], Item F.1.f[a]: Discuss and analyze how smoke ventilation will be accomplished, under fire conditions, in the diesel generator building.

(c) Page II-95[a], Item H.1.i[a]: Provide a fire hazard analysis assuming a leak in a fuel line of the day tank and spilling of its contents through the floor penetrations or as a result of the line failing in the room below. Seal all floor penetrations.

RESPONSE:

(a) Engineering drawing 13-A-ZYD-031

(1) Trains A and B within the diesel generator building (fire areas IV and V) are separated by 3-hour rated fire barriers. Refer to the fire hazards analysis provided in section 9B.2.

(2) No hose stations are provided inside the diesel generator building. However, hose stream coverage is provided as discussed in the response to Question 9A.115(a).

---

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

(b) Smoke removal will be accomplished through a combination of normal and emergency ventilation fans, if operable, or portable smoke removal units. As the diesel generators are separated by 3-hour rated fire boundaries, no safety impact results from delay in smoke removal.

c) The day tank rooms door curbs are sized to a height to contain the full volume of the day tank and its associated piping. Floor penetrations are sealed or (provided with noncombustible penetration sleeves which extend to at least the height of the door curb.

If a line fails in the room below and a fire occurs, the preaction sprinkler systems present in both the day tank rooms, and the rooms below, will be initiated.

QUESTION 9A.87 (FPER Question 18) (9B.2)

Fuel Building

a. Page II-107[a], Items I.2.c[a] and I.2.d[a]: Appendix A, Section F.13, states that fire detection for the spent fuel area should be provided. Verify that you comply with this position.

RESPONSE: Smoke detectors for the spent fuel area are provided.

---

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.88 (FPER Question 19a) (9B.2)

Auxiliary Building

Page II-146[a], Item M.1.c(1)[a]: Engineering drawing 13-A-ZYD-023 (formerly FPER Figure 14) seems to show an open grating separating fire zone 38 from fire zone 37. An exposure fire in either of these zones could spread to the other zone. Provide automatic sprinklers in these zones at each level or provide fire barriers.

RESPONSE: Fire zones 37C and 37D (formerly zone 37) have been expanded to include fire zone 38. See engineering drawing 13-A-ZYD-023 (formerly FPER Figure 14) and the revised fire hazards analysis of section 9B.2.

QUESTION 9A.89 (FPER Question 19b) (9B.2)

Auxiliary Building

Page II-149[a], Item M.2.c(1)[a]: You state that all walls, ceilings, and floors are heavy concrete construction. Verify that equipment in the pipeways containing Train A and Train B are separated from each other by 3-hour fire barriers.

RESPONSE: The only safe shutdown equipment in the pipeways (zones 39A and 39B) other than piping is train A and train B raceway which contain the redundant power circuits for the condensate transfer pumps. This raceway is located in Fire Zone 39B. The susceptibility of piping to an exposure fire is negligible, and barrier separation

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

between train A and train B piping is not required. The condensate transfer pumps provide make-up to the essential chilled water expansion tank to maintain cold shutdown. In the event of a fire damaging both the train A and B condensate transfer pumps circuitry, makeup water for the essential chilled water expansion tank is available from the fire protection system. Therefore, the condensate transfer pumps are not required for safe shutdown for a fire in these fire zones.

QUESTION 9A.90 (FPER Question 19c) (9B.2)

Auxiliary Building

Page II-152[a]: You state that the electrical chase shafts "are open at the floor level to level 70." Appendix A, Section D.3, states that fire barriers and fire detection should be provided in cable shafts, both vertical and horizontal. Verify that you comply with Appendix A in that each electrical chase is cut off at each floor and describe how fire detection will be accomplished. Describe the fire rating of the cutoff used.

RESPONSE: Electrical chases previously shown in zones 40 and 41 have been incorporated into zones 37A and 37B and are cut off at floor levels 70 feet and 100 feet by a 3-hour fire barrier. Refer to the revised fire hazard analysis of section 9B.2.

Smoke detection is provided along with portable fire suppression.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.91 (FPER Question 19d) (9B.2)

Page II-160[a], Item N.1[a] and Page II-179[a], Item 0.1[a]: Provide vertical and horizontal separation distances between trains A and B, in zones 42A, 42B, 47A, and 47B (formerly zones 42 and 47) where the containment walls are penetrated, or provide sufficient information to show that you meet the position in Appendix A, Section F.3-b.

RESPONSE: Zones 42A and 47A are separated from zones 42B and 47B by the south access shaft, a distance of greater than 40 feet.

QUESTION 9A.92 (FPER Question 19e) (9B.2)

Auxiliary Building

Page II-175[a], Item N.6[a]:

1. Fire zone 42C is not shown on figure 9B-21 (formerly FPER figure 15). Identify the location of zone 42C.
2. Describe the overall functions of channels C and B cable trays in this zone as well as the need for additional fire suppression and fire barriers to protect these safety-related cable trays.

RESPONSE:

1. Fire zone 42C is shown on engineering drawing 13-A-ZYD-024 (formerly FPER Figure 15).

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

2. The safe shutdown equipment in the channel C cable tray is the power and control circuitry for valve J-SIC-UV653. In the event of a fire in this fire zone the manual operation of this valve is required. The operation of this valve is required beyond 8 hours into the fire event. Therefore, no additional fire suppression or fire barriers are required to protect these safety-related cable trays. Reference Calculation 13-MC-FP-318.

<u>QUESTION 9A.93</u> (FPER Question 19f) (9B.2)

<u>Auxiliary Building</u>

Page II-184[a], Item 0.2[a]: Fire zone 48 contains train A and train B essential cooling water surge tanks with its associated control and instrumentation cables and a chemical storage area, but no fire detection system. Install a detection system.

RESPONSE: A smoke detection system is installed in this fire zone.

<u>QUESTION 9A.94</u> (FPER Question 19g) (9B.2)

Page II-209[a], Item 0.14[a]: Channels A and D safety-related cable trays are located in this area. Provide an analysis to show that the plant can be shut down in the event an exposure fire involves both divisions, or provide an automatic suppression and detection system.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: Zone 52 has been subdivided into two parts -- zones 52A and 52D separated by a 1-hour rated fire barrier. The cable trays in zones 52A and 52D are provided with automatic water suppression and a zonal smoke detection system.

<u>QUESTION 9A.95</u> (FPER Question 19h) (9B.2)

Page II-215[a], Item 0.16.c(1)[a]: Fire zone 54 contains the reactor trip switchgear and cable trays for train A and train B. We do not have sufficient information to evaluate the area with regard to the guidelines given in Appendix A, Section D.1. Provide sufficient information and verify that you meet the guidelines of Appendix A, which states that 3-hour separation between the redundant trains in zone 54 be provided. Describe the additional measures that will be taken to properly protect each division.

RESPONSE: A failure of the reactor trip switchgear does not preclude a reactor trip.

<u>QUESTION 9A.96</u> (FPER Question 20a) (9B.2)

<u>Containment Building</u>

Page II-270[a], Item R.1.1.c(3)[a]: Describe the operational modes of the isolation valves in the ducts inside containment for the ventilation system during a fire situation. Provide an analysis of the loss of these valves due to a fire and the ability to perform a cold shutdown.

---

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: Loss of function of the ventilation duct isolation valves has no adverse affect on achieving cold shutdown. The isolation valves in the containment building ventilation ducts are duplicate valves located at the containment building wall, one inside and one outside the wall for each ventilation duct penetration.

The refueling purge isolation valves are opened for control of airborne radioactivity during refueling only. The power-access purge valves are open for about 16 hours per week during normal power operation. Upon a containment isolation signal, both inside and outside containment isolation valves are closed. No other ventilation isolation valves are provided inside containment.

QUESTION 9A.97 (FPER Question 20b) (9B.2)

Containment Building

Page II-271[a], Item R.1.1.e[a]: You state that the standpipes inside containment are normally dry, and that primary fire suppression is manual hose streams. It is our position in Appendix A, Section F.1, that filled standpipes and fixed suppression systems be provided in containment. Modify your design to meet our guidelines.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: When the containment building is occupied for any significant time period (such as during refueling or during a maintenance outage), the standpipes within the building will be pressurized with fire water.

During times when the containment building is not occupied, the standpipes will be filled and the isolation valve closed to assure that no fire water is inadvertently discharged within the containment building. Also refer to responses to Questions 9A.98 and 9A.130.

QUESTION 9A.98 (FPER Question 20c) (9B.2)

Containment Building

Page II-272[(a)], Item 2.1.1.k[(a)]:

1. For the reactor coolant pumps, provide an oil containment or collection system.

2. Verify that the redundant safe shutdown instrumentation sensing lines in the immediate area of the reactor coolant pumps are sufficiently separated to preclude the failure of the sensing lines from an exposure fire.

RESPONSE:

1. A system is provided to collect and contain lubricating oil from nonwelded joints for each reactor coolant pump and motor. The system is designed to remain functional after an SSE.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

2. In zones 63A and 63B, which contain the reactor coolant pumps (RCPs), there are 12 instrument nozzle taps with 3/8-inch diameter stainless steel sensing lines for redundant steam generator (S/G) level and pressure transmitters. The transmitters themselves are located outside the secondary shield and, therefore, beyond the area involved in a postulated fire in the vicinity of the RCPs. The sensing lines are routed 20 to 40 feet above a concrete floor. The most remote nozzle taps are separated from each other by approximately 15 feet horizontally along the circumference of the S/G. There is about 15 feet of horizontal separation between the RCP and the closest S/G nozzle. Operability of any one of the eight S/G level instruments is sufficient for the operator to fulfill his required safety function. There are no in situ combustibles directly under the sensing lines. An RCP oil collection system, which meets the requirements of 10CFR50, Appendix R, Section III.0 (refer to the response to Question 9A.126), has been provided to mitigate the effects of the major in situ combustible load. A transient load of 2-1/2 gallons of flammable liquid (approximately 400,000 Btu) would only yield a fire severity of about 1 minute in the vicinity of the S/G. Therefore, a fire of this magnitude and duration in this location would not cause the failure of all safe shutdown instrument sensing lines.

The instrument sensing lines for the differential pressure measurement across the primary side of the S/G are also located in the vicinity of the RCPs. The instrumentation is not required for safe shutdown. In event of failure of these sensing lines, the reactor coolant pressure boundary is breached. However, equipment required to mitigate this failure is located outside the S/G compartment, and both trains are unaffected by the fire. (Details of the analysis are available in chapter 15.)

QUESTION 9A.99 (FPER Question 20d) (9B.2)

Containment Building

Page II-282[a], Item 5.1.c[a]

1. The auxiliary feed pump rooms have an outside wall of 3-hour rating while the rest of the walls are heavy concrete construction. Appendix A, Section D.1(j), states that 3-hour separation including protection of all communicating openings around each auxiliary feedwater pump room be provided. Verify that you comply with this position in that the other walls and communicating openings have 3-hour rating.

2. It is our position that an outside entrance be provided for firefighting access to the motor-driven pump room rather than through the turbine-driven pump room.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE:

1. A description of the auxiliary feedwater pump rooms is provided in the revised fire hazards analysis of section 9B.2. The 3-hour fire wall that separates the auxiliary feedwater pump rooms has a watertight door. The door design is basically that of a ship's bulkhead door, i.e., reinforced steel plate leaf, heavy duty hinges, and multiple pressure "dogging" around the perimeter. A preaction sprinkler system is provided beneath the grating in the turbine-driven pump room. (Refer to the response to Question 9A.101.)

2. An emergency entrance from above is provided to the motor-driven pump room.

<u>QUESTION 9A.100</u> (FPER Question 20e) (9B.2)

<u>Containment Building</u>

Page II-282[a], Item 5.1.2(2)[a]: Secondary fire suppression to the auxiliary feed pump rooms is provided in part by "Manual Hose Streams from Hydrants on the Fire Main." Engineering drawing 13-A-ZYD-022 (formerly FPER Figure 23) does not show any hydrants near the auxiliary feed pump rooms. Show that there is a hydrant available or provide a 1-1/2-inch hose station for protection of these rooms in the immediate area.

---

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: Figure 9B-7 shows a fire hydrant located plant northwest of the MSSS for use by the site fire department. Also, hose stations with sufficient hose to reach the MSSS (response to question 9A.115) are located in the turbine building. The hose station, however, is not relied on for secondary fire suppression capability.

QUESTION 9A.101 (FPER Question 20f) (9B.2)

Containment Building

Page II-284[a], Items 5.1.j[a] and 5.1.k[a]: Identify the redundant safety-related equipment or cabling in each of these compartments and demonstrate that a fire in one compartment will not affect the operation of the auxiliary feed pump in the other compartment.

RESPONSE: Redundant safe shutdown raceway for the auxiliary feedwater pumps are protected as described in the fire hazards analysis of section 9B.2. The turbine driven auxiliary feedwater pump room (zone 72 - train A) and the motor-driven auxiliary feedwater pump room (zone 73 - train B) are separated with a 3-hour fire barrier with a watertight door. See response to Question 9A.99.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.102 (FPER Question 21) (9B.2)

Main Steam Support Structure

a. Page II-29[a], Items T.1.j[a] and T.1.k[a]: An internal or exposure fire will cause adverse effects on the safety division cabling and equipment in the support structure. Analyze, as a result of an exposure fire, the loss of redundant safety-related equipment or cabling, including control, power, or instrument cables, on the shutdown capability of the plant, and provide the necessary automatic fire suppression systems to minimize the damage.

RESPONSE: As a result of the analysis, an automatic suppression system and protective wrapping have been employed to minimize adverse effects on safety division cabling. Refer to the revised fire hazards analysis of section 9B.2.

QUESTION 9A.103 (FPER Question 22a) (9B.2)

Outside Areas

Page II-301[a], Item U.3.c.(1)[a]: Indicate on engineering drawing 13-A-ZYD-021 (formerly FPER Figure 27) the distance between zone 76 (ESF service transformers) and the switchgear building. Justify the 2-hour fire barriers separating zone 76 from zone 77, and show the separation distances between the safety-related transformers and the nonsafety-related transformers, as well as the distance from the fire barriers for the control building and diesel generator building.

---

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

RESPONSE: The distance between zone 76 (ESF service transformers) and the switchgear building is shown on engineering drawing 13-A-ZYD-021. Also shown is the distance between the ESF service transformers and the normal service transformers, and the distance between the fire barrier and the control and diesel generator buildings.

The ESF transformers are not part of the safety-related system. The area contains only nonsafety-related equipment. The nomenclature "ESF transformers" suggests that the transformers feed safety-related equipment; however, the Class 1E system starts at the incoming breakers to the ESF switchgear.

QUESTION 9A.104 (FPER Question 22b) (9B.2)

Outside Areas

Pages II-301[a] and Page II-304[a]: Provide drawings of the switchgear building showing areas of safety-related cables or equipment necessary for a safe cold shutdown, as well as the fire suppression and detection systems.

Provide a fire hazard analysis for this area.

RESPONSE: Refer to the fire hazards analysis provided in section 9B.2. The ESF transformers and switchgear are nonsafety-related equipment. The switchgear building has no safety-related equipment associated with it. The fire suppression and detection systems for this building

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

consist of two carbon dioxide hose reels and smoke detection.

QUESTION 9A.105 (FPER Question 22c) (9B.2)

Page II-323[a], Item U.13.g[a]: Verify that 3-hour fire rated vertical cutoffs on each level are provided in zones 86A and 86B (formerly zone 86) and indicate the distance between the cutoffs. Also, verify that the cable shaft is cut off at each floor level by a 3-hour rated barrier.

RESPONSE: As shown in engineering drawing 13-A-ZYD-029, zones 86A and 86B extend from below grade to elevation 160 feet 0 inch. Three-hour penetration seals are provided for all electrical trays entering zones 86A and 86B (formerly zone 86) from the auxiliary building (column line A-10) and the control building (column line J1). All trays within zones 86A and 86B are horizontal trays passing from the auxiliary building to the control building. A vertical wall separates train A cables from train B cables. It is not necessary to provide 3-hour ratings at each floor elevation in the zones, because each zone is one train related only. Automatic water suppression for all trays within zones 86A and 86B is described in section 9B.2.

a. Page/paragraph references are no longer applicable due to FPER reformatting for FSAR amendment 13.

QUESTION 9A.106 (FPER Audit Open Item No. 1) (9B.2)

Verify that doors in fire rated walls and partitions are listed for use in that type of wall or partition.

RESPONSE: All fire doors are purchased as labeled fire doors of the fire rating required for the wall rating, (i.e., 3-hour wall: A label, 3-hour door; 2-hour wall: B label, 1-1/2-hour door; 1-hour wall: C label, 3/4-hour door) with the exception of doors that have removable transoms and/or have both louver and glass view plates and control room security doors. The exceptions have been certified by the manufacturer[a],[c] to be constructed in accordance with UL listing or FM approval (but without label) offering the corresponding fire rating protection.

These doors are listed in the accompanying table:

	FIRE ZONE	DOOR NO.	WALL RATING	DOOR RATING	REMARKS
	28	F105	2 hr	B	WG&L
	29	F201	2 hr	B	WG&L
	42A	A102	2 hr	B	RT
	42A/42D	A110	2 hr	B	RT
	42B/42C	A118	2 hr	B	RT
	52A/47A	A201	2 hr	B	RT
	54/52D	A213	2 hr	B	RT
(b)	48/62L	A204	3 hr	-	RT
	47B/52D	A216	2 hr	B	RT
	55C/57N	A302	1 hr	C	WG&L
	57A/57N	A317	1 hr	C	WG&L
	57G/57N	A320	1 hr	C	WG&L
	57L/57N	A323	1 hr	C	WG&L
	57K/57N	A327	1 hr	C	WG&L
	57J/57N	A335	1 hr	C	WG&L
	59/60G	R107	2 hr	B	WG&L
	60G	R121	2 hr	B	WG&L
(d)	17	J303	3 hr	-	Security

where RT = removable transom

WG&L = wire glass and louver (series S6)

(e) The following are nonrated missile doors located in fire barriers:

FIRE ZONE	DOOR NO.	WALL RATING
14/Corridor Bldg.	J208	3 hr
Control Bldg./Corridor Bldg.	J318	3 hr
20/Corridor Bldg.	J408	3 hr
54/Corridor Bldg.	A212	3 hr
74A/Open Stairwell	C102	3 hr
74A/Open Stairwell	C201	3 hr
74A/Open Stairwell	C301	3 hr

Notes:

(a) Fenestra letter, September 13, 1983, certifies that the series S6 doors (WG&L) supplied are made with construction, material, and workmanship approved by UL for classification as 1-1/2-hour (B label) or 3/4-hour (C label) labeled doors.

(b) Door No. A204 is not labeled but is a hollow metal door constructed to general 3-hour fire door standards. This door opening is in a concrete wall separating the auxiliary building, zone 48, from the radwaste building, zone 62L. The total combustible (fire) loading in Zones 48 and 62L is low and consists primarily of cable insulation. There is a monorail passing through the upper transom doors, a cutout in the transom doors allows the monorail to penetrate the doors when they are closed. There is no redundant safe shutdown equipment in either zone, and these areas are open and readily accessible for manual firefighting. Automatic sprinklers have been added above both sides of the door to prevent any possibility of fire passing from one zone to the other through the monorail opening.

(c) Chicago Bullet Proof (CBP) Company letter, April 15, 1983, certifies that bullet proof door No. J303 is manufactured in accordance with UL procedures stated in UL files BP1942 for CBP bullet-resisting equipment and R8402 for CBP fire door assemblies.

(d) Door No. J303 is a combination bullet proof, fire-resisting, security door. The primary purpose of this door is to prevent a spread of fire from the adjacent stairwell or corridor into the control room.

Due to their operational requirements (i.e., security electric strike), the above door is provided with 1/2-inch long latch throw which is in deviation of NFPA-80, 1975 criteria of 3/4-inch latch throw, and, therefore, cannot be labeled.

With exception of the latch throw, all other aspects of the door construction are in accordance with the requirements of a 3-hour rated UL labeled door. The permanent combustible loading adjacent to door J303 on the stairwell side is light to none which minimizes the effects of fire on the door. Both the stairwell and corridor areas are open and readily accessible for manual firefighting.

(e) The doors must be modified to meet other regulatory criteria and in doing so they lose their fire rating. There are no unmitigated fire hazards within 50 ft of the doors, and they are located in exterior walls and do not separate redundant safe shutdown equipment. Where the above criterion has not been met, a redundant set of doors for door J318 have been manufactured to meet UL’s standards for listed

fire doors (door J319). Two other doors (J208 and J408), have local sprinkler protection installed. On the basis of the conditions identified above, the non-fire-rated missile doors identified represent an acceptable deviation from Section D.1 of Appendix A to BTP APCSB 9.5-1.

QUESTION 9A.107 (FPER Audit Open Item No. 2) (9B.2)

Verify that the lack of structural steel fireproofing will not cause structural collapse during a postulated fire in the following plant areas:

a. Floors and roof of diesel generator building

b. Elevation 140 feet in the main steam support structure

c. Auxiliary building zones: 42A and 42B
47A and 47B
55A (formerly 55) and 56B

RESPONSE:

a. The reinforced concrete floors and roof of the diesel generator building are self supporting. Other structural steel material is not required.

b. The main steam support structure (MSSS) is provided with water suppression on all levels except in zone 73 (elevation 81 feet 0 inch). Even an exposure fire cannot reach the roof support columns and/or structural beams. This structure is also open to the atmosphere at the roof line providing natural heat

ventilation. Additionally, water spray from the spray nozzles for elevation 140-foot area are arranged such that the columns and beams will be sprayed. These features will ensure that the structural steel will not collapse.

c. The structural steel in zones 42A and 42B and zones 47A and 47B is protected with cable tray and column sprinklers. Ceiling level sprinkler protection has been added to these zones. These systems have been modified to preaction with activation by smoke detection or heat sensed by the cable tray protectowire system, which gives early warning to the control room. The total combustible (fire) loading in Zones 42A and 47A is low and in Zones 42B and 47B is moderate. The primary combustible in these four zones consists of fire resistant cable insulation. These zones are also readily accessible for manual firefighting and have a hose station located just outside the door. The structural members are also very heavy steel beams and columns and are not easily deformed within the parameters of a design basis fire in these zones. The above will prevent structural collapse during a postulated fire in these zones.

Columns in zones 55A (formerly zone 55) and 56B have adequate protection from the ceiling level wet pipe water suppression system installed in these zones.

One-hour rated protection of structural steel supporting the fire barrier ceilings of zones 37C and 37D has been provided.

<u>QUESTION 9A.108</u> (FPER Audit Open Item No. 3) (9B.2)

Verify that the fire dampers installed in the plant are listed for the following uses:

a. Grouped dampers at floor/wall penetrations

b. Single dampers at 3-hour fire rated wall/floor penetrations

c. Dampers in drywall and metal lath and plaster partitions

RESPONSE:

a. The design for ganged fire dampers was tested and rated at 3 hours by Underwriter's Laboratory.

b. Single dampers at 3-hour rated wall/floor penetrations are rated for 3 hours. Those dampers presently labeled with 1-1/2-hour ratings are constructed to 3-hour standards. The labels have been upgraded to 3-hour ratings.

c. Dampers installed in drywall and metal lath and plaster partitions will be rated for the rating of the partition; e.g., a 1-1/2-hour damper is installed in a 2-hour partition. Waldinger drawing and field installation procedures indicate that to provide adequate fire seals, gaps which exceed 1/2 inch will be filled with "Carborundum Fiberfrax Durablanket" (6 pounds density). When small void areas do not allow the use of "Fiberfrax Durablanket," "Fiberfrax" bulk may be used to fill the void area by tamping full. The "Fiberfrax" material is UL approved.

Ruskin's installation instructions comply with UL Safety Standards 555.

In the actual installation of the dampers in the drywall and the metal lath and plaster partitions, the dampers are installed in the ductwork first, then the studwalls are built around the duct/dampers. The installation of the damper is in accordance with the field procedures and installation instructions, as for any masonry wall. However, since the size of the openings is tailored for the damper, Fiberfrax insulation material is not required. Deviations between the design and actual installation are evaluated in accordance with the criteria stated in the response to Question 9A.68.b.

UL Safety Standard 555 did not address fire dampers installed in gypsum board or metal lath and plaster walls when the Palo Verde units were initially constructed. The vendor, Ruskin Manufacturing, has subsequently issued installation instructions for installing UL Safety Standard 555 listed dampers in gypsum board walls. The actual installations of fire dampers in gypsum or metal lath and plaster barriers at Palo Verde were compared to these instructions. This comparison concluded that the fire dampers were installed in accordance with the manufacturer's instructions. This fact, together with the conservative design of the duct and hanger systems and the defense-in-depth fire protection features in the subject fire areas, provides reasonable assurance

that the duct and damper assembly will remain in place during a postulated fire. Therefore, the integrity of the fire barrier will not be compromised in the event of a postulated fire.

<u>QUESTION 9A.109</u> (FPER Audit Open Item No. 4) (9B.2)

Verify that the drywall and hollow concrete block partitions are 3-hour fire rated.

RESPONSE: The noted partitions are 3-hour fire rated because:

(1) <u>Block Walls</u>

- Designed per UBC-1973 (Table 43B[a], Item Nos. 27 through 30). The walls are fully grouted and reinforced throughout.
- Penetrations for conduit piping and cable trays are sealed in the same manner and with the same materials as those used for concrete walls.
- UL-rated fire dampers are installed in an approved design wherever HVAC ducting penetrates the barrier. (Refer to the response to Question 9A.108.)

---

a. Testing for UBC fire ratings was performed in accordance with ASTM Standard E119 (1976) (equivalent to UL 263, Fire Tests of Building Construction Materials) as noted in UBC Standard No. 43-1

(2) Drywall/Metal Lath and Plaster (ML&P) Partitions

- Designed per UBC-1973 (Table 43B[a], Item No.

Notes:

(a) All existing joints on the fire wall between the remote shutdown panels have been removed and replaced with approved No. 15 closed joints.

(b) Several ML&P walls are reclassified as 1-hour fire barriers. Other ML&P walls are classified as "rated" where life safety is the only factor (separation of safe shutdown equipment is not a factor). Refer to the response to Question 9A.118.

(c) The acceptance criteria (UBC Section 43.114) for the testing performed for nonbearing walls and partitions are as follows:

1. The wall or partition shall have withstood the fire-endurance test without passage of flame or gases hot enough to ignite cotton waste, for a period equal to that for which classification is desired.

2. The wall or partition shall have withstood the fire and hose stream test as specified in Section 43.108, without passage of

a. Testing for UBC fire ratings was performed in accordance with ASTM Standard E119 (1976) (equivalent to UL 263, Fire Tests of Building Construction Materials) as noted in UBC Standard No. 43-1

flame, of gases hot enough to ignite cotton waste, or of the hose stream. The assembly shall be considered to have failed the hose stream test if an opening develops that permits a projection of water from the stream beyond the unexposed surface during the time of the hose stream test.

3. Transmission of heat through the wall or partition during the fire-endurance test shall not have been such as to raise the temperature of its unexposed surface more than 250F above the initial temperature.

- Conduit penetration seals are installed in a metal retaining sleeve as shown in ICMS Drawing No. M-01-90, Specification No. AM-208. (This design has been approved with a 3-hour rating by ANI for use in ML&P walls). The acceptance criteria (per ANI/MAERP Standard Method of Fire Tests of Cable and Pipe Penetration Fire Stops) for the testing performed for penetration seals are as follows:

  1. Fire shall not propagate to the unexposed side of the test assembly nor shall any visible flaming be observed.

  2. No individual thermocouple on the unexposed surface of the fire stop shall exceed 325F above ambient temperature.

3. No opening develops that permits a projection of water from the stream beyond the unexposed surface during the hose stream test.

- There are no cable trays that pass through 3-hour rated ML&P walls
- UL-rated fire dampers are installed in an approved design wherever HVAC ducting penetrates the barrier.

QUESTION 9A.110 (FPER Audit Open Item No. 5) (9B.2)

Verify that cable tray penetration seals will not fail upon tray collapse.

RESPONSE: The cable trays utilized at PVNGS are typically "trough" type trays that are 4 inches deep and 24 inches wide. The trays are constructed of 14 gauge sheet metal and are manufactured by U.S. Gypsum/Globe. The supports for the trays are "Unistrut" channels (typically P1000 or P1001), or equivalent, that are manufactured from 12 gauge strip steel. The cable trays are clamped to the supports. These design features are typical of the current designs that are utilized throughout the industry.

The cable trays that penetrate fire walls which protect safe shutdown and safety related equipment from potential fire hazards have one or more of the following design features:

a. The first support is located within 24 inches of the first barrier. This is typical of most of the cable tray installations. This design feature has received

NRC approval throughout the industry as a method of preventing tray collapse and penetration seal failure.

b. In cases where it was not possible to locate a support within 24 inches of the barrier, the support was located as close as possible to the barrier. In addition, most of these tray configurations are protected by an area and/or cable tray automatic suppression system.

c. In the few cases where an automatic suppression system is not provided, defense-in-depth fire protection features protect the tray from being deformed to the extent that the penetration seal would be compromised during a postulated fire. These defense-in-depth features include limited combustibles in the area, fire detection systems and an immediate response (within 30 minutes) from the on-site fire department if a fire were to occur.

Based on the above information and the cable tray fire testing that has been performed by the industry for cable trays, there is reasonable assurance that the cable trays will not fail to the extent that the penetration seals would be compromised during a postulated fire.

<u>QUESTION 9A.111</u> (FPER Audit Open Item No. 6) (9B.2)

Verify that lead powder/iron powder type penetration seals are appropriate for use in a fire-rated partition.

RESPONSE: All penetration seals which have a dual purpose (i.e., radiation shielding and fire protection) have been tested and rated for 3 hours.

QUESTION 9A.112 (FPER Audit Open Item No. 7) (9B.2)

Verify the presence of fire dampers at walls, floor, and shaft penetrations in the following areas:

a. Control building elevation 74 feet (zones 1 and 2)

b. Control building elevation 100 feet (zones 7A and 7B [formerly zone 7])

c. HVAC chase at zone 18A (formerly zone 18)

d. Auxiliary building, elevation 51 feet 6 inches (zones 30A, 30B, 31A, and 31B [formerly zones 30 and 31])

RESPONSE: Every duct that penetrates a fire barrier has a fire damper. As was observed during the audit, small ducting does not have access panels to allow maintenance personnel to reset fire dampers. The PVNGS design uses removable sections of duct to access the fire dampers in those ducts smaller than 12 inches.

QUESTION 9A.113 (FPER Audit Open Item No. 8) (9B.2)

Verify that a single break or ground fault condition will not cause the loss of power to multiplex concentrators.

RESPONSE: PVNGS uses the guidance of NFPA 72D (1975) (Section 2220) and BTP APCSB 9.5-1, Section E.1, regarding power supplies.

Each PVNGS unit's power block is equipped with remote terminal concentrators (RTCs). These RTCs are powered from the PVNGS security electrical distribution system. The security electrical distribution system is fed by offsite power, as the primary source, a diesel generator, the secondary source, which starts automatically on low system voltage and a tertiary source, another diesel generator, which is auto start but manually loaded onto the security electrical system. The security electrical distribution system supplies power to the RTCs through an uninterruptible power supply and parallel circuits to each unit. The loss of a power circuit will not affect more than two RTCs, and in most cases, only one RTC. The loss of power to an RTC does not preclude actuation of the fire protection system. The loss of power to an RTC does not affect the operation of the local fire panels since these are powered separately from the essential lighting system, with battery backup for areas required to be manned for safe shutdown.

<u>QUESTION 9A.114</u> (FPER Audit Open Item No. 9) (9B.2)

Verify that a trouble condition/fire alarm signal will continue to be displayed on multiplex system display until condition is rectified.

RESPONSE: The trouble condition/fire alarm signal remains displayed on the system display until the condition is acknowledged and cleared by an operator.

QUESTION 9A.115 (FPER Audit Open Item No. 10) (9B.3)

To meet Section E.3 of BTP ASB 9.5-1, the applicant committed to equip hose stations with not more than 100 feet of fire hose. The applicant should verify that the existing hose stations will be able to protect all of the following areas with not more than 100 feet of hose:

a. Zones 21A, 21B, 22A, 22B, 24A, and 24B (formerly zones 21, 22, and 24)

b. Zones 74A and 74B (formerly zone 74)

c. Zones 37C and 37D (formerly zone 37)

RESPONSE: The PVNGS commitment to BTP APCSB 9.5-1 stipulated that no more than 100 feet of 1-1/2-inch hose would be used for interior hose stations. That commitment has been met except as discussed below:

a. Zones 21A, 21B, 22A, 22B, 24A, and 24B (formerly zones 21, 22, and 24)

Zones 23A, 23B, 24A, 24B, 25A, and 25B (formerly zones 23, 24, and 25) can be reached from hose station No. 90 (in the control building) which is provided with a 150-foot length of hose.

Additionally, APS has installed another hose station, No. 108, with 150 feet of hose in the control building near the exit to the diesel generator building. This hose is able to reach zones 21A, 21B, 22A, and 22B (formerly zones 21 and 22).

b. <u>Zones 74A and 74B (formerly zone 74)</u>

Main steam support structure (MSSS) zones 74A and 74B (formerly zone 74) can be reached throughout the 100-foot (grade) elevation and 140-foot level from standpipe and hose stations at those levels located at the northwest corner of the turbine building. These hose reels are equipped with 150 feet of 1-1/2-inch hose from hose station No. 63 (100-foot elevation) and 100 feet of 1-1/2-inch hose from hose station No. 72 (140-foot elevation). The 120-foot elevation of the MSSS is an open grating and hose streams can be directed at all areas of that level upward from the 100-foot elevation and downward from the 140-foot elevation (which is also an open grating.) The hose nozzles will reach within 30 feet of all areas of the building.

c. <u>Zones 37C and 37D (formerly zone 37)</u>

All areas of the auxiliary building zones 37C and 37D (formerly zone 37) can be reached within 30 feet by 125 feet of 1-1/2-inch hose from hose station No. 25.

d. Zone 39A, pipeway, can be reached by Hose Station No. 29 or by 150 feet of 1 1/2 inch hose from Hose Station No. 31 located in Zone 39B.

e. <u>Zone 67A</u>

Zone 67A at the 100 - foot elevation of the Containment Bldg. can be reached from hose station No. 08, which is provided with a 150 - foot length of hose.

f. Zone 67B

Zone 67B at the 140 - foot elevation of the Containment Bldg. can be reached from hose station No. 13, which is provided with a 150 - foot length of hose.

g. Zone 66A

Zone 66A at the 140 - foot elevation of the Containment Bldg. can be reached from hose station No. 14, which is provided with a 150 - foot length of hose.

h. Zone 88A

Zone 88A at the 51 foot 6 inch elevation of the Auxiliary Bldg. can be reached from hose station No. 21, which is provided with a 150 - foot length of hose.

i. Zone 88B

Zone 88B at the 51 foot 6 inch elevation of the Auxiliary Bldg. can be reached from hose station No. 22, which is provided with a 150 - foot length of hose.

j. Zone 42D

Zone 42D at the 100 - foot elevation of the Auxiliary Bldg. can be reached from hose stations No. 33 and 35, which are provided with a 150 - foot length of hose.

k. Zone 42C

Zone 42C at the 100 - foot elevation of the Auxiliary Bldg. can be reached from hose station No. 36, which is provided with a 150 - foot length of hose.

l. Zone 52D

Zone 52D at the 120 - foot elevation of the Auxiliary Bldg. can be reached from hose station No. 40, which is provided with a 150 - foot length of hose.

m. Zone 57N

Zone 57N at the 140 - foot elevation of the Auxiliary Bldg. can be reached from hose station No. 44, which is provided with a 150 - foot length of hose.

n. Zone 62L

Zone 62L at the 120 - foot elevation of the Rad Waste Bldg. can be reached from hose station No. 54, which is provided with a 150 - foot length of hose.

QUESTION 9A.116 (FPER Audit Open Item No. 11) (9B.3)

The applicant in the Fire Protection Evaluation committed to comply with Section E.1 of BTP ASB 9.5-1 concerning the design and installation of fire detection systems. We observed that fire detectors were absent from the following areas which contain safety-related equipment.

a. Condensate transfer pump room (zone 83)

b. Elevation 131 feet, diesel generator building (zones 25A and 25B [formerly zone 25])

c. Above auxiliary control cabinets (control room)

d. In computer room adjacent to the control room, within the control room complex

e. (DELETED)

f. "Dead air space" such as in zones 37C and 37D (formerly zone 37) (elevation 70 feet, auxiliary building)

g. ECW heat exchanger rooms (zone 43)

h. Charging pump rooms (zones 46A, 46B, and 46C [formerly zone 46])

i. Spray chemical accumulator room

j. Spray chemical storage tank room (zone 51B)

RESPONSE: The area listed as "g" contains no safety-related equipment susceptible to fire damage. The only safety-related component within zone 43 is the essential cooling water heat exchanger (i.e., the heat exchanger shell). No significant combustible loading is present; therefore, no detectors are required.

Area "d," the computer room adjacent to the control room, has fire detectors to detect fire and activate the Halon suppression system.

Potential dead air spaces between heavy beam ceiling supports have been previously identified and reviewed (through site walkdowns) by the detector supplier. Additional detectors were added based on air flow and configuration. The remaining "dead air spaces," noted as area "f," are not of sufficient size to cause appreciable

delays in the response of the current detector arrangement.

The train related DG air start receiver/compressor rooms are part of Fire Zones 25A and 25B (area listed as b.). The only safety related component in the room is the air start receivers. The air dryer package in each room does not provide a significant combustible load contribution. The compressor oil system is not pressurized and the oil is contained in the base of the compressor crankcase. The limited combustible loading will not result in a challenge to the integrity of the air start receivers. Therefore, no detectors are required for the DG air start receiver/compressor rooms.

To address technical specification restrictions regarding operation with only one train of safety-related equipment available, additional detectors have been added to areas labeled "a," "b," "c," "h," "i," and "j". Note: Item "i" is interpreted to be the spray chemical storage tank room (zone 51B).

See referenced zone descriptions in appendix 9B.

QUESTION 9A.117 (FPER Audit Open Item No. 12) (9B.2)

Penetration seals are not provided at bus duct penetration of fire walls.

RESPONSE: Fire-rated penetration seals have been installed.

QUESTION 9A.118 (FPER Audit Open Item No. 13) (9B.2)

The fire wall in the control room complex is not continuous.

RESPONSE: The fire walls in the control room complex generally extend from the floor slab to the ceiling. The walls near the shift manager's office, kitchen, and lavatory are rated primarily for life safety reasons and extend only to the non-combustible (less than 25 flame spread rating) acoustic tile ceiling above the exit corridor (J-312) located on the plant north side of the shift manager's office. This is one of two egress paths out of the control room. From a life safety or control room evacuation standpoint, there is another egress path available. The other function of this exit corridor ceiling, because the walls are not continuous to the concrete floor slab above at the 160 ft. elevation, would be to impede a fire originating in the adjacent rooms such as rest rooms, kitchen, and/or shift manager office, from exposing the control room cabinets and equipment. In other words, a fire would have to propagate from an adjacent room, into the plenum space above its ceiling, then back down through the exit corridor ceiling into the electrical cabinet area of the control room complex. This downward direction would not be a normal propagation path for a fire and there are not sufficient combustibles to support this propagation path. The plenum space is non-combustible construction with approximately 10 feet of vertical air space and very low combustible loading primarily consisting of a limited amount of cable trays

with IEEE-383 cable. Smoke detection is installed above the ceiling for early warning. For the above reasons, the exit corridor ceiling does not have an hourly fire resistance rating. A postulated fire of this type would have no adverse effect on the ability to achieve and maintain safe shutdown as alternate shutdown capability from the remote shutdown panel remains available outside the control room. (Refer to the response to Audit Open Item 4(2)(b) [Question 9A.109]).

QUESTION 9A.119 (FPER Audit Open Item No. 14) (9B.2)

Curbs are not provided at diesel generator rooms to contain oil spill.

RESPONSE: Each diesel engine room contains a pipe trench with a sump and two sump pumps. Each trench is approximately 21 feet long, 4 feet wide and 6 feet deep. The sumps are approximately 5 feet deep x 4 feet square (with about 48 cubic feet of usable volume above the pump low level cutoff). The floors are sloped to floor drains which run to the sumps. The total volume in the trench and sump for each room is approximately 550 cubic feet, or 4115 gallons.

Each diesel generator contains approximately 1000 gallons of oil, and each sprinkler system is designed for approximately 350 gallons per minute. Therefore, there is capacity in the sump for all the oil and approximately 9 minutes of sprinkler flow. The usual criteria for curbs

is containment of all oil plus 10 minutes of sprinkler flow.

QUESTION 9A.120 (FPER Audit Open Item No. 15) (9B.2)

Removable block walls are provided throughout the plant for equipment servicing.

RESPONSE: A typical blockout is equal to the surrounding wall thickness (exceeding 24 inches). The design requires the solid concrete blocks to be staggered, both horizontally and vertically. There are no penetrations through the blockout. This design has the equivalent fire-resistance of a 3-hour barrier.

QUESTION 9A.121 (FPER Audit Open Item No. 16) (9B.2)

Unprotected openings were observed in the following fire walls:

a. Wall separating zones 1 and 2 (control building elevation 74 feet) from adjoining pipe chase.

b. Wall opening between elevation 120 feet of the main steam support structure and the turbine building.

c. Wall opening between elevation 88 feet of the auxiliary building and radwaste building.

d. Seismic gap (both horizontal and vertical) at the containment building.

RESPONSE:

a. The openings from fire zones 1 and 2 into the pipe chase area between the control and the auxiliary buildings have been sealed to a 3-hour rating.

b. The wall openings between the MSSS and the turbine building are unsealed to allow cooling of the hot piping anchor/support attachments at the concrete structure. A compartment devoid of in situ combustibles is located between zones 74A and 74B (formerly zone 74) of the MSSS and the turbine building. Ventilation exhaust fans use this compartment as a supply plenum to pull cooling air flow over the pipe support/anchors from the turbine building and the MSSS. The air flow is away from the safety-related equipment in zones 74A and 74B.

c. The openings between the pipe chase at elevation 88 feet 0 inch of the auxiliary building and the radwaste building have been sealed to a 3-hour rating.

d. The 6-inch (nominal) gap between the auxiliary building and the containment building has been sealed so as to provide a continuous 3-hour rated boundary.

QUESTION 9A.122 (FPER Audit Open Item No. 17) (9B.2)

Fusible-link type open devices were observed on fire doors throughout the plant.

RESPONSE: The fusible-link, hold-open devices on swinging type (hinged) fire doors have been removed. Verification of the position of the doors in rated fire barriers will be performed in accordance with section 13.5.

QUESTION 9A.123 (FPER Audit Open Item No. 18) (9B.2)

A PVC drain pipe was observed to penetrate a fire-rated floor assembly.

RESPONSE: Chlorinated polyvinyl chloride (CPVC) piping is used as vent piping from the battery room acid drain neutralizing pit. The vent piping does not penetrate boundaries separating trains A and B. Accordingly, adequate separation is provided. The small pipe opening is exposed to the essential chiller room elevation 74 feet, which is the room below the PVC pipe opening. The essential chiller rooms (zones 1 and 2) have a 26-foot ceiling height and the total combustible (fire) loading is categorized as low, consisting of charcoal contained in metal filter units. The calculated fire severity is very conservative since it provides an allowance for transient charcoal sufficient to refill the filter. This exposure is light and does not present a significant danger of fire spread between these zones and the zones above, which are in the same train. Smoke detection is provided, and manual fixed suppression is provided for the charcoal filters.

The vent piping also penetrates the nominal 8-inch thick, 3 hour rated concrete block walls between fire zones 6A

(DC Equipment Room C), 8A (Battery Room C) and 9A (Battery Room A), all in the same train (A) at approximate elevation 108 feet. The configuration is similar but involves only one wall for the Train B side between zones 8B and 9B (battery rooms) at approximate elevation 113 feet. The penetrations are located between column lines J1-J3 and JB-JD. The zones have a 20 foot ceiling height. The DC Equipment Room, Zone 6A has a moderate combustible (fire) loading consisting primarily of fire resistant IEEE 383-rated cable. The Battery Rooms, Zones 8A, 9A, 8B and 9B have a combustible (fire) loading classed as low, consisting almost entirely of thermoplastic battery casings. Smoke and heat detection is provided. Primary suppression for the battery rooms is automatic CO_2 total flooding; therefore, a fire would be automatically detected and suppressed in its early stages. With the automatic detection and suppression provided and the readily accessible location at the 100-foot level, prompt fire department response would also be expected, to manually extinguish the fire and prevent spread to adjacent fire zones. The vent pipes are located at approximately 8 to 13 feet above the floor and are in the corners of the rooms several feet away from combustibles which could potentially result in direct flame exposure and approximately 7 to 12 feet below the ceiling where heat from a fire would accumulate; therefore damage to equipment in the adjacent zone (same train) would not be expected to occur before either automatic or manual suppression is accomplished to prevent it. The

penetrations are all in fire barriers located within the same train. Barriers separating redundant safe shutdown equipment do not contain CPVC pipe penetrations. Therefore, the arrangement will have no adverse effect on the ability to achieve and maintain safe shutdown of the plant.

QUESTION 9A.124 (FPER Audit Open Item No. 19) (9B.3)

To meet Section E.3 of BTP ASB 9.5-1, the applicant committed to provide automatic sprinkler protection for the following areas. We noticed that sprinklers were missing in these areas which is contrary to the commitment:

a. Elevation 140 feet, main steam support structure (zones 74A and 74B [formerly zone 74])

b. Auxiliary building, elevation 51 feet 6 inches (zones 30A, 30B, 32A, and 32B [formerly zones 30 and 32]) (partial system).

RESPONSE:

a. The sprinkler system for the main steam support structure at elevation 140 feet has been installed both above and below elevation 140 feet to service all of zones 74A and 74B.

b. The sprinkler system for the LPSI and containment spray pump rooms has the sprinkler nozzles located below the grating in the center of the room and none on the ceiling. The combustible loading for any of the compartments during normal plant operations will

be well below a value that would challenge the integrity of the 3-hr fire rated barriers. The installation has been approved by the insurers. Per Paragraph 4-1.2 of NFPA 13-1976, a partial installation may be approved by the authorities having jurisdiction. The present design is adequate. The sprinkler system is part of the original plant design and is not required to meet BTP APCSB 9.5-1 or 10CFR50, Appendix R. The pumps are surrounded by 3-hour fire barriers.

<u>QUESTION 9A.125</u> (FPER Audit Open Item No. 20) (9B.2)

In Amendment 3 to the Fire Protection Evaluation, the applicant committed to provide 8-hour, battery-powered emergency lighting units in all areas needed for operation of safe shutdown equipment. We noticed that an emergency light was not installed in the ECW pump room (zones 34A and 34B [formerly zone 34]) which is contrary to that commitment.

RESPONSE: Zones 34A and 34B (formerly zone 34) do not have safe shutdown equipment that requires operator manual action in the event of a fire. Therefore, 8-hour emergency lighting is not required to be installed in these zones. However, 1-1/2 hour emergency lighting is provided in zones 34A and 34B.

<u>QUESTION 9A.126</u> (FPER Audit Open Item No. 21) (9B.1)

In Amendment 3 to the Fire Protection Evaluation, the applicant committed to comply with Section III.0 of Appendix R concerning

an oil collection system for the reactor coolant pumps. We were concerned that the piping, oil collection tank, and protection for the lift pumps would not collect oil leakage after a safe shutdown earthquake. The applicant agreed to respond to our concern by providing design details of the system.

RESPONSE: The pressurized[a] and unpressurized portions of reactor coolant pump (RCP) lube oil system (for pump and motor) have been analyzed to determine whether or not the components would survive an SSE without pressurized spray or leakage. Based upon that analysis, various mechanical joints (e.g., flanges), RTD connections, and sight glasses in the unpressurized section were identified as potential leakage paths. Piping and welded joints within the pressurized section were determined to remain intact. The lift pump discharge connection flange is considered subject to failure and is housed within a light weight silicon-treated, glass cloth shroud attached to the top of the lube oil reservoir. The shroud provides an envelope for the oil spray, and serves to collect and direct the oil to the collection system like any other oil leakage. The light weight shroud is attached to the lube oil reservoir by multiple fasteners on each side of the reservoir to assure it will remain functional for a SSE.

a. The external portions of the RCP lube oil system that can be considered pressurized are normally operated for about 30 minutes prior to starting the RCP and 30 minutes during the RCP shutdown sequence. The system may be periodically pressurized to replenish the RCP thrust bearing with recovered oil from leaking oil seals. The lift pump is normally secured. All other pressurized portions of the system are internal to the pump and motor.

The shroud will be inspected every refueling outage and as part of the fire protection test program.

To collect any leakage from the postulated leakage points, the criteria given in Section III.0 of 10CFR50, Appendix R, were applied. Postulated leakage points are provided with open "cans", catch trays, or enclosed in shields. These devices drain by gravity to a piping system. The interface point between the RCP collection devices and the piping system is an open funnel. The piping system drains by gravity to two collection tanks. Each tank can contain all the oil from two RCPs, plus 10%, and is equipped with a flame arrestor and sight glass. The tanks are located below the RCPs, and are not near any ignition sources. No flanges are provided in the collection piping, except at the collection tanks.

In addition to collecting devices, some modifications were made to eliminate leakage points by seal welding threaded joints or removing flanges and replacing the flange by a welded connection. Part of the collection system within the pump housing utilizes compression-type tube fittings. (As the drain system is not pressurized, compression-type fittings are justified for this application.)

<u>QUESTION 9A.127</u> (FPER Audit Open Item No. 22) (9B.2)

The applicant should commit to the reapplication of fire-proofing to all sections of structural steel that have lost the original fireproofing due to construction activities.

RESPONSE: We commit to the reapplication of fireproofing to all sections of structural steel that have lost the original fireproofing due to construction activities.

QUESTION 9A.128 (FPER Audit Open Item No. 23) (9B.3)

To comply with Section E.1 of BTP ASB 9.5-1, the applicant should clarify which fire alarm/detection circuits are Class A and Class B.

RESPONSE:

Plant Areas Protected by Detection Only

All wiring from the detectors to the local fire panels is Class A. All wiring from the local fire panels to the security system is Class B. The security system is Class A.

Plant Areas Protected by Water Suppression or CO_2

The initiating device circuits for the CO_2 systems protecting ESF switchgear rooms and battery rooms are Class B from the detectors to the local fire panel and from the fire panel to the security system remote terminal concentrator. However, there are two independent detection zones (circuits) serving each of these rooms. They are cross-zoned for actuation of the CO_2 system. If one zone experienced a trouble condition, operations personnel would be dispatched to investigate. The other zone would still be able to transmit a fire alarm signal to the control room. If a fire condition existed, the CO_2 system could be manually initiated to extinguish the fire

from just outside the switchgear room. Since the switchgear and battery rooms are located in the control building, immediate response would be anticipated. The redundant trains and separate rooms are surrounded by 3-hour fire barriers. Portable extinguishers and manual hose stations equipped with Class C nozzles are also provided. Therefore, the installed detection and suppression systems meet the BTP APCSB 9.5-1, Appendix A, "Guidelines for Specific Plant Areas", Item D.5 and D.7 switchgear and station battery rooms. In addition, the cable trays in the switchgear rooms are adequately protected as described above against a potential fire which might develop. In summary, failure of one detection zone will not prevent a fire alarm to the control room. Failure of the Class B circuit from the local control panel to the remote terminal concentrator will not prevent automatic actuation of the CO_2 suppression system.

The following water suppression systems are wired Class B from the detectors to the local fire panel, and Class A from the local fire panel to the security system. The signals that are wired Class A are the ac power on, water flow, alarm, and trouble. In case of a wet pipe system, only the water flow switch is Class A.

1. Fuel building railroad bay, elevation 100 feet, zone 27

2. Upper cable spreading room, elevation 160 feet of control building, zone 20

3. Lower cable spreading room, elevation 120 feet of control building, zone 14
4. Diesel generator rooms A and B, elevation 100 feet, zones 21A and 21B (formerly zone 21)
5. Diesel generator fuel oil day tank rooms, elevation 131 feet, zones 23A and 23B (formerly zone 23)
6. Auxiliary building systems, elevation 100 feet, zones 42C, 42D, 46A, 46B, and 46C (formerly zone 46)
7. Electrical penetration rooms, C and B, elevation 100 feet, zones 42A and 42B
8. Electrical penetration rooms, A and D, elevation 120 feet, zones 47A and 47B
9. Auxiliary building systems, elevation 120 feet, zones 52A and 52D
10. Dead space compartments A and B. Areas between control building and auxiliary building elevation 100 feet and 120 feet (zones 86A and 86B).
11. Turbine-driven auxiliary feed pump, elevation 80 feet of MSSS, zone 72
12. MSSS, zones 74A and 74B (formerly zone 74), elevation 100 feet, 120 feet, and 140 feet. (Note: This system is wired such that it utilizes a detection only signal to actuate the water suppression system.)

Fire Pump House

The diesel fire pumps have Class A circuits for indicating "pump running" to the control room. Indication "system

failure," including "controller not in Auto," is Class B. The Class A circuits for the motor-driven fire pump are "motor running" and "loss of power."

QUESTION 9A.129 (Audit Open Item No. 24) (9B.3)

To comply with Section B.5 of BTP ASB 9.5-1, the applicant should develop a procedure to restrict the use of the emergency radio communications frequency to authorized personnel. In addition, the applicant should clarify the need to use a fixed repeater and to commit to protect it from damage if one is installed.

RESPONSE: Emergency radio communications at PVNGS are accomplished on the plant two-way radio system. Refer to UFSAR section 9.5.2.2.1.6 for a description of the radio system. Because the system employs trunking repeater technology, there is no single frequency reserved for emergency radio communications. The system has a total of seven repeaters and therefore seven different frequency pairs. At any given time, one of the repeaters will be handling the radio system control channel function and the remaining six will be serving as talk channels. A particular radio conversation may occur on any one of the six talk channel frequency pairs regardless of whether it is a routine communication or an emergency communication. Talk channel repeaters are automatically assigned by the system to handle both private and "talkgroup" radio conversations. A talkgroup essentially defines a particular set of user radios (e.g., all of the fire department radios or all of the security force radios).

Each of the system's portable, mobile, and fixed radio transceivers has been preprogrammed to permit affiliation with one or more PVNGS talkgroups. The programmed talkgroups can be selected one at a time using the transceiver's mode selector switch. Talkgroup radio conversations occur between radios which are set to the same talkgroup. When one of the radios in a talkgroup is keyed to begin a conversation, the system responds by assigning a talk channel repeater to the talkgroup if one is available. The talkgroup retains sole use of the assigned repeater for the duration of the conversation or until a sufficiently long gap occurs between transmissions. At the end of the conversation, the talk channel repeater becomes available for other conversations. Talk channel repeater assignments are made on a "first come, first served" basis until all six talk channel repeaters are in use. When all six talk channel repeaters are busy, additional requests for a talk channel are prioritized, based on the function of the talkgroup selected on the requesting radio, and placed in a queue in the radio system memory. When one of the six active talkgroup conversations ends, the associated talk channel repeater is released, and the queued requests are processed in accordance with talkgroup priority to reassign the newly available repeater to a new talkgroup conversation.

The portable, mobile, and fixed radio transceivers used by the PVNGS fire and operations departments have preprogrammed talkgroups which are used exclusively by

those organizations for fire department communications and safe shutdown communications. The portable, mobile, and fixed radio transceivers used by the PVNGS security force has pre-programmed talkgroups which are used exclusively by that organization for security communications. These emergency talkgroups are not available on radios used by other PVNGS departments. Consequently, use of the emergency talkgroups by unauthorized personnel is not an issue. The radio system priority levels which have been assigned to the PVNGS fire department, operations department, and security force radio talkgroups guarantee that these emergency response organizations will experience little or no delay in acquiring an open talk channel when needed.

The use of PVNGS fire department emergency talkgroups during fires and other emergencies is controlled under the Fire Response Procedure.

The radio system uses multiple repeaters, redundant site central controllers, redundant ac power supplies, and battery-backed uninterruptible power supplies (UPSs) to enhance the ability of the system to withstand equipment failures, power failures, fires, and other damage.

QUESTION 9A.130 (FPER Audit Open Item No. 25) (9B.1)

In Amendment 3 to the Fire Protection Evaluation, the applicant proposed to utilize administrative controls to prevent fire damage to redundant shutdown division inside containment.

Administrative controls alone are insufficient to justify an exemption from the Appendix R requirements for protection of

redundant safe shutdown systems in containment. The applicant should provide the technical requirements in Section III.G.2 for inside containment to provide reasonable assurance that one train of equipment will be free of fire damage.

RESPONSE: APS has reviewed the separation of safe shutdown components within containment. Fire protection is based primarily on adequate separation between redundant equipment or alternate paths to accomplish a safety function when equipment is not totally redundant. Smoke detectors, portable fire extinguishers and manual hose stations are provided as described in section 9B.2. Administrative controls for transient combustibles, however effective, are not assumed to eliminate the possibility of all postulated fires.

With the current design (backfit to provide a radiant energy shield[a] for the train A pressurizer auxiliary spray circuitry from the train B circuitry) PVNGS meets 10CFR50, Appendix R, Section III.G.2, separation criteria with the exception that there are some intervening combustibles consisting of insulated cable with intermittent installations of Thermo-Lag 330-1 material.

a. The radiant energy shield for the train A pressurizer auxiliary spray valve and circuitry consists of metallic reflectorized insulation to protect the valve body and Thermo-Lag 330-1 insulation to protect the valve's circuitry. The Thermo-Lag 330-1 insulation is provided on the Train A raceway until at least 20 feet of separation is provided between this raceway and the redundant, Train B raceway. Beyond the Train A raceway section that is protected by Thermo-Lag 330-1, the raceway is located such that the concrete pressurizer shield walls provide additional radiant energy shielding between the two redundant trains.

At a minimum, intervening cable is IEEE-383 qualified. (Tests conducted by Electric Power Research Institute indicate that flame spread in a horizontal tray would be less than in a vertical tray). Vertical cable trays exist within containment but they do not transit between redundant safe shutdown trains. Thermo-Lag 330-1 is also used in various location inside the containment building. This material, however, does not represent a more easily ignited combustible than the cables. The Thermo-Lag 330-1 installations are, in most cases, less than four feet in length along the cable trays. The minimum horizontal cable tray distance for a fire to spread between redundant trains is 50 feet, as in the pressurizer auxiliary spray circuitry. In this case, it is a stack of two trays. Table 9A-1 (formerly FPER Table A-2) itemizes the extent of horizontal cable tray lengths between trains.

Also, the containment building height will dissipate heat from any fire exposing the cable trays as opposed to fire in a confined space or small room, thus further reducing the potential for flame spread.

APS requests approval for deviation from the technical provisions of Appendix A of BTP APCSB 9.5-1 and from Appendix R, Section III.G.2, of 10CFR50 for the intervening combustibles listed in table 9A-1 (formerly FPER Table A-2) because:

1. The cable and Thermo-Lag 330-1 material are limited in quantity.

2. The cable and Thermo-Lag 330-1 material are fire-resistant and demonstrate limited flame spread.

3. The minimum horizontal cable tray distance for a fire to spread between redundant trains is in excess of 20 feet, and ranges from 50 feet to 166 feet.

4. The space is not confined, thus allowing heat to dissipate.

For these reasons, a postulated fire will not affect both redundant safe shutdown trains.

10CFR50, Appendix R, Section III.G.2.f requires separation of cables and equipment and associated non-safety circuits of redundant trains by a non-combustible radiant energy heat shield (RES). The RES protecting the Train A pressurizer auxiliary spray valve and associated circuits deviates from this requirement in that Thermo-Lag 330-1, which has been determined to be combustible, is utilized as part of the RES. Testing has shown that Thermo-Lag is a combustible material with an ignition temperature of approximately 1000°F. APS meets this Appendix R requirement based on qualitative and independent quantitative engineering analyses that demonstrate that the RES for the Train A pressurizer auxiliary spray valve will not be exposed to temperatures in excess of 1000°F. Therefore, the RES as designed and installed meets the intent of 10CFR50, Appendix R, which is to ensure that the ability to achieve and maintain safe shutdown in the event of a postulated fire is maintained.

The Appendix R Safe Shutdown Analysis assumes that for fires inside containment, specifically Fire Zones 65 (pressurizer cubicle) and 67A (general area, northwest containment), the Train B pressurizer auxiliary spray valve will be disabled. The Train A auxiliary spray valve will remain operable since the valve and associated circuits are protected with a RES which is comprised of Thermo-Lag 330-1 and metallic reflectorized insulation. A description of the fire zones and the physical location of the RES is described below.

The Train A auxiliary spray valve is located above the pressurizer, in the pressurizer cubicle, at approximately the 154 ft. elevation. The valve has flex conduit running east from the valve to the east wall of the cubicle where the raceway enters a junction box. A rigid conduit from the junction box runs to the north wall where it turns west and runs for an additional two feet. The conduit then exits the cubicle through the north wall in an embedded conduit. The valve and this portion of the valve's circuit are located in Fire Zone 65. Metallic reflectorized insulation is provided for the valve body as part of the RES. This insulation has been previously approved for use as a RES. The entire circuit in the pressurizer cubicle (Fire Zone 65) is enclosed with a Thermo-Lag 330-1 RES, with the exception of the solenoid actuator, which is mounted above the valve body.

Once the circuit exits the north wall of the pressurizer cubicle, it enters Fire Zone 67A. The north wall of the pressurizer cubicle defines the southern boundary for this

fire zone. The Thermo-Lag 330-1 enclosed conduit exits the pressurizer cubicle at approximately the 154 ft. elevation, runs vertically down the north side of the north wall of the pressurizer cubicle, through two junction boxes, to the 138 ft. elevation. The conduit then turns west and runs horizontally along the north wall of the pressurizer cubicle until the wall turns south. The conduit runs south along the wall, where the RES ends after approximately five feet. The unprotected circuit continues on to the containment electrical penetration, where it exits the containment building.

The following fire mitigation features assure that the RES will not be subjected to temperatures in excess of 1000°F, thereby preventing ignition of the RES:

a) <u>Low Fire Loading</u> - the fire loading in both of the affected fire zones is low. The resultant postulated fire size is so small that the RES would not be exposed to temperatures that would be sufficient to cause combustion of the RES. In addition, the spatial separation between the RES and the fixed combustibles is such that any credible fire would not expose the RES to temperatures in excess of 1000°F.

b) Fire Protection Features - the existing fire protection features in, or near, these fire zones include smoke detectors at the ceiling level, line-type heat detectors in the cable trays, manual hose stations, portable fire extinguishers* and reinforced concrete walls.

c) Fixed Ignition Sources - the lack of fixed ignition sources in both fire zones is such that a fire due to these sources is highly unlikely.

d) Transient Combustible and Ignition Source Administrative Controls - the procedural restrictions for transient combustibles and/or transient ignition sources in either fire zone while the unit is in Modes 1, 2, 3 or 4 ensures that a fire due to these sources is highly unlikely.

e) Ventilation Features and Ceiling Height - these features ensure that a hot gas layer will not form from any postulated fire.

f) Independent Quantification of Potential Fire Effects on the RES - credible fires due to fixed combustibles in the subject fire zones and the resultant exposure to the RES has been evaluated in Engineering Study 13-CS-A12. This study has determined that the RES would not be subjected to temperatures in excess of 1000°F during a postulated fire.

---

*The portable fire extinguishers are removed from containment in Modes 1-4, but would be brought into containment by the Fire Department on an as-needed basis in the event of a fire in containment.

g) Emergency Response Capability - APS maintains a dedicated, on-site, professional Fire Department to respond to fire emergencies.

In summary, the qualitative and quantitative analyses described above demonstrate the acceptability of using Thermo-Lag as the RES for the Train A pressurizer auxiliary spray valve and associated circuits. The design and programmatic fire protection features ensure that the RES would not be exposed to temperatures such that combustion of the RES material would occur in the event of any credible fire. Therefore, the ability to achieve and maintain safe shutdown conditions would not be impacted by any postulated fire scenario. The RES, as designed, meets the intent of 10CFR50, Appendix R, Section III.G.2.f.

Table 9A-1

CABLE TRAY LENGTHS BETWEEN TRAINS

Safe Shutdown Function	Minimum Continuous Cable Tray Span Between Trains (feet)	Quantity of Intervening Combustible Material
Pressurizer pressure Pressurizer level	67	1 tray stack with 5 trays and intermittent installations of Thermo-Lag 330-1 material
Shutdown cooling isolation	80	1 tray stack with 2 trays and intermittent installations of Thermo-Lag 330-1 material
RCS hot leg and cold leg temperature	166	1 tray stack with 4 trays and intermittent installations of Thermo-Lag 330-1 material
Steam generator pressure Steam generator level	140[a]	1 tray stack with 2 trays and intermittent installations of Thermo-Lag 330-1 material
Pressurizer auxiliary spray	50	1 tray stack with 2 trays and intermittent installations of Thermo-Lag 330-1 material

a. Only one steam generator is required to achieve shutdown.

QUESTION 9A.131 (FPER Audit Open Item No. 26) (9B.2)

The applicant should document in the Fire Protection Evaluation the fire hazards analysis for the corridor areas on elevation 40 feet and 51 feet 6 inches of auxiliary building.

RESPONSE: Engineering drawing 13-A-ZYD-023 (formerly FPER Figures 11 and 12) have been revised to show new zones 87A, 87B, 88A, and 88B. These new zones are documented in section 9B.2 in the manner of other identified fire zones.

QUESTION 9A.132 (FPER Audit Open Item No. 27) (9B.2)

The applicant should protect the propane piping in the corridor on elevation 140 feet of the auxiliary building so as not to be subject to damage from corridor traffic.

RESPONSE: The propane line at elevation 140 feet has been rerouted to be above the structural framework of the drop ceiling so as to be protected from impact from personnel transiting through the corridor.

Note: Propane is no longer used, but the piping is still in use for other gasses and remains routed above the drop ceiling.

QUESTION 9A.133 (FPER Audit Open Item No. 28) (9B.2)

The applicant should assess the need for forced ventilation in the flammable gas storage room in elevation 140 feet of the auxiliary building.

RESPONSE: Ventilation for flammable gas storage, per the guidance contained in NFPA 51 (1974), Paragraph 22, (fuel gas cylinder storage) has been provided.

QUESTION 9A.134 (NRC Request for Additional Information, RSB)[a] (9.3.4)

By letter (NRC to C-E) dated March 27, 1984, the staff expressed concern related to the availability of the auxiliary pressurizer spray (APS) system to perform its required safety functions for CESSAR System 80 plants (Palo Verde, WNP-3) which are designed without PORVs. As noted in the subject letter, the staff considers that the CESSAR System 80 APS should be treated as safety-related in accordance with Appendix A to 10CFR50 and 10CFR100 since it is required for safe shutdown of the plant and to mitigate the consequences of a SGTR accident should the main pressurizer spray system become unavailable. APS flow is initiated from the control room by opening at least one of the redundant (parallel) auxiliary spray valves (CH-203 or CH-205) in combination with the closure of the existing loop charging valve (CH-240). The staff expressed concern that a failure of CH-240 to close would negate the safety function of the APS system.

After being informed of the staff's concern, C-E committed (September 18, 1984 letter) to modify CESSAR System 80 to provide a valve in series with the existing loop charging valve (CH-240). However, discussions with C-E revealed that CH-240 and the new series valve would be powered from non-Class 1E

a. Letter from G. W. Knighton, NRC, to E. E. Van Brunt, Jr., APS, dated December 13, 1984.

buses even though the valves are considered to be safety-related. The staff finds this unacceptable since these valves are required to perform a safety function as discussed above and no analysis has been provided to justify the use of nonsafety-related buses to provide power for operation of the subject valves. It should be noted that Branch Technical Position RSB 5-1 states that suitable redundancy should be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.

It is the staff's position that if equipment (pumps, valves) is required to perform a safety-related function, the mechanical and electrical components including any associated electrical power source should be treated as safety-related and implemented as such. Thus, the existing loop charging valve (CH-240) and the additional series valve used to isolate normal charging flow should satisfy the single failure criterion and should not be dependent on the use of nonsafety-related equipment including power supplies. Specifically, each valve should be powered from a separate, electrically independent Class 1E power source, or the use of non-Class 1E power to the valves should be justified on some other defined basis.

It is the staff's understanding that the Palo Verde (first CESSAR System 80 reference plant) applicant has elected to implement C-E's proposed design and intends to power the series loop charging valves from nonsafety-related power buses. Although it is recognized that these valves will fail closed on

loss of power, information provided to date is insufficient to determine that all possible failures or design basis events will result in a fail-safe (closed) condition. Therefore, a failure modes and effects analysis should be performed by the Palo Verde applicant to show that the capability of the subject valves to perform the intended protective functions cannot be degraded below an acceptable level as a result of all possible circumstances (i.e., low voltage, low frequency, design basis events, etc.) associated with the offsite power supply system and its associated non-Class 1E buses. Alternately, the staff will consider the implementation of Class 1E electrical protective devices within the non-Class 1E power system as a means to assure that the capability of the valves to perform the intended safety functions is not degraded below an acceptable level. The applicant should provide for staff review information to describe the results of the required analysis and any non-Class 1E power supply system design changes that may be proposed as a result of the analysis.

RESPONSE: CH-240 and the new series valve (CH-239) are to be powered from non-Class 1E buses. These valves will fail closed on loss of power.

The concern specifically addresses insufficient information to determine that all possible failures or design basis events associated with the offsite power supply system and its associated non-Class 1E buses, will result in a fail-safe (closed) condition such that the protective functions are performed.

The failure modes and effects analysis (FMEA) provided as table 9A-2 examines the non-Class 1E dc power system that isolates the control solenoids for loop isolation valves CHE-239 and CHE-240. It demonstrates that there is no credible event that could prevent the delivery of auxiliary pressurizer spray. The analysis considered loss of power, grounding, short circuiting, overvoltage, undervoltage, loss of air, and a seismic event. Due to spatial separation, a pipe break or a fire cannot defeat the ability of the system to close. Refer to the PVNGS fire hazards analysis in appendix 9B and the PVNGS spurious actuation analysis submitted by ANPP-31101, dated November 13, 1984.

Auxiliary pressurizer spray has no safety function during a LOCA, and, consequently, LOCA effects were not analyzed.

However, due to the NRC's concern, Class 1E overvoltage protection isolation relays will be added to the non-Class 1E control circuitry for valves CHE-PDY-239B and CHE-PDY-240B. This plant modification will be complete prior to restart following the first refueling outage of PVNGS Unit 1, prior to exceeding 5% power for PVNGS Unit 2, and prior to fuel load for PVNGS Unit 3.

Air Supply	Supply air to CHE-240 and CHE-239	Loss of air	Loss of air to CHE-240 and CHE-239	Valves CHE-240 and CHE-239 close, enabling pressurizer spray

Footnotes

a. The red and green indicator lamps have GE 756 bulbs which are rated at 0.08 amps at 14 volts, corresponding to 175 ohms. Since two bulbs are connected in parallel, 88 ohms will be used. The voltage dropping resistors provide an additional 675 ohms, so the total circuit resistance is approximately 763 ohms (plus cable resistance). At a maximum battery voltage of 140 V-dc, the indicating lamp circuits would be limited to a maximum of 0.18 amps. As the required (minimum) solenoid valve operating (inrush) current is 1.5 amps, a cross-connected short could not cause the solenoid valve to open.

b. These cables do not contain conductors that could operate the solenoid.

c. This cable is a two-conductor that provides power to the solenoid. A cable conductor short could only deenergize the solenoid.

TABLE 9A-2

AUXILIARY PRESSURIZER SPRAY POWER SUPPLIES (Sheet 9 of 9)

d. A cable conductor short could short-circuit (jumper) the switch, causing energization of the solenoid. For this condition to disable auxiliary pressurizer spray, both solenoids would have to be identically affected by a cable conductor short and all bus, motor control center, and distribution panel breakers and the elementary scheme fuses would need to be incapable of being deenergized. The scheme cable for CHE-240 is routed in Seismic Category I cable tray and has a different routing (except within the Seismic Category I control cabinet) from the scheme cable for CHE-239, which is routed in non-Seismic Category I conduit that has been analyzed to withstand Seismic Category I design loads without damaging adjacent Seismic Category I equipment.

e. Note that the redundant valve is unaffected by the postulated failure.

f. Three battery chargers are connected to the dc bus. Only two of the three chargers are required to keep the battery in a fully charged state.

9B.1 INTRODUCTION AND METHODOLOGY

9B.1.1 INTRODUCTION

This appendix presents an evaluation of the fire protection provided for PVNGS Units 1, 2, and 3. The evaluation has been made by comparing the PVNGS fire protection features to the guidelines contained in Appendix A of the Branch Technical Position (BTP) APCSB 9.5-1 (revised February 24, 1977) and to 10CFR50, Appendix R, Part III, Sections G, J, and O (issued September 1, 1982). Units 1, 2, and 3 are replicate plants with virtually identical fire protection systems within the power block. All three units are served from a common underground fire water main loop using common fire pumps and water storage tanks. This report provides an evaluation that is applicable to all three units.

The objective of the PVNGS fire protection program is to minimize both the probability and consequences of fire such that in the event of a fire, the plant may be brought to a safe (cold) shutdown both with and without the availability of offsite power. This is accomplished by using a defense-in-depth approach that includes a suitable combination of fire prevention, detection and suppression capabilities, and plant safety systems designed with redundancy and separation to safely withstand the effects of a fire.

The plant design has been reviewed and design provisions have been included for the preservation of at least one success path which can accomplish the safe shutdown functions. Physical barriers (i.e., walls or rated fire-retardant protective coatings) or spatial separation is the predominant means for

establishing this protection. Alternate shutdown capability is provided in the event of control room evacuation.

The results of the evaluation program are that PVNGS can reach and maintain cold shutdown conditions following a postulated fire. Details of the plant design which provide that assurance are set forth in sections 9B.2 and 9B.3 of this appendix. The fire protection provisions of PVNGS are examined from three viewpoints: (1) to provide a fire hazards analysis, (2) to identify the compliance with Appendix A of BTP APCSB 9.5-1, and (3) to identify the compliance with 10CFR50, Appendix R, Part III, Sections G, J, and O.

9B.1.2 EVALUATION CRITERIA

PVNGS has been evaluated to determine that the overall fire protection program provides reasonable assurance that a fire will not cause an undue risk to the health and safety of the public, will not prevent the performance of necessary safe shutdown functions, and will not significantly increase the risk of radioactive release to the environment. Appendix A of BTP APCSB 9.5-1 and 10CFR50, Appendix R, Part III, Sections G, J, and O provide specific guidelines which can be used to review the fire protection program for an operating plant. These guidelines have been addressed whenever applicable; but to provide broader guidelines, the following criteria have also served as the basis for the evaluation of the PVNGS fire protection program:

A. General Design Criterion 3 (10CFR50, Appendix A)

Fire Protection - "Structures, systems, and components important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions. Noncombustible and heat-resistant materials shall be used wherever practical throughout the unit, particularly in locations such as the containment and control room. Fire detection and firefighting systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effects of fires on structures, systems, and components important to safety. Firefighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of these structures, systems, and components." (See subsection 3.1.3.)

B. Defense-in-Depth Criterion (Paraphrased from BTP APCSB 9.5-1, Section B.1)

The fire protection program should extend the concept of defense-in-depth to fire protection in fire areas important to safety, with the following objectives:

- to prevent fires from starting;
- to detect rapidly, control, and extinguish promptly those fires that do occur;

- to provide protection for structures, systems, and components important to safety so that a fire that is not promptly extinguished by the fire suppression activities will not prevent the safe shutdown of the plant.

C. Single Failure Criterion (BTP APCSB 9.5-1, Section C.1.c.(2))

"A single active failure or a crack in a moderate-energy line (pipe) in the fire suppression system should not impair both the primary and backup fire suppression capability...."

D. Fire Suppression Systems Capacity and Capability (Paraphrased from BTP APCSB 9.5-1, Appendix A, Section E.2.(e))

Fire suppression capability shall be provided, with capacity adequate to extinguish any fire which may credibly occur and have adverse effects on equipment and components important to safe shutdown in the event of a fire.

E. Backup Fire Suppression Capability (BTP APCSB 9.5-1, Section C.1.c.(1))

"Total reliance should not be placed on a single fire suppression system. Appropriate backup fire suppression capability should be provided."

F. Occurrence of Fire and Other Phenomena (BTP APCSB 9.5-1, Section C.1.d.(1))

"Fires need not be postulated to be concurrent with nonfire-related failures in safety systems, other plant accidents, or the most severe natural phenomena."

Although specific guidelines may indicate particular provisions for fire protection, the overall adequacy of the fire protection program and potential modifications to it shall be based upon evaluation of the effects of potential fire hazards throughout the plant consistent with the above criteria. This overall adequacy is documented through the fire hazards analysis of section 9B.2.

9B.1.3 METHOD OF ANALYSIS

The guidelines set forth in the BTP APCSB 9.5-1, Appendix A, were the basic means for development of the fire protection program. A detailed comparison of the Appendix A guidelines against the PVNGS design is presented in section 9B.3. Section 9B.2 is the fire hazards analysis, performed as part of the Appendix A requirements, and delineates the design provisions for compliance with the requirements of 10CFR50, Appendix R, Part III, Sections G and O. Provisions for compliance with 10CFR50, Appendix R, Part III, Section J, are delineated in section 9.5.3. The fire hazards analysis is presented by fire areas which are further subdivided into analysis areas and fire zones to adequately define specific plant locations.

9B.1.3.1 Fire Hazards Analysis Methodology

The fire hazards analysis was performed to (1) consider potential in-situ and transient fire hazards; (2) determine the consequences of fire in any location in the plant on the ability to safely shut down the reactor or on the ability to minimize the release of radioactivity to the environment; and (3) specify features for fire detection, fire suppression, and fire containment and alternative shutdown capability as required for each fire area containing structures, systems, and components important to safety in accordance with NRC guidelines and regulations.

The supporting analysis technique to determine the relative fire loading used in this report is as follows:

A. Estimate the approximate total combustible load in pounds for each type of combustible material present in each fire zone.

   (A combustible load is any material that will burn or sustain the combustion process, whether or not it exhibits flame, under the exposure fire conditions that can exist at their point of application.) Cables routed through conduit and paint applied to noncombustible surfaces are not included in the combustible loading.

   The total combustible (fire) loading includes both in situ and postulated transient combustible loads. The transient combustible load is dependent upon the type and quantity of the in situ load in each fire zone and is determined as follows:

- In each fire zone, a transient combustible load of at least 50 pounds of ordinary combustibles (approximately 400,000 Btu) or 2-1/2 gallons of flammable liquid (approximately 400,000 Btu) is postulated, and when applicable, either of the following:

- Where the predominant combustibles are consumable items, the replacement of combustibles (minimum 400,000 Btu) is considered in calculating the total transient combustible load. For example, a lube oil or charcoal filter replacement may introduce a quantity of transient oil or charcoal equal to that of the in situ load into the fire zone, or

- Where cable tray and conduit routings are the predominant combustible, an average 300 feet of replacement cable (approximately 400,000 Btu) is considered in calculating the total transient combustible load.

B. Derive the total heat release, in Btu, from the heat of combustion of the materials for the number of pounds of combustibles in the zone assuming complete combustion.

The total Btu heat release is divided by the square footage of the floor surface area of the fire zone (Btu per square foot).

C. The approximate average combustible (fire) loading (Btu/ft^2) for each zone is then categorized as follows:

- Low - Less than 60,000 Btu/ft^2 (less than 45 minutes)
- Moderate - 60,000 to 160,000 Btu/ft^2 (45 minutes to 2 hours)
- High - Over 160,000 Btu/ft^2 (over 2 hours)

These categories are more conservative than those referenced in the National Fire Protection Association (NFPA) Fire Protection Handbook, 14th edition, Chapter 8, page 6-82, British Fire Loading Studies. These studies also include a secondary higher limit for combustible loading in limited isolated areas. At combustible loading in limited isolated areas. At PVNGS some variation is expected, but because each fire zone represents a relatively small compartment within the building, no further breakdown of combustible loading, beyond the average for the zone, is calculated. Due to the fact that combustible loading in each zone is approximate, borderline cases may be classified in the next higher category to allow for minor fluctuations. The protection provided for each zone is included in the fire hazards analysis.

Table 9B.1-1 is provided from NFPA Handbook Table 6-8A which shows estimated fire severities

based on combustible loading. This table gives an approximate equivalent fire severity in hours by comparing heat release rates from building fire tests of known combustible (fire) loadings (Btu/ft^2) to the standard time-temperature curve used by the American Society for Testing and Materials (ASTM) E119 (1976) in fire resistance testing of building materials. This table is provided for reference.

9B.1.3.2 Appendix R Compliance Assessment Methodology

A detailed comparison of the 10CFR50, Appendix R, guidelines against the PVNGS design was conducted. This comparison evaluated the capability to safely shut down the plant in the event of an exposure fire that could impact electrical equipment, cables, or components necessary for safe shutdown.

A summary of the methodology is as follows:

- Identify performance goals for safe shutdown.
- Identify those plant systems and flowpaths required to satisfy safe shutdown performance goals.
- Identify specific plant components required for safe shutdown. Include those components required to be operated and those components whose spurious actuation could adversely impact safe shutdown capability. Also consider components whose failure could result in inadvertent safety signal actuation.

Table 9B.1-1

ESTIMATED FIRE SEVERITY FOR OFFICES AND LIGHT COMMERCIAL OCCUPANCIES[(a)]

Heat Potential Assumed Btu/ft^2	Equivalent Fire Severity Approximately Equivalent to that Test Under Standard Curve for the Following Periods
40,000	30 min
80,000	1 hr
120,000	1-1/2 hr
160,000	2 hr
240,000	3 hr
320,000	4-1/2 hr

a. Fire Protection Handbook, 14th Edition, NFPA, Section 6, Chapter 8, Table 6-8A.

- Identify cables whose fire-induced failure could adversely impact safe shutdown capability and determine their routing.
- Determine survivability of plant safe shutdown capability in the event of a fire in any given plant area.
- Determine compliance based upon component redundancy, operator actions, fire rated enclosures, and licensing evaluations or deviations.
- For those compliance strategies crediting an operator action, determine the feasibility of the action. A

manual action is considered feasible if there is adequate time, manpower, lighting, and communication to perform the action.

For PVNGS, many of the safe shutdown performance goals can be performed by two independent, redundant trains which are separated from a common fire by rated physical boundaries and/or by separation distances which make the spread of fire improbable. Either of these trains is capable of performing the safe shutdown function. Where fully redundant capability is not provided, alternate success paths which may involve systems having similar, but not identical, capabilities are used to assure that the safe shutdown function capabilities can, indeed, be performed. This capability to accomplish the safety functions is maintained both with and without offsite power.

9B.1.4 FIRE HAZARDS ANALYSIS DEFINITIONS AND FORMAT

9B.1.4.1 Definitions

A. Fire Areas

Fire areas are those portions of a building or plant that are separated from other areas by boundary fire barriers which will contain the spread and adverse effects of a fire. The fire areas were determined in part by plant design features relating to fire safety and in part to minimize the likelihood of fires resulting in significant radioactive release. These features included overall plant layout, fire-resistant characteristics of construction, quantity,

type, and location of radioactive and combustible materials and separation criteria relating to safe shutdown trains. Fires in nonsafety-related, nonradioactive structures within the plant, which do not contain safe shutdown components or cables, were not considered as affecting the safe shutdown of the plant and therefore were not specifically included as part of the fire hazards analysis. However, fire detection and suppression capabilities have been provided in these locations, even though they are not required to protect safety-related or safe-shutdown equipment or ensure operator access or egress for manual safe-shutdown actions or mitigate radiological releases in the event of a fire. Fire protection features for these areas (e.g., barriers, detection, suppression) are not required to be included in the scope of the NRC-mandated fire protection quality assurance program.

PVNGS has also evaluated the capability to safely shut down the plant in the event of an exposure fire that could impact redundant electrical equipment, cables, or components necessary for safe shutdown. Based on this evaluation, fire areas as shown on figures 9B-1 through 9B-6 and engineering drawing 13-P-00B-005 were defined.

Each of the fire areas is discussed in detail in the fire hazards analysis, section 9B.2.

B. Analysis Areas

Analysis areas are groupings of fire zones (or in some cases a single fire zone) that will contain a postulated fire. Analysis area selection was based on (1) fire rated boundaries, (2) an approved deviation request which demonstrates the adequacy of the separation or boundary, or (3) an engineering evaluation in accordance with Generic Letter 86-10 can be justified. Consideration in selection of analysis areas was also given to ease of operator actions required to be performed for safe shutdown due to the fire, cable routing, and components affected by cables lost due to fire within the group of zones selected.

C. Fire Zones

Fire zones are subdivisions of fire areas which may contain either combustible material, radioactive material, or equipment/components available to achieve and maintain safe shutdown in the event of a fire. Some fire zones have been established to better define and represent specific plant locations (e.g., rooms, corridors, tanks, etc.) in order to optimize fire protection response as discussed in sections 9B.2 and 9B.3 and referred to in BTP APCSB 9.5-1, Appendix A.

9B.1.4.2 Fire Hazards Analysis Format

The fire hazards analysis is organized by fire area. As necessary, each fire area is further subdivided into analysis areas and fire zones. The following information is provided for each subdivision:

9B.1.4.2.1 Fire Areas

A. Area Boundary Description

To orient the reader, a brief statement is provided describing the fire area, its location within the plant, and a figure reference. The boundaries of the fire area are then explicitly described, including those walls which are fire rated.

B. Deviations from 10CFR50, Appendix R, Section III.G

A detailed discussion of the fire area specific deviations from the requirements of 10CFR50, Appendix R, is provided.

9B.1.4.2.2 Analysis Areas

Following the description of each fire area, the analysis area(s) within the fire area are detailed. Each analysis area includes:

A. Location

To orient the reader, a brief statement is provided describing the analysis area, its location within the plant, and a figure reference.

B. Analysis Area Boundaries

The boundaries of the analysis area are explicitly described, including those boundary walls which are fire rated.

C. Safe Shutdown Related Components and Cables

A listing of systems with safe shutdown related cables and of major safe shutdown related components within each analysis area is presented.

D. Summary and Conclusions

This section summarizes how safe shutdown is assured from the information presented in the 10CFR50, Appendix R, III.G/III.L compliance assessment (APS Calculation Number 13-MC-FP-318) based on component redundancy, operator action, fire rated enclosures, spatial separation, alternate shutdown capability, or an existing deviation.

9B.1.4.2.3 Fire Zones

Following the description of each analysis area, the fire zones within the fire area are detailed. Each fire zone analysis includes:

A. Location

To orient the reader, a brief statement is provided describing the fire zone, its location within the plant, and a figure reference.

B. Fire Prevention Features

The boundaries of the fire zone are explicitly described, including those zone boundary walls which are fire-rated. Openings through zone boundaries such as zone access (i.e., doors, personnel hatches), sealed electrical and pipeway penetrations, and rated HVAC dampers are also noted. In addition, structural steel members protected from fire and raceways that are coated/wrapped to meet the separation requirements of 10CFR50, Appendix R, Section III.G, are identified. HVAC ducting and electrical cable tray supports are coated/wrapped as necessary as described in the appendix 9A responses to Questions 9A.108, 9A.109, and 9A.110.

C. Safety-Related Equipment and Components

A listing of safety-related equipment and components not required for safe shutdown within each fire zone is presented.

D. Nonsafety-Related Equipment and Components

A listing of significant nonsafety-related equipment and components within each fire zone is presented.

This listing was compiled both as an aid in the identification of combustibles and of equipment and components which may be lost in the event of a fire.

E. Radioactive Material

The presence of radioactive material in tanks, filters, demineralizers, and piping is noted as

applicable. Radioactive material present in smoke detectors and radiation monitors (i.e., check sources) is generally found throughout the plant and is not specifically described. Radioactive sources are controlled in accordance with section 12.2 and unless otherwise noted are classified as none and have not been listed.

F. Combustible Loading

The combustible (fire) loading within a fire zone is determined and categorized as low, moderate, or high. For the methodology, see section 9B.1.3.1.

G. Fire Detection

The type of fire detection system utilized within the fire zone is noted.

H. Fire Suppression

Primary and secondary means of fire suppression available to extinguish a fire are listed. If a means of suppression to be used is not located within the fire zone, it has been noted and its physical location relative to the fire zone stated.

I. Ventilation

A description of smoke abatement capabilities from the fire zone is presented.

J. Drainage

The quantity and size of floor drains within a fire zone are noted. The drainage system has been sized

to prevent flooding in the event of fire suppression system operation. (See section 9.3.3.2.1.1.2)

K. Emergency Communications

The presence of sound-powered phone jacks within the fire zone is noted.

9B.2 FIRE HAZARDS ANALYSIS

9B.2.0 INTRODUCTION

This section presents the results of the PVNGS fire hazards analysis performed for each of the fire areas (figures 9B-1 through 9B-6 and engineering drawing 13-P-00B-005) and fire zones (engineering drawings 13-A-ZYD-029, -031, -030, -023, -024, -026, -022, and –021).

The fire protection features provided for safe shutdown and safety-related structures, systems, and components (including access and egress for manual operator actions) or in areas important to safety where significant radioactive release is credible in the event of fire, are required to be included in the fire protection quality assurance program (Reference table 9B.3-1, Item C, Quality Assurance Program). Fire protection features which are not relied upon for protection of safe shutdown or safety-related structures, systems, and components or to ensure operator actions for safe shutdown or to control the release of radioactive material in the event of a fire are not required to be included in the fire protection quality assurance program. Examples of areas not required to be included in the quality assurance program are found in Miscellaneous Analysis Area section 9B.2.20. See also the deviation described below in section 9B.2.0.A.1.

With each fire area description, a detailed itemization of fire area specific deviations from the separation requirements of 10CFR50, Appendix R, Section III.G, is also presented. In addition, several generic deviations with relevance to many of the fire areas are:

A. In general, exterior walls, basemats, and roofs are not rated when:

1. They are not required to separate a safe shutdown-related train inside the fire area from a significant fire hazard (e.g., oil filled transformers) outside the fire area, and

2. They do not separate safety-related areas from nonsafety-related areas that present a significant fire threat to the safety-related areas.

The existing design which includes nonrated exterior walls, basemats, and roofs is an acceptable alternative to the separation requirements of 10CFR50, Appendix R, Section III.G.2.

B. Some fire doors have been modified to include security system hardware. In general, the modifications have a minimal impact on the door fire resistance as the modification affects a limited area of one side of the door. Further, these modifications are necessary to provide adequate station security. The modifications are in accordance with industry practice and are considered acceptable in that without modification the doors would cause a condition detrimental to overall facility safety.

C. Some fire doors have not been installed in strict compliance with the originally tested configuration which formed the basis for labeling per NFPA-80. The

deviations are limited to door-to-frame gaps, door-to-floor gaps, and latchset throw. All fire doors, however, are or will be purchased as labeled fire doors except as noted in question 9A-106.

The fire door installation deviations from the tested configuration and NFPA-80 have been found acceptable based on additional fire tests performed at Warnock-Hersey laboratory. The special test configurations were chosen to conservatively represent the configurations as installed in the field. Since the field installation of the fire doors is not in strict compliance with the original tested configuration, the requirement to maintain a label from a nationally recognized laboratory on the fire doors per NFPA-80 is no longer applicable. Maintenance of fire doors with respect to door-to-frame gaps, door-to-floor gaps and latch throw shall conform to the special test configuration as tested at Warnock-Hersey laboratory. All other aspects of the fire doors, other than gaps and latch throw, will be maintained in accordance with NFPA-80.

Minor deviations of the installed fire doors from the Warnock-Hersey tested configuration will be safety reviewed and evaluated and documented on a case-by-case basis by a qualified fire protection engineer.

D. DELETED

E. Five different safe shutdown actions for postulated fire scenarios exist that require activity in outside

yard areas which are not provided with 8-hour battery-powered emergency lights specified in Section III.J of Appendix R to 10CFR50. Portable hand-held lanterns will be used in these outside areas in lieu of fixed 8-hour battery-powered emergency lighting units (refer to subsection 9.5.3.2.2.3).

1. Access to the Train B Diesel Generator Local Control Panel During a Postulated Fire in Fire Zone 5B

   For a postulated fire in Zone 5B (train B switchgear room located in the control building at the 100-foot elevation), the train B diesel generator must be disabled at the local control panel located in Zone 22B of the diesel generator building to preclude or overcome adverse consequences of an engineered safety features actuation signal to train B components. The normal access path to Zone 22B from the control room is through Zone 5B, but if a fire exists in Zone 5B an alternate path is via the southwest exit door of the control building, through the control building hardened barrier controlled access point, and across the outside yard area, and into the train B side of the diesel generator building through the missile door. No fixed 8-hour battery-powered emergency lighting is installed in the outside yard area for this access/egress path. However, fixed

8-hour battery-powered emergency lighting is provided for access/egress and required actions inside the control building, the control building hardened barrier controlled access point, and the diesel generator building. Portable hand-held lanterns are readily available for use by the operators for traversing the outside area, and pole-mounted security lighting, though not provided for Appendix R compliance, also provides illumination for this outside area.

2. Access to the Condensate Storage Tank Pump House During a Postulated Fire in Fire Zones 42B or 42C.

For a postulated fire in Zones 42B (train B electrical penetration room located in the auxiliary building at the 100-foot elevation) or 42C, (east corridors located in the auxiliary building at the 100-foot elevation), the train B condensate manual discharge valve located in Zone 83, the condensate storage tank pump house, must be closed to preclude the loss of condensate storage tank volume via gravity draining through a spurious opening of a remotely operated discharge valve. The access/egress path to the condensate storage tank pump house is from the control building through the turbine breezeway, across the outside yard area, and through the condensate

storage tank hardened barrier controlled access point. No fixed 8-hour battery-powered emergency lighting is installed in the outside yard area for this access/egress path. However, fixed 8-hour lighting is provided for access/egress and required actions inside the control building, turbine breezeway, condensate storage tank hardened barrier controlled access point, and condensate storage tank pump house. Portable hand-held lanterns are readily available for use by the operators for traversing the outside area, and pole-mounted security lighting, though not provided for Appendix R compliance, also provides illumination for this outside area.

3. Access to the Condensate Storage Tank Pump House During a Postulated Fire in Fire Zones 42D, 47A, or 52A.

For a postulated fire in Zones 42D (west corridors located in the auxiliary building at the 100-foot elevation), 47A (train A electrical penetration room located in the auxiliary building at the 120-foot elevation), or 52A (west corridors located in the auxiliary building at the 120-foot elevation), the train A condensate manual discharge valve located in Zone 83, the condensate storage tank pump house, must be closed to preclude the loss of condensate storage tank volume via gravity

draining through a spurious opening of a remotely operated discharge valve. The access/egress path to the condensate storage tank pump house is from the control building through the turbine breezeway, across the outside yard area, and through the condensate storage tank hardened barrier controlled access point. No fixed 8-hour battery-powered emergency lighting is installed in the outside yard area for this access/egress path. However, fixed 8-hour lighting is provided for access/egress and required actions inside the control building, turbine breezeway, condensate storage tank hardened barrier controlled access point, and condensate storage tank pump house. Portable hand-held lanterns are readily available for use by the operators for traversing the outside area, and pole-mounted security lighting, though not provided for Appendix R compliance, also provides illumination for this outside area.

4. Access to the Condensate Storage Tank Pump House During a Postulated Fire in Fire Zone 17.

   For a postulated fire in Zone 17 (control room area), the condensate storage tank level must be monitored using the local level indicator located in Zone 83, the condensate storage tank pump house. The access/egress path to the condensate storage tank pump house is from the

control building through the turbine breezeway, across the outside yard area, and through the condensate storage tank hardened barrier controlled access point. No fixed 8-hour battery-powered emergency lighting is installed in the outside yard area for this access/egress path. However, fixed 8-hour lighting is provided for access/egress and required actions inside the control building, turbine breezeway, condensate storage tank hardened barrier controlled access point, and condensate storage tank pump house. Portable hand-held lanterns are readily available for use by the operators for traversing the outside area, and pole-mounted security lighting, though not provided for Appendix R compliance, also provides illumination for this outside area.

5. Access to and Operation of a Manual Isolation Valve at the Reactor Makeup Water Tank During a Postulated Fire in Fire Zones 14, 52D, 53, 50B, or 86B.

   For a postulated fire in Zone 14 (lower cable spreading room located in the control building at the 120-foot elevation), 52D (east corridor located in the auxiliary building at the 120 foot elevation), 53 (process radiation monitor and boronometer room located in the auxiliary building at the 120-foot elevation), 50B (valve gallery located in the auxiliary

building at the 120-foot elevation), or 86B (train B compartment between the auxiliary and control buildings between the 74-foot and the 156-foot, 4-inch elevations), a 3-inch manual valve (P-CHN-V771) located in an outside area at the reactor makeup water tank in Zone 79 must be closed to ensure the ability to prevent an inadvertent boron dilution. The access/egress path to the subject valve from the control room is via the southwest exit door of the control building, through the control building hardened barrier controlled access point, and across the outside yard area. No fixed 8-hour battery powered emergency lighting is installed in the outside yard area at the location of the subject valve or for access/egress across the outside yard to the valve location. Fixed 8-hour battery-powered lighting is provided for the access/egress route inside the control building and control building hardened barrier controlled access point. Portable hand-held lanterns are readily available for use by the operators for traversing the outside area and for operating the manual valve, and pole-mounted security lighting, though not provided for Appendix R compliance, also provides illumination for the outside transit area.

For the five situations presented above, the affected potential safe-shutdown activities consist of simply traversing outside

yard areas between buildings in four cases, or traversing an outside yard area to operate a 3-inch manual valve at an outside yard area in the fifth case. These are short duration, non-complex activities, where the use of portable lanterns can provide sufficient illumination for the required tasks with minimal distraction or interference. The traversing or valve closing that may be required to be performed in the outside yard areas can be easily performed by utilizing a hand-held lantern. The lanterns will be readily available in or near the control room at elevations 140 feet and 100 feet. They are regularly maintained to ensure proper operation and will only need to be energized for the relatively short time that an operator is outside the plant buildings. In addition to utilizing hand-held lanterns for illumination in these outside areas, pole-mounted security lights are installed in the outside yard areas which, though not provided for Appendix R compliance, also provide a reliable source of yard illumination for traversing. The security lights are supplied by their own backup diesel generator which would not be affected by the fires identified in the above scenarios. Access/egress routes through plant buildings will continue to be provided with fixed 8-hour battery-powered emergency lights, as will the safe-shutdown areas inside the plant buildings.

F. A deviation is taken from Appendix R, Section III.L using the guidance provided in Generic Letter 86-10, Questions 3.8.4 and 5.3.10, to the extent that it requires the reactor coolant system process variables, as discussed below, to be maintained within those predicted for a normal loss of AC power

and the reactor coolant make-up function to be capable of maintaining the reactor coolant level within the level indication in the pressurizer.

Discussion

10CFR50, Appendix R, Section III.L states:

1. During the postfire shutdown, the reactor coolant system process variables shall be maintained within those predicted for a loss of normal a.c. power, and the fission product boundary integrity shall not be affected; i.e., there shall be no fuel clad damage, rupture of any primary coolant boundary, or rupture of the containment boundary.

2. The performance goals for the shutdown functions shall be:

    a. The reactivity control function shall be capable of achieving and maintaining cold shutdown reactivity conditions. The reactor coolant makeup function shall be capable of maintaining the reactor coolant level above the top of the core for BWRs and be within the level indication in the pressurizer for PWRs.

    b. The reactor heat removal function shall be capable of achieving and maintaining decay heat removal.

c. The process monitoring function shall be capable of providing direct readings of the process variables necessary to perform and control the above functions.

d. The supporting functions shall be capable of providing the process cooling, lubrication, etc., necessary to permit the operation of the equipment used for safe shutdown functions.

Generic Letter 86-10, Question 3.8.4 states:

> The damage to the system in the control room for a fire that causes evacuation of the control room cannot be predicted. A bounding analysis should be made to assure that safe conditions can be maintained from outside the control room.

A bounding analysis was performed for the control room fire scenario to assure that safe shutdown conditions could be maintained from outside the control room. This bounding analysis (ref. calculation 13-MC-FP-318, 10CFR50 Appendix R IIIG/IIIL Compliance Assessment and 13-MC-FP-317, 10CFR50 Appendix R Operational Considerations) assumed the worst case spurious actuations as well as loss of all automatic function (such as ESFAS, DG auto start and sequencing) of components whose control circuits could be affected by a fire in the control room. This conservative analysis indicated that the required reactor coolant system process variables and their indications, i.e., pressurizer level, RCS temperature and

pressure could exceed those predicted for a loss of offsite power. These transients could occur until positive control of equipment affected by the fire and restoration of charging flow is established within 30 minutes.

Conclusions

The bounding analysis evaluated the consequences of these transients and demonstrated that safe shutdown can be accomplished satisfactorily (ref. calculation 13-MC-FP-317, 10CFR50 Appendix R Operational Considerations and calculation 13-MC-FP-316, 10CFR50 Appendix R Manual Action Feasibility) and concluded that:

1. The plant would not be placed in an unrecoverable condition,
2. Fuel damage would not occur, and
3. The process variables would be restored once positive control of the equipment and restoration of charging flow was established, within 30 minutes. This has been verified to be accomplished by a timed walkdown of the Control Room Fire procedure.

Therefore there is no adverse effect on the ability to achieve and maintain safe shutdown in the event of any postulated fire as a result of this deviation.

9B.2.1 FIRE AREA I

9B.2.1.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area I (figure 9B-1, 9B-3, 9B-4, engineering drawing 13-P-00B-005, and (9B-5) contains train A components found in the control building. The fire area includes Analysis Area IA (Zone 1, HVAC Chase J-102, and HVAC Chase J-104), IB (Zones 3A, 4A, 11A, 15A, and 18A), IC (Zone 86A), ID (Zones 6A, 7A, 8A, and 9A), IE (Zone 10A), IF (Zone 5A and Stair C), and IG (Zone 20) engineering drawing 13-A-ZYD-029.

At elevation 74 feet 0 inch, Fire Area I is below grade and bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the east by a 3-hour rated barrier common to Fire Area II (the east wall of Zone 86A is a nonrated barrier common to Fire Area II), and to the west and south by nonrated exterior walls. The west walls of Zones 3A and 86A are 3-hour rated and nonrated, respectively, with both walls common to Fire Area X. The southwest stairwell walls are 2-hour rated. The basemat is nonrated.

At elevation 100 feet 0 inch, Fire Area I is bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the south by a 3-hour rated barrier common to the diesel/control building seismic gap and by a non-rated heavy concrete exterior wall, and a 2-hour rated wall common to the southwest stairwell,

to the east by 3-hour rated barriers common to Fire Area II, and to the west by a 3-hour rated barrier common to Fire Area X. The east and west wall of Zone 86A common to Fire Areas II and X, respectively, is nonrated. The east wall to Zone 10A, common to Zone 10B, is 2-hour rated. The ceilings to Zones 5A, 6A, 7A, 8A, 9A, and 10A are 3-hour rated and common to Fire Area II.

At elevation 120 feet 0 inch, Fire Area I consists of the northwest and southwest corners of the control building. In the northwest corner, Fire Area I includes the northwest HVAC chase and Zones 11A and 86A, bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the south and east by 2-hour and 3-hour rated barriers common to Fire Area II and to the west by a 3-hour rated barrier common to Fire Area X. The east and west wall of Zone 86A common to Fire Areas II and X is nonrated. In the southwest corner, Fire Area I includes the southwest HVAC chase, bounded to the north and east by 2-hour rated barriers common to Fire Area II, to the south by a 2-hour rated wall common to the southwest stairwell and to the west by a 3-hour rated barrier common to Fire Area X.

At elevation 140 feet 0 inch, Fire Area I consists of the northwest and southwest corners of the control building. In the northwest corner, Fire Area I includes the northwest HVAC chase and Zones 15A and 86A, bounded to the north by a 3-hour rated barrier

common to Fire Area XV, to the south and east by 2-hour and 3-hour rated barriers common to Fire Area III and by a nonrated barrier common to Fire Area II, and to the west by a 3-hour rated barrier common to Fire Area X. The west and east walls of Zone 86A, common to Fire Areas X and II, respectively, are nonrated. The ceiling to Zone 86A is a nonrated barrier and common to the roof. In the southwest corner, Fire Area I includes the southwest HVAC chase, bounded to the north and east by 2-hour rated barriers common to Fire Area III, to the south by a 3-hour rated wall common to the southwest stairwell and to the west by a 3-hour rated barrier common to Fire Area X.

At elevation 160 feet 0 inch, Fire Area I is bounded to the north by nonrated and 3-hour rated exterior walls, to the south by a 2-hour rated wall common to the southwest stairwell, a nonrated exterior wall, a 3-hour rated barrier common to the diesel/control building seismic gap and a 2-hour rated barrier common to Fire Area II (Zone 19), to the west by a 3-hour rated exterior wall, and to the east by 3-hour rated barriers common to Fire Area II (Zone 18B) and the corridor building and a 2-hour rated barrier common to Fire Area II (Zone 19). The floor of Zone 20 is 3-hour rated and common to Fire Area III. The ceiling, which is also the roof of the control building, is nonrated.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated barriers to separate circuits of redundant trains.

<u>Discussion</u>

The south and east walls of the northwest HVAC chase (which is adjacent to Fire Area I, Zones 1, 3A, 4A, 5A, 11A, 15A, 18A, 20, and 86A) are common boundaries with Fire Area II (Zone 14) at elevation 120 feet 0 inch and Fire Area III (Zone 17) at elevation 140 feet 0 inch. The HVAC chase has walls of reinforced concrete construction rated for 2 and 3 hours. For a fire to propagate between redundant trains, the fire must burn through at least two 2-hour rated fire barriers. The HVAC chase itself is virtually devoid of combustibles. Fire dampers used in the 2-hour rated wall sections are identical in material and construction to 3-hour labeled devices. Fire detection and automatic suppression are provided in the vicinity of the chase at elevations 100 feet 0 inch, 120 feet 0 inch, and 160 feet 0 inch. Fire detection alone is provided in the vicinity of the chase at elevations 74 feet 0 inch and 140 feet 0 inch. Fire department response (within 20 minutes) is expected, well before degradation

to the existing fire barriers would occur. Access to the chase for the fire department response is available at elevation 100 feet 0 inch (through Zone 5A) and at elevation 120 feet 0 inch (through Zone 11A).

Conclusion

The existing design provides equivalent protection of that required by Section III.G.2, and upgrading the existing design for 3-hour ratings would not significantly enhance the protection currently provided.

2. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated barriers to separate circuits of redundant trains.

Discussion

The north and east walls of the southwest HVAC chase (adjacent to Fire Area I, Zones 1 and 5A) are common boundaries with Fire Area II (Zone 14) at elevation 120 feet 0 inch and with Fire Area III (Zone 17) at elevation 140 feet 0 inch. The HVAC chase has walls of reinforced concrete construction rated for 2 and 3 hours. For a fire to propagate between redundant trains, the fire must burn through at least two 2-hour rated fire barriers. The HVAC chase itself is virtually devoid of combustibles. Fire dampers used in the 2-hour rated wall

sections are identical in material and construction to 3-hour labeled devices. Fire detection and automatic suppression are provided in the vicinity of the chase at elevations 100 feet 0 inch and 120 feet 0 inch. Fire detection alone is provided in the vicinity of the chase at elevations 74 feet 0 inch and 140 feet 0 inch. Fire department response (within 20 minutes) is expected, well before degradation to the existing fire barriers would occur. Access to the chase for the fire department response is available at elevation 100 feet 0 inch (through Zone 5A).

Conclusion

The existing design provides equivalent protection of that required by Section III.G.2, and upgrading the existing design for 3-hour ratings would not significantly enhance the protection currently provided.

3. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour barriers to separate circuits of redundant trains.

Discussion

The north wall of the southwest stairwell (adjacent to Fire Area I, Zones 1, 5A, and 20) is a common boundary with Fire Area II (Zone 14) at elevation 120 feet 0 inch and with Fire Area III (Zone 17) at elevation 140 feet 0 inch.

The stairwell has walls of reinforced concrete construction rated for 2 and 3 hours. For a fire to propagate between redundant trains, the fire must burn through at least two 2-hour rated fire barriers. The stairwell itself is devoid of combustibles. Fire doors utilized in the stairwell are B label (1-1/2 hours). Fire detection and automatic suppression are provided in the vicinity of the stairwell at elevations 100 feet 0 inch, 120 feet 0 inch, and 160 feet 0 inch. Fire detection only is provided in the vicinity of the stairwell at elevations 74 feet 0 inch and 140 feet 0 inch. Fire department response (within 20 minutes) is expected, well before degradation of the existing barriers would occur.

Conclusion

The existing design provides equivalent protection of that required by Section III.G.2, and upgrading the existing design for 3-hour ratings would not significantly enhance the protection currently provided.

4. A deviation is requested to Section III.G.2 to the extent that it requires installation of a 1 hour fire rated barrier and an area-wide suppression system.

Discussion

The west wall of Zone 86A is a fire area boundary between Fire Area I and Fire Area X at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch. The boundary contains two 6-inch (nominal) seismic gaps which are covered with nonrated, solid 18-gauge sheet metal flashings on each side of a reinforced concrete stub wall or pillar. The metal flashings would retard the passage of heat and/or smoke. Fire Area X contains no safe shutdown equipment or cables. Therefore, a postulated fire within Zone 86A would have no effect upon safe shutdown capability, even if the fire did spread into Fire Area X.

Within the Fire Area X side of this boundary, there are negligible combustibles; the compartment adjacent to the seismic gap is a large HVAC and pipe chase with floor dimensions approximately 13 feet by 50 feet. Within Fire Area I, Zone 86A is separated from the remainder of the fire area by 2- and 3-hour rated walls. Zone 86A is separated from Zone 86B (Fire Area II) by a nonrated barrier (see Fire Area I, deviation No. 5, for the Zone 86A/Zone 86B separation considerations). Zonal detection and automatic deluge water spray covers the predominant in situ combustible (cable trays at elevations 100 feet 0 inch and 120 feet 0 inch).

The combustible (fire) loading for Zone 86A is high. This apparently high combustible loading is attributed to the calculation method, in that the combustible material is located in an area with a relatively small floor area combined with a high ceiling. Fire department response (within 20 minutes) is expected, well before significant degradation of the existing fire barriers would occur. Access to Zone 86A for fire department response is available at elevation 100 feet 0 inch (through Zone 5A).

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to a 1-hour rating plus suppression would not significantly enhance protection currently provided.

5. A deviation is requested to Section III.G.2 to the extent that it requires 3-hour rated barriers to separate circuits of redundant trains.

Discussion

The central wall of the dead space compartment between the auxiliary and control buildings is a fire area boundary common to Fire Area I (Zone 86A) and Fire Area II (Zone 86B) at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch. The wall

is reinforced concrete with a nominal 6-inch seismic gap. The seismic gap is covered by solid 1/4-inch steel plates bolted to each side of the concrete wall. The fit is snug and there is no path for heat or smoke to travel through the plate steel.

The dead air space between the steel plates will have an insulating quality, thus minimizing radiant heat transfer to the other side as well as eliminating convected heat through the barrier. Zonal detection and automatic deluge water spray covers the predominant in situ combustible (cable trays at elevations 100 feet 0 inch and 120 feet 0 inch). Train A cable tray are located 8 to 9 feet from the center wall in zone 86A. Train B cable trays are located more than 10 feet from the opposite side of the center wall in Zone 86B. The compliance strategies for the components associated with the "N" raceways do not rely on components whose cables are within 10 feet of the center wall. The total combustible (fire) loading for each of Zones 86A and 86B is high. This apparently high combustible loading is attributed to the calculation method, in that the combustible material is located in an area with a relatively small floor area combined with a high ceiling. Fire department response (within 20 minutes) is expected before significant degradation of the

existing fire barriers would occur. Access to Zone 86A for fire department response is available at elevation 100 feet 0 inch (through Zone 5A). Access to Zone 86B for fire department response is available at elevation 100 feet 0 inch (through Zone 5B).

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to a 3-hour rating would not significantly enhance the protection currently provided.

6. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated barriers to separate circuits of redundant trains.

Discussion

The east wall of Fire Zone 10A is a 2-hour rated barrier common to Fire Area II, Fire Zone 10B. The wall, which separates the two remote shutdown panel rooms, is of metal lath and plaster construction and contains a 3-hour rated fire door. This fire area boundary is not rated at 3 hours due to the lack of a tested configuration featuring a 3-hour rated door frame installed in a 3-hour rated metal lath and plaster wall. Only train A circuitry is routed

through Zone 10A. Zone 10B contains both train B circuitry and some train A conduit.

The combustible (fire) loading in Zones 10A and 10B is moderate. Each of the fire zones is protected by smoke detectors and thermal detectors. A Halon 1301 suppression system prealarmed by smoke and actuated by thermal detectors is installed in each fire zone. Fire department response (within 20 minutes) is expected, well before significant degradation of the existing fire barriers would occur. Access to each of Zones 10A and 10B is possible through the adjacent ESF switchgear rooms.

<u>Conclusion</u>

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to a 3-hour rating would not significantly enhance the protection currently provided.

7. See subsection 9B.2.2 for a deviation common to Fire Area II and the section 9B.2 introduction for generic deviations.

9B.2.1.2 <u>Analysis Area IA</u>

A. Location

Analysis Area IA consists of Fire Zone 1, HVAC Chase J-102, and HVAC Chase J-104.

Fire Zone 1 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

HVAC Chase J-102 is located in the control building at elevations 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, and 160 feet 0 inch.

HVAC Chase J-104 is located in the control building at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 3A 3-hour rated wall common to Zone 86A at column line J1

South: 2-hour rated wall common to the southwest stairwell at column line J4
Nonrated exterior wall of heavy concrete construction at column line J4

East: 3-hour rated wall common to Fire Area II, Zone 2, at column line JC

West: Nonrated exterior wall of heavy concrete construction at column line JA 3-hour rated wall common to Zone 3A

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zones 5A, 6A, 7A, 8A, 9A, and 10A

HVAC Chase J-102

North: 2-hour rated wall common to Zone 86A at elevation 100 feet 0 inch

3-hour rated wall common to Zone 86A at elevations 120 feet 0 inch and 140 feet 0 inch

Nonrated exterior wall of heavy concrete construction at elevation 160 feet 0 inch

South: 2-hour rated wall common to Zones 5A and 20

2-hour rated wall common to Fire Area II, Zone 14

2-hour rated wall common to Fire Area III, Zone 17

East: 2-hour rated wall common to Zones 5A and 20

2-hour rated wall common to Fire Area II, Zone 14

2-hour rated wall common to Fire Area III, Zone 17

West: 3-hour rated wall common to Zones 4A, 11A, 15A, and 18A

Floor: Open to Zone I at elevation 100 feet 0 inch

Ceiling: 3-hour rated barrier common to Zone 20 at elevation 169 feet 4 inch

<u>HVAC Chase J-104</u>

North: 2-hour rated wall common to Zone 5A

2-hour rated wall common to Fire Area II, Zone 14

2-hour rated wall common to Fire Area III, Zone 17

South: 2-hour rated wall common to the south stairwell at elevation 100 feet 0 inch and elevation 120 feet 0 inch

3-hour rated wall common to the south stairwell at elevation 140 feet 0 inch

East: 2-hour rated wall common to Zone 5A

2-hour rated wall common to Fire Area II, Zone 14

2-hour rated wall common to Fire Area III, Zone 17

West: 3-hour rated exterior wall

Floor: Open to Zone 1 at elevation 100 feet 0 inch

Ceiling: 3-hour rated barrier common to Zone 20

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control (Unit 2 & 3 only)

  Essential chilled water

Essential cooling water

Control building HVAC

Miscellaneous HVAC

Main steam

Essential spray pond

Nuclear sampling

- Train B cables associated with the following systems:

  Control building HVAC

- Nontrain related cables associated with the following systems:

  Control building HVAC (Units 2 & 3 only)

- Train A essential chiller and associated components

- Train A essential chilled water expansion tank and associated components

- Train A essential cooling water components

- Train A control building engineered safety feature switchgear room essential air handling unit and associated dampers

- Train A control room essential air handling unit and associated dampers

- Train B control room HVAC damper

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of train A components or to establish equipment lineups required to achieve the shutdown function. One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.3 Analysis Area IB

A. Location

Analysis Area IB consists of fire zones 3A, 4A, 11A, 15A, and 18A.

Fire Zone 3A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inches.

Fire Zone 4A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inches.

Fire Zone 11A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inches.

Fire Zone 15A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 140 feet 0 inches.

Fire Zone 18A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inches.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 86A at column line J1

South: 3-hour rated wall common to Zone 1 (elevation 74 feet 0 inch)

3-hour rated wall common to Zone 5A (elevation 100 feet 0 inch)

3-hour rated wall common to Fire Area II, Zone 14 (elevation 120 feet 0 inch)

3-hour rated wall common to Fire Area III, Zone 17 (elevation 140 feet 0 inch)

3-hour rated wall common to Zone 20 (elevation 160 feet 0 inch)

East: 3-hour rated wall common to Zone 1 (elevation 74 feet 0 inch)

3-hour rated wall common to the northwest HVAC chase (elevation 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, 160 feet 0 inch)

West: 3-hour rated wall common to Fire Area X at column line JA (elevation 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch)

3-hour rated exterior wall at column JA (elevation 160 feet 0 inch)

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Diesel generator HVAC

  Control building HVAC

  Miscellaneous HVAC

Nuclear cooling water

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of train A components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.4 Analysis Area IC

A. Location

Analysis Area IC consists of Fire Zone 86A.

Fire Zone 86A (engineering drawing 13-A-ZYD-029) is the compartment between the auxiliary and control buildings between the auxiliary and control buildings between elevations 74 feet 0 inch and 156 feet 4 inches.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area XV at column line A10

South: 3-hour rated wall at column line J1 common to:

- Zones 1 and 3A at elevation 74 feet 0 inch
- Zones 4A and 6A at elevation 100 feet 0 inch
- Zone 11A and the northwest HVAC chase at elevation 120 feet 0 inch
- Zone 15A and the northwest HVAC chase at elevation 140 feet 0 inch

2-hour rated wall common to Zone 5A and the northwest HVAC chase at column line J1 (elevation 100 feet 0 inch)

3-hour rated wall common to Fire Area II, Zone 14, at column line J1 (elevation 120 feet 0 inch)

3-hour rated wall common to Fire Area III, Zone 17, at column line J1 (elevation 140 feet 0 inch)

East: Nonrated wall of heavy concrete construction common to Fire Area II, Zone 86B, at column line JC

West: Nonrated wall common to Fire Area X at column line JA

Floor: Nonrated basemat of light concrete paving at elevation 74 feet 0 inch

Ceiling: Nonrated roof at elevation 156 feet 0 inch

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Control building HVAC

  Miscellaneous HVAC

  Nuclear cooling water

  Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following system:

  Reactor coolant

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train B system will remain available from the control room, in conjunction with operator action, outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.5 Analysis Area ID

A. Location

Analysis Area ID consists of Fire Zones 6A, 7A, 8A, and 9A

Fire Zones 6A, 7A, 8A, and 9A (engineering drawing 13-A-ZYD-029) are located in the control building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 86A at column line J1

South: 3-hour rated wall common to Zone 5A and 10A

East: 3-hour rated wall common to Fire Area II, Zones 6B, 7B, 8B, and 9B at column line JC

West: 3-hour rated wall common to Zone 5A

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Diesel generator

  Control building HVAC

  Main steam

  Safety injection and shutdown cooling

  Electrical power distribution

  Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Control building HVAC

  Reactor coolant

- Train A battery chargers
- Train A 125 V-dc control centers and distribution panels
- Various train A control building HVAC components
- Channel A and C battery room ventilation exhaust fans and associated equipment
- Train A 480/120V voltage regulator
- Train A 120 V-ac vital instrument distribution panel A
- Train A, Channel C, 480 V-ac inverter
- Train A 120 V-ac inverter
- Train A 120 V-ac swing inverter, if implemented per DMWO 3232547
- Train A battery C
- Train A battery A

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown, has been demonstrated to remain available for use based on fire barriers provided. The redundant train B system

will remain available from the control room, in conjunction with operator action, both inside and outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.6 Analysis Area IE

A. Location

Analysis Area IE consists of Fire Zone 10A.

Fire Zone 10A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North:	3-hour rated wall common to Zone 7A
	3-hour rated wall common to Fire Area II, Zone 7B
South:	3-hour rated area boundary wall common to the diesel/control building seismic gap at column line J4
East:	2-hour rated wall common to Fire Area II, Zone 10B
West:	1-hour rated wall common to Zone 5A
Floor:	3-hour rated barrier common to Zone 1

3-hour rated barrier common to Fire Area II, Zone 2

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Diesel generator HVAC

  Control building HVAC

  Miscellaneous HVAC

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Essential spray pond

  Electrical power distribution

  Engineered safety feature actuation

- Train A remote shutdown panel A

  Train A auxiliary feedwater pump instrumentation and control

- Various train A control building ventilation dampers

- Train A atmospheric dump valve control

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of train A components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.7 Analysis Area IF

A. Location

Analysis Area IF consists of Fire Zone 5A and Stairwell C.

Fire Zone 5A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

Stairwell C is located in the control building at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, and 160 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 4A

2-hour rated wall common to Zone 86A at column line J1

2-hour rated walls common to the northwest HVAC chase

South: 2-hour rated walls common to the southwest HVAC chase

Non-rated heavy concrete exterior wall at column line J4

East: 3-hour rated walls common to Zones 6A, 7A, 8A, and 9A

1-hour rated wall common to Zone 10A

West: 3-hour rated wall common to Fire Area X at column line JA

2-hour rated wall common to the northwest HVAC chase

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

Stairwell C

North: 2-hour rated barrier common to Zone 1, Zone 5A, Zone 20, and Fire Area II, Zone 14

2-hour rated barrier common to the southwest HVAC chase at elevation 100 feet 0 inch and 120 feet 0 inch

3-hour rated barrier at elevation 140 feet 0 inch common to the southwest HVAC chase and Fire Area III, Zone 17

South: Nonrated exterior wall of heavy concrete construction at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, and 160 feet 0 inch

East: Nonrated exterior wall of heavy concrete construction at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, and 160 feet 0 inch

West: Nonrated exterior wall of heavy concrete construction at elevations 74 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, 140 feet 0 inch, and 160 feet 0 inch

Floor: Nonrated floor of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Diesel generator HVAC

  Control building HVAC

  Miscellaneous HVAC

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Essential spray pond

  Electrical power distribution

  Engineered safety feature actuation

- Non-train related cables associated with the following systems

  Control building HVAC

  Reactor coolant

- Train A 4.16 kV, Class 1E switchgear
- Train A 480V, Class 1E motor control centers
- Train A 480V, Class 1E load centers
- Train A 125 V-dc distribution auxiliary relay cabinets
- Train A 120 V-ac distribution panels
- Train A engineered safety feature switchgear room ventilation isolation dampers and solenoid valves
- Train A engineered safety feature equipment room essential air handling unit and associated dampers
- Train A control building isolation dampers

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown, has been demonstrated to remain available for use based on fire barriers provided. The redundant train B system will remain available from the control room, in conjunction with operator action, outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.8 Analysis Area IG

A. Location

Analysis Area IG consists of Fire Zone 20.

Fire Zone 20 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated exterior wall of heavy concrete construction at column line Jl

3-hour rated wall common to Zone 18A

3-hour rated wall common to Fire Area II, Zone 18B

2-hour rated wall common to the northwest HVAC chase

South: Nonrated exterior wall of heavy concrete construction at column line J4

3-hour rated area boundary wall common to the diesel/control building seismic gap at column line J4

2-hour rated wall common to the southwest stairwell

2-hour rated wall common to Fire Area II, Zone 19

East: 3-hour rated wall common to the corridor building at column line JE

2-hour rated wall common to Fire Area II, Zone 19

3-hour rated wall common to Fire Area II, Zone 18B

West: 3-hour rated exterior wall at column line JA

2-hour rated wall common to the northwest HVAC chase

Floor: 3-hour rated barrier common to Fire Area III, Zones 16 and 17

Ceiling: Nonrated roof of heavy concrete construction

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Diesel generator HVAC

Control building HVAC

Nuclear cooling water

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of train A components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain

available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.1.9 Fire Area I, Fire Zone 1, Train A Essential Chiller Room

A. Location

Fire Zone 1 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 3A

3-hour rated wall common to Zone 86A at column line J1

South: 2-hour rated wall common to the southwest stairwell at column line J4

Nonrated exterior wall of heavy concrete construction at column line J4

East: 3-hour rated wall common to Fire Area II, Zone 2, at column line JC

West: Nonrated exterior wall of heavy concrete construction at column line JA

3-hour rated wall common to Zone 3A

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zones 5A, 6A, 7A, 8A, 9A, and 10A

2. Zone Access

- One Class B door in the 2-hour rated south wall to the southwest stairwell
- One Class A door in the 3-hour rated east wall to Zone 2
- One Class A sliding door in the 3-hour rated east wall to Zone 2

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour fire ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Control building engineered safety feature normal air handling unit
- Control building normal air handling unit
- Chemical addition tank
- Neutralizing sump
- Control building outside air normal air washer unit
- Conduit
- Sump Pump

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Polycarbonate battery casing
    - Cable insulation
    - Oil
    - Hydraulic fluid
    - Charcoal
2. Transient Combustible Load Type
    - Charcoal
    - Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel

2. Secondary

Two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Nine 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.1.10 Fire Area I, Fire Zone 3A, Train A Cable Shaft

A. Location

Fire Zone 3A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86A at column line J1

South: 3-hour rated wall common to Zone 1

East: 3-hour rated wall common to Zone 1

West: 3-hour rated wall common to Fire Area X at column line J1

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zone 4A

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 1

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

Cable Insulation

2. Transient Combustible Load Type

- Cable insulation
- Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 1.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 1.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.1.11 Fire Area I, Fire Zone 4A, Train A Cable Shaft

A. Location

Fire Zone 4A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86A at column line J1

South: 3-hour rated wall common to Zone 5A

East: 3-hour rated wall common to the northwest HVAC chase

West: 3-hour rated wall common to Fire Area X at column line JA

Floor: 3-hour rated barrier common to Zone 3A

Ceiling: 3-hour rated barrier common to Zone 11A

2. Zone Access

   One Class A door in the 3-hour rated south wall to Zone 5A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

Cable insulation

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 5A.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 5A.

I. Ventilation

None. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communication

None

9B.2.1.12 Fire Area I, Fire Zone 5A, Train A ESF Switchgear Room

A. Location

Fire Zone 5A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 4A

2-hour rated wall common to Zone 86A at column line J1

2-hour rated walls common to the northwest HVAC chase

South: 2-hour rated walls common to the southwest HVAC chase

2-hour rated wall common to the southwest stairwell at column line J4

non-rated heavy concrete exterior wall at column line J4

East: 3-hour rated walls common to Zones 6A, 7A, 8A, and 9A

1-hour rated wall common to Zone 10A

West: 3-hour rated wall common to Fire Area X at column line JA

2-hour rated wall common to the northwest HVAC chase

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

- One Class B door in the 2-hour rated south wall to the southwest stairwell
- One nonrated missileproof door in the non-rated south exterior wall at column line J4
- One Class A door (pair) in the 3-hour rated east wall to Zone 6A
- One Class C door in the 1-hour rated east wall to Zone 10A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train A isolation relay cabinet

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Battery casing (polycarbonate)
      - Thermo-Lag 330-1

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   Actuation of the ionization smoke detector system(s) and the thermal detector system(s) activates the

automatic CO_2 gas system. Either detector system alone provides early warning.

H. Fire Suppression

1. Primary

Automatic CO_2 total flooding

2. Secondary

One manual hose reel, two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.1.13 Fire Area I, Fire Zone 6A, Train A (Channel C) DC Equipment Room

A. Location

Fire Zone 6A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86A at column line J1

South: 3-hour rated wall common to Zone 8A

East: 3-hour rated wall common to Fire Area II, Zone 6B, at column line JC

West: 3-hour rated wall common to Zone 5A

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

- One Class A door (pair) in the 3-hour rated west wall to Zone 5A
- One Class A door in the 3-hour rated east wall to Zone 6B
- One Class A door in the 3-hour rated south wall to Zone 8A, if implemented per DMWO 3232547

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Thermo-Lag 330-1
   - Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 5A.

2. Secondary

Two portable CO_2 fire extinguishers are located in Zone 5A.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communication

Sound powered phone jack(s) is provided.

9B.2.1.14 Fire Area I, Fire Zone 7A, Train A (Channel A) DC Equipment Room

A. Location

Fire Zone 7A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 9A

South: 3-hour rated wall common to Zones 5A and 10A

East: 3-hour rated wall common to Fire Area II, Zone 7B, at column line JC

West: 3-hour rated wall common to Zone 5A

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

One Class A door (pair) in the 3-hour rated west wall to Zone 5A

One Class A door in the 3-hour rated east wall to Zone 7B, if implemented per DMWO 3232547

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating. (Refer to the appendix 9A response to Question 9A.112.)

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Essential lighting isolation transformer V01
- Line voltage regulator V13

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible

- Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detectors system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 5A.

2. Secondary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 5A.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.1.15 Fire Area I, Fire Zone 8A, Train A (Channel C) Battery Room

A. Location

Fire Zone 8A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 6A

South: 3-hour rated wall common to Zone 9A

East: 3-hour rated wall common to Fire Area II, Zone 8B, at column line JC

West: 3-hour rated wall common to Zone 5A

Floor: 3-hour rated barrier common to Zone 1

Ceiling: 3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

One Class A door in the 3-hour rated west wall to Zone 5A

One Class A door in the 3-hour rated north wall to Zone 6A, if implemented per DMWO 3232547

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings. (Refer to the appendix 9A response to Question 9A.123.)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Conduit
   - Normal exhaust fan

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Thermoplastic battery cases
      - Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible

- Thermoplastic battery cases

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of the ionization smoke detector system(s) and the thermal detector system(s) activates the automatic CO_2 gas system. Either detector system alone can provide early warning.

H. Fire Suppression Systems

1. Primary

   Automatic CO_2 total flooding

2. Secondary

   One manual hose reel and two portable CO_2 fire extinguishers are located in adjacent Zone 5A.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.1.16 Fire Area I, Fire Zone 9A, Train A (Channel A) Battery Room

A. Location

Fire Zone 9A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 8A
South:	3-hour rated wall common to Zone 7A
East:	3-hour rated wall common to Fire Area II, Zone 9B, at column line JC
West:	3-hour rated wall common to Zone 5A
Floor:	3-hour rated barrier common to Zone 1
Ceiling:	3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

One Class A door in the 3-hour rated west wall to Zone 5A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings. (Refer to the appendix 9A response to Question 9A.123.)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Conduit
   - Normal exhaust fan

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Thermoplastic battery cases
      - Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible

- Thermoplastic battery cases

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of the ionization smoke detector system(s) and the thermal detector system(s) activates the automatic CO_2 gas system. Either detector system alone can provide early warning.

H. Fire Suppression

1. Primary

   Automatic CO_2 total flooding

2. Secondary

   One manual hose reel and two portable CO_2 fire extinguishers are located in adjacent Zone 5A.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.1.17 Fire Area I, Fire Zone 10A, Train A Remote Shutdown Room

A. Location

Fire Zone 10A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 7A
	3-hour rated wall common to Fire Area II, Zone 7B
South:	3-hour rated area boundary wall common to the diesel/control building seismic gap at column line J4
East:	2-hour rated wall common to Fire Area II, Zone 10B
West:	1-hour rated wall common to Zone 5A
Floor:	3-hour rated barrier common to Zone 1
	3-hour rated barrier common to Fire Area II, Zone 2
Ceiling:	3-hour rated barrier common to Fire Area II, Zone 14

2. Zone Access

- One Class B door in the 2-hour rated east wall to Zone 10B

- One Class C door in the 1-hour rated west wall to Zone 5A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A remote shutdown panel C
- Remote shutdown panel N

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation

- Paper
- Plastic (telephones)
- Polycarbonate battery casing
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning and thermal detectors will actuate the automatic Halon 1301 gas system.

H. Fire Suppression

1. Primary

Automatic Halon 1301 fire extinguishing system.

2. Secondary

One manual hose reel and two portable CO_2 fire extinguishers are located in adjacent Zone 5A.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.1.18 Fire Area I, Fire Zone 11A, Train A Cable Shaft

A. Location

Fire Zone 11A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 86A at column line J1
South:	3-hour rated wall common to Fire Area II, Zone 14
East:	3-hour rated wall common to the northwest HVAC chase
West:	3-hour rated wall common to Fire Area X at column line JA
Floor:	3-hour rated barrier common to Zone 4A
Ceiling:	3-hour rated barrier common to Zone 15A

2. Zone Access

   - One Class A door in the 3-hour rated south wall to Zone 14

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Cable insulation

2. Transient Combustible Load Type

    - Ordinary combustible
    - Cable insulation

3. Total Combustible (Fire) Loading

    High

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

    One manual hose reel is located in adjacent Zone 14.

2. Secondary

    Four portable CO_2 fire extinguishers are located in adjacent Zone 14.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.1.19 Fire Area I, Fire Zone 15A, Train A Cable Shaft

A. Location

Fire Zone 15A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 86A at column line J1
South:	3-hour rated wall common to Fire Area III, Zone 17
East:	3-hour rated wall common to the northwest HVAC chase
West:	3-hour rated wall common to Fire Area X at column line JA
Floor:	3-hour rated barrier common to Zone 11A
Ceiling:	3-hour rated barrier common to Zone 18A

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 17

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Five portable CO_2 fire extinguishers in adjacent zone 17.

2. Secondary

Four portable pressurized water fire extinguishers are located in adjacent Zone 17 and a manual hose station outside the control room.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.1.20 Fire Area I, Fire Zone 18A, Train A Cable Shaft

A. Location

Fire Zone 18A (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated exterior wall at column line J1
South:	3-hour rated wall common to Zone 20
East:	3-hour rated wall common to the northwest HVAC chase
West:	3-hour rated exterior wall at column line JA
Floor:	3-hour rated barrier common to Zone 15A
Ceiling:	Nonrated roof of heavy concrete construction

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 20

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

   Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 20.

2. Secondary

Four portable CO_2 fire extinguishers are located in adjacent Zone 20.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.1.21 Fire Area I, Fire Zone 20, Upper Cable Spreading Room

A. Location

Fire Zone 20 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line J1

3-hour rated wall common to Zone 18A

3-hour rated wall common to Fire Area II, Zone 18B

2-hour rated wall common to the northwest HVAC chase

South: Nonrated exterior wall of heavy concrete construction at column line J4

3-hour rated area boundary wall common to the diesel/control building seismic gap at column line J4

2-hour rated wall common to the southwest stairwell

2-hour rated wall common to Fire Area II, Zone 19

East: 3-hour rated wall common to the corridor building at column line JE

2-hour rated wall common to Fire Area II, Zone 19

3-hour rated wall common to Fire Area II, Zone 18B

West: 3-hour rated exterior wall at column line JA

2-hour rated wall common to the northwest HVAC chase

Floor: 3-hour rated barrier common to Fire Area III, Zones 16 and 17

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class B door in the 2-hour rated south wall to the southwest stairwell
- One nonrated missile door in the 3-hour rated east wall to the corridor building (Refer to Appendix 9A response to Question 9A.106)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A ERFDAD termination cabinets
- Train A radiation monitor

D. Nonsafety-Related Equipment and Components

- Cable trays and conduit
- Nontrain-related ERFDAD termination cabinets

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Thermo-Lag 330-1
   - Cable insulation
2. Transient Combustible Load Type
   - Ordinary combustible
   - Cable insulation
3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Actuation of either ionization detector system(s) or line-type thermal detector system(s) activates the automatic preaction water sprinkler system. Either detector system alone can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system

2. Secondary

One manual hose reel, four portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Six 6-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.1.22 Fire Area I, Fire Zone 86A, Train A Compartment Between Auxiliary and Control Buildings

A. Location

Fire Zone 86A (engineering drawing 13-A-ZYD-029) is the compartment between the auxiliary and control

buildings between elevations 74 feet 0 inch and 156 feet 4 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XV at column line A10

South: 3-hour rated wall at column line J1 common to:

- Zones 1 and 3A at elevation 74 feet 0 inch
- Zones 4A and 6A at elevation 100 feet 0 inch
- Zone 11A and the northwest HVAC chase at elevation 120 feet 0 inch
- Zone 15A and the northwest HVAC chase at elevation 140 feet 0 inch

2-hour rated wall common to Zone 5A and the northwest HVAC chase at column line J1 and elevation 100 feet 0 inch

3-hour rated wall common to Fire Area II, Zone 14, at column line J1 and elevation 120 feet 0 inch

3-hour rated wall common to Fire Area III, Zone 17, at column line J1 and elevation 140 feet 0 inch

East: Nonrated wall of heavy concrete construction common to Fire Area II, Zone 86B, at column line JC

West: Nonrated wall common to Fire Area X at column line JA

Floor: Nonrated basemat of light concrete paving at elevation 74 feet 0 inch

Ceiling: Nonrated roof at elevation 156 feet 0 inch

2. Zone Access

One Class B door in the 2-hour rated south wall, elevation 100 feet 0 inch, to Zone 5A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable Insulation

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Actuation of both the ionization detector system(s) and the line-type thermal detector system(s) activates the automatic water spray system. Either detection system alone can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic deluge water spray system covering the cable trays only. (At elevations 100 feet 0 inch and 120 feet 0 inch only, see engineering drawing 13-A-ZYD-029)

2. Secondary

Two portable CO_2 fire extinguishers and one manual hose reel are located at elevation 100 feet 0 inch in adjacent Zone 5A.

I. Ventilation

Manually controlled smoke venting through the seismic gap in the ceiling. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.2 FIRE AREA II

9B.2.2.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area II contains train B components found in the control building. This fire area includes Analysis Areas IIA (Zone 2, 19, HVAC Chase J-115, outside

airchase J-A09 and HVAC Chase J-118), IIB (Zones 3B, 4B, 11B, 15B, and 18B), IIC (Zone 86B), IID (Zones 6B, 7B, 8B, and 9B), IIE (Zone 10B), IIF (Zone 5B), and IIG (Zones 12, 13, 14, and 19) (engineering drawing 13-A-ZYD-029).

At elevation 74 feet 0 inch, Fire Area II is below grade and bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the west by a 3-hour rated barrier common to Fire Area I, and to the south and east by nonrated exterior walls and 2-hour rated walls common to the east stairwell and a cable riser shaft. The east exterior wall of Zone 3B is 3-hour rated. The wall of Zone 86B common to Fire Area I, Zone 86H, is nonrated. The basemat is nonrated. An HVAC equipment access area is located near the southeast corner and is fitted with a 3-hour rated missileproof hatch at grade level.

At elevation 100 feet 0 inch, Fire Area II is bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the west by 3-hour rated barriers common to Fire Area I, to the east by a 3-hour rated barrier common to the corridor building, and a non-rated heavy concrete exterior wall and to the south by a 3-hour rated barrier common to the diesel/control building seismic gap. The west wall of Zone 86B common to Fire Area I, Zone 86A, is nonrated. The east wall of Zone 86B common to the corridor building is nonrated. The west wall of Zone 10B common to Fire Area I, Zone 10A, is 2-hour rated.

At elevation 120 feet 0 inch, Fire Area II is bounded to the north by 3-hour rated barriers common to Fire Areas I and XV and by 2-hour rated barriers common to the northwest HVAC chase (Fire Area I), to the west by a 3-hour rated barrier common to Fire Area X, to the east by a 3-hour rated barrier common to the corridor building and by a non-rated heavy concrete exterior wall. The east wall of Zone 86B common to the corridor building is nonrated. The west wall of Zone 86B common to Fire Area I, Zone 86A, is nonrated. Fire Area II is bounded to the south by 2-hour rated barriers common to Fire Area I, the southwest HVAC chase and stairwell by a 3-hour rated barrier common to the diesel/control building seismic gap and by a nonrated exterior wall. The ceilings to Zones 12, 13, and 14 are 3-hour rated and common to Fire Area III.

At elevation 140 feet 0 inch, Fire Area II consists of the northeast and southeast corners of the control building. In the northeast corner, Fire Area II consists of Zones 15B and 86B, bounded to the north by a 3-hour rated barrier common to Fire Area XV, to the south by 3-hour rated barriers common to Fire Area III, to the west by 3-hour rated barriers common to Fire Areas I and III, and to the east by a 3-hour rated barrier common to the corridor building. The east wall of Zone 86B common to the corridor building is nonrated. The west wall of Zone 86B common to Fire Area I, Zone 86A, is nonrated. The ceiling to

Zone 86B is a nonrated barrier common to the roof. In the southeast corner, Fire Area II includes the southeast outside air and HVAC chases, bounded to the north and west by 2-hour rated barriers common to Fire Area III, to the south by a 3-hour rated barrier common to the diesel/control building seismic gap, and to the southeast by non-rated heavy concrete exterior walls.

At elevation 160 feet 0 inch, Fire Area II consists of the northeast and southeast corners of the control building. In the northeast corner, Fire Area II consists of Zone 18B, bounded to the north by a 3-hour rated exterior wall, to the west and south by 3-hour rated barriers common to Fire Area I, and to the east by a 3-hour rated barrier common to the corridor building. In the southeast corner, Fire Area II includes Zone 19 and is bounded to the north and west by 2-hour rated barriers common to Fire Area I, to the south by a 3-hour rated barrier common to the diesel/control building seismic gap and a nonrated exterior wall, and to the east by a 3-hour rated barrier common to the corridor building and a nonrated heavy concrete exterior wall. The floor to Zone 19 is a 3-hour rated barrier partially common to Fire Area III. The ceiling to Zones 18B and 19, which is also the roof of the control building, is nonrated.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated barriers to separate circuits of redundant trains.

<u>Discussion</u>

The west and north walls of the southeast outside air and HVAC chases (adjacent to Fire Area II, Zones 2, 5B, 12, 13, 14, and 19) are common boundaries with Fire Area III, Zones 16 and 17, at elevation 140 feet 0 inch. The outside air and HVAC chases have walls of reinforced concrete construction rated for 2 or 3 hours. For a fire to propagate between redundant trains, the fire must burn through at least two 2-hour rated fire barriers. The outside air and HVAC chases are virtually devoid of combustibles. Fire dampers used in the two hour rated wall portions are identical in material and construction to 3-hour labeled devices. Each floor section is also provided with a fire damper. Fire detection and automatic suppression are provided in the vicinity of the chase at elevations 100 feet 0 inch, 120 feet 0 inch, and 160 feet 0 inch. Fire detection is provided in the vicinity of the chase at elevations 74 feet 0 inch and 140 feet 0 inch. Fire department response

(within 20 minutes) is expected before degradation to the existing fire barriers would occur. Access to the chase for the fire department response is available at elevation 100 feet 0 inch (through Zone 5B).

Conclusion

The existing design provides equivalent protection of that required by Section III.G.2, and upgrading the existing design for 3-hour ratings would not significantly enhance the protection currently provided.

2. A deviation is requested to Section III.G.2 to the extent that it requires installation of a 1-hour fire-rated barrier and an area-wide suppression system.

Discussion

The east wall of Zone 86B is a fire area boundary between Fire Area II and the corridor building at elevations 90 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch. The boundary contains a 6-inch (nominal) seismic gap which is covered with nonrated, solid, 18-gauge sheet metal flashings on each side of a reinforced concrete stub wall. The metal flashings would retard the passage of heat and/or smoke. The corridor building contains – non-safety related HVAC damper control cables and non-safety related RCP control cables. The

ability to achieve and maintain safe shutdown is demonstrated by calculations 13-MC-FP-316 and 13-MC-FP-318.

Within Fire Area II, Zone 86B is separated from the remainder of the fire area by 2- and 3-hour rated walls. Zone 86B is separated from Zone 86A (Fire Area I) by a nonrated barrier (see Fire Area I, deviation No. 5, for the Zone 86A/Zone 86B separation considerations). Zonal detection and automatic deluge water spray covers the predominant in situ combustible (cable trays at elevation 100 feet 0 inch and 120 feet 0 inch). The total combustible (fire) loading for Zone 86B is high. The apparently high combustible loading is attributed to the calculation method in that the combustible material is located in an area with a relatively small floor space combined with high ceilings. Fire department response (within 20 minutes) is expected before significant degradation of the existing fire barriers would occur. Access to Zone 86A for fire department response is available at elevation 100 feet 0 inch (through Zone 5A).

Because the metal flashings are tight against the concrete stub walls, smoke and hot gases would not propagate to the adjoining area pending arrival of the fire department.

Therefore, these boundaries form valid fire areas, as required by section III of appendix R.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to a 1-hour rating plus suppression would not significantly enhance protection currently provided.

3. This deviation evaluation assesses the adequacy of preaction cable tray fire suppression versus general area fire suppression in Fire Area II, Fire Zone 14, Lower Cable Spreading Room. Appendix R, Section III.G.2.c requires enclosure of cables, equipment and associated non-safety circuits of one redundant train in a fire barrier having a 1-hour rating. In addition, fire detectors and an (areawide) automatic fire suppression system shall be installed in the fire area. The deviation is for the automatic fire suppression system which is installed for the protection of the cable trays in the fire area but not at the ceiling level for full areawide protection.

Discussion

Fire Area II, Fire Zone 14, Lower Cable Spreading Room contains Train B cables. This zone is bounded on all sides, including floors

and ceilings by 1, 2 and 3 hour rated continuous fire barriers.

There is a small (2' x 6') enclosed vertical cable chase along the north wall in Zone 14, floor elevation 120 feet at column JC - J1. The chase contains Train A, IEEE 383 fire rated cables. The enclosure around the Train A cables is 2-hour fire rated, 8-inch concrete masonry unit (CMU) block construction from floor to ceiling (UL Design U904 and Uniform Building Code Table No. 43-B). There are two 4' x 4' access hatches with Class B labeled, 1-1/2 hour rated hatch covers. The chase is sealed with 3-hour fire seals at the floor and ceiling. The installed chase enclosure exceeds the 1-hour fire barrier requirement of 10CFR50, Appendix R, Section III.G.2.C.

Fire detection in the zone consists of thermistor wire in each cable tray and smoke detection at the ceiling. Preaction water spray suppression systems are installed in each cable tray. Manual hose stations and portable fire extinguishers are provided. The cable spreading room is typically not subject to transient combustibles and does not contain equipment or components which require frequent maintenance, surveillance or testing activities. The room is a very low personnel activity room and the potential for fire involving transient

combustibles is extremely low. The room is readily accessible for manual fire fighting.

The train separation and protection provided complies with Appendix R, Section III G.2.c, except that the suppression system installed is a preaction water spray system covering all the cable trays in lieu of ceiling level coverage for the entire area. The unsprinklered areas of the room are those without cable trays and are not in the immediate proximity of the Train A cable chase. The enclosed cable chase is not exposed to unprotected combustible loads. The chase does not contain a sprinkler system nor combustibles other than the IEEE-383 fire resistant cables.

Cable tray only suppression for compliance with 10CFR50, Appendix R, Section III.G.2.c has been previously accepted by the NRC in lieu of general ceiling area sprinkler protection in another PVNGS fire zone as described in NUREG 0857, Supplement No. 6, Safety Evaluation Report related to the operation of PVNGS, Section 9.5.1.6, dated October 1984, Page 9-10.

Conclusion

The existing design provides equivalent protection to that required by 10CFR50, Appendix R, Section III.G.2.c. and provides an acceptable level of protection to assure that

there will be no adverse impact on the ability to achieve and maintain safe shutdown.

4. See subsection 9B.2.1 for deviations common to Fire Area I and section 9B.2, Fire Hazards Analysis, for generic deviations.

9B.2.2.2 Analysis Area IIA

A. Location

Analysis Area IIA consists of Fire Zone 2, HVAC Chase J-115, HVAC Chase J-118, outside Air Chase J-A09 and Fire Zone 19.

Fire Zone 2 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

HVAC Chase J-115 is located in the control building at elevation 100 feet 0 inch.

HVAC Chase J-118 is located in the control building at Elevation 91 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

Outside Air Chase J-A09 is located in the control building at elevations 91, 100, 120, 140, and 160 feet 0 inch.

Fire Zone 19, fan room, is located at elevation 160 feet 0 inch.

B. Analysis Area Boundaries

Fire Zone 2

North: 3-hour rated wall common to Zone 3B

3-hour rated wall common to Zone 86B at column line J1

South: Nonrated exterior wall of heavy concrete construction at column line J4

East: 2-hour rated wall common to the east stairwell at column line JE

Nonrated area boundary exterior wall of heavy concrete construction at column line JE

3-hour rated wall common to Zone 3B

2-hour rated wall common to the cable riser shaft between elevations 80 feet 0 inch and 100 feet 0 inch, at column line JE

West: 3-hour rated wall common to Fire Area I, Zone 1, at column line JC

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zones 5B, 6B, 7B, 8B, 9B, and 10B

3-hour rated barrier common to Fire Area I, Zone 10A

NOTE

> A 3-hour rated outside air plenum and a 2-hour rated soffit to the southeast HVAC chase are located near column line J4.

HVAC Chase J-115

North: 3-hour rated wall common to Zone 86B

South: 2-hour rated wall common to Zone 5B

East: 3-hour rated wall common to Zone 4B

West: 2-hour rated wall common to Zone 5B

Floor: Open to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

HVAC Chase J-118

North: 3-hour rated wall common to Zone 5B

2-hour rated wall common to Zones 12 and 13

2-hour rated wall common to Fire Area III, Zone 17

South: 3-hour rated wall common to the diesel/control building seismic gap at column line J4, 5 feet 6 inches west of column line JE at elevation 140 feet 0 inch

East: Nonrated wall of heavy concrete construction

West: Nonrated wall of heavy concrete construction common to the outside air chase

Floor: Open to Zone 2

Ceiling: Nonrated barrier common to Zone 19

<u>Outside Air Chase J-A09</u>

North: 3-hour rated soffit common to Zone 3

3-hour rated wall common to Zone 5B

2-hour rated wall common to Zones 12 and 13

2-hour rated wall common to Fire Area III, Zone 17

Nonrated wall common to Zone 19

South: 3-hour rated wall common to diesel/control building seismic gap at column line J4

East: 2-hour rated wall common to HVAC Chase J-118

Nonrated wall common to Zone 19

West: 3-hour rated wall common to Zone 1

2-hour rated wall common to Zone 5B

2-hour rated wall common to Zone 14

2-hour rated wall common to Zone 16

Nonrated wall common to Zone 19

<u>Fire Zone 19</u>

North: 2-hour rated wall common to Zone 20

South: 3-hour rated wall common to diesel generator building exhaust stack and nonrated concrete exterior wall

East: Nonrated concrete exterior wall

West: 2-hour rated wall common to Zone 20

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Chemical and volume control (Units 2 & 3 only)

  Essential chilled water

  Essential cooling water

  Control building HVAC

  Miscellaneous HVAC

  Main steam

  Essential spray pond

  Nuclear sampling

  Engineered safety featured actuation

- Train A cables associated with the following system: Control building HVAC

- Train B essential chiller and associated components

- Train B essential chilled water expansion tank and associated level control equipment

- Train B control room essential air handling unit and associated components

- Train A and train B dampers associated with control room cooling

- Train B engineered safety feature switchgear room essential air handling unit and associated dampers
- Engineered safety feature activation (CREFAS)

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train A systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function. One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.3 Analysis Area IIB

A. Location

Analysis Area IIB consists of Fire Zones 3B, 4B, 11B, 15B, and 18B.

Fire Zone 3B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

Fire Zone 4B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

Fire Zone 11B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

Fire Zone 15B (engineering drawing 13-A-ZYD-029) is located in the control building between elevations 132 feet 0 inch and 160 feet 0 inch.

Fire Zone 18B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 86B at column line J1

South: 3-hour rated wall common to Zone 2 (elevation 74 feet 0 inch)

3-hour rated wall common to Zone 5B (elevation 100 feet 0 inch)

3-hour rated wall common to Zone 14 (elevation 120 feet 0 inch)

3-hour rated wall common to Zone 14 (between elevation 132 feet 0 inch and 140 feet 0 inch)

3-hour rated wall common to Fire Area III, Zone 17 (elevation 140 feet 0 inch)

3-hour rated wall common to Fire Area I, Zone 20 (elevation 160 feet 0 inch)

East: 3-hour rated wall at column line JE (elevation 74 feet 0 inch)

West: 3-hour rated wall common to Zone 2 (elevation 74 feet 0 inch)

3-hour rated wall common to the northeast HVAC Chase (elevation 100 feet 0 inch)

3-hour rated wall common to Zone 14 (elevation 120 feet 0 inch)

3-hour rated wall common to Zone 14 (between elevation 132 feet 0 inch and 140 feet 0 inch)

3-hour rated wall common to Fire Area III, Zone 17 (elevation 140 feet 0 inch)

3-hour rated wall common to Fire Area I, Zone 20 (elevation 160 feet 0 inch)

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

Diesel fuel oil and transfer

Diesel generator

Essential chilled water

Essential cooling water

Auxiliary building HVAC

Diesel generator HVAC

Control building HVAC

Nuclear cooling water

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation.

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train A systems available from

the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.4 Analysis Area IIC

A. Location

Analysis Area IIC consists of Fire Zone 86B.

Fire Zone 86B (engineering drawing 13-A-ZYD-029) is the compartment between the auxiliary and control buildings between elevations 74 feet 0 inch and 156 feet 4 inches.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area XV at column line A10

South: 3-hour rated wall at column line J1 common to:

- Zones 2 and 3B at elevation 74 feet 0 inch
- Zones 4B and 6B at elevation 100 feet 0 inch

- Zones 11B and 14 at elevation 120 feet 0 inch
- Zone 15B between elevations 132 feet 0 inch and 156 feet 4 inches

2-hour rated wall common to Zone 5B and the northeast HVAC chase at column line Jl (elevation 100 feet 0 inch)

3-hour rated wall common to Fire Area III, Zone 17, at column line Jl (elevation 140 feet 0 inch)

East: Nonrated exterior wall at column line JE and elevation 74 feet 0 inch

Nonrated wall common to the corridor building at column line JE, at elevations 100 feet 0 inch, 120 feet 0 inch and 140 feet 0 inch

West: Nonrated wall of heavy concrete construction common to Fire Area I, Zone 86A, at column line JC

Floor: Nonrated basemat of light concrete paving at elevation 74 feet 0 inch

Ceiling: Nonrated roof of heavy concrete construction at elevation 156 feet 4 inches

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Nuclear cooling water

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

  Electrical power distribution

  Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Control building HVAC

  Nuclear cooling water

  Reactor coolant

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.5 Analysis Area IID

A. Location

Analysis Area IID consists of Fire Zones 6B, 7B, 8B, and 9B.

Fire Zone 6B, 7B, 8B, and 9B (engineering drawing 13-A-ZYD-029) are located in the control building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 86B at column line J1

South: 3-hour rated wall common to Zone 5B and 10B

3-hour rated wall common to Fire Area I, Zone 10A

East: 3-hour rated wall common to Zone 5B

West: 3-hour rated wall common to Fire Area I, Zone 6A, 7A, 8A, and 9A at column line JC

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Essential chilled water

  Diesel generator HVAC

  Control building HVAC

  Main steam

  Safety injection and shutdown cooling

  Electrical power distribution

  Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Control building HVAC

  Reactor coolant

- Various train A and train B control building HVAC components

- Train B battery rooms ventilation exhaust fans and associated equipment

- Train B 125 V-dc control centers and distribution panels
- Train B battery B
- Train B battery D
- Train B battery chargers
- Train B 120 V-ac vital instrument distribution panel B
- Train B 120 V-ac inverters and voltage regulator
- Train A 120 V-ac swing inverter, if implemented per DMWO 3232547

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown, has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.6 Analysis Area IIE

A. Location

Analysis Area IIE consists of Fire Zone 10B.

Fire Zone 10B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 7B

South: 3-hour rated wall common to the diesel/control building seismic gap at column line J4

East: 1-hour rated wall common to Zone 5B

West: 2-hour rated wall common to Fire Area I, Zone 10A

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Control building HVAC

  Reactor coolant

  Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Train A cables associated with the following systems:

  Control building HVAC

  Electrical power distribution

- Nontrain related cables associated with the following systems:

- Control building HVAC

- Train A battery room fire dampers

- Train B remote shutdown room fire damper

- Train B remote shutdown panel

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve

the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.7 Analysis Area IIF

A. Location

Analysis Area IIF consists of Fire Zone 5B.

Fire Zone 5B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 4B

2-hour rated wall common to Zone 86B at column line J1

2-hour rated walls common to the northeast HVAC chase

South: 3-hour rated walls common to the southeast outside air and HVAC chases

3-hour rated wall common to the diesel/control building seismic gap at column line J4

East: 3-hour rated wall common to the corridor building and non-rated heavy concrete exterior wall at column line JE

2-hour rated wall common to the northeast HVAC chase

2-hour rated wall common to the southeast outside air chase

West: 3-hour rated walls common to Zones 6B, 7B, 8B, and 9B

1-hour rated wall common to Zone 10B

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zones 12, 13, and 14

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Control building HVAC

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Diesel generator HVAC

  Control building HVAC

Miscellaneous HVAC

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Control building HVAC

  Reactor coolant

- Train B engineered safety feature switchgear room ventilation isolation dampers and solenoid valves
- Train B engineered safety feature equipment room air handling unit and associated dampers
- Train A battery room fire dampers
- Train B battery room fire dampers
- Various ventilation dampers
- Train B 4.16 kV Class 1E switchgear
- Train B 480V Class 1E motor control centers

- Train B 480V Class 1E load centers
- Train B 120 V-ac distribution panels
- Train B 125 V-dc distribution auxiliary relay cabinets

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown, has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.8 Analysis Area IIG

A. Location

Analysis Area IIG consists of Fire Zones 12, 13, and 14.

Fire Zone 12 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

Fire Zone 13 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

Fire Zone 14 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area I, Zone 11A

3-hour rated wall common to Fire Area I, Zone 86A, at column line J1

2-hour rated wall common to Fire Area I, the northwest HVAC chase

3-hour rated wall common to Zone 86B at column line Jl

3-hour rated wall common to Zone 11B

3-hour rated wall common to Zone 15B between elevations 132 feet 0 inch and 140 feet 0 inch

South: 2-hour rated wall common to the southeast HVAC and outside air chases

2-hour rated walls common to Fire Area I, the southwest stairwell and HVAC chase

3-hour rated wall common to the diesel/control building seismic gap at column line J4

Nonrated exterior wall at column line J4 (elevation 120 feet 0 inch)

East: non-rated exterior wall at column line JE

3-hour rated wall common to the corridor building at column line JE

2-hour rated wall common to the southeast outside air chase (elevation 120 feet 0 inch)

3-hour rated wall common to Zones 11B and 15B (elevation 120 feet 0 inch)

West: 3-hour rated wall common to Fire Area X at column line JA 2-hour rated wall common to

Fire Area I, the northwest HVAC chase

2-hour rated wall common to Fire Area I, the southwest HVAC chase

2-hour rated wall common to Fire Area I, the southwest HVAC chase

Floor: 3-hour rated barrier common to Fire Area I, Zones 5A, 6A, 7A, 8A, 9A, and 10A (elevation 120 feet 0 inch)

3-hour rated barrier common to Zones 5B, 6B, 7B, 8B, 9B, and 10B (elevation 120 feet 0 inch)

3-hour rated barrier common to Fire Area III, Zone 17 (160 feet 0 inch)

Ceiling: 3-hour rated barrier common to Fire Area III, Zones 16 and 17 (elevation 120 feet 0 inch)

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Control building HVAC

  Main steam

  Electrical power distribution

  Engineered safety feature actuation

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Diesel fuel oil and transfer

  Diesel generator

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Diesel generator HVAC

  Control building HVAC

  Nuclear cooling water

  Reactor coolant

  Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Control building HVAC

  Nuclear cooling water

  Reactor coolant

- Communications room isolation dampers

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.2.9 Fire Area II, Fire Zone 2, Train B Essential Chiller Room

A. Location

Fire Zone 2 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 3B

3-hour rated wall common to Zone 86B at column line J1

South: Nonrated exterior wall of heavy concrete construction at column line J4

East: 2-hour rated wall common to the east stairwell at column line JE

Nonrated area boundary exterior wall of heavy concrete construction at column line JE

3-hour rated wall common to Zone 3B

2-hour rated wall common to the cable riser shaft between elevations 80 feet

0 inch and 100 feet 0 inch, at column line JE

West: 3-hour rated wall common to Fire Area I, Zone 1, at column line JC

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zones 5B, 6B, 7B, 8B, 9B, and 10B

3-hour rated barrier common to Fire Area I, Zone 10A

NOTE

A 3-hour rated outside air plenum and a 2-hour rated soffit to the southeast HVAC chase are located near column line J4.

2. Zone Access

- One Class B door in the 2-hour rated east wall to the east stairwell
- One Class A sliding door in the 3-hour rated west wall to Zone 1
- One Class A door in the 3-hour rated west wall to Zone 1

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating. (Refer to the appendix 9A response to Question 9A.112.)

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Chemical addition tank
   - Neutralizing sump
   - Control room normal air handling unit
   - Conduit
   - Sump pumps

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Oil
      - Charcoal
      - Polycarbonate battery casing

- Lubricating grease

2. Transient Combustible Load Type

   - Charcoal
   - Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel

2. Secondary

   Two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside through the corridor building using portable smoke removal equipment.

J. Drainage

Seven 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.10 Fire Area II, Fire Zone 3B, Train B Cable Shaft

A. Location

Fire Zone 3B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 74 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86B at column line J1

South: 3-hour rated wall common to Zone 2

East: 3-hour rated exterior wall at column line JE

West: 3-hour rated wall common to Zone 2

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Zone 4B

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 2

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings

4. Fire Dampers

None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation

   2. Transient Combustible Load Type

      - Cable insulation
      - Ordinary Combustible

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 2.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 2.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside through the corridor building. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.2.11 Fire Area II, Fire Zone 4B, Train B Cable Shaft

A. Location

Fire Zone 4B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86B at column line J1

South: 3-hour rated wall common to Zone 5B

East: 3-hour rated wall common to the corridor building at column line JE

West: 3-hour rated wall common to the northeast HVAC chase

Floor: 3-hour rated barrier common to Zone 3B

Ceiling: 3-hour rated barrier common to Zone 11B

2. Zone Access

   One Class A door in the 3-hour rated south wall to Zone 5B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour fire ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Ionization smoke detector(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 5B.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in the adjacent corridor building near Zone 5B.

I. Ventilation

Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.2.12 Fire Area II, Fire Zone 5B, Train B ESF Switchgear Room

A. Location

Fire Zone 5B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 4B

2-hour rated wall common to Zone 86B at column line J1

2-hour rated walls common to the northeast HVAC chase

South: 3-hour rated walls common to the south-east outside air and HVAC chases

3-hour rated wall common to the diesel/control building seismic gap at column line J4

East: 3-hour rated wall common to the corridor building and non-rated heavy concrete exterior wall at column line JE

2-hour rated wall common to the northeast HVAC chase

West: 3-hour rated walls common to Zones 6B, 7B, 8B, and 9B

1-hour rated wall common to Zone 10B

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zones 12, 13, and 14

2. Zone Access

- One Class A door in the 3-hour rated south wall to Fire Area V (DG Building)
- One Class A door (pair) in the 3-hour rated east wall to the corridor building

- One Class A door (pair) in the 3-hour rated west wall to Zone 6B
- One Class C door in the 1-hour rated west wall to Zone 10B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B isolation relay cabinet

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Lubricating grease
- Polycarbonate battery casing
- Cable insulation
- Plastic
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Actuation of the ionization smoke detector system(s) and the thermal detector system(s) activates the automatic CO_2 gas system. Either detector system alone provides early warning.

H. Fire Suppression

1. Primary

Automatic CO_2 total flooding

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher. One portable CO_2 fire

extinguisher and one manual hose reel are located in the adjacent corridor building.

I. Ventilation

Manually controlled smoke exhaust venting to the smoke removal HVAC chase using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.13 Fire Area II, Fire Zone 6B, Train B (Channel D) DC Equipment Room

A. Location

Fire Zone 6B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86B at column line J1

South: 3-hour rated wall common to Zone 8B

East: 3-hour rated wall common to Zone 5B

West: 3-hour rated wall common to Fire Area I, Zone 6A, at column line JC

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

2. Zone Access

- One Class A door (pair) in the 3-hour rated east wall to Zone 5B
- One Class A door in the 3-hour rated west wall to Zone 6A

3. Sealed Penetrations

Seals equal or exceed fire barrier rating.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Polycarbonate battery casing
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 5B.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are

located in adjacent corridor building near Zone 5B.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.14 Fire Area II, Fire Zone 7B, Train B (Channel B) DC Equipment Room

A. Location

Fire Zone 7B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 9B

South: 3-hour rated wall common to Zones 5B and 10B

3-hour rated wall common to Fire Area I, Zone 10A

East: 3-hour rated wall common to Zone 5B

West: 3-hour rated wall common to Fire Area I, Zone 7A, at column line JC

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

2. Zone Access

One Class A door (pair) in the 3-hour rated east wall to Zone 5B

One Class A door in the 3-hour rated west wall to Zone 7A, if implemented per DMWO 3232547

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating. (Refer to the appendix 9A response to Question 9A.112.)

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Essential lighting isolation transformer V02

- Line voltage regulator V14

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Cable insulation
   - Polycarbonate battery casing
   - Thermo-Lag 330-1
2. Transient Combustible Load Type
   - Ordinary combustible
   - Cable insulation
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 5B.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in adjacent corridor building near Zone 5B.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.15 Fire Area II, Fire Zone 8B, Train B (Channel D) Battery Room

A. Location

Fire Zone 8B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 6B

South: 3-hour rated wall common to Zone 9B

East: 3-hour rated wall common to Zone 5B

West: 3-hour rated wall common to Fire Area I, Zone 8A, at column line JC

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

2. Zone Access

   One Class A door in the 3-hour rated east wall to Zone 5B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings. (Refer to the appendix 9A response to Question 9A.123.)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Conduit
- Normal exhaust fan

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Thermoplastic battery cases
   - Cable insulation

2. Transient Combustible Load Type

   - Thermoplastic battery cases
   - Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of the ionization smoke detector system(s) and the thermal detector system(s) activates the automatic CO_2 gas system. Either detector system alone can provide early warning.

H. Fire Suppression Systems

1. Primary

   Automatic CO_2 total flooding

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in the adjacent corridor building near Zone 5B.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.2.16 Fire Area II, Fire Zone 9B, Train B (Channel B) Battery Room

A. Location

Fire Zone 9B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 8B

South: 3-hour rated wall common to Zone 7B

East: 3-hour rated wall common to Zone 5B

West: 3-hour rated wall common to Fire Area I, Zone 9A, at column line JC

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

2. Zone Access

One Class A door in the 3-hour rated east wall to Zone 5B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings. (Refer to the appendix 9A response to Question 9A.123.)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Conduit
- Normal exhaust fan

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Thermoplastic battery cases
   - Cable insulation
2. Transient Combustible Load Type
   - Thermoplastic battery cases
   - Ordinary combustible
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of the ionization smoke detectors system(s) and the thermal detector system(s) activates the automatic CO_2 gas system. Either detector system alone can provide early warning.

H. Fire Suppression

1. Primary

   Automatic CO_2 total flooding

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in adjacent corridor building near Zone 5B.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.2.17 Fire Area II, Fire Zone 10B, Train B Remote Shutdown Room

A. Location

Fire Zone 10B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 7B

South: 3-hour rated wall common to the diesel/control building seismic gap at column line J4

East: 1-hour rated wall common to Zone 5B

West: 2-hour rated wall common to Fire Area I, Zone 10A

Floor: 3-hour rated barrier common to Zone 2

Ceiling: 3-hour rated barrier common to Zone 14

2. Zone Access

- One Class B door in the 2-hour rated west wall to Zone 10A

- One Class C door in the 1-hour rated east wall to Zone 5B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B remote shutdown panel D

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Paper
   - Plastic (telephones)
   - Polycarbonate battery casing
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning and thermal detectors will actuate the automatic Halon 1301 gas system.

H. Fire Suppression

1. Primary

Automatic Halon 1301 fire extinguishing system

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in adjacent corridor building near Zone 5B.

I. Ventilation

(Refer to the appendix 9A response to Question 9A.70.) Manually controlled smoke venting to the adjacent zone where portable smoke removal equipment exhausts smoke to the smoke removal HVAC chase.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.18 Fire Area II, Fire Zone 11B, Train B Cable Shaft

A. Location

Fire Zone 11B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 86B at column line J1
South:	3-hour rated wall common to Zone 14
East:	3-hour rated wall common to the corridor building at column line JE
West:	3-hour rated wall common to Zone 14
Floor:	3-hour rated barrier common to Zone 4B
Ceiling:	3-hour rated barrier common to Zone 15B at elevation 132 feet 0 inch

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 14

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

All building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

Cable insulation

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 14.

2. Secondary

Four portable CO_2 fire extinguishers are located in adjacent Zone 14. One portable CO_2 fire extinguisher and one manual hose reel are located in the adjacent corridor building near Zone 14.

I. Ventilation

None. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.2.19 Fire Area II, Fire Zone 12, Communications Room

A. Location

Fire Zone 12 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 14

South: 2-hour rated wall common to the southeast HVAC chase

East: Nonrated exterior wall at column line JE

3-hour rated wall common to the corridor building at column line JE

West: 1-hour rated wall common to Zone 13

Floor: 3-hour rated barrier common to Zone 5B

Ceiling: 3-hour rated barrier common to Fire Area III, Zone 17

2. Zone Access

One Class B door (pair) in the 1-hour rated north wall to Zone 14

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating, with the exception of fire dampers in the north and west walls in Unit 1 communicating with Fire Zones 14 and 13 respectively, which are not installed in accordance with the fire tested configuration. The barriers containing these dampers are not required to achieve separation in accordance with 10CFR50, Appendix R, Section III.G.2.

5. Protected Raceways

None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit and cable trays

   In-plant communications

   Battery and communications equipment

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Plastic
      - Cable insulation
      - Thermo-Lag 330-1

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

   3. Total Combustible (Fire) Loading

      Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning and in a cross-zoned mode actuates the automatic Halon 1301 gas system.

H. Fire Suppression

1. Primary

Automatic Halon 1301 gas system

2. Secondary

One manual hose reel and four portable CO_2 fire extinguishers are located in adjacent Zone 14.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.2.20 Fire Area II, Fire Zone 13, Inverter Room

A. Location

Fire Zone 13 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 14

South: 2-hour rated wall common to the southeast HVAC and outside air chases, 1-hour rated wall common to Zone 14

East: 1-hour rated wall common to Zone 12

West: 1-hour rated walls common to Zone 14

Floor: 3-hour rated barrier common to Zone 5B

Ceiling: 3-hour rated barrier common to Fire Area III, Zones 16 and 17

2. Zone Access

One Class B door (pair) in the 1-hour rated north wall to Zone 14

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating, with the exception of fire dampers in the east and west walls in Unit 1 communicating with Fire Zones 12 and 14 respectively, which are not installed in accordance with the fire tested configuration. The barriers containing these dampers are not required to achieve

separation in accordance with 10CFR50, Appendix R, Section III.G.2.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Inverter equipment
   - Conduit and cable trays

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Thermo-Lag 330-1
      - Plastic

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   Ionization smoke detector systems are provided for early warning and in a cross-zoned mode actuates the automatic Halon 1301 gas system.

H. Fire Suppression

1. Primary

   Automatic Halon 1301 gas system

2. Secondary

   One manual hose reel and four portable CO_2 fire extinguishers are located in adjacent Zone 14.

I. Ventilation

   Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

   None

K. Emergency Communications

   Sound powered phone jack(s) is provided.

9B.2.2.21 Fire Area II, Fire Zone 14, Lower Cable Spreading Room

A. Location

Fire Zone 14 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area I, Zone 11A

3-hour rated wall common to Fire Area I, Zone 86A, at column line J1

2-hour rated wall common to Fire Area I, the northwest HVAC chase

3-hour rated wall common to Zone 86B at column line J1

3-hour rated wall common to Zones 11B and 15B

1-hour rated wall common to Zone 13

South: 2-hour rated walls common to Fire Area I, the southwest stairwell and HVAC chase

3-hour rated wall common to the diesel/control building seismic gap at column line J4

	Nonrated exterior wall at column line J4
	1-hour rated wall common to Zone 12
	1-hour rated wall common to Zone 13
East:	3-hour rated wall common to the corridor building at column line JE
	2-hour rated wall common to the southeast outside air chase
	1-hour rated wall common to Zone 13
	3-hour rated wall common to Zones 11B and 15B
West:	3-hour rated wall common to Fire Area X at column line JA
	2-hour rated wall common to Fire Area I, the northwest HVAC chase
	2-hour rated wall common to Fire Area I, the southwest HVAC chase
Floor:	3-hour rated barrier common to Fire Area I, Zones 5A, 6A, 7A, 8A, 9A, and 10A
	3-hour rated barrier common to Zones 5B, 6B, 7B, 8B, 9B, and 10B
Ceiling:	3-hour rated barrier common to Fire Area III, Zones 16 and 17

2. Zone Access

   - One nonrated missile door in the 3-hour rated east wall to the corridor building (Refer to Appendix 9A response to Question 9A.106)
   - One Class A door in the 3-hour rated south wall to Fire Area V (DG Building)
   - One Class B door in the 2-hour rated south wall to the southwest stairwell

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating, with the exception of fire dampers in the east and south walls in Unit 1 communicating with Fire Zones 13 and 12 respectively, which are not installed in accordance with the fire tested configuration. The barriers containing these dampers are not required to achieve separation in accordance with 10CFR50, Appendix R, Section III.G.2.

5. Protected Raceways

   Train A auxiliary feedwater main steam and electrical power distribution cables are

enclosed in a 2-hour rated cable chase near column lines J1/JC.

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   Train B ERFDAD cabinets

   Train B radiation monitors

D. Nonsafety-Related Equipment and Components

   Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Plastic
   - Polycarbonate battery casing
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

   Actuation of either the ionization smoke detector system(s) or the line-type thermal detector system(s) activates the automatic preaction water sprinkler system. Either detector system alone can provide early warning capability.

H. Fire Suppression

   1. Primary

      Automatic zoned preaction water sprinkler system

   2. Secondary

      One manual hose reel and four portable CO_2 fire extinguishers

I. Ventilation

   Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

   Six 6-inch drains

K. Emergency Communications

   Sound powered phone jack(s) is provided.

9B.2.2.22 Fire Area II, Fire Zone 15B, BOP Cable Shaft

A. Location

Fire Zone 15B (engineering drawing 13-A-ZYD-029) is located in the control building between elevations 132 feet 0 inch and 160 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 86B at column line Jl

South: 3-hour rated wall common to Fire Area III, Zone 17

3-hour rated wall common to Zone 14 between elevations 132 feet 0 inch and 140 feet 0 inch

East: 3-hour rated wall common to the corridor building at column line JE

West: 3-hour rated wall common to Fire Area III, Zone 17

3-hour rated wall common to Zone 14 between elevations 132 feet 0 inch and 140 feet 0 inch

Floor: 3-hour rated barrier common to Zone 11B at elevation 132 feet 0 inch

Ceiling: 3-hour rated barrier common to Zone 18B

2. Zone Access

   One Class A door in the 3-hour rated west wall to Zone 14 at elevation 132 feet 0 inch.

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Cable trays

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable Insulation

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 14 at elevation 120 feet 0 inch.

2. Secondary

   Four portable CO_2 fire extinguishers are located in adjacent Zone 14 at elevation 120 feet 0 inch.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.2.23 Fire Area II, Fire Zone 18B, BOP Cable Shaft

A. Location

Fire Zone 18B (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated exterior wall at column line J1

South: 3-hour rated wall common to Fire Area I, Zone 20

East: 3-hour rated wall common to the corridor building at column line JE

West: 3-hour rated wall common to Fire Area I, Zone 20

Floor: 3-hour rated barrier common to Zone 15B

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 20

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 20.

2. Secondary

   Four portable CO_2 fire extinguishers are located in adjacent Zone 20.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.2.24 Fire Area II, Fire Zone 19, Normal Smoke Exhaust Room

A. Location

Fire Zone 19 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 160 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Fire Area I, Zone 20

South: 3-hour rated wall common to the diesel/control building seismic gap at column line J4

Nonrated exterior wall of heavy concrete construction at column line J4

East: 3-hour rated wall common to the corridor building at column line JE

Nonrated exterior wall of heavy concrete construction at column line JE

West: 2-hour rated wall common to Fire Area I, Zone 20, at column line JD

Floor: 3-hour rated barrier common to Fire Area III, Zone 17

Open continuation of the southeast HVAC chase

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class B door in the 2-hour rated north wall to Zone 20.

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barrier are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Normal smoke exhaust fan
- Conduit

- Communication equipment uninterruptible power supply, and batteries (In those units where DMWO 4493762 has been implemented)

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Lubricating grease
   - Rubber
   - Communication equipment uninterruptible power supply, and batteries (In those units where DMWO 4493762 has been implemented)
   -

2. Transient Combustible Load Type

   - Ordinary combustible
   - Lubricating grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Two manual hose reels are located in adjacent Zone 20 and the corridor building.

2. Secondary

Four portable CO_2 fire extinguishers are located in adjacent Zone 20. One portable CO_2 fire extinguisher is located in the adjacent corridor building.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside. (Refer to the appendix 9A response to Questions 9A.70 and 9A.80.)

J. Drainage

None

K. Emergency Communications

None

9B.2.2.25 Fire Area II, Fire Zone 86B, Train B Compartment Between Auxiliary and Control Buildings

A. Location

Fire Zone 86B (engineering drawing 13-A-ZYD-029) is the compartment between the auxiliary and control buildings between elevations 74 feet 0 inch and 156 feet 4 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XV at column line A10

South: 3-hour rated wall at column line J1 common to:

- Zones 2 and 3B at elevation 74 feet 0 inch
- Zones 4B and 6B at elevation 100 feet 0 inch
- Zones 11B and 14 at elevation 120 feet 0 inch
- Zone 15B between elevations 132 feet 0 inch and 156 feet 4 inches

2-hour rated wall common to Zone 5B and the northeast HVAC chase at column line Jl and elevation 100 feet 0 inch

3-hour rated wall common to Fire Area III, Zone 17, at column line Jl and elevation 140 feet 0 inch

East: Nonrated exterior wall at column line JE and elevation 74 feet 0 inch

Nonrated wall common to the corridor building at column line JE, at elevations 100 feet 0 inch, 120 feet 0 inch and 140 feet 0 inch

West: Nonrated wall of heavy concrete construction common to Fire Area I, Zone 86A, at column line JC

Floor: Nonrated basemat of light concrete paving at elevation 74 feet 0 inch

Ceiling: Nonrated roof of heavy concrete construction at elevation 156 feet 4 inches

2. Zone Access

One Class B door in the 2-hour rated south wall, elevation 100 feet 0 inch, to Zone 5B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Actuation of both the ionization detector system(s) and the line-type thermal detector system(s) activates the automatic water spray system. Either detection system alone can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic deluge water spray system. (At elevations 100 feet 0 inch and 120 feet 0 inch only, see engineering drawing 13-A-ZYD-029.)

2. Secondary

One portable CO_2 fire extinguisher and one manual hose reel are located at elevation 100 feet 0 inch in adjacent Zone 5B. One portable CO_2 fire extinguisher and one manual hose reel are located in adjacent corridor building near Zone 5B.

I. Ventilation

Manually controlled smoke venting through the seismic gap in the ceiling. (Refer to the appendix 9A responses to Questions 9A.70 and 9A.80.)

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.3 FIRE AREA III

9B.2.3.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area III (engineering drawing 13-P-00B-005) contains both train A and train B components found in the control and computer rooms of the control building at elevation 140 feet 0 inch. This fire area includes Analysis Area IIIA only (fire zones 16 and 17) (engineering drawing 13-A-ZYD-029).

Fire Area III is bounded to the north by 3-hour rated barriers common to Fire Areas I and II, and by 2-hour

rated barriers common to the northwest HVAC chase (Fire Area I). The south boundaries are 3-hour rated barriers common to Fire Areas I, IV, and V, a non-rated heavy concrete exterior wall, 2-hour rated barriers common to the southwest HVAC chase (Fire Area I), and 2-hour rated barriers common to the southeast outside air and HVAC chases (Fire Area II). The west boundary is a 3-hour rated barrier common to Fire Area X. The east boundary is a 3-hour rated barrier common to the corridor building and a non-rated heavy concrete exterior wall. Fire Area III does not include the vestibule adjacent to the corridor building. The walls of the vestibule are 3-hour rated. The ceiling above and floor below Fire Area III are 3-hour rated barriers.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. The main control room (Zone 17) contains redundant safe shutdown cables and equipment. Alternative safe shutdown capability is provided as required by Section III.G.3 of Appendix R.

2. See subsection 9B.2.1 for deviations common to Fire Area I and subsection 9B.2.2 for a deviation common to Fire Area II.

3. A deviation is taken from Section III.L to the extent that it allows credit for only one action in the control room prior to evacuation. (See Generic Letter 86-10, Question 3.8.4.)

In accordance with the guidance of Generic Letter 86-10, Questions 3.8.4 and 5.3.10, a bounding analysis was performed for the control room fire scenario to assure that safe shutdown conditions could be maintained from outside the control room (ref. calculation 13-MC-FP-318, 10CFR50 Appendix R IIIG/IIIL Compliance Assessment and 13-MC-FP-317, Appendix R Operational Considerations). This bounding analysis assumed worst case spurious actuations as well as loss of all automatic function (such as ESFAS, DG auto start and sequencing) of components whose control circuits could be affected by a fire in the control room. This conservative analysis indicated that the steam generator may overfill in approximately two minutes if a main steam isolation signal is not initiated prior to control room evacuation. This assures a malfunction of the main feedwater control valves upon reactor trip. The action to isolate main steam is located on the same control board as the reactor trip push-button. The action in the control room prevents a very unlikely series of events, which includes spurious actuation and failure of specific automatic functions. If these series of events were to occur, however, main steam can be isolated outside the control room, regardless of the circuit damage in the control room.

9B.2.3.2 Analysis Area IIIA

A. Location

Analysis Area IIIA consists of Fire Zones 16 and 17. Fire Zones 16 and 17 (engineering drawing 13-A-ZYD-029) are located in the control building at elevation 140 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area I, Zone 86A, at column line J1

3-hour rated wall common to Fire Area II, Zone 86B, at column line J1

3-hour rated wall common to Fire Area I, Zone 15A

3-hour rated wall common to Fire Area II, Zone 15B

2-hour rated wall common to Fire Area I, the northwest HVAC chase

South: 2-hour rated walls common to Fire Area I, the southwest HVAC chase

2-hour rated wall common to Fire Area II, the southeast outside air and HVAC chases

Nonrated exterior wall at column line J4

3-hour rated wall common to the diesel/ control building seismic gap at column line J4

East: 2-hour rated wall common to Fire Area II, the outside air chase

3-hour rated wall common to the corridor building at column line JE

NOTE

Entrance to the control room is made through a 3-hour rated vestibule, which is not considered part of Zone 17.

Non-rated heavy concrete exterior wall at column line JE

3-hour rated wall common to Fire Area II, Zone 15B

West: 3-hour rated wall common to Fire Area X at column line JA

2-hour rated wall common to Fire Area I, the northwest HVAC chase

2-hour rated wall common to the air lock

Floor: 3-hour rated barrier common to Fire Area II, Zones 12, 13, and 14

Ceiling: 3-hour rated barrier common to Fire Area I, Zones 19 and 20

C. Safe Shutdown Related Components and Cables

- Train A and train B and nontrain related cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

Condensate storage and transfer

Diesel fuel oil and transfer

Diesel generator

Essential chilled water

Essential cooling water

Auxiliary building HVAC

Diesel generator HVAC

Control building HVAC

Miscellaneous HVAC

Nuclear cooling water

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Essential spray pond

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Train A control panels and circuits
- Train B control panels and circuits
- Train A NSSS process protection instrumentation
- Train B NSSS process protection instrumentation

- Train A BOP analog instrumentation cabinet
- Train B BOP analog instrumentation cabinet
- Train A MSIV logic cabinet
- Train B MSIV logic cabinet
- Various train A and train B control room fire dampers

D. Summary and Conclusion

Alternate shutdown is credited for a fire in this area. One train of systems, Train B, has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Sections III.G and III.L.

9B.2.3.3 Fire Area III, Fire Zone 16, Computer, Office, and Storage Rooms

A. Location

Fire Zone 16 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Zone 17

South: non-rated heavy concrete exterior wall at column line J4

3-hour rated wall common to the diesel/control building seismic gap at column line J4

East: 2-hour rated walls common to Zone 17

2-hour rated wall common to Fire Area II, the outside air chase

West: 2-hour rated wall common to Zone 17 and the air lock

Floor: 3-hour rated barrier common to Fire Area II, Zones 13 and 14

Ceiling: 3-hour rated barrier common to Fire Area I, Zone 20

2. Zone Access

- One Class B door (pair) in the 2-hour rated north wall to Zone 17
- One Class B door in the 2-hour rated west wall to Zone 17

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Computer equipment
   - Conduit and gutters

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Polycarbonate battery casing
      - Cable insulation
      - Magnetic tape
      - Vinyl asbestos floor tile
      - Paper
      - Plastic

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Vinyl asbestos floor tile

3. Total Combustible (Fire) Loading

High

G. Fire Detection

The computer room ionization smoke detector system(s) is provided for early warning and in a cross-zoned mode will actuate the automatic Halon 1301 gas system in the computer room. The computer room is also provided with an ionization smoke detector system located above the suspended ceiling for early warning only. The office and storage rooms are provided with ionization smoke detector system(s) for early warning only.

H. Fire Suppression

1. Primary

Automatic Halon 1301 gas system for the computer room

2. Secondary

Five portable CO_2 fire extinguishers, four portable pressurized water fire extinguishers, and one manual hose reel are located in adjacent Zone 17.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.3.4 Fire Area III, Fire Zone 17, Control Room

A. Location

Fire Zone 17 (engineering drawing 13-A-ZYD-029) is located in the control building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area I, Zone 86A, at column line J1

3-hour rated wall common to Fire Area II, Zone 86B, at column line J1

3-hour rated wall common to Fire Area I, Zone 15A

2-hour rated wall common to Fire Area I, the northwest HVAC chase

3-hour rated wall common to Fire Area II, Zone 15B

South: 2-hour rated walls common to Zone 16

2-hour rated walls common to Fire Area I, the southwest HVAC chase

3-hour rated wall common to the southwest stairwell at column line J4

2-hour rated wall common to Fire Area II, the southeast outside air and HVAC chases

East: 3-hour rated wall common to the corridor building at column line JE

NOTE

Entrance to the control room is made through a 3-hour rated vestibule, which is not considered part of Zone 17.

Non-rated heavy concrete exterior wall at column line JE

3-hour rated wall common to Fire Area II, Zone 15B

West: 3-hour rated wall common to Fire Area X at column line JA

2-hour rated wall common to Fire Area I, the northwest HVAC chase

Floor: 3-hour rated barrier common to Fire Area II, Zones 12, 13, and 14

Ceiling: 3-hour rated barrier common to Fire Area I, Zones 19 and 20

2. Zone Access

- One Class A door (pair) in the 3-hour rated east wall to the vestibule adjacent to the corridor building
- One Class A door in the 3-hour rated wall to the southwest stairwell

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Building structural columns and beams are protected by coatings with 3-hour ratings.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- ERFDAD and instrumentation cabinets
- Plant protection system cabinets
- Qualified safety parameter display system isolation cabinets
- Safety-related equipment status systems cabinets

- Site radiation monitoring system control room cabinets

D. Nonsafety-Related Equipment and Components

- Water heater
- Cable trays, conduit, and gutters
- Instrument cabinets
- Plant annunciator cabinets
- Electrical instrumentation and protection cabinets

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

    - Cable insulation
    - Vinyl asbestos floor tile
    - Carpet or resilient floor covering
    - Paper, clothing, wood, and plastic
    - Polycarbonate battery casing
    - Thermo-Lag 330-1
    - Corian Desk Top

2. Transient Combustible Load Type

    - Ordinary combustible

- Vinyl asbestos floor tile

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Five portable CO_2 fire extinguishers

2. Secondary

   Four portable pressurized water fire extinguishers, one manual hose reel

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.4 FIRE AREA IV

9B.2.4.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area IV contains train A components found in the diesel generator building. This fire area includes Analysis Area IVA (Zones 21A, 22A, 23A, 24A, and 25A) (engineering drawing 13-A-ZYD-031) only.

At elevations 100 feet 0 inch and 115 feet 0 inch, Fire Area IV is bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the east by 3-hour rated barriers common to Fire Area V, and to the west and south by nonrated exterior walls. A portion of the ceiling of Zone 21A is 3-hour rated and common to Fire Area V, the central staircase. The basemat is nonrated.

At elevation 131 feet 0 inch, Fire Area IV is bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the east by a 3-hour rated barrier common to Fire Area V, and to the west and south by nonrated exterior walls. The ceiling to Zones 23A and 25A, which is also the roof of the diesel generator building, is nonrated.

At elevation 146 feet 0 inch, Fire Area IV includes the train A exhaust stack bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the east by a 3-hour rated barrier common to the train B exhaust stack (Fire Area V), and to the south and west by nonrated exterior walls. Above elevation 180 feet 4 inches, Fire Area IV is bounded by nonrated exterior walls. The top of the exhaust stack is covered by a nonrated

barrier at elevation 193 feet 9 inches, with openings to atmosphere on the north and south faces.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested to Section III.G.2 to the extent that it required 3-hour, fire-rated barriers to separate circuits of redundant trains.

Discussion:

The diesel generator building is separated from the control building by a 6-inch seismic gap which is necessary to allow for relative seismic motion of the two buildings. The gap extends from elevation 94 feet 0 inch to the roof at elevation 148 feet 0 inch. In essence, the seismic gap creates a closed space which adjoins train A and B fire areas associated with the diesel generator and control buildings. Control cables associated with the diesel generators are routed from the diesel generator building Fire Areas IV and V into the control building Fire Areas I and II. The train A and train B cables transverse the seismic gap through conduit expansion/deflection fittings and open cable trays. There is no fire-rated barrier providing vertical separation or fire detection and automatic suppression within the 6-inch seismic gap. Cable routing outside of the seismic gap

space, however, is in full compliance with the separation criteria of Section III.G.

This configuration is considered an acceptable deviation due to the following technical reasons:

a. The diesel generator building and the control building are separated by two, independent, 3-hour fire-rated walls. All penetrations through the walls are sealed with materials of equivalent fire resistance. This configuration assures that a fire originating in either the control building or diesel generator building will not propagate into the seismic gap.

b. The doorway penetrations through the seismic gap (100- and 120-foot elevations) are to be sealed with a 1-hour, fire-rated assembly. The purpose for the addition of fire-rated seals at the door penetrations is to eliminate fire exposure to safe shutdown circuits due to transient combustibles. The corridor and stairway area where the seals will be installed is void of fixed combustibles. The only fire exposure to the seal would be due to transient combustibles. Using the criteria in paragraph 9B.1.3.2, listing F,

combustible loading, anticipated fires due to transient combustibles would have a duration much less than 1 hour. The installation of a 1-hour, fire-rated assembly, therefore, will provide adequate protection against fires occurring in the corridor and stairway area.

c. The area within the seismic gap contains minimal exposed combustibles. There are two train A and two train B cable trays which transverse the gap. The horizontal separation between the tray stacks is approximately 23 feet 1 inch. The total weight of cable insulation is approximately 6 pounds. The cables are at a minimum IEEE-383 qualified at 70,000 Btu/hr for flame testing. Conduits that penetrate the two fire walls utilize an expansion/ deflection fitting to transverse the gap. The fittings consist of a tin/copper braided bonding jumper, bronze end couplings, molded neoprene rubber sleeve, and stainless steel bands. Neoprene rubber is used as a weather shield across the top of the gap. The spacial configuration of the trays and conduits in conjunction with limited combustibles will eliminate the potential for fire spread.

d. The expansion/deflection fittings used to transverse the seismic gap will provide a significant level of fire resistance. Since the assembly is not a fire-tested device, a rating cannot be claimed. Based on the natural fire-resistant characteristics of neoprene rubber, however, it is reasonable to assume that some degree of resistance to heat transfer will be obtained. The wall thickness of the neoprene sleeve is greater than 1/2 inch for all fittings and is tightly secured over the end couplings by stainless steel bands.

e. There are no exterior fixed combustibles to present an exposure hazard to the seismic gap. The openings of the gap at the exterior walls are provided with sheet metal flashing. In addition, sidewalks on both sides of the gap opening provide effective curbing against liquid spills.

f. Flammable liquid spills from within the diesel generator building will not expose the seismic gap. This condition has been previously evaluated and documented in the response to Question 9A.119 in appendix 9A.

g. There are no credible ignition sources within the seismic gap. The gap is

effectively sealed against external sources and the cables are provided with circuit protection to prevent auto-ignition due to fault conditions. In addition, the buildings are provided with lightning protection.

h. The configuration of the conduit and tray penetrations through the seismic gap provides adequate separation between redundant circuits and protection from a hot gas layer below the roof seal. Since there are no fixed or transient combustibles below the penetrations, fire propagation is not a credible event. All safe shutdown circuits are routed through the gap at approximately elevation 110 feet 0 inch. The horizontal distance between train A and B cables, routed through expansion/deflection fittings, is approximately 11 feet 3 inches and the distance between redundant trays is approximately 23 feet 1 inch. The vertical distance from the highest cable to the roof seal is approximately 35 feet. With the limited fixed combustibles within the gap and elimination of transient combustibles, the development of a thermal gas layer over 35 feet thick is highly unlikely. In essence, the cable separation in

conjunction with the vertical distance to the roof provides reasonable assurance that, if a fire occurred, one train of cables will remain undamaged.

2. See subsection 9B.2.0 for generic deviations.

9B.2.4.2 Analysis Area IVA

A. Location

Analysis Area IVA consists of Fire Zones 21A, 22A, 23A, 24A, and 25A.

Fire Zone 21A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevations 100 feet 0 inch and 115 feet 0 inch.

Fire Zone 22A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 100 feet 0 inch.

Fire Zones 23A and 25A (engineering drawing 13-A-ZYD-031) are located in the diesel generator building at elevation 131 feet 0 inch.

Fire Zone 24A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 115 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area V, the central staircase, at column line G2 (elevation 100 feet 0 inch and 115 feet 0 inch)

3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

3-hour rated wall common to Fire Area V, the central staircase Vestibule Room G211 (elevation 131 feet 0 inch)

South: Nonrated exterior wall of heavy concrete construction at column line G3

One 7 x 16-foot opening to the outside for room air intake (elevation 131 feet 0 inch)

East: 3-hour rated wall common to Fire Area V, Zone 21B, at column line GB

3-hour rated wall common to Fire Area V, the central staircase

3-hour rated wall common to Vistible Room G211.

3-hour rated wall common to Fire Area V, Zone 23B, at column line GB

3-hour rated wall common to Fire Area V, Zone 25B, at column line GB

West: Nonrated exterior wall of heavy concrete construction at column line GA

Nonrated walls of heavy concrete construction about the diesel combustion air intake stack

Floor: Nonrated basemat of heavy concrete construction at elevation 100 feet 0 inch, including a sump pit at elevation 89 feet 0 inch

Nonrated basemat of heavy concrete construction including pipe trench to elevation 94 feet 0 inch

Ceiling: Nonrated roof of heavy concrete construction above Fire Zone 25A

3-hour rated roof above Fire Zone 23A

3-hour rated barrier common to Vestibule Room G211.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Diesel fuel oil and transfer

  Diesel generator

  Diesel generator HVAC

  Electrical power distribution

- Train A diesel generator fuel oil day tank, day tank level controller, and associated equipment

- Train A diesel generator and associated control and regulating panels and equipment

- Train A diesel engine and associated starting and control components

- Train A diesel generator cooling water components
- Train A diesel generator control room air handling unit and diesel generator room exhaust fan

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.4.3 Fire Area IV, Fire Zone 21A, Train A Diesel Generator Room

A. Location

Fire Zone 21A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevations 100 feet 0 inch and 115 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall, at column line G2, common to:

- Zone 22A at elevation 100 feet 0 inch
- Zone 24A at elevation 115 feet 0 inch

3-hour rated wall common to Fire Area V, the central staircase, at column line G2

South: Nonrated exterior wall of heavy concrete construction at column line G3

East: 3-hour rated wall common to Fire Area V, Zone 21B, at column line GB

West: Nonrated exterior wall of heavy concrete construction at column line GA

Floor: Nonrated basemat of heavy concrete construction at elevation 100 feet 0 inch, including a sump pit at elevation 89 feet 0 inch

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 25A

3-hour rated barrier common to Zone 23A

3-hour rated barrier common to Fire Area V, the central staircase

3-hour rated barrier common to Vestibule Room G211.

2. Zone Access

   - One non-rated door in the 2-hour rated north wall to Zone 22A

   - One nonrated missileproof door in the nonrated west exterior wall

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Sump pump

   - 25-ton hoist and monorail

   - 25-ton crane

- Diesel generator room normal unit heaters
- Intake air silencer
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Oil/grease
   - Diesel fuel oil
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil
3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Actuation of the ultraviolet or thermal detector systems activates the automatic preaction sprinkler system.

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system
2. Secondary

One portable CO_2 fire extinguisher. One manual hose reel is located in the adjacent control building at elevation 100 feet 0 inch. Outside hydrant is available if access is blocked by the diesel generator control room roll-up door.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86).

J. Drainage

Seven 4-inch drains

K. Emergency Communications

None

9B.2.4.4 Fire Area IV, Fire Zone 22A, Train A Diesel Generator Control Room

A. Location

Fire Zone 22A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: 2-hour rated wall common to Zone 21A at column line G2

East: 3-hour rated wall common to Fire Area V, the central staircase

West: Nonrated exterior wall of heavy concrete construction at column line GA

Floor: Nonrated basemat of heavy concrete construction including pipe trench to elevation 94 feet 0 inch

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 24A

2. Zone Access

- One Class A door in the 3-hour rated east wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Neutral grounding transformer
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Cable insulation
   - Polycarbonate battery cases
   - Thermo-Lag 330-1

2. Transient Combustible Load Type
   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher

2. Secondary

One manual hose reel is located in the adjacent control building at elevation 100 feet 0 inch.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.4.5 Fire Area IV, Fire Zone 24A, Train A Combustion Air Intake Room

A. Location

Fire Zone 24A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 115 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: 2-hour rated wall common to Zone 21A at column line G2

East: 3-hour rated wall common to Fire Area V, the central staircase

West: Nonrated exterior wall of heavy concrete construction at column line GA

Floor: Nonrated barrier of heavy concrete construction common to Zone 22A

Ceiling: 2-hour rated barrier common to Zone 25A

2. Zone Access

- Two Class A doors in the 3-hour rated east wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Diesel generator control room normal air handling unit
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ultraviolet smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in the adjacent control building at elevation 120 feet 0 inch.

2. Secondary

One portable CO_2 fire extinguisher is located in the adjacent control building at elevation 120 feet 0 inch.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.4.6 Fire Area IV, Fire Zone 23A, Train A Fuel Oil Day Tank Vault

A. Location

Fire Zone 23A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 131 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 25A

3-hour rated wall common to the central staircase Vestibule Room G211.

South: 3-hour rated wall common to Zone 25A

East: 3-hour rated wall common to Fire Area V, Zone 23B, at column line GB

West: 3-hour rated wall common to Zone 25A

Floor: 3-hour rated barrier common to Zone 21A

Ceiling: 3-hour rated roof

2. Zone Access

- One Class A door in the 3-hour rated west wall to Zone 25A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Fuel oil

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Thermal detector system(s) is provided to actuate the automatic preaction sprinkler system and for early warning. (Refer to the appendix 9A response to Question 9A.73.)

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 25A.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86).

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.4.7 Fire Area IV, Fire Zone 25A, Train A Silencer Room

A. Location

Fire Zone 25A (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 131 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: Nonrated exterior wall of heavy concrete construction at column line G3

One 7 x 16-foot opening to the outside for room air intake

East: 3-hour rated wall common to Fire Area V, Zone 25B

3-hour rated walls about Zone 23A

3-hour rated wall common to Fire Area V, the central staircase

3-hour rated wall common to Vestibule Room G211.

West: Nonrated exterior wall of heavy concrete construction at column line GA

Nonrated walls of heavy concrete construction about the diesel combustion air intake stack

Floor: Nonrated barrier of heavy concrete construction common to Zone 21A

2-hour rated barrier common to Zone 24A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class A door in the 3-hour rated east wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Air compressors
   - Air dryers
   - Diesel generator room normal exhaust fan
   - Air compressor room vent fan
   - Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Grease/oil

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ultraviolet detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher

2. Secondary

   One manual hose reel is located in the adjacent control building at elevation 120 feet 0 inch.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.5 FIRE AREA V

9B.2.5.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area V contains train B components found in the diesel generator building. This fire area includes Analysis Area VA (Zones 21B, 22B, 24B, 23B, and 25B) (engineering drawing 13-A-ZYD-031).

At elevations 100 feet 0 inch and 115 feet 0 inch, Fire Area V is bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the west by 3-hour rated barriers common to Fire Area IV, and to the east and south by nonrated exterior walls. The basemat is nonrated.

At elevation 131 feet 0 inch, Fire Area V is bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the west by a 3-hour rated barrier common to Fire Area IV, and to the east and south by nonrated exterior walls. A portion of the stairwell floor is 3-hour rated and common to Zone 21A. The ceiling to Zones 23B and 25B, which is also the roof of the diesel generator building, is nonrated.

At elevation 146 feet 0 inch, Fire Area V includes the train B exhaust stack bounded to the north by a 3-hour rated barrier common to the diesel/control building seismic gap, to the west by a 3-hour rated barrier common to the train A exhaust stack (Fire Area IV), and to the south and east by nonrated

exterior walls. Above elevation 180 feet 4 inches, Fire Area V is bounded by nonrated exterior walls. The top of the exhaust stack is covered by a nonrated barrier at elevation 193 feet 9 inches, with openings to atmosphere on the north and south faces.

B. Deviations from 10CFR50 Appendix R, Section III.G.

1. See paragraph 9B.2.4.1, subitem B, for deviation concerning the seismic gap separating the diesel generator building and control building.

2. See subsection 9B.2.0 for generic deviations.

9B.2.5.2 Analysis Area VA

A. Location

Fire Zone 21B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevations 100 feet 0 inch and 115 feet 0 inch.

Fire Zone 22B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 100 feet 0 inch.

Fire Zones 23B and 25B (engineering drawing 13-A-ZYD-031) are located in the diesel generator building at elevation 131 feet 0 inch.

Fire Zone 24B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 115 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

3-hour rated wall common to Vestibule Room (G211).

South: 3-hour rated wall common to the central staircase at column line G2 and Fire Area IV

3-hour rated wall common to the central staircase and the Vestibule Room (G211)

Nonrated exterior wall of heavy concrete construction at column line G3

One 7 x 16-foot opening to the outside for room air intake

East: Nonrated exterior wall of heavy concrete construction at column line GC

Nonrated walls of heavy concrete construction about the diesel combustion air intake stack (elevation 131 feet 0 inch)

West: 3-hour rated wall common to Fire Area IV, Zone 21A, at column line GB

3-hour rated wall common to Vestibule Room (G211)

3-hour rated wall common to Fire Area IV, Zones 22A and 24A

3-hour rated wall common to Fire Area IV, Zone 23A, at column line GB

3-hour rated wall common to Fire Area IV, Zone 25A (elevation 131 feet 0 inch)

Floor: Nonrated basemat of heavy concrete construction at elevation 100 feet 0 inch, including a sump pit at elevation 89 feet 0 inch

Nonrated basemat of heavy concrete construction including pipe trench to elevation 94 feet 0 inch

Ceiling: 3-hour rated barrier common to Vestibule Room (G211)

3-hour rated roof (above Fire Zone 23B)

Nonrated roof of heavy concrete construction (above Fire Zone 25B)

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Diesel fuel oil and transfer

  Diesel generator

- Train B cables associated with the following systems:

  Diesel fuel oil and transfer

  Diesel generator

  Diesel generator HVAC

  Electrical power distribution

- Train B diesel generator fuel oil day tank, day tank level controller, and associated equipment

- Train B diesel generator and associated control and regulating panels and equipment

- Train B diesel engine and associated starting and control components

- Train B diesel generator cooling water components

- Train B diesel generator control room air handling unit and exhaust fan

D. Summary and Conclusions

The Train A diesel fuel oil transfer pump control circuit is in room G211, which is enclosed with three hour rated barriers and therefore not susceptible to fire damage. The train A fuel oil transfer pump will therefore be available for use by the Control Room.

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on

fire barriers provided, with the exception of the diesel fuel transfer pumps as described above. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.5.3 Fire Area V, Fire Zone 21B, Train B Diesel Generator Room

A. Location

Fire Zone 21B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevations 100 feet 0 inch and 115 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall, at column line G2, common to:

- Zone 22B at elevation 100 feet 0 inch
- Zone 24B at elevation 115 feet 0 inch

2-hour rated wall common to the central staircase at column line G2

South: Nonrated exterior wall of heavy concrete construction at column line G3

East: Nonrated exterior wall of heavy concrete construction at column line GC

West: 3-hour rated wall common to Fire Area IV, Zone 21A, at column line GB

Floor: Nonrated basemat of heavy concrete construction at elevation 100 feet 0 inch, including a sump pit at elevation 89 feet 0 inch

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 25B

3-hour rated barrier common to Zone 23B

2-hour rated barrier common to the central staircase

3-hour rated barrier common to Vestibule Room G211

2. Zone Access

- One non-rated door in the 2-hour rated north wall to Zone 22B
- One nonrated missileproof door in the nonrated east exterior wall

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Sump pump
- 25-ton hoist and monorail
- 5-ton crane
- Diesel generator room normal unit heaters
- Intake air silencer
- Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Oil/grease
- Diesel Fuel

2. Transient Combustible Load Type

- Ordinary combustible
- Oil

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Actuation of the ultraviolet or thermal detector systems activates the automatic preaction water sprinkler system.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system

2. Secondary

One portable CO_2 fire extinguisher.

Additionally, one manual hose reel is located in adjacent control building at elevation 100 feet 0 inch.

Outside hydrant is available if access is blocked by the diesel generator control room roll-up door.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

Seven 4-inch drains

K. Emergency Communications

None

9B.2.5.4 Fire Area V, Fire Zone 22B, Train B Diesel Generator Control Room

A. Location

Fire Zone 22B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Fire Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: 2-hour rated wall common to Zone 21B at column line G2

East: Nonrated exterior wall of heavy concrete construction at column line GC

West: 2-hour rated wall common to the central staircase

Floor: Nonrated basemat of heavy concrete construction including pipe trench to elevation 94 feet 0 inch

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 24B

2. Zone Access

- One Class A door in the 2-hour rated west wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Neutral grounding transformer
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Polycarbonate battery cases

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One portable CO_2 fire extinguisher

2. Secondary

One manual hose reel is located in the control building at elevation 100 feet 0 inch

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

(Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.5.5 Fire Area V, Fire Zone 24B, Train B Combustion Air Intake Room

A. Location

Fire Zone 24B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 115 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: 2-hour rated wall common to Zone 21B at column line G2

East: Nonrated exterior wall of heavy concrete construction at column line GC

West: 2-hour rated wall common to the central staircase

Floor: Nonrated barrier of heavy concrete construction common to Zone 22B.

Ceiling: 2-hour rated barrier common to Zone 25B

2. Zone Access

- Two Class A doors in the 2-hour rated west wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Diesel generator control room normal air handling unit
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ultraviolet smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in the adjacent control building at elevation 120 feet 0 inch.

2. Secondary

   One portable CO_2 fire extinguisher is located in the adjacent control building at elevation 120 feet 0 inch.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.5.6 Fire Area V, Fire Zone 23B, Train B Fuel Oil Day Tank Vault

A. Location

Fire Zone 23B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 131 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	3-hour rated wall common to Zone 25B
	3-hour rated wall common to the central staircase Vestibule Room G211
South:	3-hour rated wall common to Zone 25B
East:	3-hour rated wall common to Zone 25B
West:	3-hour rated wall common to Fire Area IV, Zone 23A, at column line GB
Floor:	3-hour rated barrier common to Zone 21B
Ceiling:	3-hour rated roof

2. Zone Access

   - One Class A door in the 3-hour rated east wall to Zone 25B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Fuel oil

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Thermal detector system(s) is provided to actuate the automatic preaction sprinkler system and for early warning. (Refer to the appendix 9A response to Question 9A.73.)

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 25B.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.5.7 Fire Area V, Fire Zone 25B, Train B Silencer Room

A. Location

Fire Zone 25B (engineering drawing 13-A-ZYD-031) is located in the diesel generator building at elevation 131 feet 0 inch

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated area boundary wall common to the diesel/control building seismic gap at column line G1

South: Nonrated exterior construction at column line G3

One 7- x 16-foot opening to the outside for room air intake

East: Nonrated exterior wall of heavy concrete construction at column line GC

Nonrated walls of heavy concrete construction about the diesel combustion air intake stack

West: 2-hour rated wall common to the central staircase

3-hour rated wall common to Vestibule Room G211

3-hour rated walls common to Zone 23B

3-hour rated wall common to Fire Area IV, Zone 25A

Floor: Nonrated barrier of heavy concrete construction common to Zone 21B

2-hour rated barrier common to Zone 24B

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class A door in the 2-hour rated west wall to the central staircase

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Air compressors
- Air dryers
- Diesel generator room normal exhaust fan
- Air compressor room vent fan
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil/grease

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ultraviolet detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher

2. Secondary

One manual hose reel is located in adjacent control building at elevation 120 feet 0 inch.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment. (Refer to the appendix 9A response to Question 9A.86.)

J. Drainage

Three 4-inch drains

K. Emergency Communications Sound powered phone jack(s) is provided.

9B.2.6 FIRE AREA VI

9B.2.6.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area VI (figures 9B-3, 9B-4, and engineering drawing 13-P-00B-005) is the fuel building and includes all components located within the building. This fire area includes Zones 27, 28, 29, and 29A (engineering drawing 13-A-ZYD-030).

Fire Area VI is bounded to the north, south, east, and west by nonrated exterior barriers, except at the southeast corner where 3-hour rated barriers are common to Fire Areas XV and XVI. Both the basemat and roof are nonrated barriers.

No safe shutdown equipment is present in Fire Area VI.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.6.2 Fire Area VI, Fire Zone 27, Exhaust Essential Air Filtration Unit Area and Railroad Bay

A. Location

Fire Zone 27 (engineering drawing 13-A-ZYD-030) is located in the fuel building at elevations 100 feet 0 inch and 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line Fl

South: Nonrated exterior wall of heavy concrete construction at column line F3

East: Nonrated wall of heavy concrete construction, at column line FC, common to Zone 28 at elevation 100 feet 0 inch

Nonrated splash curtain, at column line FC, common to Zone 29A at elevation 120 feet 0 inch

Nonrated wall of heavy concrete construction common to the cask loading pit, at Zone 29A at column line FC

Nonrated walls of heavy concrete construction about the sump pump and storage room, common to Zones 28 and 29A

West: Nonrated exterior wall of heavy concrete construction at column line FA

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated partial ceiling at elevation 140 feet 0 inch with open interface to Zone 29A.

2. Zone Access

- One nonrated door in the nonrated west exterior wall
- One nonrated rollup door in the nonrated north exterior wall
- Open corridor to Zone 28 at elevation 100 feet 0 inch

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A fuel and auxiliary building exhaust essential air filtration unit
- Train B fuel and auxiliary building exhaust essential air filtration unit

D. Nonsafety-Related Equipment and Components

- New fuel handling crane
- Sump pumps
- Cable trays and conduit

E. Radioactive Material

Fire Zone 27 will contain radioactive materials during fuel loading and unloading shipping operations only.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation

- Wood
- Charcoal
- Plastic
- Rubber
- Grease
- Hydraulic fluid

2. Transient Combustible Load Type

- Ordinary combustible
- Charcoal

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

A wet pipe sprinkler system is provided, except for the sump pump and storage room. A manual water spray system is provided for the charcoal filters.

NOTE

A wet pipe sprinkler system is positioned at the ceiling to Zone 29A and will service Zone 27 through the open area of the Zone 27 partial ceiling.

2. Secondary

Two manual hose reels and two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Six 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.6.3 Fire Area VI, Fire Zone 28, Spent Fuel Pool Cooling Pumps and Heat Exchangers Area

A. Location

Fire Zone 28 (engineering drawing 13-A-ZYD-030) is located in the fuel building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 27 and 29A near column line F2

2-hour rated wall common to the southeast stairwell

South: Nonrated exterior wall of heavy concrete construction at column line F3

3-hour rated wall common to an elevator shaft at column line F3

East: 3-hour rated wall common to Fire Areas XV and XVI at column line FF

2-hour rated wall common to the southeast stairwell.

West: Nonrated wall of heavy concrete construction common to Zone 27 at column line FC

Floor: Nonrated basemat of heavy concrete construction at elevation 100 feet 0 inch with a piping penetration pit below

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 29

3-hour rated barrier common to Zone 29A

2. Zone Access

   - Open corridor to Zone 27
   - One Class B door in the 2-hour rated southeast stairwell south wall
   - One Class A door in the 3-hour rated east wall to Fire Area XV (Aux Building)
   - One nonrated door in the nonrated south exterior wall

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train A spent fuel cooling system pump
   - Train A spent fuel pool heat exchanger
   - Train B spent fuel cooling system pump
   - Train B spent fuel pool heat exchanger

D. Nonsafety-Related Equipment and Components

- Spent fuel pool cleanup pumps
- Cable trays and conduit

E. Radioactive Material

Fire Zone 28 contains radioactive materials in process piping.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Grease and oil
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Grease and oil

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel

2. Secondary

One portable ABC powder fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Six 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.6.4 Fire Area VI, Fire Zone 29, Electrical Equipment Area

A. Location

Fire Zone 29 (engineering drawing 13-A-ZYD-030) is located in the fuel building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated walls common to the new fuel storage racks, Zone 29A

Nonrated wall of heavy concrete construction common to the new fuel inspection pit, Zone 29A

Nonrated wall of heavy concrete construction common to the fuel transfer canal

2-hour rated wall common to the southeast stairwell

South: 3-hour rated wall common to an elevator shaft at column line F3

Nonrated exterior wall of heavy concrete construction at column line F3

East: 3-hour rated wall common to Fire Areas XV and XVI at column line FF

2-hour rated wall common to the southeast stairwell

West: Open to Zone 27 at column line FC

Floor: Nonrated barrier of heavy concrete construction common to Zone 28

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 29A

2. Zone Access

- One Class A door in the 3-hour rated east wall to Fire Area XV
- One Class B door in the 2-hour rated west wall of the southeast stairwell
- Open corridor to Zone 27

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Motor control center
   - Load center
   - Cable trays and conduit

E. Radioactive Material

   None

F Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Oil and grease
      - Rubber

- Plastic
- Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel

2. Secondary

   One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.6.5 Fire Area VI, Fire Zone 29A, New and Spent Fuel Storage Areas

A. Location

Fire Zone 29A (engineering drawing 13-A-ZYD-030) is located in the fuel building at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line Fl

South: Nonrated wall of heavy concrete construction about the spent fuel pool common to Zone 28 at elevation 100 feet 0 inch

Nonrated walls of heavy concrete construction common to the fuel transfer canal at elevations 100 feet 0 inch and 120 feet 0 inch

Nonrated walls of heavy concrete construction about the new fuel inspection pit common to Zones 27 and 29 at elevation 120 feet 0 inch

3-hour rated walls about the new fuel storage racks common to Zone 29 at elevation 120 feet 0 inch

Nonrated exterior wall of heavy concrete construction at column line F3 at elevation 140 feet 0 inch

3-hour rated wall common to an elevator shaft at column line F3 and elevation 140 feet 0 inch

East: Nonrated exterior walls of heavy concrete construction at column line FF

3-hour rated area boundary wall common to Fire Areas XV and XVI at elevation 140 feet 0 inch at the southeast corner

2-hour rated walls about the southeast stairwell at elevation 140 feet 0 inch

West: Nonrated wall of heavy concrete construction common to Zone 27 and about the cask loading pit at elevations 100 feet 0 inch and 120 feet 0 inch

Nonrated exterior wall of heavy concrete construction at column line FA and elevation 140 feet 0 inch

Nonrated splash curtain at column line FC, common to Zone 27 at elevation 120 feet 0 inch

Floor: Nonrated area boundary basemat of heavy concrete construction for the spent fuel pool

Nonrated barriers of heavy concrete construction for the new fuel inspection pit

Nonrated barrier of heavy concrete construction common and partially open to Zone 27

2-hour rated new fuel storage rack cover at elevation 140 feet 0 inch

3-hour rated barrier beneath the new fuel storage racks area, common to Zone 28.

Ceiling: Nonrated barrier of heavy concrete construction common to the roof

2. Zone Access

- One Class A door (pair) in the 3-hour rated east wall to Fire Area XV (Aux. Building elevation 140 feet 0 inch)
- One Class B door in the 2-hour rated west wall of the southeast stairwell
- Partial open floor to Zone 27 at elevation 140 feet 0 inch

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of corresponding rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- New fuel storage racks
- Spent fuel storage racks
- Fuel pool control panel
- Spent fuel handling machine
- Upender hydraulic drive unit
- Pool cooling purification panel
- New fuel elevator drive package
- 5-ton monorail
- 10-ton new fuel handling crane
- 150-ton cask handling crane
- Conduit

E. Radioactive Material

Fire Zone 29A is designated for the storage of radioactive material consisting of new and spent reactor fuel assemblies.

F. Combustible Loading

1. In Situ Combustible Load Type

- Oil and grease
- Cable insulation
- Plastic
- Rubber
- Wood
- Hydraulic fluid

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided over the new fuel area for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located at elevation 120 feet 0 inch. One manual hose reel is located at elevation 140 feet 0 inch.

2. Secondary

Three portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

- Three 4-inch drains at elevation 120 feet 0 inch
- Eleven 4-inch drains at elevation 140 feet 0 inch

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.7 FIRE AREA VII

9B.2.7.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area VII (figure 9B-3) contains train A essential spray pond components found in the outside areas. This fire area includes Analysis Area VIIA (Zone 84A) only (engineering drawing 13-A-ZYD-021).

Fire Area VII is the train A half of the spray pond pump house. The train B half of the pump house is adjacent to the south. The pump house is divided by a 3-hour rated barrier and bounded by the yard to the north, east, and west.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.7.2 Analysis Area VIIA

A. Location

Analysis Area VIIA consists of Fire Zone 84A.

Fire Zone 84A (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated exterior wall of heavy concrete construction common to the yard

South: 3-hour rated wall at column line S1, separating the train A half of the pump house from the train B half (Fire Area VIII, Zone 84B)

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the yard

C. Safe Shutdown Components and Cables

- Train A cables associated with the following systems:

  Miscellaneous HVAC

  Essential spray pond

- Train A essential spray pond pump and associated flow control valves

- Train A essential spray pond pump house exhaust fan

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room to achieve hot standby and cold shutdown. This area has been evaluated to be in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.7.3 Fire Area VII, Fire Zone 84A, Train A Spray Pond Pump House

A. Location

Fire Zone 84A (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction common to the yard

South: 3-hour rated wall at column line S1, separating the train A half of the pump house from the train B half (Fire Area VIII, Zone 84B)

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the yard

2. Zone Access

   One nonrated gate in the train A pump room nonrated north exterior wall

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Smoke detectors are provided in the pump house for early warning.

H. Fire Suppression

Manual hose streams from hydrants on the yard fire main.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.8 FIRE AREA VIII

9B.2.8.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area VIII (figure 9B-3) contains train B essential spray pond components found in the outside areas. This fire area includes Analysis Area VIIIA (Zone 84B) only (engineering drawing 13-A-ZYD-021).

Fire Area VIII is the train B half of the spray pond pump house. The train A half of the pump house is adjacent to the north. The pump house is divided by a 3-hour rated barrier and bounded by the yard to the south, east, and west.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.8.2 Analysis Area VIIIA

A. Location

Analysis Area VIIIA consists of Fire Zone 84B.

Fire Zone 84B (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall at column line S1, separating the train B half of the pump house from the train A half (Fire Area VII, Zone 84A)

South: Nonrated exterior wall of heavy concrete construction common to the yard

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the yard

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Miscellaneous HVAC

  Essential spray pond

- Train B essential spray pond pump and associated flow control valves

  Train B essential spray pond pump house exhaust fan

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train A systems available from the control room to achieve hot standby and cold shutdown. This area has been evaluated to be in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.8.3 Fire Area VIII, Fire Zone 84B, Train B Spray Pond Pump House

A. Location

Fire Zone 84B (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall at column line S1, separating the train B half of the pump house from the train A half (Fire Area VII, Zone 84A)

South: Nonrated exterior wall of heavy concrete construction common to the yard

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the yard

2. Zone Access

One nonrated gate in the train B pump room nonrated south exterior wall

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In-Situ Combustible Load Type

      Oil and grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

Smoke detectors are provided in the pump house for early warning.

H. Fire Suppression

Manual hose streams from hydrants on the yard fire main

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.9 FIRE AREA IX

9B.2.9.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area IX (figure 9B-3) contains the condensate storage tank pump house components found in the outside areas. This fire area includes Analysis Area IXA (Zone 83) only (engineering drawing 13-A-ZYD-021).

Fire Area IX is located in the yard north-northeast of the containment building (Fire Area XI), north of the main steam support structure (Fire Area XII), and south of the abandoned auxiliary boilers (Zone 85A).

B. Deviations From 10CFR50, Appendix R, Section III.G

1. A deviation is requested to Section III.G.2 to the extent that it requires redundant equipment to be separated by at least 20 feet without intervening combustibles, fire detection, and fire suppression.

<u>Discussion</u>

The train A and train B condensate transfer pumps are located in a common pump house. The pump house structure, including the dividing wall between the two pumps, is of nonrated, reinforced concrete construction. The dividing wall is a floor-to-ceiling solid wall extending from the structure west wall to a point just past the pump foundation such that the two pumps and associated drivers are physically separated. Electrical circuits for the two pumps are routed in conduit. The pumps are approximately 15 horizontal feet apart. The in situ combustible loading is predominantly the oil and grease associated with the pumps themselves. The combustible (fire) loading in Zone 83 is low. Fire detection is provided which will alert the fire department in event of fire.

The safety function performed by the condensate transfer system is to provide makeup for the essential chilled water surge tank, essential cooling water surge tank, and the diesel

generator cooling water systems. Loss of the pumps will not preclude the operator from achieving hot shutdown. Establishing an alternate makeup from the FP system for the cooling water systems, can be accomplished in a time frame which permits the operator to achieve cold shutdown within 72 hours.

Conclusion

One train of equipment required to achieve hot shutdown is currently free of fire damage. Loss of both trains of condensate transfer pumps will not preclude the operator from achieving hot shutdown. Establishment of an alternate makeup from the FP system for the cooling water systems can be accomplished in a time frame which permits the operator to achieve cold shutdown within 72 hours.

2. See subsection 9B.2.0 for generic deviations.

9B.2.9.2 Analysis Area IXA

A. Location

Analysis Area IXA consists of Fire Zone 83 only.

Fire Zone 83 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch. The condensate tunnel is located at elevation 87 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated exterior wall of heavy concrete construction common to the yard south of the abandoned auxiliary boilers (Zone 85A)

South: Nonrated exterior wall of heavy concrete construction common to the yard NNE of the containment building and north of the main steam support structure

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the condensate storage tank

NOTE

The two condensate transfer pumps are each located within the same pump house. However, a nonrated dividing wall of heavy concrete construction extends from the structure west wall to a point just past the pump foundation such that the two pumps, along with their drivers, are physically separated. The pumps are approximately 15 horizontal feet apart. The tunnel extends southward from the pump house along the 3-hour rated east wall of the main steam support structure and the nonrated east wall of the auxiliary building, fire Area XV, at column line AL.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Condensate storage and transfer

- Train B cables associated with the following systems:

  Condensate storage and transfer

  Main steam

- Train A condensate transfer pump and associated components

- Train B condensate transfer pump and associated components

- Condensate storage tank and associated level control components and instrumentation

D. Summary and Conclusions

Based on the previously described deviation, (item 9B.2.9.1.B.1). Loss of both trains of condensate transfer pumps will not preclude the operator from achieving hot shutdown. Establishment of an alternate makeup from the FP system for the cooling water systems can be accomplished in a time frame which permits the operator to achieve cold shutdown within 72 hours. One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided.

The redundant train A main steam system will remain available from the control room, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.9.3 Fire Area IX, Fire Zone 83, Condensate Storage Tank, Pump House and Tunnel

A. Location

Fire Zone 83 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet. The condensate tunnel is at elevation 87 feet.

B. Fire Protection Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction common to the yard south of the abandoned auxiliary boilers (Zone 85A)

South: Nonrated exterior wall of heavy concrete construction common to the yard NNE of the containment building, and north of the main steam support structure

East: Nonrated exterior wall of heavy concrete construction common to the yard

West: Nonrated exterior wall of heavy concrete construction common to the condensate storage tank. The west

nonrated wall of the condensate tunnel common to the east nonrated wall of the auxiliary building, Fire Area XV at elevation 88 feet.

2. Zone Access

   One nonrated gate in the nonrated north wall of the pump house, leading to the yard

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train A condensate storage tank to nonessential auxiliary feedwater pump valves

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Smoke detectors are located in the pump house.

H. Fire Suppression

Manual hose streams from hydrants on the fire yard main.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.10 FIRE AREA X

9B.2.10.1 Fire Area Description

A. Area Boundary Description

Fire Area X (figures 9B-1, 9B-3, 9B-4, and engineering drawing 13-P-00B-005) is the radwaste building and includes all components located within the building. This fire area includes Zones 58, 59, 60, 60D, 60E, 60F, 60G, 61A, 61B, 61C, 62, 62A, 62B, 62C, 62D, 62E, 62F, 62G, 62H, 62I, 62J, 62K, and 62L (engineering drawing 13-A-ZYD-026).

Fire Area X is bounded to the north, south, and west by nonrated exterior barriers. A portion of the north barrier is adjacent to the 3-hour rated south barrier of Fire Area XV (auxiliary building). A 6-by 10-foot pipe chase extends into the auxiliary building (Fire Area XV) at elevation 120 feet 0 inch and column lines R1 and RE. Inside the auxiliary building the chase is bounded by 3-hour rated barriers on all sides. The east barrier of Fire Area X is common to the 3-hour rated west barrier of Fire Areas I, II, and III (control building). The northeast corner common to the dead space between the auxiliary and control buildings (Fire Area I, Zone 86A) is nonrated and includes a pipe chase which descends to elevation 88 feet 0 inch; the walls about the pipe chase are nonrated. Both the basemat and roof are nonrated barriers.

No safe shutdown nor safety-related equipment is present within Fire Area X.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.1 for a deviation common to Fire Area I, subsection 9B.2.15 for a deviation common to Fire Area XV, and subsection 9B.2.0 for generic deviations.

9B.2.10.2 Fire Area X, Fire Zone 58, Waste Compactor, Truck Loading, and Storage Area

A. Location

Fire Zone 58 (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated walls of heavy concrete construction common to Zone 59

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: 2-hour rated wall common to Zones 60 and 60G at column line RB and at elevation 100 feet 0 inch

2-hour rated wall common to Zones 60 and 60E at column line RB and at elevation 110 feet 0 inch

West: Nonrated exterior wall of heavy concrete construction at column line RA

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open at elevation 120 feet 0 inch

2. Zone Access

- One nonrated door (pair) in the 2-hour rated east wall at elevation 100 feet 0 inch to Zone 60G
- One nonrated door in the nonrated south exterior wall at elevation 100 feet 0 inch
- One nonrated door in the nonrated west exterior wall at elevation 100 feet 0 inch
- One nonrated rollup door in the nonrated west exterior wall at elevation 100 feet 0 inch

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater ratings.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Area radiation monitors
   - 55-gallon drum uprighting device
   - 55-gallon drum grapple
   - 55-gallon drum pallet grapple
   - 80-cubic foot container grapple
   - Dry waste compactor
   - Cement feed tank
   - Chemical addition skid
   - Secondary flush skid
   - Additive feed skid
   - Cable trays and conduits

E. Radioactive Material

   Area containing radioactive material

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Charcoal

- Paper and fabric
- Plastic
- Rubber
- Resin
- Wood
- Cable insulation
- Hydraulic fluid
- Grease and oil

2. Transient Combustible Load Type

- Ordinary combustible
- Hydraulic fluid

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel. Partial coverage over the dry waste compactor area with a wet pipe sprinkler system.

2. Secondary

One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.10.3 Fire Area X, Fire Zone 59, Waste Solidification Area

A. Location

Fire Zone 59 (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line R1

South: Nonrated walls of heavy concrete construction common to Zone 58

East: 2-hour rated wall common to Zone 60E at column line RB.

West: Nonrated exterior wall of heavy concrete construction at column line RA

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open at elevation 120 feet 0 inch

2. Zone Access

- Two nonrated gates in the nonrated south walls at elevation 100 feet 0 inch to Zone 58

- Open ceiling to space also common to Zone 58

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Area radiation monitors
- Waste feed tank
- Radwaste feed pump skid
- 10-ton transfer cart
- Capping machine assembly
- Waste cement mixer
- Conduit

E. Radioactive Material

Area containing radioactive material consisting of spent filters, spent resins and evaporator concentrates, and evaporator concentrates and other stored radioactive materials.

F. Combustible Loading

1. In Situ Combustible Load Type

    - Oil and grease
    - Cable insulation
    - Clothing
    - Paper
    - Plastic
    - Rubber

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 58.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 58.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Six 4-inch drains

K. Emergency Communications

None

9B.2.10.4 Fire Area X, Fire Zone 60, LRS Waste Holdup Pump Room and Valve Gallery

A. Location

Fire Zone 60 (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 60G

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated wall of heavy concrete construction common to Zone 60G at column line RC

West: 2-hour rated wall common to Zone 58 at column line RB

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62F

2. Zone Access

- One nonrated gate in the nonrated north wall to Zone 60G

- Open nonrated gate in the nonrated east wall to Zone 60G

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - LRS waste holdup pumps
   - LRS recycle monitor tank pump
   - Conduit

E. Radioactive Material

   Radioactive material in process equipment.

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil and grease
      - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   Two manual hose reels are located in adjacent Zone 60G. One manual hose reel is located in adjacent Zone 58.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 60G. One portable CO_2 fire extinguisher is located in adjacent Zone 58.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Three 4-inch drains

K. Emergency Communications

None

9B.2.10.5 Fire Area X, Fire Zone 60D, Electrical Chase

A. Location

Fire Zone 60D (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to an HVAC and pipe chase at column line R3

South: 2-hour rated wall common to the southeast staircase

2-hour rated wall common to Zone 60G

East: 3-hour rated wall common to Fire Area I at column line JA

West: 2-hour rated wall common to Zone 60G at column line RD

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 2-hour rated barrier common to Zone 62D

2. Zone Access

One Class B door in the 2-hour rated west wall to Zone 60G

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Heat tracing panels
   - Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

   Ionization smoke detector system is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 60G.

2. Secondary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 60G.

I. Ventilation

   Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

   One 4-inch drain

K. Emergency Communications

   None

9B.2.10.6 Fire Area X, Fire Zone 60E, Controlled Machine Shop, and Tool and Storage Area

A. Location

Fire Zone 60E (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction, adjacent to the 3-hour rated wall of Fire Area XV, at column line R1

Nonrated exterior wall of heavy concrete construction at column line R1

Open to a pipe chase above elevation 114 feet 0 inch

South: Nonrated wall of heavy concrete construction common to Zone 60G

East: Nonrated wall of heavy concrete construction common to Zone 60G

West: 2-hour rated wall common to Zone 59 at column line RB

2-hour rated wall common to Zone 58 at column line RB and elevation 110 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to northwest HVAC chase and Zones 62E, 62F, and 62L

2. Zone Access

   - One nonrated door (pair) in the nonrated south wall to Zone 60G

   - One nonrated door (pair) in the nonrated east wall to Zone 60G

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Area radiation monitor

   - Tools and supplies

- 2-ton monorail
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Paper and fabric
   - Oil
   - Rubber
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher

2. Secondary

Two manual hose reels are located in adjacent Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

None

9B.2.10.7 Fire Area X, Fire Zone 60F, Spent Resin Transfer/ Dewatering Pump Room and Valve Gallery

A. Location

Fire Zone 60F (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated walls of heavy concrete construction common to Zone 62 at elevation 100 feet 0 inch

Nonrated wall of heavy concrete construction common to a pipe chase above elevation 110 feet 0 inch

South: Nonrated walls of heavy concrete construction common to Zone 60G

East: Nonrated wall of heavy concrete construction common to Zone 60G at elevation 100 feet 0 inch

Nonrated wall of heavy concrete construction common to a valve gallery above elevation 110 feet 0 inch

West: Nonrated wall of heavy concrete construction common to Zone 60G at elevation 100 feet 0 inch

Nonrated wall of heavy concrete construction common to a pipe chase above elevation 114 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62L and 62B

2. Zone Access

- One nonrated gate in the nonrated south wall to Zone 60G
- Open doorway in the nonrated south wall to an aisle

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Spent resin transfer/dewatering pump
   - Cable trays and conduits

E. Radioactive Material

   Radioactive material in process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Plastic

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 60G.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.10.8 Fire Area X, Fire Zone 60G, Corridor Area

A. Location

Fire Zone 60G (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	- 3-hour rated wall common to Fire Area XV at column line A10
	Central Corridor	- Nonrated walls of heavy concrete construction common to Zones 60E, 60F, and 62
South:	Central Corridor	- Nonrated walls of heavy concrete construction common to Zones 60, 61A, and 61C
	SW Corridor	- Nonrated exterior wall of heavy concrete construction at column line R4
	SE Corridor	- Nonrated exterior wall of heavy concrete construction at column line R4
East:	North Corridor	- Nonrated wall of heavy concrete construction common to Zones 60F and 62
	Central Corridor	- Nonrated wall of heavy concrete construction common to an HVAC and pipe chase at column line RD
	SW Corridor	- Nonrated wall of heavy concrete construction common to Zones 61B and 61C
	SE Corridor	- 2-hour rated walls common to Zone 60D

			2-hour rated wall common to the southeast stairwell
West:	North Corridor	-	Nonrated wall of heavy concrete construction common to Zone 60E
	Central Corridor	-	2-hour rated wall common to Zone 58 at column line RB
	SW Corridor	-	Nonrated wall of heavy concrete construction common to Zone 60
	SE Corridor	-	Nonrated walls of heavy concrete construction common to Zone 61A
Floor:	Nonrated basemat of heavy concrete construction		
Ceiling:	Nonrated barriers of heavy concrete construction common to Zones 62A, 62B, 62E, 62F, and 62L		

2. Zone Access

- One Class A door (pair) in the 3-hour rated north wall to Fire Area XV (Zone 42D)
- One nonrated door (pair) in the 2-hour rated central corridor west wall to Zone 58
- One nonrated door in the nonrated SW corridor south exterior wall

- One Class B door in the 2-hour rated SE corridor east wall to the southeast stairwell

3. Sealed Penetrations

   Seals equal or exceed fire barrier rating.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Concentrate monitor tank level panel
   - Motor control center
   - Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Plastic
- Rubber
- Cable insulation
- Fabric
- Oil/grease

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided at the motor control center for early warning.

H. Fire Suppression

1. Primary

Two manual hose reels

2. Secondary

Two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Seven 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.10.9 Fire Area X, Fire Zone 61A, LRS Concentrate Monitor Tank Rooms

A. Location

Fire Zone 61A (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 60G

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated walls of heavy concrete construction common to Zone 60G

West: Nonrated wall of heavy concrete construction common to Zones 61B and 61C

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62B and 62C

2. Zone Access

- One nonrated gate in the nonrated east wall to Zone 60G
- One nonrated gate in the nonrated west wall to Zone 61C

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- LRS concentrate monitor tanks
- Conduit

E. Radioactive Material

Radioactive material in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   Plastic

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   Two manual hose reels are located in adjacent Zone 60G

2. Secondary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.10.10 Fire Area X, Fire Zone 61B, LRS Concentrate Monitor Pumps Room

A. Location

Fire Zone 61B (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 61C

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated wall of heavy concrete construction common to Zone 61A

West: Nonrated wall of heavy concrete construction common to Zone 60G

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62C and 62E

2. Zone Access

One nonrated gate in the nonrated west wall to Zone 60G

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- LRS concentrate monitor pumps
- Conduit

E. Radioactive Material

Radioactive evaporator concentrate material in process

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 60G.

2. Secondary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.10.11 Fire Area X, Fire Zone 61C, Operating Aisle and Valve Gallery

A. Location

Fire Zone 61C (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 60G

South: Nonrated wall of heavy concrete construction common to Zone 61B

East: Nonrated wall of heavy concrete construction common to Zone 61A

West: Nonrated wall of heavy concrete construction, common to Zone 60G

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62B and 62E

2. Zone Access

One open doorway in the nonrated north wall to Zone 60G

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

Radioactive material in process.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   Two manual hose reels are located in adjacent Zone 60G.

2. Secondary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.10.12 Fire Area X, Fire Zone 62, High and Low Activity Spent Resin Tank Rooms

A. Location

Fire Zone 62 (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 100 feet 0 inch and 110 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction, adjacent to the 3-hour rated wall of Fire Area XV, at column line R1

South: Nonrated walls of heavy concrete construction common to Zone 60F and to Zone 60G at elevation 100 feet 0 inch

Nonrated wall of heavy concrete construction common to a valve gallery above elevation 110 feet 0 inch

East: Nonrated wall of heavy concrete construction common to an HVAC and pipe chase

West: Nonrated wall of heavy concrete construction, common to Zone 60G

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62A

2. Zone Access

Two nonrated gates in the nonrated south walls to an aisle

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- High activity spent resin tank
- Low activity spent resin tank
- Conduit

E. Radioactive Material

Radioactive spent resins in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

- Ordinary combustible
- Resin

3. Total Combustible (Fire) Loading

High

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in Zone 60G.

2. Secondary

Two portable CO_2 fire extinguishers are located in Zone 60G.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.10.13 Fire Area X, Fire Zone 62A, Boric Acid Condensate Ion Exchanger, LRS Mixed Bed Ion Exchangers, LRS Adsorption Bed, and Valve Gallery

A. Location

Fire Zone 62A (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction, adjacent to the 3-hour rated wall of Fire Area XV, at column line R1

South: Nonrated wall of heavy concrete construction common to Zone 62L

East: Nonrated wall of heavy concrete construction common to an HVAC and pipe chase at column line RD

West: Nonrated wall of heavy concrete construction common to Zone 62L

Floor: Nonrated barrier of heavy concrete construction common to Zones 60G and 62

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62H and 62I

2. Zone Access

- One nonrated gate in the nonrated south wall to Zone 62L

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Boric acid condensate ion exchanger
- LRS mixed bed ion exchangers
- LRS adsorption bed

- Conduit

E. Radioactive Material

Radioactive material in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

- Plastic
- Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Resin beads

3. Total Combustible (Fire) Loading

High

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 62L.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Six 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.10.14 Fire Area X, Fire Zone 62B, Radwaste Control Room

A. Location

Fire Zone 62B (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 62L

South: Nonrated wall of heavy concrete construction common to Zone 62C

East: Nonrated wall of heavy concrete construction common to Zone 62L

West: Nonrated wall of heavy concrete construction common to Zone 62E

Floor: Nonrated barrier of heavy concrete construction common to Zones 60G, 61A, and 61C

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62J

2. Zone Access

One nonrated door (pair) in the nonrated north wall to zone 62L

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Radwaste system control panels
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Paper and fabric
- Plastic
- Rubber
- Wood

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization Smoke Detector System(s) is provided for early warning.

H. Fire Suppression

1. Primary

Two manual hose reels are located in adjacent Zone 62L.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.10.15 Fire Area X, Fire Zone 62C, Acid, Caustic, and Antifoam Tanks and Pumps Room

A. Location

Fire Zone 62C (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 62B

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated wall of heavy concrete construction common to Zone 62L

West: Nonrated wall of heavy concrete construction common to Zone 62E

Floor: Nonrated barrier of heavy concrete construction common to Zones 61A and 61B

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62I

2. Zone Access

One nonrated gate in the nonrated east wall to Zone 62L

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Acid batch tank
- Acid tank
- Caustic batch tank
- Caustic tank

- Antifoam tank
- Antifoam pump
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Plastic
    - Oil and grease
2. Transient Combustible Load Type
    - Ordinary combustible
    - Oil and grease
3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

    One manual hose reel is located in adjacent Zone 62L.

2. Secondary

    One portable CO_2 fire extinguisher is located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.10.16 Fire Area X, Fire Zone 62D, Electrical Chase

A. Location

Fire Zone 62D (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to an HVAC and pipe chase at column line R3

South: 2-hour rated wall common to the southeast stairwell

2-hour rated wall common to Zone 62L.

East: 3-hour rated wall common to Fire Area II at column line JA

West: 2-hour rated wall common to Zone 62L at column line RD

Floor: 2-hour rated barrier common to Zone 60D

Ceiling: 2-hour rated barrier common to Zone 62G

2. Zone Access

One Class B door in the 2-hour rated west wall to Zone 62L

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater ratings.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Radios
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 62L.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.10.17 Fire Area X, Fire Zone 62E, Boric Acid Concentrator and Valve Gallery

A. Location

Fire Zone 62E (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 62L

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated wall of heavy concrete construction common to Zones 62B and 62C

West: Nonrated walls of heavy concrete construction common to Zone 62F

Floor: Nonrated barrier of heavy concrete construction common to Zones 60G, 61B, and 61C

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62I

2. Zone Access

- Two nonrated gates in the nonrated west walls to Zone 62F

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Boric acid concentrator
- Conduit

E. Radioactive Material

Radioactive material in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

- Oil and grease
- Plastic

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 62L.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Three 4-inch drains

K. Emergency Communications

None

9B.2.10.18 Fire Area X, Fire Zone 62F, Evaporator Equipment Rooms and Valve Gallery

A. Location

Fire Zone 62F (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevations 120 feet 0 inch and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to zone 62L at elevation 120 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 62I at column line R3 at elevation 140 feet 0 inch

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated walls of heavy concrete construction common to Zone 62E at elevation 120 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 62I at elevation 140 feet 0 inch

West: 2-hour rated wall common to the open space above Zones 58 and 59 at column line RB and at elevation 120 feet 0 inch

Nonrated exterior wall of heavy concrete construction at column line RB and at elevation 140 feet 0 inch

Floor: Nonrated barrier of heavy concrete construction common to Zones 60 and 60G

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 62I at elevation 120 feet

Nonrated roof of heavy concrete construction at elevations 120 feet and 140 feet

2. Zone Access

- One nonrated door in the nonrated north wall to Zone 62L

3. Sealed Penetrations

Seals equal or exceed fire barrier rating.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater ratings.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Evaporator concentrate pumps
   - Evaporator steam condensate pump
   - Evaporator main recycle pump
   - Evaporator surface condenser
   - Evaporator vapor body
   - 3-ton monorail
   - Cable trays and conduits
   - Evaporator distilation pumps, cooling and heating element

E. Radioactive Material

   Radioactive material in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Oil and grease
- Plastic

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 62L.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 62L.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.10.19 Fire Area X, Fire Zone 62G, Electrical Chase

A. Location

Fire Zone 62G (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to an HVAC and pipe chase at column line R3

South: 2-hour rated wall common to the southeast stairwell

2-hour rated wall common to Zone 62K

East: 3-hour rated wall common to Fire Area III at column line JA

West: 2-hour rated wall common to Zone 62J at column line RD

Floor: 2-hour rated barrier common to Zone 62D

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class B door in the 2-hour rated south wall to the southeast stairwell

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater ratings.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 62K

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 67K.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.10.20 Fire Area X, Fire Zone 62H, Waste Gas Compressor Rooms and Valve Galleries

A. Location

Fire Zone 62H (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 62I

South: Nonrated walls of heavy concrete construction common to Zone 62J

East: Nonrated wall of heavy concrete construction common to an HVAC and pipe chase

West: Nonrated walls of heavy concrete construction common to Zone 62I

Floor: Nonrated barrier of heavy concrete construction common to Zones 62A and 62L

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

   - One nonrated gate in the nonrated north wall to Zone 62I
   - One nonrated gate in the nonrated south wall to Zone 62J
   - One nonrated gate in the nonrated west wall to Zone 62I

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Waste gas compressors
   - Conduit

E. Radioactive Material

   Radioactive gases in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 62I.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 62I.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

None

9B.2.10.21 Fire Area X, Fire Zone 62I, Access Corridors and Ion Exchanger Hatch Laydown Area

A. Location

Fire Zone 62I (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	- Nonrated wall of heavy concrete construction, adjacent to the 3-hour rated wall of Fire Area XV, at column line R1 Nonrated exterior wall of heavy concrete construction at column line Rl
	South Corridor	- Nonrated wall of heavy concrete construction common to Zone 62J

South:	North Corridor	- Nonrated wall of heavy concrete construction common to Zone 62H
	South Corridor	- Nonrated exterior wall of heavy concrete construction at column line R4
	Central Corridor	- Nonrated wall of heavy concrete construction common to Zone 62F
East:	North Corridor	- Nonrated wall of heavy concrete construction common to an HVAC and pipe chase
	South Corridor	- Nonrated wall of heavy concrete construction common to Zone 62K
	Central Corridor	- Nonrated walls of heavy concrete construction common to Zones 62H and 62J
West:	Nonrated wall of heavy concrete construction common to Zone 62F	
	Nonrated exterior wall of heavy concrete construction at column line RB	
	Nonrated walls of heavy concrete construction common to the northwest HVAC chase	

Floor: Nonrated barrier of heavy concrete construction common to Zones 62A, 62C, 62E, 62F, and 62L

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class A door (pair) in the 3-hour rated north wall to Fire Area XV (Aux. Building)
- One open doorway in the nonrated south corridor east wall to Zone 62K

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Waste gas decay tank exhaust monitor
- Load center

- H_2 and O_2 analyzer
- Waste gas area combined exhaust monitor
- 10-ton monorail
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Cable insulation
    - Hydrogen
    - Plastic
    - Oxygen
    - Paper
    - Rubber
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization smoke detector system(s) is provided at the load center and sorting area for early warning.

H. Fire Suppression

1. Primary

One manual hose reel

2. Secondary

One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Eight 4-inch drains

K. Emergency Communication

Sound powered phone jack(s) is provided.

9B.2.10.22 Fire Area X, Fire Zone 62J, Waste Gas Decay and Surge Tank Rooms and Valve Gallery

A. Location

Fire Zone 62J (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated walls of heavy concrete construction common to Zone 62H

South: Nonrated walls of heavy concrete construction common to Zones 62I and 62K

East: Nonrated wall of heavy concrete construction common to an HVAC and pipe chase

2-hour rated wall common to Zone 62G

West: Nonrated walls of heavy concrete construction common to Zone 62I

Floor: Nonrated barrier of heavy concrete construction common to Zones 62B and 62L

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One nonrated gate in the nonrated north wall to Zone 62H
- Two nonrated gates in the nonrated west walls to Zone 62I
- One nonrated gate in the nonrated south wall to Zone 62I

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Waste gas surge tank
   - Waste gas decay tanks
   - Conduit

E. Radioactive Material

   Radioactive gases in process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Hydrogen
      - Oil/grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 62I.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent 62I.

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

None

9B.2.10.23 Fire Area X, Fire Zone 62K, Hatch Laydown Area

A. Location

Fire Zone 62K (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 62J

2-hour rated wall common to Zone 62G

South: Nonrated exterior wall of heavy concrete construction at column line R4

East: 2-hour rated wall common to the southeast stairwell

West: Nonrated wall of heavy concrete construction common to Zones 62I and 62J

Floor: Nonrated barrier of heavy concrete construction common to Zone 62L

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class B door in the 2-hour rated east wall to the southeast stairwell
- One open doorway in the nonrated west wall to Zone 62I
- One nonrated watertight steel equipment hatch in the nonrated floor to Zone 62L

3. Sealed Penetrations

   Seals equal or exceed fire barrier rating.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater ratings.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Motor control center
   - Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible

- Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided at the motor control center for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel nozzle

2. Secondary

   One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.10.24 Fire Area X, Fire Zone 62L, Corridor Area

A. Location

Fire Zone 62L (engineering drawing 13-A-ZYD-026) is located in the radwaste building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XV at column line A10

Nonrated wall of heavy concrete construction common to Zone 62A

Nonrated exterior wall of heavy concrete construction at column line R1

Nonrated walls of heavy concrete construction common to the northwest HVAC chase

South: Nonrated wall of heavy concrete construction common to Zones 62B, 62E, and 62F

Nonrated exterior wall of heavy concrete construction at column line R4

East: Nonrated wall of heavy concrete construction common to Zone 62A

Nonrated wall of heavy concrete construction common to HVAC and pipe chases

2-hour rated walls common to Zone 62D

2-hour rated wall common to the southeast stairwell

West: Nonrated wall of heavy concrete construction common to the open space above Zones 58 and 59

Nonrated wall of heavy concrete construction common to Zones 62B and 62C

Floor: Nonrated barrier of heavy concrete construction common to Zones 60E, 60F, and 60G

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 62H, 62I, 62J, and 62K

2. Zone Access

- One nonrated door (pair) and transom in the 3-hour rated north wall to Fire Area XV (Aux. Building)
- One Class B door in the 2-hour rated east wall to the southeast stairwell

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit
   - 5-ton monorail
   - Radwaste control room normal air handling unit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Plastic

   2. Transient Combustible Load Type

      - Ordinary combustible

- Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   Two manual hose reels. Sprinkler coverage at the access door to Fire Area XV, Zone 48

2. Secondary

   Two portable CO_2 fire extinguishers

I. Ventilation

   Manually controlled smoke exhaust venting to the adjacent zone/outside using portable smoke removal equipment.

J. Drainage

   Six 4-inch drains

K. Emergency Communications

   Sound powered phone jack(s) is provided.

9B.2.11 FIRE AREA XI

9B.2.11.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XI (figures 9B-1, 9B-2, 9B-3, 9B-4, and engineering drawing 13-P-00B-005) is the containment building and includes all components located within the building. This fire area includes Analysis Area XIA (Fire Zones 66A, 67A, and 71A), XIB (Zones 66B, 67B, and 71B), XIC (Zone 63A), XID (Zone 63B), XIE (Zone 64), XIF (Zone 65), and XIG (Zone 70) (engineering drawing 13-A-ZYD-022).

Fire Area XI is cylindrical in shape, bounded to the south by a 3-hour rated barrier common to Fire Areas XV, XVI, and XVII, to the east by a 3-hour rated barrier to a seismic gap common to the unrated barrier of Fire Area XII, and to the north and west by a nonrated exterior barrier. The basemat and roof of the containment building are nonrated.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires separation of cables and equipment by a horizontal distance of more than 20 feet without intervening combustibles or fire hazards.

Discussion

A description of the existing condition is provided in the appendix 9A response to Question 9A.130.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design would not significantly enhance the protection currently provided.

2. See the response to Question 9A.130 in Appendix 9A for a deviation from 10CFR50, Appendix R, Section III.G.2.f, regarding separation of cables and equipment and associated non-safety related circuits of redundant trains by a non-combustible radiant energy heat shield.

3. See subsection 9B.2.0 for generic deviations.

9B.2.11.2 Analysis Area XIA

A. Location

Analysis Area XIA consists of Fire Zones 66A, 67A, and 71A.

Fire Zone 66A and 67A (engineering drawing 13-A-ZYD-022) are located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

Fire Zone 71A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 140 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of heavy concrete construction common to Zone 63B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 64 at elevation 80 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch and 120 feet 0 inch

Nonrated exterior wall of heavy concrete construction

Nonrated wall of steel construction common to Zone 67B (elevation 140 feet 0 inch)

South: 3-hour rated wall common to Fire Area XV at elevations 80 feet 0 inch and 140 feet 0 inch

3-hour rated barrier common to Fire Area XVI at elevations 100 feet 0 inch and 120 feet 0 inch

3-hour rated barrier common to the south access shaft

Nonrated wall of heavy concrete construction common to Zone 63A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 64 at elevation 80 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 65 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 63A

East: Open to Zone 66B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71B at elevation 140 feet 0 inch

Open to Zone 67B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

West: Nonrated exterior wall of heavy concrete construction

Floor: Nonrated basemat of heavy concrete construction

Nonrated barrier of steel construction common to Zone 67B

Ceiling: Nonrated barrier of steel construction common to the containment atmosphere

Open to the containment atmosphere

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

  Engineered safety feature actuation

- Train B cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

  Main steam

  Safety injection and shutdown cooling

  Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Train A nuclear sampling isolation valves
- Train A shutdown cooling high/low pressure interface valves
- Train A safety injection tank 1A vent and isolation valves
- Train B safety injection tank 1A vent valve
- Train A safety injection tank 1B vent and isolation valves
- Train A safety injection tank 2A vent valve
- Train A safety injection tank 2B vent valve
- Train B safety injection tank 2B vent and isolation valves
- Train B steam generator 1 and 2 level transmitters
- Train A steam generator 1 blowdown sample isolation valves
- Train B steam generator 2 blowdown sample isolation valves
- Train A pressurizer pressure and level instrumentation

- Train B pressurizer pressure and level instrumentation
- Train A and train B steam generator 2 pressure transmitters
- Nontrain related reactor coolant pump bleedoff isolation valves
- Nontrain related pressurizer spray valves
- Nontrain related regenerative heat exchanger
- Nontrain related seal injection control valves
- Nontrain related reactor coolant pump seal bleedoff control valves
- Nontrain related nuclear cooling instruments and valves
- Train A reactor coolant pump bleed off valves
- Non train related charging line valves

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on spatial separation and the radiant energy shield provided on the raceway for the train A pressurizer auxiliary spray valve. The redundant train A system will remain available from the control room, in conjunction with operator action, inside and outside of this analysis area to prevent or overcome the

consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

9B.2.11.3 Analysis Area XIB

A. Location

Analysis Area XIB consists of Fire Zones 66B, 67B, and 71B.

Fire Zone 66B and 67B (engineering drawing 13-A-ZYD-022) are located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

Fire Zone 71B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 140 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated walls of heavy concrete construction common to Zone 63B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 120 feet 0 inch and 140 feet 0 inch

Nonrated exterior wall of heavy concrete construction

Nonrated wall of heavy concrete construction common to Zone 63B

South: 3-hour rated wall common to Fire Area XV at elevations 80 feet 0 inch and 140 feet 0 inch

3-hour rated wall common to Fire Area XVII at elevations 100 feet 0 inch and 120 feet 0 inch

3-hour rated barrier common to the south access shaft

Nonrated walls of heavy concrete construction common to Zone 63A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated wall of steel construction common to Zone 66A (elevation 140 feet 0 inch)

East: 3-hour rated wall to a seismic gap common to the unrated barrier of Fire Area XII

West: Open to Zones 66A and 67A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71A at elevation 140 feet 0 inch

Nonrated wall of steel construction common to Zone 66A

Floor: Nonrated basemat of heavy concrete construction

Nonrated barrier of steel construction common to Zone 66A

Ceiling: Open to the containment atmosphere (above Fire Zones 66B and 67B)

Nonrated barrier of steel construction common to the containment atmosphere (above Fire Zone 71B)

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Chemical and volume control (Unit 1 only)

  Reactor coolant

  Main steam

  Safety injection and shutdown cooling

  Engineered safety feature actuation

- Train B cables associated with the following systems:

  Chemical and volume control

  Nuclear cooling water

  Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Train B and nontrain related nuclear cooling water flow control valves
- Train A steam generator 1 blowdown isolation valve
- Train B steam generator 2 blowdown isolation valve
- Train A steam generator level transmitter
- Train B steam generator level transmitter
- Train A steam generator 1 pressure transmitter
- Train B steam generator 1 pressure transmitter
- Train A safety injection tank 2A vent valve
- Train B safety injection tank 1A vent valve
- Train A safety injection tank 1B vent and isolation valves
- Train B safety injection tank 1B vent valve

- Train B safety injection tank 2B vent and isolation valves
- Train B safety injection tank 2A vent and isolation valves
- Train B shutdown cooling high/low pressure interface valves

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area, in conjunction with operator action, both inside and outside this analysis area, to establish equipment lineups, has been demonstrated to remain available due to spatial separation provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.11.4 Analysis Area XIC

A. Location

Analysis Area XIC consists of Fire Zone 63A only.

Fire Zone 63A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of heavy concrete construction common to Zones 67A and 67B

Nonrated wall of heavy concrete construction common to Zone 71A at elevation 140 feet 0 inch

South: Nonrated wall of heavy concrete construction common to:

- The reactor vessel shield at elevations 80 feet 0 inch and 100 feet 0 inch
- Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 63B at elevation 80 feet 0 inch

East: Nonrated wall of heavy concrete construction common to Zone 67B

West: Nonrated wall of heavy concrete construction common to:

- Zones 64 and 67A at elevation 80 feet 0 inch
- Zones 65 and 67A at elevations 100 feet 0 inch and 120 feet 0 inch
- Zone 67A at elevation 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere at elevation 155 feet 0 inch

Nonrated barrier of heavy concrete construction common to Zone 70 at elevation 100 feet 0 inch

C. Safe Shutdown Related Components and Cables

- Train A, train B, and nontrain related cables associated with the following system:

  Reactor coolant

- Train A safety injection and shutdown cooling
- Train A reactor coolant head vent valve
- Train A reactor coolant loop 1 temperature instrumentation
- Train B reactor coolant loop 1 temperature instrumentation
- Reactor coolant pump seal coolers and associated components
- Reactor coolant pump 1A
- Reactor coolant pump 1B

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area, in conjunction with operator action outside of this analysis area to prevent or overcome the consequences of spurious operation of component, or to establish equipment lineups, has been demonstrated to remain available

due to spatial separation provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.11.5 Analysis Area XID

A. Location

Analysis Area XID consists of Fire Zone 63B only.

Fire Zone 63B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of heavy concrete construction common to:

- The reactor vessel shield at elevations 80 feet 0 inch and 100 feet 0 inch
- Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 63A at elevation 80 feet 0 inch

South: Nonrated wall of heavy concrete construction common to Zones 66A and 66B
Nonrated wall of heavy concrete construction common to Zone 71B at elevation 140 feet 0 inch

East: Nonrated wall of heavy concrete construction common to Zone 66B

West: Nonrated wall of heavy concrete construction common to:

- Zones 64 and 66A at elevation 80 feet 0 inch
- Zone 66A at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere at elevation 155 feet 0 inch

Nonrated barrier of heavy concrete construction common to Zone 70 at elevation 100 feet 0 inch

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Train B cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Nontrain related cables associated with the following system:

  Reactor coolant

- Train A and train B letdown isolation valves
- Train A and train B reactor coolant loop 2 temperature instruments
- Reactor coolant pump seal coolers and associated components
- Reactor coolant pump 2A
- Reactor coolant pump 2B

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area, in conjunction with operator action outside of this analysis area to prevent or overcome the consequences of spurious operation of component, or to establish equipment lineups, has been demonstrated to remain available due to spatial separation provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.11.6 Analysis Area XIE

A. Location

Analysis Area XIE consists of Fire Zone 64.

Fire Zone 64 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 80 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of heavy concrete construction common to Zones 63A and 67A

South: Nonrated wall of heavy concrete construction common to Zones 63B and 66A

East: Nonrated wall of heavy concrete construction common to Zones 63A and 63B

West: Nonrated wall of heavy concrete construction common to Zones 66A and 67A

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 65, 67A, and 70

C. Safe Shutdown Related Components and Cables

None

D. Summary and Conclusion

Normal shutdown is credited for a fire in this area. The safe shutdown equipment credited for a fire in this area is expected to remain available in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.11.7 Analysis Area XIF

A. Location

Analysis Area XIF consists of Fire Zone 65.

Fire Zone 65 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 100 feet 0 inch and 120 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of heavy concrete construction common to Zone 67A

South: Nonrated wall of heavy concrete construction common to Zone 67A

Nonrated walls of heavy concrete construction common to Zone 70

East: Nonrated wall of heavy concrete construction common to Zone 63A

West: Nonrated wall of heavy concrete construction common to Zone 67A

Floor: Nonrated barrier of heavy concrete construction common to Zones 63A, 64, and 67A

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 67A at elevation 161 feet 6 inches

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Pressurizer
- Train A and train B pressurizer auxiliary spray valves
- Train A and train B pressurizer vent valves
- Train A and train B reactor coolant system vent valves
- Nontrain related pressurizer relief valves
- Train A and train B 1E pressurizer backup and proportional heaters
- Nontrain related pressurizer backup and proportional heaters

D. Summary and Conclusions

The following systems are affected for a fire in this analysis area:

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area, in conjunction with operator action, outside this analysis area, to establish equipment lineups, has been demonstrated to remain available due to spatial separation and the

radiant energy shield provided on the Train A pressurizer auxiliary spray valve and raceway. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.11.8 Analysis Area XIG

A. Location

Analysis Area XIG consists of Fire Zone 70.

Fire Zone 70 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Analysis Area Boundaries

North: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 63A, 65, 67A, and 67B at elevation 100 feet 0 inch and 120 feet 0 inch
- Zone 63A at elevation 140 feet 0 inch

South: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 63B, 66A, and 66B at elevations 100 feet 0 inch and 120 feet 0 inch
- Zone 63B at elevation 140 feet 0 inch

East: Nonrated wall of stainless steel and heavy concrete construction common to Zones 66B

and 67B at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

West: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 65 and 67A at elevation 100 feet 0 inch
- Zone 67A at elevation 120 feet 0 inch
- Zones 66A and 67A at elevation 140 feet 0 inch

Floor: Nonrated barrier of stainless steel and heavy concrete construction common to Zones 63A, 63B, 64, 66A, and 66B

Ceiling: Open to the containment atmosphere

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following system:

  Reactor coolant

- Train A and train B reactor vessel head vent valves

D. Summary and Conclusions

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area has been demonstrated to remain free of fire damage due to spatial separation provided. Based on area

construction this analysis area is in compliance with the criteria of 10CFR50, Appendix R, Section III.G.

9B.2.11.9 Fire Area XI, Fire Zone 63A, No. 1 Reactor Coolant Pumps and Steam Generator Area

A. Location

Fire Zone 63A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 67A and 67B

Nonrated wall of heavy concrete construction common to Zone 71A at elevation 140 feet 0 inch

South: Nonrated wall of heavy concrete construction common to:

- The reactor vessel shield at elevations 80 feet 0 inch and 100 feet 0 inch
- Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 63B at elevation 80 feet 0 inch

East: Nonrated wall of heavy concrete construction common to Zone 67B

West: Nonrated wall of heavy concrete construction common to:

- Zones 64 and 67A at elevation 80 feet 0 inch
- Zones 65 and 67A at elevations 100 feet 0 inch and 120 feet 0 inch
- Zone 67A at elevation 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere at elevation 155 feet 0 inch

Nonrated barrier of heavy concrete construction common to Zone 70 at elevation 100 feet 0 inch

2. Zone Access

- Open to the containment atmosphere at elevation 155 feet 0 inch
- Open to Zone 63B at elevation 80 feet 0 inch

- One nonrated gate in the nonrated west wall to Zone 67A at elevation 80 feet 0 inch
- One nonrated gate in the nonrated east wall to Zone 67B at elevation 80 feet 0 inch and elevation 100 feet 0 inch
- Open doorway in the nonrated west wall to Zone 64 at elevation 80 feet 0 inch

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Cable trays and conduit
- Cavity cooling fans
- Lube oil collection tank
- Jib cranes and supports

E. Radioactive Material

Radioactive material in process piping and equipment.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Oil and grease
   - Hydraulic fluid

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

NOTE

Refer to the appendix 9A response to Question 9A.126 for a description of the reactor coolant pump lube oil collection system and compliance with 10CFR50, Appendix R, Section III.0.

G. Fire Detection

Line-type thermal detectors installed in the cable trays and ionization and photoelectric smoke detectors are provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 67A at elevation 80 feet 0 inch. One manual hose reel is located in adjacent Zone 67B at elevation 80 feet 0 inch.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 67A at elevation 80 feet 0 inch. One portable CO_2 fire extinguisher is located in adjacent Zone 67B at elevation 80 feet 0 inch.

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

- Two 4-inch drains at elevation 87 feet 0 inch
- One 4-inch drain at elevation 80 feet 0 inch

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.11.10 Fire Area XI, Fire Zone 63B, No. 2 Reactor Coolant Pumps and Steam Generator Area

A. Location

Fire Zone 63B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to:

- The reactor vessel shield at elevations 80 feet 0 inch and 100 feet 0 inch
- Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 63A at elevation 80 feet 0 inch

South: Nonrated wall of heavy concrete construction common to Zones 66A and 66B

Nonrated wall of heavy concrete construction common to Zone 71B at elevation 140 feet 0 inch

East: Nonrated wall of heavy concrete construction common to Zone 66B

West: Nonrated wall of heavy concrete construction common to:

- Zones 64 and 66A at elevation 80 feet 0 inch
- Zone 66A at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere at elevation 155 feet 0 inch

Nonrated barrier of heavy concrete construction common to Zone 70 at elevation 100 feet 0 inch

2. Zone Access

- Open to the containment atmosphere at elevation 155 feet 0 inch
- Open to Zone 63A at elevation 80 feet 0 inch
- One nonrated gate in the nonrated west wall to Zone 66A at elevation 80 feet 0 inch
- One nonrated gate in the nonrated east wall to Zone 66B at elevation 80 feet 0 inch

- One nonrated gate in the nonrated east wall to Zone 66B at elevation 100 feet 0 inch

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

   - Train A conduit[a]
   - Train B conduit[a]

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit
   - Cavity cooling fans
   - Lube oil collection tank
   - Jib cranes and supports

E. Radioactive Material

   Radioactive material in process piping and equipment

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Hydraulic fluid
- Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

NOTE

Refer to the appendix 9A response to Question 9A.126 for a description of the reactor coolant lube oil collection system and compliance with 10CFR50, Appendix R, Section III.0.

G. Fire Detection

Ionization and photoelectric smoke detectors are provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 66A at elevation 80 feet 0 inch. One manual hose reel is located on each level in

adjacent Zone 66B at elevations 80 feet 0 inch and 100 feet 0 inch.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 66A at elevation 80 feet 0 inch. One portable CO_2 fire extinguisher is located on each level in adjacent Zone 66B at elevations 80 feet 0 inch and 100 feet 0 inch.

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

- Two 4-inch drains at elevation 88 feet 0 inch
- One 4-inch drain at elevation 80 feet 0 inch

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.11.11 Fire Area XI, Fire Zone 64, Reactor Drain Tank Room

A. Location

Fire Zone 64 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 80 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 63A and 67A

South: Nonrated wall of heavy concrete construction common to Zones 63B and 66A

East: Nonrated wall of heavy concrete construction common to Zones 63A and 63B

West: Nonrated wall of heavy concrete construction common to Zones 66A and 67A

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 65, 67A, and 70

2. Zone Access

Open doorway in the nonrated north wall to Zone 63A

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Reactor drain tank
   - Conduit

E. Radioactive Material

   Radioactive material in process piping and equipment.

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

   2. Transient Combustible Load Type

      Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 67A.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 67A.

I. Ventilation

   Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

   One 4-inch drain

K. Emergency Communications

   None

9B.2.11.12 Fire Area XI, Fire Zone 65, Pressurizer Room

A. Location

Fire Zone 65 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 100 feet 0 inch and 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 67A

South: Nonrated wall of heavy concrete construction common to Zone 67A

Nonrated walls of heavy concrete construction common to Zone 70

East: Nonrated wall of heavy concrete construction common to Zone 63A

West: Nonrated wall of heavy concrete construction common to Zone 67A

Floor: Nonrated barrier of heavy concrete construction common to Zones 63A, 64, and 67A

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 67A at elevation 161 feet 6 inches

2. Zone Access

- One nonrated door in the nonrated south wall to Zone 67A at elevation 100 feet 0 inch
- One open doorway in the nonrated south wall to Zone 67A at elevation 120 feet 0 inch
- Stairs leading to Zone 67A at elevation 146 feet 0 inch

3. Sealed Penetration

   None

4. Fire Dampers

   None

5. Protected Raceways

   Train A pressurizer auxiliary spray valve and raceway is protected by a radiant energy shield consisting of metallic reflectorized insulation and 1/2-inch-thick Thermo-Lag insulation.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Conduit
   - Pressurizer area normal recirculation fans

E. Radioactive Material

Radioactive material in process piping and equipment.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Grease
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Line-type thermal detectors are provided for early warning.

H. Fire Suppression

1. Primary

   Two portable CO_2 fire extinguishers are located in adjacent Zone 67A at elevation 100 feet 0 inch. One portable CO_2 fire extinguisher is located in adjacent Zone 67A at elevation 120 feet 0 inch.

2. Secondary

One portable CO_2 fire extinguisher is located in Zone 7B at elevation 100 feet 0 inch.

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

None

K. Emergency Communications

None

9B.2.11.13 Fire Area XI, Fire Zone 66A, Southwest Perimeter of the Containment Building

A. Location

Fire Zone 66A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 63B at

elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 64 at elevation 80 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch and 120 feet 0 inch

Open to Zone 67A at elevations 80 feet 0 inch and 140 feet 0 inch

South: 3-hour rated wall common to Fire Area XV at elevations 80 feet 0 inch and 140 feet 0 inch

3-hour rated barrier common to Fire Area XVI at elevations 100 feet 0 inch and 120 feet 0 inch

3-hour rated barrier common to the south access shaft

East: Open to Zone 66B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71B at elevation 140 feet 0 inch

West: Nonrated exterior wall of heavy concrete construction

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere

2. Zone Access

   - Open to the containment atmosphere
   - Open to Zone 66B
   - Open to Zone 67A at elevations 80 feet 0 inch and 140 feet 0 inch
   - One nonrated gate in the nonrated east wall to Zone 63B at elevation 80 feet 0 inch
   - Nonrated personnel access hatch at elevation 140 feet 0 inch, in the 3-hour rated south wall to Fire Area XV

3. Sealed Penetrations

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

- Train B containment refueling purge supply isolation damper
- Train B containment power ascension purge exhaust isolation damper
- Train A containment isolation valve
- Train A containment hydrogen control damper
- Train A containment sump isolation valve

D. Nonsafety-Related Equipment and Components

- Radwaste sump pump
- Regenerative heat exchanger
- Normal air cooling unit
- Normal air cooling unit duct heater
- Fuel carriage winch
- Hydraulic power rack
- Transfer system control console
- Cable trays and conduit

E. Radioactive Material

Radioactive material in process piping and equipment.

F. Combustible Loading

1. In Situ Combustible Load Type

    - Thermo-Lag 330-1

- Cable insulation
- Oil and grease
- Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization and line-type thermal detection systems covering the cable trays are provided for early warning.

H. Fire Suppression

1. Primary

   Four manual hose reels one each at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

2. Secondary

   Six portable CO_2 fire extinguishers, two each at elevations 80 feet 0 inch and 100 feet 0 inch, one each at elevations 120 feet 0 inch and 140 feet 0 inch

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operations. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

- Three 4-inch drains at elevation 80 feet 0 inch
- Three 4-inch drains at elevation 100 feet 0 inch

K. Emergency Communications

Sound powered phone pack(s) is provided.

9B.2.11.14 Fire Area XI, Fire Zone 66B, Southeast Perimeter of the Containment Building

A. Location

Fire Zone 66B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated walls of heavy concrete construction common to Zone 63B at elevations 80 feet 0 inch, 100 feet

0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 120 feet 0 inch and 140 feet 0 inch

Open to Zone 67B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

South: 3-hour rated wall common to Fire Area XV at elevations 80 feet 0 inch and 140 feet 0 inch

3-hour rated wall common to Fire Area XVII at elevations 100 feet 0 inch and 120 feet 0 inch

3-hour rated barrier common to the south access shaft

East: 3-hour rated wall to a seismic gap common to the unrated barrier of Fire Area XII

West: Open to Zone 66A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71B at elevation 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere

2. Zone Access

- Open to the containment atmosphere
- Open to Zones 66A and 67B
- One nonrated gate in the nonrated west wall to Zone 63B at elevation 80 feet 0 inch
- One nonrated gate in the nonrated west wall to Zone 63B at elevation 100 feet 0 inch

3. Sealed Penetrations

Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members None

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B containment hydrogen control damper
- Train B containment sump isolation valve

- Train B containment isolation valve
- Train A containment refueling purge exhaust damper
- Train A containment building power ascension purge exhaust isolation damper
- Train A containment radwaste drain system isolation valve

D. Nonsafety-Related Equipment and Components

- Radwaste sump pump
- Wet layup pump
- Normal air cooling unit
- Normal air cooling unit duct heater
- Cable trays and conduit

E. Radioactive Material

Radioactive material in process piping and equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Oil and grease
   - Hydraulic fluid
   - Plastic
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization and line-type thermal detection systems covering the cable trays are provided for early warning.

H. Fire Suppression

1. Primary

   Three manual hose reels, one each at elevations 80 feet 0 inch, 100 feet 0 inch, and 120 feet 0 inch

2. Secondary

   Four portable CO_2 fire extinguishers, one each at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned

on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

- Three 4-inch drains at elevation 80 feet 0 inch
- Two 4-inch drains at elevation 100 feet 0 inch
- Two 4-inch drains at elevation 120 feet 0 inch
- Three 4-inch drains at elevation 140 feet 0 inch

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.11.15 Fire Area XI, Fire Zone 67A, Northwest Perimeter of the Containment Building

A. Location

Fire Zone 67A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction

South: Nonrated wall of heavy concrete construction common to Zone 63A at elevations 80 feet 0 inch, 100 feet

0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 64 at elevation 80 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 65 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 66A at elevations 80 feet 0 inch and 140 feet 0 inch

East: Open to Zone 67B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71A at elevation 140 feet 0 inch

West: Nonrated exterior wall of heavy concrete construction

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere

2. Zone Access

   - Open to the containment atmosphere
   - Open to Zone 66A at elevations 80 feet 0 inch and 140 feet 0 inch
   - Open to Zone 67B
   - One nonrated gate in the nonrated east wall to Zone 63A at elevation 80 feet 0 inch
   - Nonrated equipment hatch in the nonrated north exterior wall

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   Train A pressurizer auxiliary spray valve raceway is protected by a radiant energy shield consisting of 1/2 inch thick Thermo-Lag insulation.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Normal air cooling unit
- Normal air cooling unit duct heater
- Cable trays and conduit

E. Radioactive Material

Radioactive material in process piping and equipment

F. Combustible Loading

1. In Situ Combustible Load Type
   - Cable insulation
   - Oil and grease
   - Plastic
   - Thermo-Lag 330-1
2. Transient Combustible Load Type
   - Ordinary combustible
   - Cable insulation
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Line-type thermal detection system covering the cable trays are provided for early warning.

H. Fire Suppression

1. Primary

Three manual hose reels, one each at elevations 80 feet 0 inch, 100 feet 0 inch, and 120 feet 0 inch

2. Secondary

Six portable CO_2 fire extinguishers, two each at elevations 80 feet 0 inch and 100 feet 0 inch, one each at elevations 120 feet 0 inch and 140 feet 0 inch

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.11.16 <u>Fire Area XI, Fire Zone 67B, Northeast Perimeter of the Containment Building</u>

A. Location

Fire Zone 67B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations

80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction

South: Nonrated walls of heavy concrete construction common to Zone 63A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of heavy concrete construction common to Zone 70 at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to Zone 66B at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

East: 3-hour rated wall to a seismic gap common to the unrated barrier of Fire Area XII

West: Open to Zone 67A at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Nonrated walls of steel construction common to Zone 71A at elevation 140 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the containment atmosphere

2. Zone Access

   - Open to the containment atmosphere
   - Open to Zones 66B and 67A
   - One nonrated gate in the nonrated west wall to Zone 63A at elevation 80 feet 0 inch
   - One nonrated gate in the nonrated west wall to Zone 63A at elevation 100 feet 0 inch
   - One nonrated emergency exit air lock in the nonrated north exterior wall at elevation 100 feet 0 inch

3. Sealed Penetrations

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Wet layup pump
- Normal air cooling unit
- Normal air cooling unit duct heater
- Closure head lift rig assembly
- Cable trays and conduit

E. Radioactive Material

Radioactive material in process piping and equipment

F. Combustible Loading

1. In Situ Combustible Load Type
    - Cable insulation
    - Oil and grease
    - Plastic
    - Rubber
    - Thermo-Lag 330-1
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Line-type thermal detection system covering cable trays is provided for early warning.

H. Fire Suppression

1. Primary

Four manual hose reels, one each at elevations 80 feet 0 inch, 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

2. Secondary

Three portable CO_2 fire extinguishers, one each at elevations 80 feet 0 inch, 100 feet 0 inch, and 140 feet 0 inch

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

Ten 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.11.17 Fire Area XI, Fire Zone 70, Refueling Pool and Canal Area

A. Location

Fire Zone 70 (engineering drawing 13-A-ZYD-022) is located in the containment building at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 63A, 65, 67A, and 67B at elevation 100 feet 0 inch and 120 feet 0 inch
- Zone 63A at elevation 140 feet 0 inch

South: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 63B, 66A, and 66B at elevations 100 feet 0 inch and 120 feet 0 inch
- Zone 63B at elevation 140 feet 0 inch

East: Nonrated wall of stainless steel and heavy concrete construction common to Zones 66B and 67B at elevations

100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

West: Nonrated wall of stainless steel and heavy concrete construction common to:

- Zones 65 and 67A at elevation 100 feet 0 inch
- Zone 67A at elevation 120 feet 0 inch
- Zones 66A and 67A at elevation 140 feet 0 inch

Floor: Nonrated barrier of stainless steel and heavy concrete construction common to Zones 63A, 63B, 64, 66A, and 66B

Ceiling: Open to the containment atmosphere

2. Zone Access

Open to the containment atmosphere.

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

Incore instrumentation transfer assembly

D. Nonsafety-Related Equipment and Components

- Fuel upender and carriage
- Core support barrel lift rig
- Refueling machine
- Cable trays and conduits

E. Radioactive Material

Radioactive material in process piping and equipment

F. Combustible Loading

1. In Situ Combustible Load Type
    - Plastic
    - Rubber
    - Cable Insulation
    - Hydraulic fluid (Fyrquel)
    - Oil and grease
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization and line-type thermal detection systems installed covering the cable trays are provided for early warning.

H. Fire Suppression

1. Primary

One portable CO_2 fire extinguisher in each of adjacent Zones 66B and 67B at elevation 140 feet 0 inch

2. Secondary

One portable CO_2 fire extinguisher in each of adjacent Zones 66A and 67A at elevation 140 feet 0 inch

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

Two 10-inch and one 4-inch refueling pool drains

K. Emergency Communications

None

9B.2.11.18 Fire Area XI, Fire Zone 71A, North Preaccess Normal Air Filtration Unit Area

A. Location

Fire Zone 71A (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	Nonrated wall of steel construction common to Zones 67A and 67B
South:	Nonrated wall of heavy concrete construction common to Zone 63A
East:	Nonrated wall of steel construction common to Zone 67B
West:	Nonrated wall of steel construction common to Zone 67A
Floor:	Nonrated barrier of steel construction common to Zones 67A and 67B
Ceiling:	Nonrated barrier of steel construction common to the containment atmosphere

2 Zone Access

Nonrated unit access doors in the nonrated north wall to Zones 67A and 67B

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Preaccess normal air filtration unit
   - Conduit

E. Radioactive Material

   Potentially contaminated charcoal media

F. Combustible Loading

1. In Situ Combustible Load Type

   - Charcoal
   - Grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Charcoal

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Photoelectric smoke detection system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Local manually controlled water spray system

2. Secondary

One manual hose reel is located in adjacent Zone 67B. One portable CO_2 fire extinguisher is located in adjacent Zone 67A.

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

The air filtration unit is equipped with internal drains.

K. Emergency Communications

None

9B.2.11.19 Fire Area XI, Fire Zone 71B, South Preaccess Normal Air Filtration Unit Area

A. Location

Fire Zone 71B (engineering drawing 13-A-ZYD-022) is located in the containment building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 63B

South: Nonrated wall of steel construction common to Zones 66A and 66B

East: Nonrated wall of steel construction common to Zone 66B

West: Nonrated wall of steel construction common to Zone 66A

Floor: Nonrated barrier of steel construction common to Zones 66A and 66B

Ceiling: Nonrated barrier of steel construction common to the containment atmosphere

2. Zone Access

Nonrated unit access doors in the nonrated south wall to Zones 66A and 66B

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   Train A and B conduits

D. Nonsafety-Related Equipment and Components

   - Preaccess normal air filtration unit
   - Conduit

E. Radioactive Material

   Potentially contaminated charcoal media

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Charcoal
      - Grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Charcoal

   3. Total Combustible (Fire) Loading

      High

G. Fire Detection

Photoelectric smoke detection system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Local manually controlled water spray system

2. Secondary

One manual hose reel is located in adjacent Zone 66A. One portable CO_2 fire extinguisher is located in each of adjacent Zones 66A and 66B.

I. Ventilation

Recirculation from containment normal cooling fan and recirculation from reactor cavity cooling fan during normal plant operation. The refueling purge and power access purge systems are manually turned on to exhaust air to the outside. These systems are turned on prior to entry into containment. These systems, when available, will be used to remove smoke.

J. Drainage

The air filtration unit is equipped with internal drains

K. Emergency Communications

None

9B.2.12 FIRE AREA XII

9B.2.12.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XII (figures 9B-1, 9B-3, 9B-4, and engineering drawing 13-P-00B-005) contains train A and train B components found in the main steam support structure (MSSS). This fire area includes Analysis Areas XIIA (Zone 74A), XIIB (Zone 72), and XIIC (Zones 73 and 74B) (engineering drawing 13-A-ZYD-022).

At elevation 81 feet 0 inch, Fire Area XII is below grade and bounded to the north by a nonrated exterior wall, and a 3-hour rated barrier common to a turbine building stairwell, to the south by a 3-hour rated wall common to Fire Area XV and a 3-hour rated exterior wall, to the east by a 3-hour rated exterior wall, and to the west by a 3-hour rated barrier common to Fire Area XI. The basemat is nonrated.

Above elevation 100 feet 0 inch, Fire Area XII is above grade and bounded to the north by a nonrated exterior wall and a 3-hour rated barrier common to a turbine building stairwell, to the south by a 3-hour rated barrier common to Fire Areas XV and XVII and a 3-hour rated exterior wall, to the east by a nonrated exterior wall adjacent to the turbine building, and to the west by an unrated barrier to a seismic gap common to the 3-hour rated barrier of Fire Area XI. A nonrated missile barrier roof is raised above the

tops of these four walls, supported by steel structural members.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires a 3-hour rated barrier between adjacent fire areas separating circuits of redundant trains.

   Discussion

   The mechanical penetrations in the containment boundary are not rated. Mechanical containment penetrations are fitted with flued heads constructed of steel with a minimum thickness of 1/8 inch. The special construction of the flued heads was designed to maintain the integrity of the containment building.

   Conclusion

   The existing design provides equivalent protection to that required by Section III.G.2. The design is standard within the industry.

2. A deviation is requested from Section III.G.2 to the extent that it requires a 1-hour fire barrier between redundant safe shutdown equipment in addition to fire detection and automatic fire suppression.

   Discussion

   The MSSS is a single fire area provided with fire detection and automatic suppression

throughout, except in Zones 72 and 73 which are provided with fire detection and partial automatic suppression. The MSSS above elevation 100 feet 0 inch contains redundant safe shutdown components and conduit in both Zone 74A and Zone 74B. In order to meet interface requirements set by the NSSS vendor (to satisfy single failure criteria), Zone 74A contains both train A and train B valves which service the north (No. 1) steam generator, and Zone 74B contains both train A and train B valves which service the south (No. 2) steam generator.

Within the MSSS, there is a central wall of reinforced concrete construction separating Zones 74A and 74B. This wall is heavy concrete construction. Piping and conduit penetrations are sealed to a 3-hour fire rating. The wall contains a 3-hour constructed door at elevation 100 feet 0 inch. The door has been certified by the manufacturer to be constructed to 3-hour fire door standards, but is not labeled since it is slightly oversized and has a removable transom. There is also an 8.5-foot high opening between the top of the wall (elevation 156 feet 0 inch) and the bottom of the missile shield which allows the structure to vent pressures developed during postulated high energy line breaks. (Note: This opening extends about the entire perimeter of Area XII at elevation

156 feet 0 inch.) Closure of the MSSS would be detrimental to overall facility safety.

A postulated fire in either zone can result in the loss of operability of both ADVs associated with one steam generator due to actuator, solenoid valve, or pneumatic supply accumulator damage. However, hot standby and cold shutdown can be obtained by manual operation (via handwheel) of the unaffected ADVs.

The total combustible (fire) loading in each zone is moderate. Since detection and automatic water suppression is provided, full development of the fire is not expected. Additionally, fire department response is expected within 20 minutes. The MSSS is accessible via stairwells from the yard and from the turbine building.

Conclusion

The existing design assures that one train of equipment necessary to achieve hot shutdown is operable locally. Fire damage to valve actuating equipment required to reach cold shutdown is limited such that an ADV can be manually operated within a reasonable time. Additionally, to meet complete fire barrier separation per Section III.G.2 requires modifications which would be detrimental to

overall facility safety and would not enhance the current level of protection.

3. A deviation is requested from Section III.G.2 to the extent that it requires a 3-hour rated barrier to separate circuits of redundant trains.

Discussion

The central wall of the MSSS separating the auxiliary feedwater (AFW) pump rooms is 3-hour rated below elevation 100 feet 0 inch except that it contains a nonrated watertight door. Because the door is constructed of steel and has automatic water suppression on each side, it would act as an effective fire barrier. Replacement of the watertight door with a rated fire door would degrade overall facility safety by subjecting both pumps to potential loss due to flooding of the subcompartments.

Zones 72 and 73 have smoke detection and an automatic preaction sprinkler system providing coverage for lube oil hazard and common doorway.

The total combustible (fire) loading in Zone 72 is low and in Zone 73 is moderate. Fire department response is expected within 20 minutes.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2. Modification to meet the requirement would be detrimental to overall facility safety.

4. A deviation is requested from Section III.G.2 to the extent that it requires installation of a 1-hour fire rated barrier in addition to an area-wide suppression system.

Discussion

The east wall of the MSSS is nonrated above elevation 100 feet 0 inch. There is a second nonrated wall which abuts the turbine building from approximately elevation 110 feet 0 inch to elevation 140 feet 0 inch and establishes two void spaces adjacent to Zones 74A and 74B, respectively. Each void is approximately 10 feet by 20 feet and has no combustibles. No detection or suppression is provided within this void space, but both Zones 74A and 74B have automatic suppression and detection. (For additional information, refer to the appendix 9A response to Question 9A.121).

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to a 1-hour

rating would not significantly enhance the protection currently provided.

5. DELETED

6. DELETED

7. Following is a fire protection evaluation of the fire barrier separating Analysis Areas XIIA (Zone 74A) from XIIB (Zone 72), which are both located within safety train A.

   Discussion

   The elevation 100 feet 0 inch floor of the MSSS separating Analysis Areas XIIA (Zone 74A) from XIIB (Zone 72), both of which are located within safety train A, is heavy reinforced concrete construction, 3 feet 6 inches thick with sealed penetrations. The floor contains one nonrated equipment hatch, 5 feet x 9 feet in size, covered by a 1/2-inch thick steel plate reinforced with T sections. The plate overlaps the opening by approximately 6 inches all around and is fastened down with 1/2-inch bolts 6 inches apart around the perimeter. A 4-inch curb surrounds the hatch opening. The equipment hatch has an integral manway[a] that is constructed of 3/8 inch steel top plate with a 1/2 inch thick metal frame. Both Analysis Areas

[a] The equipment hatch manway has been installed only in those units where DMWO 4345887 has been implemented.

XIIA and XIIB are protected by smoke detection and an automatic preaction sprinkler system. The total combustible (fire) loading in Zone 72 is low and in Zone 74A is moderate.

Conclusion

The substantial construction of the floor, steel hatch cover and equipment hatch manway[a], together with the other fire protection features, will prevent the passage of flames, smoke, and hot gases through the barrier. Access to the unaffected analysis area will remain available to perform any manual actions as may be required. The train B side of the building (Analysis Area XIIC) would also remain free of fire damage.

8. See subsection 9B.2.0 for generic deviations.

9B.2.12.2 Analysis Area XIIA

A. Location

Analysis Area XIIA consists of Fire Zone 74A.

Fire Zone 74A (engineering drawing 13-A-ZYD-022) is located in the MSSS at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

[a] The equipment hatch manway has been installed only in those units where DMWO 4345887 has been implemented.

B. Analysis Area Boundaries

North: 3-hour rated wall common to a turbine building stairwell

Nonrated exterior wall of heavy concrete construction

Open to the atmosphere above elevation 156 feet 0 inch

South: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 74B (Ref. 9B.2.12.1.B.2)

Open to Zone 74B above elevation 156 feet 0 inch

East: Nonrated exterior wall, adjacent to the turbine building, of heavy concrete construction

Open to the atmosphere above elevation 156 feet 0 inch

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Open to the atmosphere above elevation 156 feet 0 inch

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 72 (Ref. 9B.2.12.1.B.7)

Ceiling: Nonrated missile barrier roof raised above the top of the four walls, supported by steel structural beams

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following systems:

  Auxiliary feedwater

  Auxiliary building HVAC

  Main steam

- Train A steam generator 1 auxiliary feedwater pump steam supply valves
- Train A steam generator 1, line 1, atmospheric dump valve and associated components
- Train B steam generator 1, line 2, atmospheric dump valve and associated components
- Train A and train B steam generator 1 feedwater isolation valves
- Train B steam generator 1 blowdown isolation valve
- Steam generator 1 main steam isolation valves and bypass valves
- Steam generator 1 safety relief valves

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area, in conjunction with operator action, to prevent or overcome the consequences of spurious operation of components, has been demonstrated to remain available due to spatial separation and fire barriers provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.12.3 Analysis Area XIIB

A. Location

Analysis Area XIIB consists of Fire Zone 72

Fire Zone 72 (engineering drawing 13-A-ZYD-022) is located in the MSSS at elevation 81 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to a turbine building stairwell

Nonrated exterior wall of heavy concrete construction

South: 3-hour rated wall common to Zone 73

East: 3-hour rated exterior wall

West: An unrated barrier to a seismic gap common to the 3-h Fire Area XI

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Barrier of heavy concrete construction with electrical pipe and penetrations sealed to a 3-hour rating common to Zone 74A (Ref. 9B.2.12.1.B.7) our rated wall of

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Auxiliary building HVAC

  Main steam

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Main steam

- Train A auxiliary feedwater pump, control panel, and associated components
- Train A auxiliary feedwater regulation and isolation valves
- Train A auxiliary feedwater pump room essential air control unit and associated components
- Train A atmospheric dump valve's associated components

- Train B atmospheric dump valve associated components
- Train B steam generator 1 auxiliary feedwater flow instrumentation

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room, in conjunction with operator action, both inside and outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.12.4 Analysis Area XIIC

A. Location

Analysis Area XIIC consists of Fire Zones 73 and 74B.

Fire Zone 73 (engineering drawing 13-A-ZYD-022) is located in the MSSS at elevation 81 feet 0 inch.

Fire Zone 74B (engineering drawing 13-A-ZYD-022) is located in the MSSS at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Zone 72 (elevation 80 feet 0 inch)

Wall of heavy concrete construction with electrical pipe penetrations sealed to a 3-hour rating common to Zone 74A (Ref. 9B.2.12.1.B.2) (elevation 100 feet 0 inch, 120 feet inch and 140 feet 0 inch)

Open to Zone 74A above elevation 156 feet 0 inch

South: 3-hour rated wall common to Fire Area XV (elevation 80 feet 0 inch)

3-hour rated wall common to:

- Fire Area XVII at elevations 100 feet 0 inch and 120 feet 0 inch
- Fire Area XV at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to the atmosphere above elevation 156 feet 0 inch

East: 3-hour rated exterior wall (elevation 80 feet 0 inch)

Nonrated exterior wall of heavy concrete construction adjacent to the turbine building (elevation 100 feet 0 inch, 120 feet 0 inch and 140 feet 0 inch)

Open to the atmosphere above elevation 156 feet 0 inch

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Open to the atmosphere above elevation 156 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof raised above the top of the four walls, supported by steel structural beams

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following systems:

  Auxiliary feedwater

  Auxiliary building HVAC

  Main steam

- Train B auxiliary feedwater pump and associated components
- Train B auxiliary feedwater regulating and isolation valves
- Train A and train B steam generator 2 auxiliary feedwater flow instrumentation
- Train B auxiliary feedwater pump room essential air control unit and associated components

- Train A steam generator 2, line 2, atmospheric dump valve and associated components
- Train B steam generator 2, line 1, atmospheric dump valve and associated components
- Train A and train B steam generator 2 feedwater isolation valves
- Steam generator 2 main steam isolation valves and bypass valve
- Train A steam generator 2 auxiliary feedwater pump steam supply valves
- Train A steam generator 2 blowdown isolation valve
- Steam generator 2 safety relief valves

D. Summary and Conclusions

Cable EHA06AC1RB is enclosed in a 1-hour rated protective envelope with appropriate detection and suppression and, therefore, is not susceptible to fire damage.

One train of the systems necessary to achieve and maintain hot standby and cold shutdown conditions independent of the subject fire area (with the above exception), in conjunction with operator action, to prevent or overcome the consequences of spurious operation of components, has been demonstrated to remain available due to spatial separation and fire

barriers provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.12.5 Fire Area XII, Fire Zone 72, Turbine-Driven Auxiliary Feedwater Pump Room

A. Location

Fire Zone 72 (engineering drawing 13-A-ZYD-022) is located in the main steam support structure at elevation 81 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to a turbine building stairwell

Nonrated exterior wall of heavy concrete construction

South: 3-hour rated wall common to Zone 73

East: 3-hour rated exterior wall

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 74A (Ref. 9B.2.12.1.B.7)

2. Zone Access

   - One nonrated watertight door in the 3-hour rated south wall to Zone 73. (Refer to the appendix 9A response to Question 9A.99.)

   - One nonrated watertight door in the 3-hour rated north wall to the stairwell

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Oil and grease
- Plastic

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detection is provided for actuating the deluge valve of the preaction sprinkler system and early warning.

H. Fire Suppression

1. Primary

Automatic preaction sprinkler system covering lube oil hazard

2. Secondary

One portable CO_2 fire extinguisher and/or yard hydrant

I. Ventilation

Flow to outside

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.12.6 Fire Area XII, Fire Zone 73, Motor-Driven Auxiliary Feedwater Pump Room

A. Location

Fire Zone 73 (engineering drawing 13-A-ZYD-022) is located in the main steam support structure at elevation 81 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 72

South: 3-hour rated wall common to Fire Area XV

East: 3-hour rated exterior wall

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction to Zone 74B

2. Zone Access

   - One nonrated watertight door in the 3-hour rated north wall to Zone 72. (Refer to the appendix 9A response to Question 9A.99.)

   - One nonrated watertight emergency hatch in the nonrated ceiling to Zone 74B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Thermo-Lag 330-1
   - Oil and grease
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detection is provided for early warning.

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher. Partial coverage by a preaction water sprinkler system near the nonrated door in the north wall

2. Secondary

   One portable CO_2 fire extinguisher (located in adjacent Zone 72) and/or yard hydrant

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.12.7 Fire Area XII, Fire Zone 74A, Main Steam Isolation and Dump Valves Area

A. Location

Fire Zone 74A (engineering drawing 13-A-ZYD-022) is located in the main steam support structure at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to a turbine building stairwell

Nonrated exterior wall of heavy concrete construction

Open to the atmosphere above elevation 156 feet 0 inch

South: Wall of heavy concrete construction with electrical and pipe penetrations

sealed to a 3-hour rating common to Zone 74B (Ref. 9B.2.12.1.B.2)

Open to Zone 74B above elevation 156 feet 0 inch

East: Nonrated exterior wall, adjacent to the turbine building, of heavy concrete construction

Open to the atmosphere above elevation 156 feet 0 inch

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Open to the atmosphere above elevation 156 feet 0 inch

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 72 (Ref. 9B.2.12.1.B.7)

Ceiling: Nonrated missile barrier roof raised above the top of the four walls, supported by steel structural beams

2. Zone Access

- One 3-hour constructed maintenance door (pair) and transom in the nonrated south wall to Zone 74B at elevation 100 feet 0 inch (Ref. 9B.2.12.1.B.2)

- Three nonrated missile doors in the 3-hour rated north wall to the stairwell, one each at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch. (Refer to the appendix 9A response to Question 9A.106.)

- One nonrated missile door in the nonrated north exterior wall at elevation 100 feet 0 inch

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   Train B auxiliary feedwater system and auxiliary building HVAC safe shutdown related conduits are enclosed by 1-hour rated protective envelopes.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Thermo-Lag 330-1
- Plastic
- Oil/grease
- Rubber
- Cable insulation
- Hydraulic fluid (Fyrquel)

2. Transient Combustible Load Type

- Ordinary combustible
- Hydraulic fluid (Fyrquel)

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Heat actuated devices are provided for actuating the deluge valve of the preaction sprinkler system and to provide early warning.

H. Fire Suppression

1. Primary

Automatic preaction sprinkler system

2. Secondary

One portable CO_2 fire extinguisher at 100 feet 0 inch. A manual hose reel located in the

adjacent turbine building may be used as an additional backup. The hose station, however, is not relied on for secondary fire suppression capability.

I. Ventilation

Flow to outside

J. Drainage

One 4-inch drain is provided at elevation 100 feet 0 inch.

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.12.8 Fire Area XII, Fire Zone 74B, Main Steam Isolation and Dump Valves Area

A. Location

Fire Zone 74B (engineering drawing 13-A-ZYD-022) is located in the main steam support structure at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 74A (Ref. 9B.2.12.1.B.2)

Open to Zone 74A above elevation 156 feet 0 inch

South: 3-hour rated wall common to:

- Fire Area XVII at elevations 100 feet 0 inch and 120 feet 0 inch
- Fire Area XV at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch

Open to the atmosphere above elevation 156 feet 0 inch

East: Nonrated exterior wall of heavy concrete construction adjacent to the turbine building

Open to the atmosphere above elevation 156 feet 0 inch

West: An unrated barrier to a seismic gap common to the 3-hour rated wall of Fire Area XI

Open to the atmosphere above elevation 156 feet 0 inch

Floor: Nonrated barrier of heavy concrete construction common to Zone 73

Ceiling: Nonrated roof raised above the top of the four walls, supported by steel structural beams

2. Zone Access

   - One 3-hour constructed maintenance door (pair) and transom in the north wall to Zone 74A at elevation 100 feet 0 inch (Ref. 9B.2.12.1.B.2)

   - Two 3-hour constructed doors in the north wall to Zone 74A, one each at elevations 120 feet 0 inch and 140 feet 0 inch (Ref. 9B.2.12.1.B.2)

   - One nonrated watertight emergency hatch in the nonrated floor to Zone 73

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   Train A auxiliary building HVAC safe shutdown related conduits are enclosed by 1-hour rated protective envelopes.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Thermo-Lag 330-1
   - Cable insulation
   - Oil/grease
   - Hydraulic fluid (Fyrquel)

2. Transient Combustible Load Type

   - Ordinary combustible
   - Hydraulic fluid (Fyrquel)

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Heat actuated devices are provided for actuating the deluge valve of the preaction sprinkler system and to provide early warning.

H. Fire Suppression

1. Primary

   Automatic preaction sprinkler system

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 74A at elevation 100 feet 0 inch. A manual hose reel located in the adjacent turbine building may be used as an additional backup. The hose station, however, is not relied on for secondary fire suppression capability.

I. Ventilation

Flow to outside

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.13 FIRE AREA XIII

9B.2.13.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XIII (figure 9B-1) contains the train A ESF pump rooms of the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches. This fire area includes Analysis Area XIIIA (Zones 30A, 31A, and 32A) only (engineering drawing 13-A-ZYD-023).

Fire Area XIII is below grade and bounded to the north, south, and west by 3-hour rated barriers common to Fire Area XV, and to the east by 3-hour

rated barriers common to Fire Areas XIV and XV. The ceiling is 3-hour rated and common to Fire Area XV. The basemat is nonrated.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.13.2 Analysis Area XIIIA

A. Location

Analysis Area XIIIA consists of Fire Zones 30A, 31A, and 32A.

Fire Zones 30A, 31A, and 32A (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Analysis Area Boundaries

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Fire Area XV, Zone 90

3-hour rated wall at column line A9 common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch

- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

East: 3-hour rated wall common to Fire Area XIV, Zone 31B, at column line AF

3-hour rated wall common to Fire Area XV, Zone 90, at column line AE

West: 3-hour rated wall at column line AD common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches.

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zones 35A, 37A, 37B, and 37E

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary building HVAC

  Safety injection and shutdown cooling

- Train A low-pressure safety injection pump room essential air control unit and associated components

- Train A low-pressure safety injection pump and associated system valves
- Train A high-pressure safety injection pump
- Train A containment spray pump
- Train A high-pressure safety injection pump room essential air control unit and associated components
- Train A high-pressure safety injection discharge isolation valve
- Train A high-pressure safety injection long-term recirculation isolation valve
- Train A high-pressure safety injection pump recirculation to refueling water tank valve

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.13.3 Fire Area XIII, Fire Zone 30A, Train A Containment Spray Pump Room

A. Location

Fire Zone 30A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Zone 32A

East: 3-hour rated wall common to Zone 31A at column line AE

West: 3-hour rated wall at column line AD common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches.

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zones 35A and 37A

2. Zone Access

   One Class A door in the 3-hour rated west wall to Zone 88A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A containment spray pump essential air cooling unit
- Train A containment spray recirculation to refueling water tank valve.

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In-Situ Combustible Load Type

- Cable insulation
- Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detection is provided for early warning and to actuate the preaction water sprinkler system.

H. Fire Suppression

1. Primary

Preaction water sprinkler system

2. Secondary

Two manual hose reels and two portable ABC powder fire extinguishers are located in adjacent Zone 88A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.13.4 Fire Area XIII, Fire Zone 31A, Train A High-Pressure Safety Injection Pump Room

A. Location

Fire Zone 31A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Fire Area XV, Zone 90

East: 3-hour rated wall common to Fire Area XIV, Zone 31B, at column line AF

West: 3-hour rated wall common to Zone 30A at column line AE

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zones 37B and 37E

2. Zone Access

One Class A door in the 3-hour rated north wall to Zone 88A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detection is provided for early warning and to actuate the preaction water sprinkler system.

H. Fire Suppression

1. Primary

   Preaction water sprinkler system

2. Secondary

Two manual hose reels and two portable ABC powder fire extinguishers are located in adjacent Zones 88A and 88B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.13.5 Fire Area XIII, Fire Zone 32A, Train A Low-Pressure Safety Injection Pump Room

A. Location

Fire Zone 32A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 30A

South: 3-hour rated wall at column line A9 common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch

- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

East: 3-hour rated wall common to Fire Area XV, Zone 90, at column line AE

West: 3-hour rated wall at column line AD common to:

- Fire Area XV, Zone 87A, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88A, at elevation 51 feet 6 inches

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zone 35A

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 88A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.14 FIRE AREA XIV

9B.2.14.1 Fire Area Description

A. Area Boundary Description

Fire Area XIV (figure 9B-1) contains the train B ESF pump rooms of the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches. This fire area includes Analysis Area XIVA (Zones 30B, 31B, and 32B) only (engineering drawing 13-A-ZYD-023).

Fire Area XIV is below grade and bounded to the north, south, and east by 3-hour rated barriers common to Fire Area XV, and to the west by 3-hour rated barriers common to Fire Areas XIII and XV. The ceiling is 3-hour rated and common to Fire Area XV. The basemat is nonrated.

B. Deviations from lOCFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.14.2 Analysis Area XIVA

A. Location

Analysis Area XIVA consists of Fire Zones 30B, 31B, and 32B.

Fire Zones 30B, 31B, and 32B (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Analysis Area Boundaries

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Fire Area XV, Zone 89

3-hour rated wall at column line A9 common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

East: 3-hour rated wall at column line AH common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

West: 3-hour rated wall common to Fire Area XIII, Zone 31A, at column line AF

3-hour rated wall common to Fire Area XV, Zone 89, at column line AG

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zones 35B, 37B, and 37E

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Auxiliary building HVAC

  Safety injection and shutdown cooling

- Train B low-pressure safety injection pump room essential air control unit and associated components
- Train B low-pressure safety injection pump and associated system valves
- Train B high-pressure safety injection pump and associated system valves
- Train B containment spray pump
- Train B high-pressure safety injection pump room essential air control unit and associated components
- Train B high-pressure safety injection long-term recirculation isolation valve.
- Train B high-pressure safety injection header discharge isolation valve.
- Train B high-pressure safety injection pump recirculation to refueling water tank valve.

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train A systems available from the control room.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.14.3 Fire Area XIV, Fire Zone 30B, Train B Containment Spray Pump Room

A. Location

Fire Zone 30B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Zone 32B

East: 3-hour rated wall at column line AH common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

West: 3-hour rated wall common to Zone 31B at column line AG

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zones 35B and 37B

2. Zone Access

   One Class A door in the 3-hour rated east wall to Zone 88B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B containment spray pump room essential air cooling unit
- Train B containment spray pump recirculation to refueling water tank valve

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detection is provided for early warning and will actuate the preaction water sprinkler system.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system

2. Secondary

Two manual hose reels and two portable ABC powder fire extinguishers are located in adjacent Zone 88B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.14.4 Fire Area XIV, Fire Zone 31B, Train B High-Pressure Safety Injection Pump Room

A. Location

Fire Zone 31B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

South: 3-hour rated wall common to Fire Area XV, Zone 89

East: 3-hour rated wall common to Zone 30B at column AG

West: 3-hour rated wall common to Fire Area XIII, Zone 31A, at column line AF

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zone 37E

2. Zone Access

One Class A door in the 3-hour rated north wall to Zone 88B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detection is provided for early warning and will actuate the preaction water sprinkler system.

H. Fire Suppression

1. Primary

   Preaction water sprinkler system

2. Secondary

Two manual hose reels and two portable ABC powder fire extinguishers are located in adjacent Zones 88A and 88B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.14.5 Fire Area XIV, Fire Zone 32B, Train B Low-Pressure Safety Injection Pump Room

A. Location

Fire Zone 32B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Zone 30B

South: 3-hour rated wall at column line A9 common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch

- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

East: 3-hour rated wall at column line AH common to:

- Fire Area XV, Zone 87B, at elevation 40 feet 0 inch
- Fire Area XV, Zone 88B, at elevation 51 feet 6 inches

West: 3-hour rated wall common to Fire Area XV, Zone 89, at column line AG

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to Fire Area XV, Zone 35B

2. Zone Access

One Class A door in the 3-hour rated south wall to Zone 88B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

      - Cable insulation
      - Oil and grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   Ionization smoke detection is provided for early warning and will actuate the preaction water sprinkler system.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system

2. Secondary

One manual hose reel and two portable ABC powder fire extinguishers are located in adjacent Zone 88B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15 FIRE AREA XV

9B.2.15.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XV (figures 9B-1, 9B-2, 9B-3, 9B-4, and engineering drawing 13-P-00B-005) contains train A and train B components found in the auxiliary building. This fire area includes Analysis Area XVA (Zones 33A, 34A, 35A, 36, 37A, 37C, 39A, 87A, 88A, and 90), XVB (Zones 33B, 34B, 35B, 37B, 37D, 37E, 39B, 87B, 88B, and 89), XVC (Zones 42D, 43, 44, 45,

48, 49A, 49B, 49C, 49D, 49E, 49F, 49G, 49H, 50A, 52A, 55A, 55C, 55E, 56A, 56B, 56C, 57A, 57B, 57C, 57D, 57E, 57F, 57G, 57H, 57J, 57K, 57L, 57M, 57N, and 57P), XVD (Zones 42C, 50B, 51A, 51B, 52D, 53, and 54), XVE (Zone 46A), XVF (Zone 46B), and XVG (Zone 46E) (engineering drawings 13-A-ZYD-023 and -024).

At elevations 40 feet 0 inch and 51 feet 6 inches, Fire Area XV is below grade and encloses Fire Areas XIII and XIV by 3-hour rated barriers. Fire Area XV is bounded to the north, south, east, and west by nonrated exterior walls. The basemat is nonrated. A portion of the north corridor ceiling, which is common to the south access shaft, is a 3-hour rated barrier.

At elevation 70 feet 0 inch, Fire Area XV is below grade, bounded to the north by both nonrated and 3-hour rated barriers common to the south access shaft, a nonrated exterior wall, and 3-hour rated barriers common to Fire Areas XI and XII; to the south by 3-hour rated barriers common to Fire Areas I, II, and X, and a nonrated exterior wall, to the east by 2-hour rated barriers common to the east stairwell and nonrated exterior walls, and to the west by a 2-hour rated barrier common to the west elevator, stairwell, and HVAC chase, and nonrated exterior walls. Portions of the floor are 3-hour rated barriers common to Fire Areas XIII and XIV.

At elevation 88 feet 0 inch, Fire Area XV is below grade, bounded to the north by a 3-hour rated barrier common to the south access shaft, a nonrated exterior wall, and 3-hour rated barriers common to Fire Areas XI and XII, to the south by 3-hour rated barriers common to Fire Areas I, II, and X, and a nonrated exterior wall, to the east by 2-hour rated barriers common to the east stairwell and nonrated exterior walls, and to the west by a 2-hour rated barrier common to the west elevator, stairwell, and HVAC chase, and nonrated exterior walls. Portions of the ceiling are 1-hour rated barriers common to Fire Areas XVI and XVII.

At elevations 100 feet 0 inch and 120 feet 0 inch, Fire Area XV is bounded to the north by 2-hour rated barriers common to Fire Areas XVI and XVII, a 3-hour rated barrier common to Fire Area XII, and both nonrated and 3-hour rated barriers common to the south access shaft, to the south by 3-hour rated barriers common to Fire Areas I, II, and X, to the east by 2-hour rated barriers common to the east stairwell, 3-hour rated exterior walls and a 3-hour rated barrier common to the corridor building, and to the west by a 2-hour rated barrier common to the west elevator, stairwell, and HVAC chase, a 3-hour rated barrier common to Fire Area VI, and a nonrated exterior wall.

At elevation 140 feet 0 inch, Fire Area XV is bounded to the north by nonrated walls common to the south

access shaft, 3-hour rated exterior wall, and 3-hour rated barriers common to Fire Areas XI and XII, to the south by a 3-hour rated barrier common to Fire Areas I, II, and X, to the east by 2-hour rated barriers common to the east stairwell, 3-hour rated exterior walls, and a 3-hour rated barrier common to the corridor building, and to the west by a 2-hour rated barrier common to the west elevator, stairwell, and HVAC chase, a 3-hour rated barrier common to Fire Area VI, and a nonrated exterior wall. Portions of the floor are 2 and 3-hour rated barriers common to Fire Areas XVI and XVII. The ceiling, which is also the roof of the auxiliary building, is nonrated.

B. Deviations from lOCFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated barriers between adjacent fire areas separating circuits of redundant trains.

Discussion

The personnel access hatch at elevation 140 feet 0 inch and the mechanical and electrical penetrations in the containment boundary are not rated. The personnel access hatch is of special construction (refer to FSAR figure 6.2.4-1 for details of access hatch construction) designed to maintain the integrity of the containment boundary. The access hatch opens to Zone 66A, which has a moderate combustible (fire) loading.

Mechanical containment penetrations are fitted with flued heads constructed of steel with a minimum thickness of 1/8 inch. Electrical containment penetrations are fitted with a stainless steel header plate with a thickness of 1.78 inches.

The special construction of the flued heads and header plates was designed to maintain the integrity of the containment building.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2. The design is standard within the industry.

2. A deviation is requested from Section III.G.2 to the extent that it requires a 1-hour rated barrier in addition to fire detection and fire suppression.

Discussion

Elevation 100 feet 0 inch of Fire Area XV contains the train A, train B and train E charging pumps, with their associated power and control electrical cables, in adjacent Zones 46A, 46B and 46E respectively.

The walls, floor, and ceiling of fire zones 46A, 46B and 46E are of reinforced concrete construction with all electrical and pipe penetrations sealed to an equivalent 3-hour fire

barrier rating. There is a non-rated personnel doorway opening to the north side corridor from each room. There are unsealed HVAC duct penetrations without flashings in the pump rooms and entry valve gallery area on the northside of the pump rooms. These HVAC ducts are not provided with fire dampers. The floor of fire zone 46E has two non-rated penetrations commom to fire zone 39B, access hatch and HVAC penetration, that are protected with steel cover plates. A horizontal distance of approximately 20 feet exists between the personnel doorway openings and the respective charging pumps. In the event of a fire in either charging pump room A or B, the high pressure safety injection system (HPSI) and the reactor coolant gas vent system (RCGVS) components are available for safe shutdown. These components provide reactor coolant system inventory and pressure control. A horizontal distance of at least 20 feet exists between the redundant safe shutdown circuits of the HPSI and charging pump components. The total combustible loading in each of the pump rooms is low and in the adjoining corridor, Fire Zone 42C, is moderate. A smoke detection and an automatic preaction water sprinkler system are provided in each of the pump rooms, and a cable tray fire detection and an automatic suppression system are provided for the cable trays running

in the corridors (Zone 42C) just outside the rooms. Fire department response is expected in less than 30 minutes.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing openings to 1-hour rated configuration would not significantly enhance the protection currently provided.

3. A deviation is requested from Section III.G.2 to the extent that it requires (1) separation of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles, and (2) fire detection and suppression.

Discussion

The redundant essential cooling water system (ECWS) pumps and their associated air handling units are located at elevation 70 feet 0 inch in Zones 34A and 34B. Fire detection systems are provided for the pump rooms and the corridors (Zones 37A and 37B), which represent the only unrestricted fire path between the redundant components. The zone boundary walls, ceilings, and portions of the floors are of nonrated, reinforced concrete construction. The remainder of the floors common to Fire Areas XIII and XIV is 3-hour rated. The total combustible (fire)

loading inside each pump room is low. Although there are no continuous, rated fire boundaries separating the ECWS pump rooms, a separation distance of approximately 200 feet exists. Two stacked cable trays are routed through the intervening distance of Zones 37A and 37B. Zones 37A and 37B have a total combustible (fire) loading classed as low. Fire department response is expected within 30 minutes of the alarm condition.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2. Modification to meet Section III.G.2 would not significantly enhance the protection currently provided.

4. A deviation is requested from Section III.G.2 to the extent that it requires: (1) separation of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles, and (2) fire detection and suppression.

Discussion

The ECWS surge tanks with their associated level control and instrumentation cables are located at elevation 120 feet 0 inch in adjacent Zones 48 and 52A. The redundant devices and circuits are separated by approximately 20 feet.

Smoke detection is provided in Zone 48. Smoke detection and cable tray suppression are provided in Zone 52A. Intervening combustibles exist in each zone, but the 20-foot separation between redundant control and instrument cables (run in conduit) is primarily located in Zone 48, where the total combustible (fire) loading is low, including an allowance for transient combustibles. The total combustible (fire) loading in Zone 52A is moderate. The fire department is expected to respond within 30 minutes. The normal operating conditions (prior to the postulated fire) would maintain at least a minimum tank level in the ECWS surge tank which would assure continued operability of the ECWS system while the operator achieved hot shutdown. Local refill capability is all that is required to restore the system capabilities needed to achieve cold shutdown. (Refer also to the appendix 9A response to Question 9A.93.)

Conclusion

The existing design assures one train of equipment necessary to achieve hot shutdown is free of fire damage. The design also assures that fire damage is unlikely, or at worst that damage to at least one train of equipment may occur and the other train is available to achieve cold shutdown. In addition, alternate makeup for the EW cooling water system can be

accomplished in a time frame which permits the operator to achieve cold shutdown within 72 hours.

5. A deviation is requested from Section III.G.2 to the extent that it requires (1) separation of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles, and (2) fire detection and suppression.

Discussion

The redundant shutdown cooling heat exchangers are located in separate subcompartments (Zones 35A and 35B) at elevation 70 feet 0 inch separated by approximately 50 feet and at least two nonrated walls. The zone boundary walls, ceilings, and floors are nonrated, reinforced concrete construction (except for removable blockwalls as described in the appendix 9A response to Question 9A.120). The total combustible (fire) loading in each zone is low. The adjacent corridor (Zone 37B) contains a stack of two cable trays, and has a total combustible (fire) loading also classed as low, including an allowance for transient combustibles. Smoke detectors are provided in both Zones 35A and 35B, and in Zone 37B. Fire department response is expected within 30 minutes. Within that time frame the heat

exchangers are not subject to fire damage since they are passive, mechanical components.

Conclusion

The existing design assures that fire damage to at least one train of equipment necessary to achieve cold shutdown is limited and the other train is available to achieve cold shutdown.

6. A deviation is requested from Section III.G.2 to the extent that it requires (1) separation of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles, and (2) fire detection and suppression.

   Discussion

   The redundant essential cooling water heat exchangers are located in separate compartments of Zone 43 at elevation 100 feet 0 inch. The zone boundary walls (including a central wall along column line A8), ceilings, and floors are nonrated, reinforced concrete construction (except for removable panels in the exterior wall which are required for heat exchanger retubing). The total combustible (fire) loading within Zone 43 is low, including an allowance for transient combustibles. Even without fire department response, a fire would not damage the heat exchangers to the degree that they could not perform their function. The adjacent

corridor (Zone 42D) outside these rooms contains cable trays and has a total combustible (fire) loading classed as moderate. Within Zone 42D ionization smoke detector and thermal detector systems are provided which actuate a preaction water suppression system for the cable trays, except for three nonsafety-related cable trays, located between column lines AA and AB, which are provided with detection only. The cable tray suppression system will prevent the heat exchangers from being involved in postulated cable tray fires. Fire department response to an alarm from Zone 42D is expected in less than 30 minutes.

Conclusion

The existing design assures that at least one train of equipment necessary to achieve hot or cold shutdown is free of fire damage.

7. A deviation is requested from Section III.G.2 to the extent that it requires 3-hour rated area boundaries.

Discussion

The south wall of Zone 48 (access door between the auxiliary building and the radwaste building) at elevation 120 feet 0 inch utilizes a nonrated door and transom at the boundary to Fire Area X. The door contains a monorail passing through the upper transom and the

transom has been modified to include a cutout for the monorail. The total combustible (fire) loading on either side of the door is low. Zonal fire detection is provided in Zone 48. A fixed sprinkler system has been positioned on both sides of the door to act as a water curtain and prevent the possibility of fire passing from one area to the other.

Fire department response is expected in less than 30 minutes. (Refer also to the appendix 9A response to Question 9A.106.)

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and modification to meet Section III.G.2 would not significantly enhance the protection provided.

8. A deviation is requested from Section III.G.2 to the extent that it requires either a 1-hour rated barrier or separation by a horizontal distance of 20 feet or more without intervening combustibles, and fire detection and suppression.

Discussion

Redundant trains of safe shutdown raceway exist on all elevations of Fire Area XV in the auxiliary building, except for elevation 40 feet 0 inch, which contains no safe shutdown raceway,

and elevation 140 feet 0 inch, which contains only train A safe shutdown conduit. Redundant safe shutdown raceway within Fire Area XV are separated by a combination of features providing spatial separation, and thereby precluding fire spread along the shortest path between redundant safe shutdown equipment. For example, the design employs small, fire-rated walls to block corridors, and sealing of piping penetrations in nonrated walls when either action can be shown to be beneficial. Another feature is the addition of localized water suppression in zones which have a higher likelihood of initiating a fire, or in those zones where additional protection for safe shutdown equipment is required. For Fire Area XV, the following table lists corresponding zones of safe shutdown equipment (by building elevation) and the total combustible (fire) loading along the separation path. Fire protection features which enhance the existing separation are also listed. Wherever fire detection is provided, fire department response is expected within 30 minutes. In all cases listed, detection is provided along the separation path.

<u>Fire Area XV Safe Shutdown Equipment and Total Combustible Loading</u>

<u>Elevation 40 feet 0 inch</u>

No safe shutdown raceway located in Fire Area XV at this elevation

Elevation 51 feet 6 inches

- Train A safe shutdown raceway located in Zone 88A
- Train B safe shutdown raceway located in Zone 88B
- 80 feet minimum horizontal separation along south corridor between column lines AD and AH
- Total combustible (fire) loading along separation path (Zone 88A, Zone 90, Zone 89, Zone 88B) is low
- Fire detection along separation path (no automatic fire suppression provided) for all zones
- 3-hour rated ECCS pump room walls, and across north corridor at column line AF
- Nonrated reinforced concrete construction wall with unsealed penetrations across south corridor at column line AF
- No redundant raceway below
- Redundant raceway above uses same separation path.

Elevation 70 feet 0 inch

- Train A safe shutdown raceway located in Zones 34A, 35A, 37A, and 37C
- Train B safe shutdown raceway located in Zones 34B, 35B, 37B, and 37D
- 80 feet minimum horizontal separation distance along south corridor between column lines AD and AH
- Total combustible (fire) loading along separation path (Zone 37C, Zone 34A, Zone 35A, Zone 37A, Zone 37B, Zone 35B, Zone 34B, Zone 37D) is low to moderate
- Fire detection along separation path (no automatic suppression provided) for all zones
- 1-hour rated wall in north corridor, 3-hour rated wall along column line AE except for south corridor (open), and nonrated reinforced concrete construction between north corridor and piping penetration rooms (2-hour rated wall about stairwell)
- Redundant raceway below uses same separation path
- Redundant raceway above is a continuation of the raceway at this elevation.

Elevation 88 feet 0 inch

- Train A safe shutdown raceway located in Zone 37C
- Train B safe shutdown raceway located in Zone 37D
- Train A and B safe shutdown raceway located in Zone 39B. (Note: These raceways contain redundant power and control circuits for the condensate transfer pumps which are only required to be stopped to achieve and maintain safe shutdown. In the event of a fire damaging both train A and train B circuitry, makeup water for the essential chilled water system may be added through connections provided on the fill side of the system's surge tanks. Makeup water to this system is available from the fire protection system.
- 80 feet minimum horizontal separation distance along north pipe chase between column lines AD and AH
- Total combustible (fire) loading along separation path (Zone 37C, Zone 39A, Zone 39B, Zone 37D) is low to moderate.
- Fire detection along separation path (no automatic suppression provided) for all zones

- Heavy concrete construction wall between pipe chase zones and piping penetration areas, 3-hour fire-rated vertical cable chases, and heavy concrete construction floor and ceiling with penetration seals for radiation shielding. 1-hour rated ceiling below Fire Area XVI (Zone 42A) and Fire Area XVII (Zone 42B)

- Redundant raceway below is a continuation of the raceway at this elevation.

- Redundant raceway above uses a similar separation path.

Elevation 100 feet 0 inch

- Train A safe shutdown raceway, for charging pump A, located in Zones 42C, 42D, 46A, 46B and 46E. (Reference Fire Area XV deviation no. 2)

- Train B safe shutdown raceway, for charging pump B, located in Zones 42C, 46A and 46B. (Reference Fire Area XV deviation no. 2)

- Train A safe shutdown raceway, for area air handling unit (AHU), located in Zone 42C.

- Train B safe shutdown raceway, for HPSI valve, located in Zone 42C.

- Train A safe shutdown raceway, for HPSI valve, located in Zone 42D.

- 25-foot minimum horizontal separation distance along north (Zone 42D) and south (Zone 42C) corridors for redundant circuits along with a 1-hour rated fire barrier across the corridors and fire detection and automatic cable tray sup-pression provided in both zones.
- Train A charging pump conduit in the south corridor of Zone 42C is provided with a protective envelope affording equivalent 1-hour rated fire barrier protection and cable tray detection and automatic suppression is provided in Zone 42C.
- Train A charging pump conduit in zones 46E and 46B is separated from the south corridor of Zone 42C by three hour fire rated barriers.
- Train A safe shutdown conduit in the north end of the Zone 42C east corridor (contain circuits for the area AHU are provided with a protective envelope affording equivalent 1-hour rated fire barrier protection and zonal detection and automatic water suppression.
- Total combustible (fire) loading along separation path (Zone 46E) is low.

The total combustible (fire) loading in Zone 42D and 42C is moderate.

- Fire detection/suppression in separation paths

  Zone 42C - Cable tray fire detection and automatic suppression

  Zone 42D - Cable tray fire detection and automatic suppression

  Zone 46A - Zonal fire detection and automatic suppression

  Zone 46B - Zonal fire detection and automatic suppression

  Zone 46E - Zonal fire detection and automatic suppression

- Column line AG wall between the north and south corridors is reinforced concrete construction with all penetrations sealed to provide 3-hour fire rating except for an HVAC duct penetration through the wall near column line A7. The opening is 12 inches wide by 12 inches high located 8 feet 10 inches above the floor.

- The floors and ceilings of Zones 44, 45, 46A, and 46B are reinforced concrete construction with all penetrations sealed to provide 3-hour fire rating.

- The floor and ceiling of Zone 46E is of reinforced concrete construction with sealed electrical and piping penetrations to a 3-hour fire rating and is also a pressure boundary. The floor has two non-rated penetrations common to fire zone 39B for personnel access and an HVAC duct penetration. The penetrations have steel cover plates.
- The 100 foot floor is reinforced concrete construction with sealed electrical and pipe penetrations to a 3-hour fire rating and is also a pressure boundary. There are non-fire rated penetrations which include several equipment and personnel hatches with steel cover plates, two stairs with non-rated doors and non-rated enclosed concrete pipe chases at column lines A7/AC and A9/AG. The combustible loading on the floor below at the 88 foot elevation pipeway consisting of piping and valves is very low which, combined with the heavy concrete floor, does not present an exposure fire hazard to cables and equipment required for safe shutdown located at the 100 foot elevation.
- The walls of Zone 46A, 46B, and 46E are described in Fire Area XV deviation No. 2.

Elevation 120 feet 0 inch

- Train A safe shutdown raceway in Zone 52A with redundant train B safe shutdown raceway in Zones 48, 51B, 53, and 50A (Note: See Fire Area XV, deviation No. 4, for the Zone 48 separation considerations.)

- Redundant train A and train B safe shutdown raceway in Zone 52D. The train A conduit in the north end of the Zone 52D east corridor is a continuation of the raceway described at elevation 100 feet 0 inch directly below and are provided with a protective envelope affording equivalent 1-hour rated fire barrier protection at this elevation also.

- 80 feet minimum horizontal separation distance along north corridor (Zones 52A and 52D) between column lines AD and AH with a 1-hour rated fire barrier across the corridor and fire detection and automatic cable tray suppression provided in both zones.

  Additionally, there are the following barriers:

  - 3-hour rated wall sections along column line AF between A7 and A8, and along column line AG between A8 and A10.

- Reinforced concrete construction wall along column line A8 between AF and AG with all penetrations sealed to provide a 3-hour fire rating.
- Reinforced concrete construction wall along column line A7 between AE and AF having two open HVAC ducting penetrations and an access door opening from the Zone 52D corridor to Zone 50A.

- Total combustible (fire) loading in separation paths (Zone 52A, Zone 50A, Zone 51B, Zone 53, Zone 52D) moderate, including allowance for transient combustibles.

- Fire detection/suppression in separation paths

  Zone 52A - Cable tray fire detection and automatic suppression system

  Zone 52D - Cable tray fire detection and automatic suppression system

  Zone 50B - None

  Zone 53 - None

  Zone 50A - None

Elevation 140 feet 0 inch

- Train A safe shutdown raceway in Zones 56B, 56C, 57N, and 57J
- 20 feet minimum horizontal distance between redundant trains located at elevations 120 feet and 140 feet. (Note: Nonrated hatch opening in floor between Zones 56C and 52D below.)
- Total combustible (fire) loading in separation path (Zone 56B, Zone 56C, Zone 52D) is moderate.
- Fire detection/suppression in separation path

  Zone 56B - Zonal fire detection and automatic wet pipe sprinkler system

  Zone 56C - Automatic wet pipe sprinkler system (including coverage above hatch)

  Zone 52D - Area suppression in northeast corner of Zone 52D, but none directly below hatch area.
- 2-hour and 3-hour rated barrier floor above Fire Area XVI (Zone 47A) and Fire Area XVII (Zone 47B). 3-hour rated barrier floor above Analysis Area XVD (zones 50B, 51A, 51B, 52D, 53, and 54) except for steel plate covered hatch and the 2-hour rated

walls of the duct chase west column AH at column A7.

Remainder of the floor area is reinforced concrete construction with all penetrations sealed to provide an equivalent 3-hour fire rating except for the steel plate covered hatch the unsealed sample piping chase opening into Zone 57C, and the HVAC shaft penetration in Zone 57J which has a 2-hour fire rating.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2, and upgrading the existing design to 1-hour rated walls, floors, and ceilings or installing area-wide detection and suppression would not significantly enhance the protection currently provided.

9. See subsection 9B.2.16 for a deviation common to Fire Area XVI, subsection 9B.2.17 for a deviation common to Fire Area XVII, and subsection 9B.2.0 for generic deviations.

9B.2.15.2 Analysis Area XVA

A. Location

Analysis Area XVA consists of Fire Zones 33A, 34A, 35A, 36, 37A, 37C, 39A, 87A, 88A, and 90

Fire Zone 33A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch and 51 feet 6 inches.

Fire Zones 34A, 35A, and 36 (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 70 feet 0 inch.

Fire Zones 37A and 37C (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 70 feet 0 inch and 88 feet 0 inch.

Fire Zone 39A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 88 feet 0 inch.

Fire Zone 87A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch)

Fire Zone 88A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 51 feet 6 inches.

Fire Zone 90 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch and 51 feet 6 inches.

B. Analysis Area Boundaries

<u>Elevations 40 feet 0 inch and 51 feet 6 inch</u>

North: Nonrated exterior wall of heavy concrete construction, north of fire zone 33A

3-hour rated wall common to Fire Area XIII, Zone 31A

North Corridor - 2-hour rated walls common to the west stairwell and access area at column line A6

Nonrated exterior wall of heavy concrete construction at column line A6

South Corridor - 3-hour rated wall common to Fire Area XIII, Zone 32A

South: Nonrated exterior wall of heavy concrete construction at column line A10

North Corridor - 3-hour rated wall common to Fire Area XIII, Zones 30A and 31A

South Corridor - Nonrated exterior wall of heavy concrete construction at column line A10

East: Nonrated exterior wall of heavy concrete construction, east of fire Zone 33A

Nonrated wall of heavy concrete construction common to Zone 89 at column line AF

Central Corridor - 3-hour rated wall common to Fire Area XIII, Zones 30A and 32A

North Corridor - 3-hour rated wall common to Zone 87B (north corridor) at column line AF

3-hour rated wall common to Zone 88B (north corridor) at column line AF

West: Nonrated exterior wall of heavy concrete construction, west of Fire Zone 33A

Nonrated exterior wall of heavy concrete construction at column line AC

2-hour rated wall common to the northwest stairwell at column line AC

3-hour rated wall common to Fire Area XIII, Zone 32A, at column line AE

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 35A, 37A, and 37B

3-hour rated barrier common to the south access shaft

Elevations 70 feet 0 inch and 88 feet 0 inch

North: 3-hour rated wall common to Fire Area XI

Nonrated exterior wall of heavy concrete construction at column line A1

3-hour rated wall common to the south access shaft

South: Nonrated exterior wall of heavy concrete construction at column line A10

3-hour rated wall common to Fire Area X at column line A10

East: Nonrated wall of heavy concrete construction common to the south access shaft at elevation 70 feet 0 inch

3-hour rated wall common to the south access shaft at elevation 88 feet 0 inch

3-hour rated wall common to Zone 37B at column line AE, elevation 70 feet 0 inch

Open to Zone 39B at column line AE

Nonrated wall of heavy concrete construction common to Zone 39B at column line AE between column lines A7 and A8

North Corridor - 1-hour rated wall common to Zone 37B at column line AE

South Corridor - Open corridor to Zone 37B at column line AE

West: Nonrated exterior wall of heavy concrete construction at column line AA4 and AA

2-hour rated wall common to the west elevator and stairwell and HVAC chase at column line AA

3-hour rated wall at column line AA

Floor: 3-hour rated barrier common to Fire Area XIII, Zones 30A and 32A

Ceiling: 1-hour rated barrier common to Fire Area XVI, Zone 42A

Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 42D and 43 (Ref 9B.2.15.1.B.8)

NOTE

Fire Zone 37A includes the two west electrical chases located at elevation 88 feet 0 inch. These chases are enclosed by 3-hour rated walls and ceilings, with floors open to the west corridors of elevation 70 feet 0 inch.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Chemical and volume control

  Essential cooling water

  Auxiliary building HVAC

  Nuclear cooling water

  Main steam

  Safety injection and shutdown cooling

- Train B cables associated with the following systems:

Chemical and volume control

Main steam

Nuclear sampling

- Nontrain related cables associated with the following systems:

  Chemical and volume Control

  Nuclear cooling water

  Nuclear sampling

- Train B reactor coolant pump seal bleedoff valve
- Nontrain related charging flowpath suction valves
- Train A, train B and nontrain related seal injection flowpath valves
- Train A essential chilled water valves
- Train A nuclear cooling to essential cooling crosstie valves
- Train A essential cooling water pump and associated components
- Train A essential cooling water pump room essential air control unit and associated components
- Train A steam generator 2 blowdown sample isolation valves

- Train B steam generator 1 blowdown sample isolation valves
- Train A safety injection and shutdown cooling instrumentation and isolation and control valves
- Train A shutdown cooling heat exchanger and associated components
- Train B nuclear sampling isolation valves
- Nontrain related nuclear sampling valves
- Train A high-pressure safety injection discharge valves
- Train A high-pressure safety injection long-term recirculation isolation valve
- Train B high-pressure safety injection discharge valves
- Train A containment sump isolation valve
- Train A refueling water tank to safety injection pump valve

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant systems available from the control room, in conjunction with operator action, both inside and outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.15.3 Analysis Area XVB

A. Location

Analysis Area XVB consists of Fire Zones 33B, 34B, 35B, 37B, 37D, 37E, 39B, 87B, 88B, and 89

Fire Zone 33B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch and 51 feet 6 inches.

Fire Zones 34B and 35B (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 70 feet 0 inch.

Fire Zones 37B, 37D, and 37E (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 70 feet 0 inch and 88 feet 0 inch.

Fire Zone 39B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 88 feet 0 inch.

Fire Zone 87B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch)

Fire Zone 88B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 51 feet 6 inches.

Fire Zone 89 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch and 51 feet 6 inches.

B. Analysis Area Boundaries

<u>Elevations 40 feet 0 inch and 51 feet 6 inch</u>

North: Nonrated exterior wall of heavy concrete construction, north of fire zone 33B

3-hour rated wall common to Fire Area XIV, Zone 31B

North Corridor - 2-hour rated wall common to the northeast stairwell and access area at column line A6

Nonrated exterior wall of heavy concrete construction at column line A6

South Corridor - 3-hour rated wall common to Fire Area XIV, Zone 32B

South: Nonrated exterior wall of heavy concrete construction at column line A10

North Corridor - 3-hour rated wall common to Fire Area XIV, Zones 30B and 31B

East: Nonrated exterior wall of heavy concrete construction, east of fire zone 33B

Nonrated exterior wall of heavy concrete construction at column line AJ

3-hour rated wall common to Fire Area XIV, Zone 32B, at column line AG

2-hour rated wall common to the northeast stairwell at column line AJ

West: Nonrated exterior wall of heavy concrete construction, west of fire zone 33B

Nonrated wall of heavy concrete construction common to Zone 90 at column line AF

Central Corridor - 3-hour rated wall common to Fire Area XIV, Zones 30B and 32B

North Corridor - 3-hour rated wall common to Zone 87A at column line AF

3-hour rated wall common to Zone 88A at column line AF

Floor: Nonrated basemat of heavy concrete construction

Ceiling: 3-hour rated barrier common to the south access shaft, between column lines AF and AG

Nonrated barrier of heavy concrete construction common to Zones 35B, 37B, and 37E

Elevations 70 feet 0 inch and 88 feet 0 inch

North: 3-hour rated wall common to Fire Area XI

3-hour rated wall common to Fire Area XII at column line A1

2-hour rated wall common to the east stairwell at column line A6.

3-hour rated wall common to the south access shaft

North Corridor - Nonrated walls of heavy concrete construction common to the south access shaft

South: 3-hour rated wall common to Fire Areas I and II at column line A10

2-hour rated wall common to the east stairwell

East: Nonrated exterior wall of heavy concrete construction at column line AL

2-hour rated wall common to the east stairwell

West: 3-hour rated wall common to Zone 35A at column line AE

1-hour rated wall common to zone 37A (north corridor) at column line AE

Open to Zone 37A (south corridor) at column line AE

Open to Zone 39A at column line AE

Nonrated wall of heavy concrete construction common to Zone 39A at column line AE, between column lines A7 and A8

Nonrated wall of heavy concrete construction common to the south access shaft at column line AG, elevation 70 feet 0 inch

3-hour rated wall common to the south access shaft at column line AG, elevation 88 feet 0 inch

Floor: Nonrated basemat of heavy concrete construction

3-hour rated barrier common to Fire Area XIII, Zone 31A

3-hour rated barrier common to Fire Area XIV, Zone 30B, 31B, and 32B

Ceiling: Barrier of heavy concrete construction with all electrical and pipe penetrations sealed to a 3-hour rating common to Zone 45 at elevation 100 feet 0 inch

1-hour rated barrier common to Fire Area XVII, Zone 42B

Barrier of heavy concrete construction with all electrical and pipe penetrations sealed to a 3-hour rating common to Zones 42C, 42D, 44, 45, 46A, 46B, and 46E (Ref. 9B.2.15.1.B.8)

NOTE

Fire Zone 37B includes the two east electrical chases located at elevation 88 feet 0 inch. These chases are enclosed by 3-hour rated walls and ceilings, with floors open to the east corridors of elevation 70 feet 0 inch.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Condensate storage and transfer

  Nuclear cooling water

  Main steam

- Train B cables associated with the following systems:

  Chemical and volume control

  Condensate storage and transfer

  Essential cooling water

  Auxiliary building HVAC

  Nuclear cooling water

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

- Nontrain related cables associated with the following system:

Nuclear cooling water

- Train B charging suction flowpath valves
- Train B seal injection valves
- Train B essential chilled water valves
- Train B essential cooling water pump and associated components
- Train B essential cooling to nuclear cooling water crosstie valves
- Train B essential cooling water pump room essential air control unit and associated components
- Train A and train B and nontrain related nuclear cooling water system isolation valves
- Train B safety injection and shutdown cooling instrumentation isolation and control valves
- Train B shutdown cooling heat exchanger and associated components
- Train B nuclear sampling isolation valves
- Train A high-pressure safety injection discharge isolation valves
- Train B high-pressure safety injection discharge isolation valves
- Train B containment sump valve

D. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant train A systems available from the control room, in conjunction with operator action, both inside and outside this analysis area, to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function.

This analysis area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.15.4 Analysis Area XVC

A. Location

Analysis Area XVC consists of Fire Zones 42D, 43, 44, 45, 48, 49A, 49B, 49C, 49D, 49E, 49F, 49G, 49H, 50A, 52A, 55A, 55C, 55E, 56A, 56B, 56C, 57A, 57B, 57C, 57D, 57E, 57F, 57G, 57H, 57J, 57K, 57L, 57M, 57N, and 57P.

Fire Zones 42D, 43, 44, and 45 (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 100 feet 0 inch.

Fire Zones 48, 49A, 49B, 49C, 49D, 49E, 49F, 49G, 49H, 50A, and 52A (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 120 feet 0 inch.

Fire Zones 55A, 55C, 55E, 56A, 56B, 56C, 57A, 57B, 57C, 57D, 57E, 57F, 57G, 57H, 57J, 57K, 57L, 57M,

57N, and 57P (engineering drawing 13-A-ZYD-023) are located in the auxiliary building at elevation 140 feet 0 inch.

B. Analysis Area Boundaries

Elevation 100 feet 0 inch

North: 2-hour rated wall common to Fire Area XVI, Zone 42A, at column lines A3 and A6

Nonrated walls of heavy concrete construction common to the south access shaft

South: 3-hour rated wall common to Fire Area X at column line A10

3-hour rated wall common to Fire Area I at column line A10

East: Nonrated walls of heavy concrete construction common to the south access shaft

2-hour rated wall common to Fire Area XVI, Zone 42A, at column line AB

Nonrated wall of heavy concrete construction common to Zone 46E at column line AG

1-hour rated wall common to Zone 42C at column line AG

West: 2-hour rated wall common to the west stairwell, HVAC chase, and elevator at column line AA

3-hour rated wall common to Fire Area VI at column line AA

Nonrated exterior wall of heavy concrete construction at column line AA

Floor: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 37C, 37E, 39A, and 39B (Ref. 9B.2.15.1.B.8)

3-hour rated barriers common to the Zone 37A electrical chases

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 51A and 52D

Elevation 120 feet 0 inch

North: Nonrated wall of heavy concrete construction common to the south access shaft

2-hour rated walls common to Fire Area XVI, Zone 47A, at column lines A3 and A6

Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 52D at column line A7 (Ref. 9B.2.15.1.B.8)

Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 51A at column line A8 (Ref. 9B.2.15.1.B.8)

South: 3-hour rated wall common to Fire Area X at column line A10

3-hour rated wall common to Fire Area X, a pipe chase, at column line A9

East: 1-hour rated wall common to Zone 52D at column line AE

2-hour rated wall common to Fire Area XVI, Zone 47A, at column line AB

Nonrated wall of heavy concrete construction common to the south access shaft

3-hour rated wall common to Zone 51B at column line AG

3-hour rated wall common to Fire Area X, a pipe chase

West: 2-hour rated wall common to the west elevator, stairwell, and HVAC chase at column line AA

Nonrated exterior wall of heavy concrete construction at column line AA

3-hour rated wall common to Fire Area VI at column line AA

3-hour rated wall common to Fire Area X, a pipe chase, at column line AE

Floor: An open pipe chase, which extends down to Zone 39B, is located in the southeast corner

Elevation 140 feet 0 inch

North: 3-hour rated exterior wall at column line A1

3-hour rated wall common to Fire Area XI

Nonrated walls of heavy concrete construction common to the south access shaft

3-hour rated wall common to Fire Area XII

South: 3-hour rated wall common to Fire Areas I and II at column line A10

3-hour rated wall common to Fire Area X at column line A10

East: Nonrated wall of heavy concrete construction common to the south access shaft

3-hour rated exterior wall at column line AL

3-hour rated wall common to the corridor building at column line AL

2-hour rated walls common to the east stairwell

West: 3-hour rated wall common to Fire Area VI at column line AA

2-hour rated wall common to the west elevator

2-hour rated wall common to the west stairwell at column line AA

2-hour rated wall common to the west HVAC chase at column line AA

Nonrated exterior wall of heavy concrete construction at column line AA

Nonrated wall of heavy concrete construction common to the south access shaft at column line AG

Floor: 2-hour rated barrier common to Fire Area XVI, Zone 47A

3-hour rated barrier common to Fire Area XVII, Zone 47B

Nonrated barrier of heavy concrete construction common to Zones 50B, 51A, 51B, 52D, 53, and 54

Ceiling: Nonrated roof of heavy concrete construction

NOTE

The HVAC chase near column lines A7 and AH is surrounded by 2-hour rated walls.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Miscellaneous HVAC

  Nuclear cooling water

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

  Electrical power distribution

  Engineered safety feature actuation

- Train B cables associated with the following systems:

  Chemical and volume control

  Essential cooling water

  Engineered safety feature actuation

- Nontrain related cables associated with the following system:

  Chemical and volume control

  Nuclear cooling water

  Reactor coolant

  Nuclear sampling

- Nontrain related seal injection heat exchanger and associated components

- Nontrain related charging to seal injection control valve

- Train A essential cooling water surge tank and associated level control components

- Train B essential cooling water surge tank and associated level control components

- Train A essential cooling water system heat exchanger and associated components

- Train B essential cooling water system heat exchanger and associated components

- Nontrain related nuclear sampling hotleg sample cooler and associated components

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train B system

will remain available from the control room, in conjunction with operator action, both inside and outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.15.5 Analysis Area XVD

A. Location

Analysis Area XVD consists of Fire Zones 42C, 50B, 51A, 51B, 52D, 53, and 54.

Fire Zone 42C (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

Fire Zones 50B, 51A, 51B, 52D, 53, and 54 (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Analysis Area Boundaries

Elevation 100 feet 0 inch

North:	North Corridor	-	2-hour rated wall common to Fire Area XVII, Zone 42B, at column line A6 3-hour rated wall common to Fire Area XII
	South Corridor	-	Wall of heavy concrete construction with penetrations

			sealed to a 3-hour rating common to Zones 46A, 46B, and 46E at column line A9 (Ref. 9B.2.15.1.B.2)
South:	North Corridor	-	Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 46A, 46B, and 46E at column line A7 (Ref. 9B.2.15.1.B.2)
	South Corridor	-	3-hour rated wall common to Fire Areas I and II at column line A10
East:	3-hour rated exterior wall at column line AL		
	3-hour rated wall common to the corridor building at column line AL		
	2-hour rated walls common to the east stairwell		
West:	North Corridor	-	1-hour rated wall common to Zone 42D at column line AG 3-hour rated wall common to the south access shaft at column line AG
	South Corridor	-	1-hour rated wall common to Zone 42D at column line AG

East Corridor - 2-hour rated wall common to Zone 42B

Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 37D and 39B (Ref. 9B.2.15.1.B.8)

3-hour rated barriers common to the Zone 37B electrical chases

Elevation 120 feet 0 inch

North: 2-hour rated wall common to Fire Area XVII, Zone 47B, at column line A6

3-hour rated walls common to the south access shaft

3-hour rated wall common to Fire Area XII

South: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 49F and 50A, and the central staircase (Ref. 9B.2.15.1.B.8)

3-hour rated wall common to Fire Areas I and II at column line A10

East: 3-hour rated exterior wall at column line AL

3-hour rated wall common to the corridor building at column line AL

2-hour rated walls common to the east stairwell

West: 1-hour rated wall common to Zone 52A at column line AE

2-hour rated wall common to Fire Area XVII, Zone 47B

3-hour rated wall common to Zones 49G and 50A at column line AG

3-hour rated wall common to the central stairwell at column line AF

Floor: Nonrated barrier of heavy concrete construction common to Zones 42D, 45, 46A, 46B, and 46E

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 56C, 57J, 57K, and 57N (Ref. 9B.2.15.1.B.8)

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

Auxiliary building HVAC

Main steam

Safety injection and shutdown cooling

Engineered safety feature actuation

- Train B cables associated with the following systems:

Auxiliary feedwater

Chemical and volume control

Condensate storage and transfer

Essential chilled water

Essential cooling water

Auxiliary building HVAC

Nuclear cooling water

Reactor coolant

Ex-core neutron monitoring

Main steam

Safety injection and shutdown cooling

Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

Chemical and volume control

Nuclear cooling water

Reactor coolant

Nuclear sampling

- Train A and train B charging pumps 2 and 3 controls
- Volume control tank to charging system isolation valves

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, inside and outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.15.6 Analysis Area XVE

A. Location

Analysis Area XVE consists of Fire Zone 46A

Fire Zone 46A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.2)

South: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9B.2.15.1.B.2)

East: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C (Ref. 9B.2.15.1.B.2)

West: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46B (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 54 (Ref. 9B.2.15.1.B.8)

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following system:

  Chemical and volume control

- Train A charging pump and associated components

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions, in conjunction with operator action, to prevent or overcome the consequences of spurious operation of components, has been demonstrated to remain available due to fire barriers provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.15.7 Analysis Area XVF

A. Location

Analysis Area XVF consists of Fire Zone 46B

Fire Zone 46B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.)

South: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9B.2.15.1.B.2)

East: Wall of heavy concrete construction with electrical and pipe penetrations sealed to

a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.2)

West: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46E at column line AH (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 53 and 54 (Ref. 9B.2.15.1.B.8)

C. Safe Shutdown Related Components and Cables

- Train A, train B, and nontrain related cables associated with the following system:

  Chemical and volume control

- Train B charging pump and associated components

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions, in conjunction with operator action, to prevent or overcome the consequences of spurious operation of components, has been demonstrated to remain available due to fire barriers provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.15.8 Analysis Area XVG

A. Location

Analysis Area XVG consists of Fire Zone 46E

Fire Zone 46E (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Analysis Area Boundaries

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.2)

South: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9B.2.15.1.B.2)

East: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46B at column line AH (Ref. 9B.2.15.1.B.2)

West: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 45 at column line AG (Ref. 9B.2.15.1.B.8)

Floor: Barrier of heavy concrete construction with electrical and piping penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 50B and 51B (Ref. 9B.2.15.1.B.8)

C. Safe Shutdown Related Components and Cables

- Train A and nontrain related cables associated with the following system:

  Chemical and volume control

- Charging pump number 3 and associated components

- Train B conduit

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown conditions has been demonstrated to remain available due to fire barriers provided. This area meets the requirements of 10CFR50, Appendix R, Section III.G.

9B.2.15.9 Fire Area XV, Fire Zone 33A, Train A Pipe Chase

A. Location

Fire Zone 33A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction

South: Open to Zone 87A at elevation 40 feet 0 inch. 2-hour rated wall common to the north stairwell at elevation 51 feet 6 inches

East: Nonrated exterior wall of heavy concrete construction

West: Nonrated exterior wall of heavy concrete construction

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to Zone 37C at elevation 70 feet 0 inch plane

2. Zone Access

- Open to Zone 87A at elevation 40 feet 0 inch
- Open to Zone 37C at elevation 70 feet 0 inch plane

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

None

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 87A.

2. Secondary

Two portable ABC powder fire extinguishers are located in adjacent Zone 87A.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.10 Fire Area XV, Fire Zone 33B, Train B Pipe Chase

A. Location

Fire Zone 33B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers North:

North: Nonrated exterior wall of heavy concrete construction

South: Open to Zone 87B at elevation 40 feet 0 inch. 2-hour rated wall common to the north stairwell at elevation 51 feet 6 inches

East: Nonrated exterior wall of heavy concrete construction

West: Nonrated exterior wall of heavy concrete construction

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to Zone 37D at elevation 70 feet 0 inch plane

2. Zone Access

- Open to Zone 87B at elevation 40 feet 0 inch
- Open to Zone 37D at elevation 70 feet 0 inch plane

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

None

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 87B.

2. Secondary

Two portable ABC powder fire extinguishers are located in adjacent Zone 87B.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.11 Fire Area XV, Fire Zone 87A, West Corridors

A. Location

Fire Zone 87A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	-	Open to Zone 33A at column line A6 Nonrated exterior wall of heavy concrete construction at column line A6
	South Corridor	-	3-hour rated wall common to Fire Area XIII, Zone 32A
South:	North Corridor	-	3-hour rated wall common to Fire Area XIII, Zones 30A and 31A
	South Corridor	-	Nonrated exterior wall of heavy concrete construction at column line A10
East:	Central Corridor	-	3-hour rated wall common to Fire Area XIII, Zones 30A and 32A

North Corridor	-	3-hour rated wall common to Zone 87B (north corridor) at column line AF
South Corridor	-	Nonrated wall of heavy concrete construction common to Zone 90 at column line AE

West: Nonrated exterior wall of heavy concrete construction at column line AC

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 88A

2. Zone Access

- Stairwell through the nonrated north corridor ceiling to Zone 88A
- Stairwell through the nonrated south corridor ceiling to Zone 88A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - ESF A sump and pumps
   - Auxiliary steam condensate receiver tank radiation monitor
   - Conduit

E. Radioactive Material

   In process piping

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Polycarbonate Battery Cases
      - Cable Insulation

   2. Transient Combustible Load Type

      Ordinary combustible

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

Two manual hose reels

2. Secondary

Two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Five 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.12 Fire Area XV, Fire Zone 87B, East Corridors

A. Location

Fire Zone 87B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 40 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	-	Open to Zone 33B at column line A6 Nonrated exterior wall of heavy concrete construction at column line A6
	South Corridor	-	3-hour rated wall common to Fire Area XIV, Zone 32B
South:	North Corridor	-	3-hour rated wall common to Fire Area XIV, Zones 30B and 31B
	South Corridor	-	Nonrated exterior wall of heavy concrete construction at column line A10
East:	Nonrated exterior wall of heavy concrete construction at column line AJ		
West:	Central Corridor	-	3-hour rated wall common to Fire Area XIV, Zones 30B and 32B

South Corridor	-	Nonrated wall of heavy concrete construction common to Zone 89 at column line AG
North Corridor	-	3-hour rated wall common to Zone 87A (north corridor) at column line AF

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 88B

2. Zone Access

- Stairwell through the north corridor ceiling to Zone 88B
- Stairwell through the south corridor ceiling to Zone 88B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - ESF B sump and pump
   - Conduit

E. Radioactive Material

   In process piping

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Polycarbonate Battery Cases
      - Cable Insulation

   2. Transient Combustible Load Type

      Ordinary combustible

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   None

H. Fire Suppression

   1. Primary

      Two manual hose reels

2. Secondary

Two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Five 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.13 Fire Area XV, Fire Zone 89, Cooling Water Holdup Tank Room

A. Location

Fire Zone 89 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XIV, Zone 31B

South: Nonrated exterior wall of heavy concrete construction at column line A10

East: 3-hour rated wall common to Fire Area XIV, Zone 32B, at column line AG

Nonrated wall of heavy concrete construction at column line AG common to:

- Zone 87B at elevation 40 feet 0 inch
- Zone 88B at elevation 51 feet 6 inches

West: Nonrated wall of heavy concrete construction common to Zone 90 at column line AF

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 37B and 37E

2. Zone Access

- Open doorway in the nonrated east wall to Zone 87B at elevation 40 feet 0 inch
- Open doorway in the nonrated east wall to Zone 88B elevation 51 feet 6 inches

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Cooling water holdup tank
   - Cooling water holdup tank pumps
   - Chemical drain tank pumps
   - Chemical drain tanks
   - Non-ESF sump and pumps
   - Conduit

E. Radioactive Material

   In process piping

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil and grease
      - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 87B. One manual hose reel is located in adjacent Zone 88B.

2. Secondary

   One portable ABC powder fire extinguisher is located in adjacent Zone 87B. One portable ABC powder fire extinguisher is located in adjacent Zone 88B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.14 Fire Area XV, Fire Zone 90, Equipment Drain Tank Room

A. Location

Fire Zone 90 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 40 feet 0 inch and 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XIII, Zone 31A

South: Nonrated exterior wall of heavy concrete construction at column line A10

East: Nonrated wall of heavy concrete construction common to Zone 89 at column line AF

West: Nonrated wall of heavy concrete construction at column line AE common to:

- Zone 87A at elevation 40 feet 0 inch
- Zone 88A at elevation 51 feet 6 inches

3-hour rated wall common to Fire Area XIII, Zone 32A, at column line AE

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 37B

2. Zone Access

- Open doorway in the nonrated west wall to Zone 87A at elevation 40 feet 0 inch
- Open doorway in the nonrated west wall to Zone 88A at elevation 51 feet 6 inches

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Equipment drain tank

- Auxiliary steam condensate receiver tank radiation monitor pump
- Auxiliary steam condensate receiver tank
- Auxiliary steam condensate pumps
- Vent condenser
- Conduit
- Reactor drain tank pumps

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type
   - Oil and grease
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil and grease
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 87A. One manual hose reel is located in adjacent Zone 88A.

2. Secondary

One portable ABC powder fire extinguisher is located in adjacent Zone 87A. One portable ABC powder fire extinguisher is located in adjacent Zone 88A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Four 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.15 Fire Area XV, Fire Zone 88A, West Corridors

A. Location

Fire Zone 88A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	- 2-hour rated walls common to the west stairwell and access area
		Nonrated exterior wall of heavy concrete construction at column line A6
	South Corridor	- 3-hour rated wall common to Fire Area XIII, Zone 32A
South:	North Corridor	- 3-hour rated wall common to Fire Area XIII, Zones 30A and 31A
	South Corridor	- Nonrated exterior wall of heavy concrete construction at column line A10
East:	North Corridor	- 3-hour rated wall common to Zone 88B (north corridor) at column line AF
	South Corridor	- Nonrated wall of heavy concrete construction common to Zone 90 at column line AE

Central Corridor - 3-hour rated wall common to Fire Area XIII, Zones 30A and 32A

West: Nonrated exterior wall of heavy concrete construction at column line AC

2-hour rated wall common to the northwest stairwell

Floor: Nonrated barrier of heavy concrete construction common to Zone 87A

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 35A, 37A, and 37B

3-hour rated barrier common to the south access shaft

2. Zone Access

- One Class B door in the 2-hour rated east wall of the northwest stairwell
- One Class A door in the 3-hour rated north corridor east wall to Zone 88B
- Stairwell through the nonrated south corridor floor to Zone 87A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Lubricating oil
      - Cable insulation

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Two manual hose reels

2. Secondary

   Two portable ABC powder fire extinguishers

I. Ventilation

   Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

   Five 4-inch drains

K. Emergency Communications

   Sound powered phone jack(s) is provided (not in service).

9B.2.15.16 Fire Area XV, Fire Zone 88B, East Corridors

A. Location

   Fire Zone 88B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 51 feet 6 inches.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	-	2-hour rated wall common to the northeast stairwell and access area Nonrated exterior wall of heavy concrete construction at column line A6
	South Corridor	-	3-hour rated wall common to Fire Area XIV, Zone 32B
South:	South Corridor	-	Nonrated exterior wall of heavy concrete construction at column line A10
	North Corridor	-	3-hour rated wall common to Fire Area XIV, Zones 30B and 31B
East:	Nonrated exterior wall of heavy concrete construction at column line AJ 2-hour rated wall common to the north-east stairwell		
West:	Central Corridor	-	3-hour rated wall common to Fire Area XIV, Zones 30B and 32B

South Corridor	-	Nonrated wall of heavy concrete construction common to Zone 89 at column line AG
North Corridor	-	3-hour rated wall common to Zone 88A at column line AF

Floor: Nonrated barrier of heavy concrete construction common to Zone 87B

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 35B and 37B

3-hour rated barrier common to the south access shaft, between column lines AF and AG

2. Zone Access

- One Class B door in the 2-hour rated west wall of the northeast stairwell
- One Class A door in the 3-hour rated north corridor west wall to Zone 88A
- Stairwell through the nonrated south corridor floor to Zone 87B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Lubricating oil

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Two manual hose reels

2. Secondary

   Two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Five 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.17 Fire Area XV, Fire Zone 34A, Train A Essential Cooling Water System Pump Room

A. Location

Fire Zone 34A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 70 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37A

South: Nonrated wall of heavy concrete construction common to Zone 36 at column line A8

East: Nonrated wall of heavy concrete construction common to Zone 35A at column line AC

Nonrated wall of heavy concrete construction common to a pipe chase at column line AC

West: Nonrated wall of heavy concrete construction common to Zone 37A at column line AB

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39A

2. Zone Access

One nonrated door (pair) in the nonrated west wall to Zone 37A

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Essential cooling water system chemical addition tank
- Essential cooling water system radiation monitor
- Conduit
- Monorail

E. Radioactive Material

   In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type
   - Cable insulation
   - Oil and grease
2. Transient Combustible Load Type
   - Ordinary combustible

- Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning

H. Fire Suppression

1. Primary

   Two manual hose reels are located in adjacent Zone 37A.

2. Secondary

   Two portable ABC powder fire extinguishers are located in adjacent Zone 37A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.18 Fire Area XV, Fire Zone 34B, Train B Essential Cooling Water System Pump Room

A. Location

Fire Zone 34B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 70 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37B at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 37B at column line A9

East: Nonrated wall of heavy concrete construction common to Zone 37B at column line AK

West: Nonrated wall of heavy concrete construction common to Zone 35B at column line AJ

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39B

2. Zone Access

   One nonrated door (pair) in the nonrated east wall to Zone 37B

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Essential cooling water system chemical addition tank
   - Essential cooling water system radiation monitor
   - Conduit
   - Monorail

E. Radioactive Material

   In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

 - Cable insulation
 - Oil and grease

2. Transient Combustible Load Type

 - Ordinary combustible
 - Grease and oil

3. Total Combustible (Fire) Loading

 Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning

H. Fire Suppression

1. Primary

 Two manual hose reels are located in adjacent Zone 37B.

2. Secondary

 Two portable ABC powder fire extinguishers are located in adjacent Zone 37B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.19 Fire Area XV, Fire Zone 35A, Train A Shutdown Cooling Heat Exchanger and Valve Gallery Rooms

A. Location

Fire Zone 35A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 70 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37A at column line A7

Nonrated wall of heavy concrete construction common to a pipe chase at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 37A at column line A9

East: 3-hour rated wall common to Zone 37B at column line AE

West: Nonrated wall of heavy concrete construction common to Zones 34A and 36 at column line AC

Floor: Nonrated barrier of heavy concrete construction common to Zone 88A

3-hour rated barrier common to Fire Area XIII, Zones 30A and 32A

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39A

2. Zone Access

Open doorway in the nonrated north wall to Zone 37A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

Train A isolation valve to shutdown cooling heat exchanger

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Polycarbonate battery casing

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 37A. One manual hose reel is located in adjacent Zone 37B.

2. Secondary

One portable ABC powder fire extinguisher is located in adjacent Zone 37A. One portable ABC powder fire extinguisher is located in adjacent Zone 37B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.20 Fire Area XV, Fire Zone 35B, Train B Shutdown Cooling Heat Exchanger and Valve Gallery Rooms

A. Location

Fire Zone 35B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 70 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37B at column line A7

Nonrated wall of heavy concrete construction common to a pipe chase at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 37B at column line A9

East: Nonrated wall of heavy concrete construction common to Zone 34B at column line AJ

West: Nonrated wall of heavy concrete construction common to Zone 37B at column line AG

Nonrated wall of heavy concrete construction common to Zone 37E at column line AG

Floor: Nonrated barrier of heavy concrete construction common to Zone 88B

3-hour rated barrier common to Fire Area XIV, Zones 30B and 32B

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39B

2. Zone Access

Open doorway in the nonrated north wall to Zone 37B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   Train B isolation valve to shutdown cooling heat exchanger

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Polycarbonate Battery Cases
   - Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning

H. Fire Suppression

1. Primary

Two manual hose reels are located in adjacent Zone 37B.

2. Secondary

Three portable ABC powder fire extinguishers are located in adjacent Zone 37B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.21 Fire Area XV, Fire Zone 36, Reactor Makeup Water and Boric Acid Makeup Pump Room

A. Location

Fire Zone 36 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 70 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 34A at column line A8

South: Nonrated wall of heavy concrete construction common to Zone 37A at column line A9

East: Nonrated wall of heavy concrete construction common to Zone 35A at column line AC

West: Nonrated wall of heavy concrete construction common to Zone 37A at column line AB

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39A

2. Zone Access

Open doorway in the nonrated south wall to Zone 37A

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Reactor makeup water pumps
   - Boric acid makeup pumps
   - Conduit

E. Radioactive Material

   In process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      Oil and grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

Ionization smoke detector(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 37A.

2. Secondary

Two portable ABC powder fire extinguishers are located in adjacent Zone 37A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.22 Fire Area XV, Fire Zone 37A, West Corridors and Electrical Chases

A. Location

Fire Zone 37A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 70 feet 0 inch and 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

NOTE

Fire Zone 37A includes the two west electrical chases located at elevation 88 feet 0 inch. These chases are enclosed by 3-hour rated walls and ceilings, with floors open to the west corridors of elevation 70 feet 0 inch. The following description applies to the Zone 37A west corridors.

North:	North Corridor	-	Nonrated walls of heavy concrete construction common to Zone 37C at column line A6
			2-hour rated walls common to the north stairwell
	South Corridor	-	Nonrated wall of heavy concrete construction common to Zones 35A and 36 at column line A9
South:	North Corridor	-	Nonrated wall of heavy concrete construction common to Zone 35A at column line A7
			Nonrated wall of heavy concrete construction common to Zone 34A

			Nonrated walls of heavy concrete construction common to a pipe chase
	South Corridor	-	Nonrated exterior wall of heavy concrete construction at column line A10
			3-hour rated wall common to Fire Area X at column line A10
East:	North Corridor	-	1-hour rated wall common to Zone 37B at column line AE
	South Corridor	-	Open corridor to Zone 37B at column line AE
	West Corridor	-	Nonrated wall of heavy concrete construction common to Zones 34A and 36 at column line AB
West:	Nonrated exterior wall of heavy concrete construction at column line AA		
	2-hour rated wall common to the west HVAC chase at column line AA		
Floor:	Nonrated basemat of heavy concrete construction		

Nonrated barrier of heavy concrete construction common to Zone 88A

3-hour rated barrier common to Fire Area XIII, Zone 30A

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39A

2. Zone Access

- One Class C door in the 1-hour rated north corridor east wall to Zone 37B
- Open stairwell through the nonrated north corridor north wall to Zone 37C
- Open south corridor to Zone 37B at column line AE.

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Chloride analyzer
- Monorail
- Cable trays and conduit

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Two manual hose reels

2. Secondary

Two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Seven 4-inch drains

K. Emergency Communications

None

9B.2.15.23 Fire Area XV, Fire Zone 37B, East Corridors and Electrical Chases

A. Location

Fire Zone 37B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 70 feet 0 inch and 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

NOTE

Fire Zone 37B includes the two east electrical chases located at elevation 88 feet 0 inch. These chases are enclosed by 3-hour rated walls and ceilings, with floors open to the east corridors of elevation 70 feet 0 inch. The following description applies to the Zone 37B east corridors.

North:	North Corridor	-	Nonrated walls of heavy concrete construction common to the south access shaft
			2-hour rated walls common to the north stairwell
			Nonrated walls of heavy concrete construction common to Zone 37D at column line A6
			2-hour rated wall common to the east stairwell at column line A6
	South Corridor	-	Nonrated wall of heavy concrete construction common to Zones 34B and 35B at column line A9
South:	North Corridor	-	Nonrated wall of heavy concrete construction common to Zone 37E
			Nonrated walls of heavy concrete construction common to a pipe chase
			Nonrated wall of heavy concrete construction common to Zones 34B and 35B at column line A7

	South Corridor	-	3-hour rated wall common to Fire Areas I and II at column line A10
East:	East Corridor	-	Nonrated exterior wall of heavy concrete construction at column line AL
	Central Corridor	-	Nonrated walls of heavy concrete construction common to Zone 37E
			Nonrated wall of heavy concrete construction common to Zone 35B at column line AG
West:	East Corridor	-	Nonrated wall of heavy concrete construction common to Zone 34B at column line AK
	Central Corridor	-	3-hour rated wall common to Zone 35A at column line AE
			1-hour rated wall common to zone 37A (north corridor) at column line AE

Open to Zone 37A (south corridor) at column line AE

Floor: Nonrated basemat of heavy concrete construction

3-hour rated barrier common to Fire Area XIII, Zone 31A

Nonrated barrier of heavy concrete construction common to Zones 88B, 89, and 90

3-hour rated barrier common to Fire Area XIV, Zone 30B

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 39B

2. Zone Access

- One Class C door in the 1-hour rated central corridor west wall to Zone 37A
- Open to Zone 37A (south corridor)
- One Class B door in the 2-hour north wall to the east stairwell

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Gas stripper instrument rack
   - Gas stripper control cabinet
   - Cable trays and conduit
   - Monorail

E. Radioactive Material

   In process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Thermo-Lag 330-1
      - Cable insulation
      - Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Three manual hose reels

2. Secondary

   Three portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Ten 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.24 Fire Area XV, Fire Zone 37C, Train A Piping Penetration Room

A. Location

Fire Zone 37C (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 70 feet 0 inch and 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

Nonrated exterior wall of heavy concrete construction at column line A1

South: Nonrated wall of heavy concrete construction at column line A6 common to:

- Zone 37A at elevation 70 feet 0 inch
- Zone 39A at elevation 88 feet 0 inch

2-hour rated wall common to the north corridor north stairwell at column line A6 and elevation 70 feet 0 inch

3-hour rated wall common to the Zone 37A electrical chase at elevation 88 feet 0 inch

East: Nonrated wall of heavy concrete construction common to the south access shaft

West: Nonrated exterior wall of heavy concrete construction at column line AA4 and AA

2-hour rated wall common to the west elevator and stairwell and HVAC chase at column line AA

Floor: Nonrated basemat of heavy concrete construction

Open to Zone 33A

Ceiling: 1-hour rated barrier common to Fire Area XVI, Zone 42A

Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42D (Ref. 9B.2.15.1.B.8)

2. Zone Access

One Class B door in the 2-hour rated east wall of the Northwest Stairwell.

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetration in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Structural steel supporting the fire barrier has been provided with coating of 1-hour rating. (Refer to the appendix 9A response to 9A.107.)

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A containment hydrogen control valves

D. Nonsafety-Related Equipment and Components

- Boronometer (abandoned in-place)
- Liquid nitrogen storage container and refill manifold
- Conduit
- Sampling equipment

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

   - Rubber

- Plastic
- Cable insulation
- Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 37A.

2. Secondary

   One portable ABC powder fire extinguisher is located in adjacent Zone 37A.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.25 Fire Area XV, Fire Zone 37D, Train B Piping Penetration Room

A. Location

Fire Zone 37D (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 70 feet 0 inch and 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

3-hour rated wall common to Fire Area XII

South: 2-hour rated wall common to the north stairwell at elevation 70 feet 0 inch and at column line A6

Nonrated walls of heavy concrete construction common to Zone 37B at elevation 70 feet 0 inch and at column line A6

3-hour rated wall common to the Zone 37B electrical chase at elevation 88 feet 0 inch and at column line A6

Nonrated wall of heavy concrete construction common to Zone 39B at elevation 88 feet 0 inch and at column line A6

2-hour rated wall common to the east stairwell

East: Nonrated exterior wall of heavy concrete construction at column line AL

2-hour rated wall common to the east stairwell.

West: Nonrated wall of heavy concrete construction common to the south access shaft at column line AG

Floor: Open to Zone 33B

Nonrated basemat of heavy concrete construction

Ceiling: 1-hour rated barrier common to Fire Area XVII, Zone 42B

Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C (Ref. 9B.2.15.1.B.8)

2. Zone Access

   One Class B door in the 2-hour rated west wall of the east stairwell at elevation 70 feet 0 inch

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   Structural steel supporting the fire barrier has been provided with coating of 1-hour rating. (Refer to the appendix 9A response to Question 9A.107.)

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B containment hydrogen control isolation valves
- Train A containment isolation valve
- Train B containment isolation valve

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

- Thermo-Lag 330-1
- Plastic
- Rubber
- Cable insulation
- Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 37B.

2. Secondary

One portable ABC powder fire extinguisher is located in adjacent Zone 37B.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.26 Fire Area XV, Fire Zone 37E, Gas Stripper Room

A. Location

Fire Zone 37E (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevations 70 feet 0 inch and 88 feet 0 inch

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37B at elevation 70 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 39B at elevation 88 feet 0 inch and at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 37B at elevation 70 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 39B at elevation 88 feet 0 inch and at column line A8

East: Nonrated wall of heavy concrete construction common to Zones 35B and 37B at elevation 70 feet 0 inch and at column line AG

Nonrated wall of heavy concrete construction common to Zone 39B at elevation 88 feet 0 feet and at column line AG

West: Nonrated wall of heavy concrete construction common to Zone 37B and a pipe chase at elevation 70 feet 0 inch

Nonrated wall of heavy concrete construction common to Zone 39B at elevation 88 feet 0 inch and at column line AF

Floor: 3-hour rated barrier common to Fire Area XIII, Zone 31A

3-hour rated barrier common to Fire Area XIV, Zone 31B

Nonrated barrier of heavy concrete construction common to Zone 89

Ceiling: Barriers of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 39B at elevation 88 feet 0 inch and Zone 45 at elevation 100 feet 0 inch (Ref. 9B.2.15.1.B.8)

2. Zone Access

One nonrated gate in the nonrated west wall to Zone 37B

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Gas stripper

- Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

    - Cable insulation
    - Oil and grease

2. Transient Combustible Load Type

    - Ordinary combustible
    - Oil and grease

3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

    One manual hose reel is located in adjacent Zone 37B.

2. Secondary

    One portable ABC powder fire extinguisher is located in adjacent Zone 37B.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.27 Fire Area XV, Fire Zone 39A, Train A Pipeway

A. Location

Fire Zone 39A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37C at column line A6

3-hour rated walls common to the Zone 37A electrical chase

3-hour rated wall common to the south access shaft

South: Nonrated exterior wall of heavy concrete construction at column line A10

3-hour rated wall common to Fire Area X at column line A10

East: Open to Zone 39B at column line AE

Nonrated wall of heavy concrete construction common to Zone 39B at column line AE between column lines A7 and A8

West: Nonrated exterior wall of heavy concrete construction at column line AA

2-hour rated wall common to the west stairwell and HVAC chase

3-hour rated walls common to the Zone 37A west electrical chase

Floor Nonrated barrier of heavy concrete construction common to Zones 34A, 35A, 36, and 37A

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 42D and 43 (Ref. 9B.2.15.B.1.8)

2. Zone Access

- Open to Zone 39B at column line AE
- Non-rated stairwell through the south corridor ceiling to Zone 42D

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel in Zone 39A and one located in adjacent Zone 39B

2. Secondary

One portable ABC powder fire extinguisher

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Eleven 4-inch drains

K. Emergency Communications

None

9B.2.15.28 Fire Area XV, Fire Zone 39B, Train B Pipeway

A. Location

Fire Zone 39B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 88 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 37D at column line A6

3-hour rated walls common to the Zone 37B electrical chases

2-hour rated wall common to the east stairwell at column line A6.

3-hour rated wall common to the south

South: 3-hour rated wall common to Fire Areas I and II at column line A10

East: Nonrated exterior wall of heavy concrete construction at column line AL

West: Open to Zone 39A at column line AE

Nonrated wall of heavy concrete construction common to Zone 39A at column line AE, between column lines A7 and A8

Floor: Nonrated barrier of heavy concrete construction common to Zones 34B, 35B, 37B, and 37E

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to

Zones 42D, 44, and 45
(Ref. 9B.2.15.1.B.8)

Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.8)

Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 42C, 46B, and 46E
(Ref. 9B.2.15.1.B.8)

2. Zone Access

- Open to Zone 39A at column line AE
- Open stairwell leading up to Zone 42C

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process piping

F. Combustible Loading

1. In Situ Combustible Load Type

    - Thermo-Lag 330-1
    - Cable Insulation

2. Transient Combustible Load Type

    Ordinary combustible

3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

    Two manual hose reels

2. Secondary

    Two portable ABC powder fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Thirteen 4-inch drains

K. Emergency Communications

None

9B.2.15.29 Fire Area XV, Fire Zone 42C, East Corridors

A. Location

Fire Zone 42C (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	-	2-hour rated wall common to Fire Area XVII, Zone 42B, at column line A6
			3-hour rated wall common to Fire Area XII

	South Corridor	-	Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 46A, 46B and 46E at column line A9 (Ref. 9B.2.15.1.B.2)
South:	North Corridor	-	Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour ratings common to Zones 46A, 46B and 46E at column line A7 (Ref. 9B.2.15.1.B.2)
	South Corridor	-	3-hour rated wall common to Fire Areas I and II at column line A10
East:	3-hour rated exterior wall at column line AL		
	3-hour rated wall common to the corridor building at column line AL		
	2-hour rated walls common to the east stairwell		
West:	North Corridor	-	1-hour rated wall common to Zone 42D at column line AG

		3-hour rated wall common to the south access shaft at column line AG
South Corridor	-	1-hour rated wall common to Zone 42D at column line AG
East Corridor	-	2-hour rated wall common to Zone 42B
		Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 37D and 39B (Ref. 9B.2.15.1.B.8)

3-hour rated barriers common to the Zone 37B electrical chases

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 51B, 52D, 53, and 54

2. Zone Access

- One Class C door (pair) in the 1-hour rated north corridor west wall to Zone 42D

- One Class C door (pair) in the 1-hour rated south corridor west wall to Zone 42D
- One Class A rollup door in the 3-hour rated east exterior wall
- One Class B door in the 2-hour rated east wall to the east stairwell

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the fire rated barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   Train A chemical and volume control system, and auxiliary building HVAC conduits are enclosed by 1-hour protective envelopes.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A and train B hydrogen recombiner equipment
- Train B post-LOCA analyzer

D. Nonsafety-Related Equipment and Components

- Hydrogen purge exhaust air filtration unit
- Cable trays and conduit
- Motor control center
- Lower level exhaust radiation monitor

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Thermo-Lag 330-1
    - Lubricating grease
    - Cable insulation
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

    Moderate

G. Fire Detection

Actuation of either ionization smoke detectors or line-type thermal detectors activates an alarm and the preaction water sprinkler system and will pressurize the piping with water. Either detector system alone can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system, covering cable trays only

2. Secondary

Two manual hose reels and two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Eight 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.30 Fire Area XV, Fire Zone 42D, West Corridors

A. Location

Fire Zone 42D (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	North Corridor	- 2-hour rated wall common to Fire Area XVI, Zone 42A, at column lines A3 and A6 Nonrated walls of heavy concrete construction common to the south access shaft
	South Corridor	- Nonrated walls of heavy concrete construction common to Zones 43, 44, and 45 at column line A9
South:	North Corridor	- Nonrated walls of heavy concrete construction common to Zones 43, 44, and 45 at column line A7
	South Corridor	- 3-hour rated wall common to Fire Area X at column line A10 3-hour rated wall common to Fire Area I at column line A10
East:	North Corridor	- 1-hour rated wall common to Zone 42C at column line AG

			2-hour rated wall common to Fire Area XVI, Zone 42A, at column line AB
	South Corridor	-	1-hour rated wall common to Zone 42C at column line AG
	Central Corridor	-	Nonrated wall of heavy concrete construction common to Zone 44 at column line AE
West:	North Corridor	-	2-hour rated wall common to the west stairwell, HVAC chase, and elevator at column line AA
			3-hour rated wall common to Fire Area VI at column line AA
			Nonrated exterior wall of heavy concrete construction at column line AA
	South Corridor	-	Nonrated exterior wall of heavy concrete construction at column line AA

Central Corridor - Nonrated wall of heavy concrete construction common to Zone 43

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 39A and 39B.
(Ref. 9B.2.15.1.B.8)

3-hour rated barriers common to the Zone 37A electrical chases

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 48, 49A, 49B, 49D, 49E, 49G, 49H, 50A, 52A, and 52D

2. Zone Access

- One Class C door (pair) in the 1-hour rated north corridor east wall to Zone 42C
- One 3-hour rated door (pair) in the 3-hour rated south corridor south wall to Fire Area X (Radwaste Building)
- One Class C door (pair) in the 1-hour rated south corridor east wall to Zone 42C
- One Class B door in the east wall of the west stairwell

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit
   - Load centers
   - Motor control center

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Lubricating grease
      - Cable insulation
      - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Actuation of either ionization smoke detector or line-type thermal detector systems activates the automatic preaction water sprinkler system. Either detector system alone can provide early warning capability. Ionization smoke detectors are provided in the southwest corridor to provide only early warning capability.

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system covering cable trays only (excluding south corridor between column lines AA and AD)

2. Secondary

   Three manual hose reels and three portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Seven 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.31 Fire Area XV, Fire Zone 43, Essential Cooling Water Heat Exchanger Rooms

A. Location

Fire Zone 43 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 42D at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 42D at column line A9

East: Nonrated wall of heavy concrete construction common to Zone 42D

West: Nonrated exterior wall of heavy concrete construction at column line AA

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations

sealed to a 3-hour rating common to Zone 39A (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 48, 49A, 49B, 49C, 49D, and 50A

2. Zone Access

- One nonrated door in the nonrated north wall to Zone 42D
- One nonrated door in the nonrated south wall to Zone 42D
- Two nonrated doors in the nonrated east wall to Zone 42D

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

Oil and grease

2. Transient Combustible Load Type

- Ordinary combustible
- Oil and grease

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

Two manual hose reels are located in adjacent Zone 42D.

2. Secondary

Two portable CO_2 fire extinguishers are located in adjacent Zone 42D.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.32 Fire Area XV, Fire Zone 44, Letdown and Seal Injection Heat Exchanger and Valve Gallery Rooms

A. Location

Fire Zone 44 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 42D at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 42D at column line A9

East: Nonrated wall of heavy concrete construction common to Zone 45 at column line AF

West: Nonrated wall of heavy concrete construction common to Zone 42D at column line AE

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 49F and 50A

2. Zone Access

- One non-rated gate in the nonrated north wall to Zone 42D
- One nonrated gate in the nonrated south wall to Zone 42D

3. Sealed Penetrations

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Conduit
- Letdown heat exchanger

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 42D.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 42D.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

None

9B.2.15.33 Fire Area XV, Fire Zone 45, Crud Pump and Crud Tank Rooms

A. Location

Fire Zone 45 (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 42D at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 42D at column line A9

Nonrated wall of heavy concrete construction common to a pipe chase

East: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46E at column line AG (Ref. 9B.2.15.1.B.8)

Nonrated wall of heavy concrete construction common to a pipe chase

West: Nonrated wall of heavy concrete construction common Zone 44 at column line AF

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 39B and 37E (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 50A and barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 51A (Ref. 9B.2.15.1.B.8)

2. Zone Access

   Non-rated gate in the nonrated north wall to Zone 42D

3. Sealed Penetrations

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Crud pump and crud tank
   - Conduit

E. Radioactive Material

   Area containing components designed to retain and collect radioactivity in process equipment.

F. Combustible Loading

   1. In Situ Combustible Load Type

      Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible

   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in adjacent Zone 42D.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 42D.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

None

9B.2.15.34 Fire Area XV, Fire Zone 46A, Train A Charging Pump and Valve Gallery Rooms

A. Location

Fire Zone 46A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.2)

South: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9A.120)

East: 3-hour rated wall common to Zone 42C

West: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46B (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 54 (Ref. 9B.2.15.1.B.8)

2. Zone Access

Non-rated gate in the north wall to Zone 42C

3. Sealed Penetrations

(Refer to Fire Area XV deviations 2 and 8.)

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Hydrogen compressors
- Conduit
- Normal air handling unit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of ionization smoke detector system(s) activates the automatic preaction water sprinkler system. The detector system(s) can provide early warning capability. (Refer to the appendix 9A response to Question 9A.116.)

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system

2. Secondary

   One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 42C.

I. Ventilation

Manually controlled smoke venting of adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.35 Fire Area XV, Fire Zone 46B, Train B Charging Pump and Valve Gallery Rooms

A. Location

Fire Zone 46B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.2)

South: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9A.120)

East: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.2)

West: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46E at column line AH (Ref. 9B.2.15.1.B.2)

Floor: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 53 and 54 (Ref. 9B.2.15.1.B.8)

2. Zone Access

Non-rated gate in the north wall to Zone 42C

3. Sealed Penetrations

(Refer to Fire Area XV deviations 2 and 8.)

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - CVCS chemical addition unit
   - Conduit
   - Normal air handling unit

E. Radioactive Material

   In process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil and grease
      - Thermo-Lag 330-1

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   Actuation of ionization smoke detector system(s) activates the automatic preaction water sprinkler

system. The detector system(s) provides early warning capability. (Refer to the appendix 9A response to Question 9A.116.)

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 42C.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.36 Fire Area XV, Fire Zone 46E, Standby Charging Pump and Valve Gallery Room

A. Location

Fire Zone 46E (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 42C at column line A7 (Ref. 9B.2.15.1.B.2)

South: Wall of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zone 42C at column line A9 (Ref. 9B.2.15.1.B.2)

East: Wall of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46B at column line AH (Ref. 9B.2.15.1.B.2)

West: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 45 at column line AG (Ref. 9B.2.15.1.B.8)

Floor: Barrier of heavy concrete construction with electrical and piping penetrations sealed to a 3-hour rating common to Zone 39B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with penetrations sealed to a 3-hour rating common to Zones 50B and 51B (Ref. 9B.2.15.1.B.8)

2. Zone Access

Non-rated gate in the north wall to Zone 42C

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- HVAC control panel
- Conduit
- Normal air handling unit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Actuation of ionization smoke detector system(s) activates the automatic preaction water sprinkler system. The detector system(s) can provide early warning capability. (Refer to the appendix 9A response to Question 9A.116.)

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system

2. Secondary

   One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 42C.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.37 Fire Area XV, Fire Zone 48, Train B Essential Cooling Water Surge Tank and South Corridor

A. Location

Fire Zone 48 (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 49H at column line A7

Open to Zone 52A at column line A7

South: 3-hour rated wall common to Fire Area X at column line A10

East: Nonrated wall of heavy concrete construction common to Zones 49A, 49C, 49E, and 50A

West: Nonrated exterior wall of heavy concrete construction at column line AA

Floor: Nonrated barrier of heavy concrete construction common to Zones 42D and 43

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 57D, 57E, 57F, 57M, and 57N

2. Zone Access

- One nonrated door (pair) in the 3-hour rated south wall to Fire Area X. (Refer to the appendix 9A response to Question 9A.106.)
- Open to Zone 52A at column line A7

3. Sealed Penetrations

Seals equal or exceed fire barrier rating.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Cable trays and conduit
- Boric acid batch tank
- Monorail

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Cable insulation
    - Plastic
    - Thermo-Lag 330-1
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel

NOTE

The passage to Fire Area X through the 3-hour rated south wall is protected by a fixed sprinkler system water curtain.

2. Secondary

One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Four 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.38 Fire Area XV, Fire Zone 49A, Boric Acid and Reactor Makeup Water Filter Rooms

A. Location

Fire Zone 49A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

a. Boric Acid Filter Room:

North: Nonrated wall of heavy concrete construction common to Zone 49H at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 49C

East: Nonrated wall of heavy concrete construction common to Zone 49B

West: Nonrated wall of heavy concrete construction common to Zone 48 at column line AC

Floor: Nonrated barrier of heavy concrete construction common to Zone 43

Ceiling: Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

b. Reactor Makeup Water Filter Room:

North: Nonrated wall of heavy concrete construction common to Zone 49H at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 49D

East: Nonrated wall of heavy concrete construction common to Zone 49F at column line AE

West: Nonrated wall of heavy concrete construction common to Zone 49B

Floor: Nonrated barrier of heavy concrete construction common to Zone 42D

Ceiling: Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

2. Zone Access

   None

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- Reactor makeup water filter
- Boric acid filter

E. Radioactive Material

Area containing components designed to retain and collect radioactivity in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

   None

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in Zone 52A.
   One manual hose reel is located in Zone 48.

2. Secondary

   One portable CO_2 fire extinguisher is located in Zone 52A. One portable CO_2 fire extinguisher is located in Zone 48.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.39 Fire Area XV, Fire Zone 49B, Liquid Radwaste System and Fuel Pool Purification Filter Rooms

A. Location

Fire Zone 49B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 49H at column line A7

South: Nonrated wall of heavy concrete construction common to Zones 49C and 49D

East: Nonrated wall of heavy concrete construction common to Zone 49A

West: Nonrated wall of heavy concrete construction common to Zone 49A

Floor: Nonrated barrier of heavy concrete construction common to Zone 42D and 43

Ceiling: Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

2. Zone Access

   None

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Liquid radwaste system filters
   - Fuel pool purification filters

E. Radioactive Material

Area containing components designed to retain and collect radioactivity in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in Zone 52A.

One manual hose reel is located in Zone 48.

2. Secondary

One portable CO_2 fire extinguisher is located in Zone 52A. One portable CO_2 fire extinguisher is located in Zone 48.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains (one in each room)

K. Emergency Communications

None

9B.2.15.40 Fire Area XV, Fire Zone 49C, Reactor Drain and Seal Injection Filter Rooms

A. Location

Fire Zone 49C (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 49A and 49B

South: Nonrated wall of heavy concrete construction to Zone 50A at column line A8

East: Nonrated wall of heavy concrete construction common to Zone 49D at column line AD

West: Nonrated wall of heavy concrete construction common to Zone 48 at column line AC

Floor: Nonrated barrier of heavy concrete construction common to Zone 43

Ceiling: Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

2. Zone Access

None

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Reactor drain filter
- Seal injection filter

E. Radioactive Material

Area containing components designed to retain and collect radioactivity in process equipment.

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in Zone 52A.

One manual hose reel is located in Zone 48.

2. Secondary

One portable CO_2 fire extinguisher is located in Zone 52A. One portable CO_2 fire extinguisher is located in Zone 48.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.41 Fire Area XV, Fire Zone 49D, Purification and Backflushable Purification Filter Rooms

A. Location

Fire Zone 49D (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 49A and 49B

South: Nonrated wall of heavy concrete construction to Zone 50A at column line A8

East: Nonrated wall of heavy concrete construction common to Zone 49F at column line AE

West: Nonrated wall of heavy concrete construction common to Zone 49C at column line AD

Floor: Nonrated barrier of heavy concrete construction common to Zones 42D and 43

Ceiling: Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

2. Zone Access

   None

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Purification filters

E. Radioactive Material

   Area containing components designed to retain and collect radioactivity in process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in Zone 48.

2. Secondary

   One portable CO_2 fire extinguisher is located in Zone 52A. One portable CO_2 fire extinguisher is located in Zone 48

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.42 Fire Area XV, Fire Zone 49E, Fuel Pool Purification and Preholdup Ion Exchanger Rooms

A. Location

Fire Zone 49E (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	Nonrated wall of heavy concrete construction common to Zone 50A at column line A9
South:	3-hour rated wall common to Fire Area X at column line A10
East:	3-hour rated wall common to Fire Area X, a pipe chase
West:	Nonrated wall of heavy concrete construction common to Zone 48 at column line AC
Floor:	Nonrated barrier of heavy concrete construction common to Zone 42D
Ceiling:	Nonrated barrier of heavy concrete construction common to Zone 57M

2. Zone Access

None

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Fuel pool purification ion exchangers
   - Pre-holdup ion exchanger

E. Radioactive Material

   Area containing components designed to retain and collect radioactivity in process equipment.

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

   2. Transient Combustible Load Type

      Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   One manual hose reel is located in Zone 57N at elevation 140 feet 0 inch.

2. Secondary

   One portable pressurized water fire extinguisher is located in Zone 57N at elevation 140 feet 0 inch.

I. Ventilation

   Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

   One 4-inch drain

K. Emergency Communications

   None

9B.2.15.43 Fire Area XV, Fire Zone 49F, Crud Tank and Crud Tank Vent Filter Room

A. Location

Fire Zone 49F (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	Nonrated wall of heavy concrete construction common to Zone 52D at column line A7
South:	Nonrated wall of heavy concrete construction common to Zone 50A at column line A8
East:	Nonrated wall of heavy concrete construction common to Zone 50A
West:	Nonrated wall of heavy concrete construction common to Zones 49A and 49D
Floor:	Nonrated barrier of heavy concrete construction common to Zone 44
Ceiling:	Nonrated barrier of heavy concrete construction at elevation 129 feet 0 inch

2. Zone Access

None

3. Sealed Penetrations

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Crud tank filter
   - Crud tank vent filter

E. Radioactive Material

   Area containing components designed to retain and collect radioactivity in process equipment.

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

   2. Transient Combustible Load Type

      Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher is located in Zone 48.

2. Secondary

   One portable CO_2 fire extinguisher is located in Zone 52A.

I. Ventilation

   Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

   One 4-inch drain

K. Emergency Communications

   None

9B.2.15.44 Fire Area XV, Fire Zone 49G, Purification and Deborating Ion Exchanger Rooms

A. Location

Fire Zone 49G (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	Nonrated wall of heavy concrete construction common to Zone 50A
South:	3-hour rated wall common to Fire Area X at column line A10
East:	3-hour rated wall common to Zone 51B, at column line AG
West:	3-hour rated wall common to Fire Area X, a pipe chase, at column line AE
Floor:	Nonrated barrier of heavy concrete construction common to Zone 42D
Ceiling:	Nonrated barrier of heavy concrete construction common to Zone 57M

2. Zone Access

None

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Purification exchanger
   - Deborating ion exchanger

E. Radioactive Material

   Area containing components designed to retain and collect radioactivity in process equipment

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

   2. Transient Combustible Load Type

      Ordinary combustible

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One portable pressurized water fire extinguisher is located in Zone 57N at elevation 140 feet 0 inch.

2. Secondary

One portable pressurized water fire extinguisher is located in the radwaste building, Zone 62I, at elevation 140 feet 0 inch.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.45 Fire Area XV, Fire Zone 49H, LRS Filters Valve Gallery

A. Location

Fire Zone 49H (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 52A

South: Nonrated wall of heavy concrete construction common to Zones 48, 49A, and 49B at column line A7

East: 1-hour rated wall common to Zone 52D at column line AE

West: Nonrated wall of heavy concrete construction common to Zone 52A

Floor: Nonrated barrier of heavy concrete construction common to Zone 42D

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 52A at elevation 127 feet 2 inches

2. Zone Access

Two nonrated gates in the nonrated north wall to Zone 52A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      High

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 52A.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 52A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.46 Fire Area XV, Fire Zone 50A, Valve Gallery

A. Location

Fire Zone 50A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 49C, 49D, and 49F at column line A8

Nonrated wall of heavy concrete construction common to Zone 52D at column line A7

Nonrated wall of heavy concrete construction common to Zone 51A at column line A8

South: Nonrated wall of heavy concrete construction common to Zones 49E and 49G at column line A9

3-hour rated wall common to Fire Area X, a pipe chase, at column line A9

East: 3-hour rated wall common to Zone 51B at column line AG

West: Nonrated wall of heavy concrete construction common to Zone 48 at column line AC

Nonrated wall of heavy concrete construction common to Zone 49F

Floor: Nonrated barrier of heavy concrete construction common to Zones 42D, 43, 44, and 45

An open pipe chase which extends down to Zone 39B is located in the southeast corner

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 57F, 57G, 57L, and 57N

2. Zone Access

- One nonrated gate in the nonrated west wall to Zone 48
- One open doorway in the nonrated west wall to Zone 48 at elevation 129 feet 0 inch
- One nonrated doorway in the nonrated north wall to Zone 52D

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings. (Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Cable tray and conduits

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil/grease
      - Polycarbonate battery casing

   2. Transient Combustible Load Type

      - Ordinary combustible

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   None

H. Fire Suppression

   1. Primary

      One manual hose reel is located in Zone 52D.
      One manual hose reel is located in Zone 48.

2. Secondary

One portable CO_2 fire extinguisher is located in Zone 52D. One portable CO_2 fire extinguisher is located in Zone 48.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Eight 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.47 Fire Area XV, Fire Zone 50B, Valve Gallery

A. Location

Fire Zone 50B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 52D at column line A7

South: Nonrated wall of heavy concrete construction common to Zone 51B at column line A8

East: Nonrated wall of heavy concrete construction common to Zone 53 at column line AH

West: Nonrated wall of heavy concrete construction common to Zone 51A at column line AG

Floor: Nonrated barrier of heavy concrete construction common to Zone 46E

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 57J

2. Zone Access

   One nonrated gate in the nonrated south wall to Zone 51B

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

In process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

None

2. Transient Combustible Load Type

- Lubricating oil
- Ordinary combustible
- Plastic

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization Smoke Detector System(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 53

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 53.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.48 Fire Area XV, Fire Zone 51A, Volume Control Tank Room

A. Location

Fire Zone 51A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

   North: Nonrated wall of heavy concrete construction common to Zone 52D at column line A7

   South: Wall of heavy concrete construction with electrical and pipe penetrations

sealed to a 3-hour rating common to Zone 50A at column line A8 (Ref. 9B.2.15.1.B.8)

East: Nonrated wall of heavy concrete construction common to Zone 50B at column line AG

West: 3-hour rated wall common to the central stairwell at column line AF

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 45 (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated barrier of heavy concrete construction common to Zone 57K

2. Zone Access

None

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

Area containing components designed to retain and collect radioactivity in process equipment

F. Combustible Loading

1. In Situ Combustible Load Type

Hydrogen

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

None

NOTE

Zone 51A is completely enclosed with walls of heavy concrete construction so as to protect plant personnel from the high radiation levels within the zone; due to the lack of zone access, no portable suppression means are possible.

I. Ventilation

None

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.49 Fire Area XV, Fire Zone 51B, Spray Chemical Storage Tank Room

A. Location

Fire Zone 51B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 50B at column line A8

South: 3-hour rated wall common to Fire Area I at column line A10

East: Nonrated wall of heavy concrete construction common to Zone 53 at column line AH

West: 3-hour rated wall common to Zones 49G and 50A at column line AG

Floor: Barrier of heavy concrete construction common to Zones 42C and 46E. Electrical and pipe penetrations common to Zone 46E are sealed to a 3-hour rating (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 57J (Ref. 9B.2.15.1.B.8)

2. Zone Access

   One open doorway in the nonrated east wall to Zone 53

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A and B spray chemical addition pumps (Abandoned in place)
- Train A conduit
- Chemical spray storage tank

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - 35% hydrazine
   - Lubricating grease
2. Transient Combustible Load Type

   Ordinary combustible
3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 53.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 53.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.50 Fire Area XV, Fire Zone 52A, West Corridors

A. Location

Fire Zone 52A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to the south access shaft

2-hour rated walls common to Fire Area XVI, Zone 47A, at column lines A3 and A6

South: Open to Zone 48 at column line A7

Nonrated wall of heavy concrete construction common to Zone 49H

Nonrated wall of heavy concrete construction common to the filter access area, at column line A7, above elevation 127 feet 2 inches

East: 1-hour rated wall common to Zone 52D at column line AE

2-hour rated wall common to Fire Area XVI, Zone 47A, at column line AB

Nonrated wall of heavy concrete construction common to the south access shaft

West: 2-hour rated wall common to the west elevator, stairwell, and HVAC chase at column line AA

Nonrated exterior wall of heavy concrete construction at column line AA

3-hour rated wall common to Fire Area VI at column line AA

Floor: Nonrated barrier of heavy concrete construction common to Zone 42D

Ceiling: Nonrated barrier of heavy concrete construction common to Zones 57A, 57B, 57C, 57H, 57N, and 57P

2-hour rated barrier common to Zones 55A and 55C

2. Zone Access

- One Class C door in the 1-hour rated east wall to Zone 52D
- One Class B door in the 2-hour rated west wall to the west stairwell
- Open to Zone 48 at column line A7
- One Class A door (pair) in the 3-hour rated west wall to Fire Area VI (Fuel Building)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A post-LOCA analyzer cabinet

D. Nonsafety-Related Equipment and Components

- 120 V-ac distribution panel
- Load center
- Cable trays and conduit
- Concentrator panel

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Oxygen (oxidizer)
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Actuation of either ionization smoke detector system(s) or line-type thermal detector system(s) activates the automatic preaction water sprinkler system and will pressurize the piping with water. Either detector system alone can provide early warning.

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system covering the cable trays only (excluding corridor adjacent to the west elevator and stairwell)

2. Secondary

   One manual hose reel and two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Four 4-inch drains

K. Emergency Communications

None

9B.2.15.51 Fire Area XV, Fire Zone 52D, East Corridors

A. Location

Fire Zone 52D (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Fire Area XVII, Zone 47B, at column line A6

3-hour rated walls common to the south access shaft

3-hour rated wall common to Fire Area XII

South: Nonrated wall of heavy concrete construction common to Zones 50B and 51A at column line A7

2-hour rated walls common to Zone 54

Open to Zone 53 at column line A7

Wall of heavy concrete construction with electrical and pipe penetrations

sealed to a 3-hour rating common to Zones 49F and 50A, and the central staircase (Ref. 9B.2.15.1.B.8)

East: 3-hour rated exterior wall at column line AL

2-hour rated walls common to the east stairwell

West: 1-hour rated wall common to Zone 52A at column line AE

2-hour rated wall common to Fire Area XVII, Zone 47B

Floor: Nonrated barrier of heavy concrete construction common to Zones 42C and 42D

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 56C, 57J, 57K, and 57N (Ref. 9B.2.15.1.B.8)

2. Zone Access

- One Class C door (pair) in the 1-hour rated west wall to Zone 52A
- One Class B door in the 2-hour rated east wall to the east stairwell

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   Train A auxiliary building HVAC conduits are enclosed by 1-hour protective envelopes.

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train A and B control element drive mechanism control system (CEDMCS) auxiliary cabinets

D. Nonsafety-Related Equipment and Components

   - Load centers
   - Motor control center
   - Auxiliary relay cabinets
   - Auxiliary building upper level exhaust radiation monitor
   - Cable trays and conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Thermo-Lag 330-1

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Actuation of either ionization smoke detector or line-type thermal detector system(s) activates the automatic preaction water sprinkler system. Either detector system can provide early warning.

H. Fire Suppression

1. Primary

   Automatic preaction water sprinkler system, covering cable trays only except in northeast corner (north of column line A3) which has area coverage

2. Secondary

   Two manual hose reels and two portable CO_2 fire extinguishers

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Eight 4-inch drains

K. Emergency Communications

None

9B.2.15.52 Fire Area XV, Fire Zone 53, Process Radiation Monitor and Boronometer Room

A. Location

Fire Zone 53 (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to Zone 52D at column line A7

South: 3-hour rated wall common to Fire Area II at column line A10

East: 2-hour rated walls common to Zone 54

West: Nonrated wall of heavy concrete construction common to Zones 50B and 51B at column line AH

Floor: Barrier of heavy concrete construction common to Zone 42C and concrete

barrier with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46B (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 57J (Ref. 9B.2.15.1.B.8)

2. Zone Access

- Open to Zone 52D
- Two Class B doors (pairs) in the 2-hour rated east wall to Zone 54

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Process radiation monitor
- Boronometer (abandoned in-place)
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel

2. Secondary

   One portable CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Four 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.53 Fire Area XV, Fire Zone 54, Reactor Trip Switchgear Room and CEDM Control System

A. Location

Fire Zone 54 (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated walls common to Zone 52D

South: 3-hour rated wall common to Fire Area II at column line A10

East: 3-hour rated exterior wall at column line AL

3-hour rated wall common to the corridor building at column line AL

West: 2-hour rated walls common to Zone 53

Floor: Barrier of heavy concrete construction common to Zone 42C concrete barrier with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 46A (Ref. 9B.2.15.1.B.8)

Ceiling: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 57J (Ref. 9B.2.15.1.B.8)

2. Zone Access

- One nonrated missile door (pair) in the 3-hour rated east wall to the corridor building
- Two Class B doors (pairs) in the 2-hour rated west wall to Zone 53
- One Class B door (pair) in the 2-hour rated north wall to Zone 52D

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviations 2 and 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train A and B reactor trip switchgear
   - Train A and B control element drive mechanism (CEDM) control cabinets

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit
   - CEDM control cabinet room normal ACU

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation
      - Oil and grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Moderate

G. Fire Detection

Ionization smoke detector system(s) and line-type thermal detector system(s) are provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 53. One manual hose reel is located in adjacent Zone 52D.

2. Secondary

One portable CO_2 fire extinguisher is located in adjacent Zone 53. One portable CO_2 fire extinguisher is located in adjacent Zone 52D.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Five 4-inch drains

K. Emergency Communication

Sound powered phone jack(s) is provided.

9B.2.15.54 Fire Area XV, Fire Zone 55A, Personnel Access Hatch Area

A. Location

Fire Zone 55A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated exterior wall at column line Al

South: Open to Zone 55C

Open to Zone 55E

East: 3-hour rated wall common to Fire Area XI

2-hour rated wall common to Zone 56A at column line AC2

West: 3-hour rated wall common to Fire Area VI at column line AA

2-hour rated wall common to the west elevator

Floor: 2-hour rated barrier common to Fire Area XVI, Zone 47A

2-hour rated barrier common to Zone 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class A door (pair) in the 3-hour rated west wall to Fire Area VI (Fuel Building)
- Open to Zone 55C

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

NOTE

Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Cable trays and conduit

- Personnel access hatch to the containment building

E. Radioactive Material

Area containing radioactive materials

F. Combustible Loading

1. In Situ Combustible Load Type

   - Fabric and paper
   - Cable insulation
   - Grease and oil
   - Plastic
   - Rubber

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Automatic wet pipe sprinkler system

2. Secondary

One manual hose reel is located in Zone 57N. One portable pressurized water fire extinguisher is located in adjacent Zone 55C.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.55 Fire Area XV, Fire Zone 55C, Clothing Storage

A. Location

Fire Zone 55C (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to Zone 55A

South: 1-hour rated wall common to Zone 57N at column A6

East: Nonrated block wall common to Zone 55E

West: 2-hour rated wall common to the west stairwell at column line AA

Floor: 2-hour rated barrier common to Fire Area XVI, Zone 47A

2-hour rated barrier common to Zone 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class B door in the 2-hour rated west wall to the west stairwell
- One certified door (pair) in the 1-hour rated south wall to Zone 57N (See response to Question 9A.106)
- Open to Zone 55A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

Train A conduits

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

Area containing radioactive materials

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Rubber
- Plastic
- Fabric
- Paper

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

Hose station located in adjacent Zone 57N

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.56 Fire Area XV, Fire Zone 55E, Decontamination Washdown Area

A. Location

Fire Zone 55E (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to Zone 55A

South: 1-hour rated wall common to Zone 57N at column line A6

East: 2-hour rated wall common to Zone 56A at column line AC2

West: Nonrated block wall common to Zone 55C

Floor: 2-hour rated barrier common to Fire Area XVI, Zone 47A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

Open to Zone 55A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

Area containing radioactive clothing

F. Combustible Loading

1. In Situ Combustible Load Type

- Fabric
- Rubber

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

Hose station located in adjacent Zone 57N

One pressurized water fire extinguisher is located in adjacent Zone 55C.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.15.57 Fire Area XV, Fire Zone 56A, Storage and Electrical Room (West)

A. Location

Fire Zone 56A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

South: 1-hour rated wall common to Zone 57N at column A6

East: Nonrated wall of heavy concrete construction common to the south access shaft

West: 2-hour rated wall common to Zones 55A and 55E at column line AC2

Floor: 2-hour rated barrier common to Fire Area XVI, Zone 47A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

   One Class C door (pair) in the 1-hour rated south wall to Zone 57N

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   NOTE

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   Duct penetrations in the rated fire barrier are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train A containment refueling purge supply isolation damper
- Train A containment power ascension purge supply isolation damper

D. Nonsafety-Related Equipment and Components

- Conduit

- Storage of miscellaneous items

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Oil and grease
   - Cable insulation
   - Charcoal
   - Fabric
   - Paper
   - Wood
   - Plastic
   - Rubber

2. Transient Combustible Load Type

   - Ordinary combustible
   - Plastic

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

One manual hose reel is located in adjacent Zone 57N

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.58 Fire Area XV, Fire Zone 56B, Storage and Electrical Equipment Room (East)

A. Location

Fire Zone 56B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XII

South: 1-hour rated wall common to Zones 57N and 57J at column line A6

East: 1-hour rated wall common to Zone 56C

Nonrated wall of heavy concrete construction common to Zone 56C

West: Nonrated wall of heavy concrete construction common to the south access shaft at column line AG

3-hour rated wall common to Fire Area XI

Floor: 3-hour rated barrier common to Fire Area XVII, Zone 47B

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class C door in the 1-hour rated south wall to Zone 57J
- One nonrated door (pair) in the nonrated east wall to Zone 56C

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   - Train B containment refueling purge exhaust isolation damper
   - Train B containment refueling purge exhaust pump
   - Train B containment power ascension purge exhaust isolation damper
   - Containment purge exhaust radiation monitor

D. Nonsafety-Related Equipment and Components

   - Motor control centers
   - Load center
   - Cable trays and conduit
   - Containment purge exhaust radiation monitor
   - Storage of miscellaneous items

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Cable insulation

- Oil and grease
- Plastic

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

One manual hose reel is located in adjacent Zone 57N. One ABC powder fire extinguisher is located in adjacent Zone 56C.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.59 Fire Area XV, Fire Zone 56C, Northeast Corridor

A. Location

Fire Zone 56C (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated common to Fire Area XII

South: Open to Zone 57N at column line A6

East: 3-hour rated exterior wall at column line AL

2-hour rated walls common to the east stairwell

West: 1-hour rated wall common to Zone 56B. Nonrated wall of heavy concrete construction common to Zone 56B

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 52D (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

    - One Class B door in the 2-hour rated west wall of the east stairwell

    - One non-rated door (pair) in the non-rated portion of the west wall to Zone 56B

    - Open to Zone 57N

3. Sealed Penetrations

    Seals equal or exceed fire barrier ratings.

    (Refer to Fire Area XV deviation 8)

4. Fire Dampers

    Duct penetrations in the rated fire barrier are provided with fire dampers of equal or greater rating.

5. Protected Raceways

    None

6. Protected Structural Members

    None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

    None

D. Nonsafety-Related Equipment and Components

    - Cable trays and conduit

    - Domestic hot water heaters

- Monorail

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   Cable insulation

2. Transient Combustible Load Type

   - Ordinary combustible
   - Cable insulation

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   Automatic wet pipe sprinkler system

2. Secondary

   One portable ABC powder fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.60 Fire Area XV, Fire Zone 57A, Hot Laboratory

A. Location

Fire Zone 57A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of metal lath and plaster common to Zone 57B

1-hour rated wall common to Zone 57N

South: 1-hour rated wall common to Zone 57N at column A8

East: Nonrated wall of heavy concrete construction common to Zone 57K at column AE

Nonrated wall of metal lath and plaster common to Zone 57B at column line AD

2-hour rated wall common to Zone 57P at column line AD

West: Nonrated walls of heavy concrete construction common to Zones 57C and 57D

Floor: Nonrated barrier of heavy concrete construction common to Zones 49H and 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One Class C door in the 1-hour rated north wall to Zone 57N
- One certified door in the 1-hour rated south wall to Zone 57N (See response to Question 9A.106)
- One nonrated door in the nonrated east wall to Zone 57K

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Laboratory equipment and fume hoods
- Conduit

E. Radioactive Material

Area containing components designed for collecting and testing for radioactivity.

F. Combustible Loading

1. In Situ Combustible Load Type
   - Paper and fabric
   - Rubber
   - Cable insulation
   - Lubricating oil
   - Resin
   - Wood
   - Organic chemicals
   - Oxygen (oxidizer)
   - Plastic
2. Transient Combustible Load Type
   - Ordinary combustible

- Oxygen (oxidizer)

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   Ionization smoke detector system(s), both above and below the suspended ceiling, is provided for early warning.

H. Fire Suppression

   1. Primary

      Two ABC powder and one CO_2 fire extinguishers

   2. Secondary

      One manual hose reel is located in adjacent Zone 57N

I. Ventilation

   Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

   Three 4-inch drains

K. Emergency Communications

   Sound powered phone jack(s) is provided

9B.2.15.61 Fire Area XV, Fire Zone 57B, Cylinder Storage Area

A. Location

Fire Zone 57B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:	2-hour rated wall common to Zone 57P
South:	Nonrated wall of metal lath and plaster construction common to Zone 57A
East:	1-hour rated wall common to Zone 57N
West:	Nonrated wall of metal lath and plaster construction common to Zone 57A at column line AD
Floor:	Nonrated barrier of heavy concrete construction common to Zone 52A
Ceiling:	Nonrated roof of heavy concrete construction

2. Zone Access

Nonrated door in the nonrated west wall to Zone 57A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Hydrogen
      - Rubber
      - Oxygen (oxidizer)

- Nitrous Oxide (oxidizer)

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in Zone 57N.

2. Secondary

   Two ABC powder fire extinguishers and one CO_2 fire extinguisher are located in adjacent Zone 57A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.62 Fire Area XV, Fire Zone 57C, Sample Room

A. Location

Fire Zone 57C (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to a pipe chase

1-hour rated wall common to Zone 57N

South: Nonrated walls of heavy concrete construction common to Zones 57A and 57D

East: Nonrated wall of heavy concrete construction common to Zone 57A

West: Nonrated wall of heavy concrete construction common to Zone 57H

Floor: Nonrated barrier of heavy concrete construction common to Zones 48 and 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

Nonrated door in the nonrated east wall to Zone 57A

3. Sealed Penetrations

   Seals equal or exceed fire barrier rating

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Laboratory equipment and two fume hoods.
   - Conduit

E. Radioactive Material

   Area containing radioactive materials.

F. Combustible Loading

   1. In Situ Combustible Load Type

      Plastic

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Two portable ABC powder fire extinguishers are located in adjacent Zone 57A.

2. Secondary

   One portable CO_2 fire extinguisher is located in adjacent Zone 57A.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Three 4-inch drains

K. Emergency Communications

None

9B.2.15.63 Fire Area XV, Fire Zone 57D, Counting Room

A. Location

Fire Zone 57D (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zones 57C and 57H at column line A7

South: 1-hour rated wall common to Zone 57N at column line A8

East: Nonrated wall of heavy concrete construction common to Zone 57A

West: 1-hour rated wall common to Zone 57N at column line AB

Floor: Nonrated barrier of heavy concrete construction common to Zone 48

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One nonrated door in the nonrated east wall to Zone 57A

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Laboratory equipment
- Conduit

E. Radioactive Material

Area containing radioactive materials.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Charcoal

- Paper and fabric
- Plastic
- Rubber
- Wood
- Organics
- Acetone

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One portable ABC powder fire extinguisher and one portable CO_2 fire extinguisher

2. Secondary

   One manual hose reel is located in Zone 57N.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.64 Fire Area XV, Fire Zone 57E, Sample Counting Room

A. Location

Fire Zone 57E (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N

South: 1-hour rated wall common to Zone 57N

Nonrated wall of heavy concrete construction common to Zone 57M

East: Nonrated wall of metal lath and plaster construction common to Zone 57F

West: 1-hour rated wall common to Zone 57N

Floor: Nonrated barrier of heavy concrete construction common to Zone 48

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

    - One Class C door in the 1-hour rated west wall to Zone 57N
    - One Class C door in the 1-hour rated north wall to Zone 57N

3. Sealed Penetrations

    Seals equal or exceed fire barrier ratings.

    (Refer to Fire Area XV deviation 8)

4. Fire Dampers

    Duct penetrations in the fire-rated barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

    None

6. Protected Structural Members

    None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Laboratory equipment
- Conduit

E. Radioactive Material

Area containing radioactive materials.

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Paper and fabric
- Rubber
- Wood
- Plastic

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 57N.

2. Secondary

One pressurized water fire extinguisher is located in adjacent Zone 57N.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.65 Fire Area XV, Fire Zone 57F, Personnel Decontamination and Radiation Protection Workroom

A. Location

Fire Zone 57F (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N

South: Nonrated masonry block wall common to Zone 57M

East: Nonrated wall of metal lath and plaster construction common to Zone 57G

West: Nonrated wall of metal lath and plaster construction common to Zone 57E

Floor: Nonrated barrier of heavy concrete construction common to Zones 48 and 50A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

Three Class C doors in the 1-hour rated north wall to Zone 57N

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Laboratory equipment

- Conduit

E. Radioactive Material

Area containing radioactive materials.

F. Combustible Loading

1. In Situ Combustible Load Type

    - Organics
    - Rubber
    - Cable insulation
    - Paper and fabric
    - Plastic

2. Transient Combustible Load Type

    Ordinary combustible

3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

    One manual hose reel is located in adjacent Zone 57N

2. Secondary

   One pressurized water fire extinguisher is located in Zone 57N.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.66 Fire Area XV, Fire Zone 57G, First Aid Room

A. Location

Fire Zone 57G (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

   North: 1-hour rated wall common to Zone 57N

   South: Nonrated masonry block wall common to Zone 57M

   East: Nonrated wall of heavy concrete construction common to Zone 57L at column line AE

West: Nonrated wall of metal lath and plaster common to Zone 57F

Floor: Nonrated barrier of heavy concrete construction common to Zone 50A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One certified door (pair) in the 1-hour rated north wall to Zone 57N (See response to Question 9A.106)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Laboratory equipment
- Conduit

E. Radioactive Material

Area containing radioactive material

F. Combustible Loading

1. In Situ Combustible Load Type

    - Paper and fabric
    - Rubber
    - Plastic
    - Wood
    - Organics

2. Transient Combustible Load Type

    Ordinary combustible

3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

    One manual hose reel is located in adjacent Zone 57N.

2. Secondary

One pressurized water fire extinguisher is located in adjacent Zone 57N.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.67 Fire Area XV, Fire Zone 57H, Hot Instrumentation and Control Shop

A. Location

Fire Zone 57H (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N

South: Nonrated wall of heavy concrete construction common to Zone 57D at column line A7

East: Nonrated wall of heavy concrete construction common to Zone 57C

1-hour rated wall common to Zone 57N

West: 1-hour rated wall common to Zone 57N

Floor: Nonrated barrier of heavy concrete construction common to Zone 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- Two Class C doors in the 1-hour rated west wall to Zone 57N
- One Class C door (pair) in the 1-hour rated north wall to Zone 57N

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-related Equipment and Components

- Domestic hot water heater
- Tools and equipment
- Conduit

E. Radioactive Material

Area containing radioactive material

F. Combustible Loading

1. In Situ Combustible Load Type
   - Hydrazine
   - Paper and fabric
   - Rubber
   - Plastic
2. Transient Combustible Load Type

   Ordinary combustible
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

One manual hose reel is located in adjacent Zone 57N. One pressurized water fire extinguisher is located in Zone 55C.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

None

9B.2.15.68 <u>Fire Area XV, Fire Zone 57J, Locker Rooms, Operations Support Center, Radiation Protection Leads and Radiation Protection Island</u>

A. Location

Fire Zone 57J (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N and 56B

South: 3-hour rated wall common to Fire Areas I and II at column line A10

East: 3-hour rated exterior wall at column line AL

West: Nonrated wall of heavy concrete construction common to Zones 57K, 57L, 57M, and 57N at column line AG

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 50B, 51B, 52D, 53, and 54 (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated roof of heavy concrete construction

NOTE

The HVAC chase near column lines A7/AH is surrounded by 2-hour rated concrete walls.

2. Zone Access

- Two Class C doors (one pair) in the 1-hour rated east wall to Zone 57N at column line A6

- One Class C door in the 1-hour rated north wall to Zone 57N
- One pair of Class A doors in the 3-hour rated east wall to the corridor building
- One nonrated door in the nonrated west wall to Zone 57N
- Open at west side to corridor, Zone 57N, at column line A8

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   Duct penetrations in the fire-rated barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit

- Supplies

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Paper and fabric
   - Charcoal
   - Rubber
   - Plastic
   - Wood
   - Methane (P-10 gas)

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

   Automatic wet pipe sprinkler system

2. Secondary

One manual hose reel, three pressurized water, and one CO_2 fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Twelve 2-inch drains

K. Emergency Communications

None

9B.2.15.69 Fire Area XV, Fire Zone 57K, Cold Laboratory

A. Location

Fire Zone 57K (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N

South: 1-hour rated wall common to Zone 57N

East: Nonrated wall of heavy concrete construction common to Zone 57J at column line AG

West: Nonrated wall of heavy concrete construction common to Zone 57A at column line AE

Floor: Barrier of heavy concrete construction with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 49F, 50A and a concrete barrier with electrical and pipe penetrations sealed to a 3-hour rating common to Zones 51A and 52D (Ref. 9B.2.15.1.B.8)

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One certified door in the 1-hour rated south wall to Zone 57N (See response to Question 9A.106)
- One nonrated door in the nonrated west wall to Zone 57A

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Cable trays and conduit
   - Laboratory equipment

E. Radioactive Material

   None

F. Combustible Loading

   1. In-Situ Combustible Load Type

      - Cable insulation
      - Paper and fabric
      - Plastic
      - Rubber
      - Oil and grease
      - Diesel fuel oil
      - Organics
      - Wood

- Resin
- Mipolam floor

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

Ionization smoke detector system(s), both above and below the suspended ceiling, is provided for early warning.

H. Fire Suppression

1. Primary

   One dry portable ABC powder and one CO_2 fire extinguisher

2. Secondary

   One manual hose reel is located in adjacent Zone 57N

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is available.

9B.2.15.70 Fire Area XV, Fire Zone 57L Chemistry

A. Location

Fire Zone 57L (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 1-hour rated wall common to Zone 57N

South: Nonrated masonry block wall common to Zone 57M

East: Nonrated wall of heavy concrete construction common to Zone 57J at column line AG

West: Nonrated wall of heavy concrete construction common to Zone 57G at column line AE

Floor: Nonrated barrier of heavy concrete construction common to Zone 50A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class C door in the 1-hour rated north wall to Zone 57N

One certified door in the 1-hour rated north wall to Zone 57N (See response to Question 9A.106)

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   (Refer to Fire Area XV deviation 8)

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   - Conduit
   - Radiation protection equipment

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Vinyl flooring
- Paper and fabric
- Rubber
- Cable insulation
- Plastic
- Wood

2. Transient Combustible Load Type

- Ordinary combustible
- Vinyl flooring

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Two manual hose reels are located in adjacent Zones 57N and 57J.

2. Secondary

One portable ABC powder and portable CO_2 fire extinguishers are located in Zone 57K.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.71 Fire Area XV, Fire Zone 57M, Ion Exchangers Access Area

A. Location

Fire Zone 57M (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated masonry block wall common to Zones 57F, 57G, and 57L

South: 3-hour rated wall common to Fire Area X at column line A10

East: Nonrated wall of heavy concrete construction common to Zone 57J at column line AG

West: 1-hour rated concrete block wall common to Zone 57N

Floor: Nonrated barrier of heavy concrete construction common to Zones 48, 49E, and 49G

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class C door (pair) in the 1-hour rated west wall to Zone 57N

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

- Monorail
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Plastic
- Cable insulation
- Rubber
- Paper fabric
- Wood

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One manual hose reel is located in adjacent Zone 57N.

2. Secondary

One pressurized water fire extinguisher is located in adjacent Zone 57N.

I. Ventilation

Manually controlled smoke venting to adjacent zone where portable smoke removal equipment exhausts smoke to the outside.

J. Drainage

None

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.15.72 Fire Area XV, Fire Zone 57N, Corridor Area

A. Location

Fire Zone 57N (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: North Corridor - 1-hour rated walls common to Zones 55C, 55E, 56A, and 56B at column line A6

2-hour rated wall common to the east stairwell at column line A6

Open to Zone 56C at column line A6

Nonrated walls of heavy concrete construction

			common to the south tendon access shaft
	South Corridor	-	1-hour rated wall common to Zones 57A, 57D, and 57K at column line A8
South:	North Corridor	-	1-hour rated walls common to Zones 57A, 57B, 57C, 57H, and 57K
			2-hour rated walls common to Zone 57P
	South Corridor	-	1-hour rated wall common to Zones 57E, 57F, 57G, and 57L
	West Corridor	-	3-hour rated wall common to Fire Area X at column line A10
East:	North Corridor	-	3-hour rated exterior wall at column line AL
			Nonrated wall of metal lath and plaster construction common to Zone 57J at column line AG
	South Corridor	-	Open to Zone 57J at column line AG
	West Corridor	-	1-hour rated walls common to Zones 57D, 57E, 57H, and 57M

West:	North Corridor	-	2-hour rated wall common to the west stairwell at column line AA
	West Corridor	-	2-hour rated wall common to the west HVAC chase at column line AA
			Nonrated exterior wall of heavy concrete construction at column line AA
Floor:	North Corridor	-	Nonrated barrier of heavy concrete construction common to Zone 52A and a concrete barrier with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 52D (Ref. 9B.2.15.1.B.8)
	South Corridor	-	Nonrated barrier of heavy concrete construction common to Zones 48, 50A and a concrete barrier with electrical and pipe penetrations sealed to a 3-hour rating common to Zone 51B and 54 (Ref. 9B.2.15.1.B.8)

West Corridor - Nonrated barrier of heavy concrete construction common to Zones 48 and 52A

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One certified door (pair) in the 1-hour rated wall to Zone 55C (See response to Question 9A.106)
- Open to Zone 57J at column line AG
- One nonrated door at the nonrated wall to Zone 57J at column line AG
- One Class A door (pair) in the 3-hour rated wall to Fire Area X (Radwaste Building)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Vinyl flooring
- Thermo-Lag 330-1
- Wood

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Ionization smoke detector system(s) is provided for early warning.

H. Fire Suppression

1. Primary

Four manual hose reels

2. Secondary

One pressurized water fire extinguisher

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

None

K. Emergency Communications

None

9B.2.15.73 Fire Area XV, Fire Zone 57P, Flammable Storage Area

A. Location

Fire Zone 57P (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 140 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Zone 57N

South: 2-hour rated wall common to Zone 57B

East: 2-hour rated wall common to Zone 57N

West: 2-hour rated wall common to Zone 57A

Floor: Nonrated barrier of heavy concrete construction common to Zone 52A.

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class B door (pair) in the 2-hour rated north wall to Zone 57N

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

(Refer to Fire Area XV deviation 8)

4. Fire Dampers

Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

Train A conduit

D. Nonsafety-Related Equipment and Components

- Acetylene cylinder

- Hydrogen cylinder
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Acetylene
   - Hydrogen
   - Plastic

2. Transient Combustible Load Type

   - Ordinary combustible
   - Acetylene

3. Total Combustible (Fire) Loading

   High

G. Fire Detection

None

H. Fire Suppression

1. Primary

   One manual hose reel is located in the adjacent Zone 57N.

2. Secondary

Two portable ABC powder and one portable CO_2 fire S[Run WPS extinguisher are located in adjacent Zone 57A.

I. Ventilation

Flow through air filtration unit to outside

J. Drainage

None

K. Emergency Communications

None

9B.2.16 FIRE AREA XVI

9B.2.16.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XVI (figures 9B-3 and 9B-4) contains the train A electrical penetration rooms of the auxiliary building at elevations 100 feet 0 inch and 120 feet 0 inch. This fire area includes Analysis Area XVIA (Zones 42A and 47A) (engineering drawing 13-A-ZYD-024).

Fire Area XVI is bounded to the north by a 3-hour rated barrier common to Fire Area XI, and a 3-hour rated exterior wall. Fire Area XVI is bounded to the west by a 3-hour rated barrier common to Fire Area VI, and by 2-hour rated barriers common to the north corridors of Fire Area XV. Fire Area XVI is

bounded to the south by a 2-hour rated barrier common to Fire Area XV, and to the east by a 2-hour rated barrier common to the south access shaft. The floor and ceiling are 1-hour and 2-hour rated barriers, respectively, common to Fire Area XV.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires a 3-hour rated barrier between adjacent fire areas separating circuits of redundant trains.

<u>Discussion</u>

The mechanical and electrical penetrations in the containment boundary are not rated Mechanical containment penetrations are fitted with flued heads constructed of steel with a minimum thickness of 1/8 inch Electrical containment penetrations are fitted with a stainless steel header plate with a thickness of 1.78 inches. The special construction of the flued heads and header plates was designed to maintain the integrity of the containment building.

<u>Conclusion</u>

The existing design provides equivalent protection to that required by Section III.G.2. The design is standard within the industry.

9B.2.16.2 Analysis Area XVIA

A. Location

Analysis Area XVIA consists of Fire Zones 42A and 47A.

Fire Zone 42A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 100 feet 0 inch.

Fire Zone 47A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area XI

3-hour rated exterior wall at column line A1

South: 2-hour rated walls common to Fire Area XV, Zone 42D, at column lines A3 and A6 (Zone 42A)

2-hour rated wall common to Fire Area XV, Zone 52A, at column line A6 (Zone 47A)

East: 2-hour rated wall common to the south access shaft

West: 2-hour rated wall common to Fire Area XV, Zone 42D, at column line AB (Zone 42A)

3-hour rated wall common to Fire Area VI at column line AA

2-hour rated wall common to Fire Area XV, Zone 52A, at column line AB (Zone 47A)

Floor: 1-hour rated barrier common to Fire Area XV, Zone 37C

Ceiling: 2-hour rated barrier common to Fire Area XV, Zones 55A, 55C, 55E, and 56A

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Miscellaneous HVAC

  Nuclear cooling water

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

  Electrical power distribution

  Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Nuclear cooling water

  Reactor coolant

  Nuclear sampling

- Train A electrical penetration room essential air control unit and associated components
- Train A 480 V-ac Class 1E motor control centers
- Train A 125 V-dc distribution auxiliary relay cabinets

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train B system will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.16.3 Fire Area XVI, Fire Zone 42A, Train A (Channel C) Electrical Penetration Room

A. Location

Fire Zone 42A (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

3-hour rated exterior wall at column line A1

South: 2-hour rated walls common to Fire Area XV, Zone 42D, at column lines A3 and A6

East: 2-hour rated wall common to the south access shaft

West: 2-hour rated wall common to Fire Area XV, Zone 42D, at column line AB

3-hour rated wall common to Fire Area VI at column line AA

Floor: 1-hour rated barrier common to Fire Area XV, Zone 37C

Ceiling: 2-hour rated barrier common to Zone 47A

2. Zone Access

   - One Certified door (pair) in the 2-hour rated south wall to Zone 42D (See response to question 9A.106)

   - One Class B door (pair) in the 2-hour rated west wall to Zone 42D

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   NOTE

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Structural steel in this zone is protected by an automatic preaction ceiling level sprinkler system.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

- SCR power controller
- Pressurizer heater panels
- Load center
- Fuse boxes
- Motor control centers
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Cable insulation
    - Plastic
    - Thermo-Lag 330-1
2. Transient Combustible Load Type
    - Ordinary combustible
    - Cable insulation
3. Total Combustible (Fire) Loading

    Low

G. Fire Detection

Actuation of either the ionization smoke detector or the line-type thermal detector systems activates an

early warning alarm and the automatic preaction system.

H. Fire Suppression

1. Primary

Automatic preaction sprinkler system covering the cable trays and structural columns

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 42D.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.16.4 Fire Area XVI, Fire Zone 47A, Train A (Channel A) Electrical Penetration Room

A. Location

Fire Zone 47A (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

3-hour rated exterior wall at column line A1

South: 2-hour rated wall common to Fire Area XV, Zone 52A, at column line A6

East: 2-hour rated wall common to the south access shaft

West: 2-hour rated wall common to Fire Area XV, Zone 52A, at column line AB

3-hour rated wall common to Fire Area VI at column line AA

Floor: 2-hour rated barrier common to Zone 42A

Ceiling: 2-hour rated barrier common to Fire Area XV, Zones 55A, 55C, 55E, and 56A

2. Zone Access

- One Class B door in the 2-hour rated south wall to Zone 52A
- One Certified door (pair) in the 2-hour rated west wall to Zone 52A (See response to question 9A.106)

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   NOTE

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   Duct penetrations in the fire-rated barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   None

6. Protected Structural Members

   Structural columns in this zone are protected by an automatic preaction ceiling level sprinkler system.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Cable insulation
- Plastic
- Thermo-Lag 330-1

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Low

G. Fire Detection

Actuation of either of the ionization smoke detector or of the line-type thermal detector systems activates the automatic preaction water sprinkler system and will pressurize the piping with water. Either detection system alone can provide an early warning alarm capability.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system covering the cable trays and structural columns

2. Secondary

Two portable CO_2 fire extinguishers and one manual hose reel are located in adjacent Zone 52A.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.17 FIRE AREA XVII

9B.2.17.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XVII (figures 9B-3 and 9B-4) contains the train B electrical penetration rooms of the auxiliary building at elevations 100 feet 0 inch and 120 feet 0 inch. This fire area includes Analysis Area XVIIA (Zones 42B and 47B) (engineering drawing 13-A-ZYD-024).

Fire Area XVII is bounded to the north by 3-hour rated barriers common to Fire Areas XI and XII, and to the west by a 2-hour rated barrier common to the south access shaft. Fire Area XVII is bounded to the south and east by 2-hour rated barriers common to the

north corridors of Fire Area XV. The floor and ceiling are 1-hour and 3-hour rated barriers, respectively, common to Fire Area XV.

B. Deviations from 10CFR50, Appendix R, Section III.G

1. A deviation is requested from Section III.G.2 to the extent that it requires a 3-hour rated barrier between adjacent fire areas separating circuits of redundant trains.

Discussion

The mechanical and electrical penetrations in the containment boundary are not rated. Mechanical containment penetrations are fitted with flued heads constructed of steel with a minimum thickness of 1/8 inch. Electrical containment penetrations are fitted with a stainless steel header plate with a thickness of 1.78 inches. The special construction of the flued heads and header plates was designed to maintain the integrity of the containment building.

Conclusion

The existing design provides equivalent protection to that required by Section III.G.2. The design is standard within the industry.

9B.2.17.2 Analysis Area XVIIA

A. Location

Analysis Area XVIIA consists of Fire Zones 42B and 47B

Fire Zone 42B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

Fire Zone 47B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Analysis Area Boundaries

North: 3-hour rated wall common to Fire Area XI

3-hour rated wall common to Fire Area XII

South: 2-hour rated wall common to Fire Area XV, Zone 42C (elevation 100 feet 0 inch), at column line A6

2-hour rated wall common to Fire Area XV, Zone 52D (elevation 120 feet 0 inch), at column line A6

East: 2-hour rated wall common to Fire Area XV, Zone 42C (elevation 100 feet 0 inch)

2-hour rated wall common to Fire Area XV, Zone 52D (elevation 120 feet 0 inch)

West: 3-hour rated wall common to the south access shaft, at column line AG

Floor: 1-hour rated barrier common to Fire Area XV, Zone 37D

Ceiling: 3-hour rated barrier common to Fire Area XV, Zone 56B

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Auxiliary feedwater

  Auxiliary building HVAC

  Main steam

- Train B cables associated with the following systems:

  Auxiliary feedwater

  Chemical and volume control

  Condensate storage and transfer

  Essential chilled water

  Essential cooling water

  Auxiliary building HVAC

  Nuclear cooling water

  Reactor coolant

  Ex-core neutron monitoring

  Main steam

  Safety injection and shutdown cooling

  Nuclear sampling

Electrical power distribution

Engineered safety feature actuation

- Nontrain related cables associated with the following systems:

  Chemical and volume control

  Reactor coolant

- Train B electrical penetration room essential air control unit and associated components
- Train B 480 V-ac Class 1E motor control centers
- Train B 125 V-dc distribution auxiliary relay cabinets
- Auxiliary relay cabinet

D. Summary and Conclusion

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. The redundant train A system will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.2.

9B.2.17.3 Fire Area XVII, Fire Zone 42B, Train B (Channel B) Electrical Penetration Room

A. Location

Fire Zone 42B (engineering drawing 13-A-ZYD-023) is located in the auxiliary building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

3-hour rated wall common to Fire Area XII

South: 2-hour rated wall common to Fire Area XV, Zone 42C, at column line A6

East: 2-hour rated wall common to Fire Area XV, Zone 42C

West: 3-hour rated wall common to the south access shaft, at column line AG

Floor: 1-hour rated barrier common to Fire Area XV, Zone 37D

Ceiling: 2-hour rated barrier common to Zone 47B

2. Zone Access

   - One Certified door (pair) in the 2-hour rated east wall to Zone 42C (See response to question 9A.106)

   - One Class B door in the 2-hour rated south wall to Zone 42C

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

   NOTE

   Containment penetrations are of special construction, but not fire-rated.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   Train A auxiliary building HVAC conduits are enclosed by 1-hour protective envelopes.

6. Protected Structural Members

   Structural columns in this zone are protected by an automatic preaction ceiling level sprinkler system.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   Auxiliary relay cabinet

D. Nonsafety-Related Equipment and Components

- Cable trays and conduit
- 125 V-dc distribution panel
- Voltage regulators
- Motor control center
- Containment atmosphere radiation monitor

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Cable insulation
   - Plastic
   - Rubber
   - Thermo-Lag 330-1
2. Transient Combustible Load Type
   - Ordinary combustible
   - Cable insulation
3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

Actuation of either the ionization smoke detector and/or line-type thermal detector systems activates

an alarm and the automatic preaction sprinkler system. Either detector system alone can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system, covering cable trays and structural columns

2. Secondary

One manual hose reel and one portable CO_2 fire extinguisher are located in adjacent Zone 42C.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Two 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.17.4 Fire Area XVII, Fire Zone 47B, Train B (Channel D) Electrical Penetration Room

A. Location

Fire Zone 47B (engineering drawing 13-A-ZYD-024) is located in the auxiliary building at elevation 120 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 3-hour rated wall common to Fire Area XI

3-hour rated wall common to Fire Area XII

South: 2-hour rated wall common to Fire Area XV, Zone 52D, at column line A6

East: 2-hour rated wall common to Fire Area XV, Zone 52D

West: 3-hour rated wall common to the south access shaft at column line AG

Floor: 2-hour rated barrier common to Zone 42B

Ceiling: 3-hour rated barrier common to Fire Area XV, Zone 56B

2. Zone Access

- One Class B door in the 2-hour rated south wall to Zone 52D
- One Certified door (pair) in the 2-hour rated east wall to Zone 52D (See response to question 9A.106)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   Duct penetrations in the rated fire barriers are provided with fire dampers of equal or greater rating.

5. Protected Raceways

   Train A auxiliary Building HVAC conduits are enclosed by 1-hour protective envelopes.

6. Protected Structural Members

   Structural columns in this zone are protected by a water spray system.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

- Train B containment atmosphere radiation monitor

D. Nonsafety-Related Equipment and Components

- Electrical penetrations alarm panel
- Load center
- Auxiliary relay cabinet
- Cable trays and conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Thermo-Lag 330-1

- Cable insulation
- Plastic

2. Transient Combustible Load Type

- Ordinary combustible
- Cable insulation

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

Actuation of either ionization smoke detector or the line-type thermal detector system(s) activates the automatic preaction water sprinkler system and will pressurize the piping with water. Either detector system can provide early warning capability.

H. Fire Suppression

1. Primary

Automatic preaction water sprinkler system covering cable trays and structural columns

2. Secondary

One portable CO_2 fire extinguisher and one manual hose reel are located in adjacent Zone 52D.

I. Ventilation

Manually controlled smoke exhaust venting to the outside using portable smoke removal equipment.

J. Drainage

Three 4-inch drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.18 FIRE AREA XVIII

9B.2.18.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XVIII (figure 9B-3) contains train A diesel generator fuel oil storage components found in the outside areas. This fire area includes Analysis Area XVIIIA (Zone 78A) only (engineering drawing 13-A-ZYD-021).

Fire Area XVIII is located to the southwest of the diesel generator building (Fire Area IV). The Unit 1 and Unit 2 train A and train B (Fire Area XIX) diesel generator fuel oil storage tanks and pumps are buried side by side. The Unit 3 train B (Fire Area XIX) tank and pump are buried separate from Fire Area XVIII, to the southeast of the diesel generator building.

B. Deviations from 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.18.2 Analysis Area XVIIIA

A. Location

Analysis Area XVIII consists of Fire Zone 78A.

Fire Zone 78A (engineering drawing 13-A-ZYD-021) is located at the outside areas below grade.

B. Analysis Area Boundaries

The diesel generator fuel oil storage tank is buried underground with earth coverage that is adequate for missile protection. Above the tank is a concrete vault, which includes a missileproof structural cover at grade level. The foundation of the vault is independent of the tank to avoid any load transfer to the tank shell.

C. Safe Shutdown Related Components and Cables

- Train A cables associated with the following systems:

  Diesel fuel oil and transfer

  Diesel generator

- Train A diesel generator fuel oil transfer pump and associated components

- Train A diesel generator fuel oil storage tank and associated components

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train B systems available from the control room.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.18.3 Fire Area XVIII, Fire Zone 78A, Train A Underground Diesel Generator Fuel Oil Storage Tank and Pump

A. Location

Fire Zone 78A (engineering drawing 13-A-ZYD-021) is located at the outside areas below grade.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

The diesel generator fuel oil storage tank is buried underground with earth coverage which is adequate for missile protection. Above the tank is a concrete vault which includes a missile-proof structural cover at grade level. The foundation of the vault is independent of the tank to avoid any load transfer to the tank shell.

2. Zone Access

- One nonrated manhole in the nonrated ceiling of the vault to the yard
- One nonrated hatch in the nonrated ceiling of the vault to the yard

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

Diesel Oil

2. Transient Combustible Load Type

   - Ordinary combustible
   - Diesel oil in tank truck

3. Total Combustible (Fire) Loading

   Due to a lack of oxygen, a fire in the buried tank and vault is not considered a credible event.

G. Fire Detection

None

H. Fire Suppression

Manual hose streams from hydrants on the yard fire main

I. Ventilation

None

J. Drainage

None

K. Emergency Communications

None

9B.2.19 FIRE AREA XIX

9B.2.19.1 Fire Area Description

A. Area Boundary Descriptions

Fire Area XIX (figure 9B-3) contains train B diesel generator fuel oil storage components found in the

outside areas. This fire area includes Analysis Area XIXA (Zone 78B) only (engineering drawing 13-A-ZYD-021).

Fire Area XIX of Units 1 and 2 is located to the southwest of the diesel generator building (Fire Area IV). The train A (Fire Area XVIII) and train B diesel generator fuel oil storage tanks and pumps are buried side by side. The Unit 3 train B tank and pump are buried separate from train A (Fire Area XVIII) to the southeast of the diesel generator building (Fire Area V).

B. Deviations From 10CFR50, Appendix R, Section III.G

See subsection 9B.2.0 for generic deviations.

9B.2.19.2 Analysis Area XIXA

A. Location

Analysis Area XIXA consists of Fire Zone 78B.

Fire Zone 78B (engineering drawing 13-A-ZYD-021) is located in the outside areas below grade.

B. Analysis Area Boundaries

The diesel generator fuel oil storage tank is buried underground with earth coverage that is adequate for missile protection. Above the tank is a concrete vault, which includes a missileproof structural cover at grade level. The foundation of the vault is independent of the tank to avoid any load transfer to the tank shell.

C. Safe Shutdown Related Components and Cables

- Train B cables associated with the following systems:

  Diesel fuel oil and transfer

  Diesel generator

- Train B diesel generator fuel oil transfer pump and associated components

- Train B diesel generator fuel oil storage tank and associated components

D. Summary and Conclusion

Safe shutdown capability will be provided by utilizing redundant train A systems available from the control room.

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.19.3 Fire Area XIX, Fire Zone 78B, Train B Underground Diesel Generator Fuel Oil Storage Tank and Pump

A. Location

Fire Zone 78B (engineering drawing 13-A-ZYD-021) is located in the outside areas below grade.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

   The diesel generator fuel oil storage tank is buried underground with earth coverage which is adequate for missile protection. Above the tank is a concrete vault which includes a missileproof structural cover at grade level. The foundation of the vault is independent of the tank to avoid any load transfer to the tank shell.

2. Zone Access

   - One nonrated manhole in the nonrated ceiling of the vault to the yard
   - One nonrated hatch in the nonrated ceiling of the vault to the yard

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

None

D. Nonsafety-Related Equipment and Components

Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

Diesel Oil

2. Transient Combustible Load Type

- Ordinary combustible
- Diesel oil in tank truck

3. Total Combustible (Fire) Loading

Due to a lack of oxygen, a fire in the buried tank and vault is not considered a credible event.

G. Fire Detection

None

H. Fire Suppression

Manual hose streams from hydrants on the yard fire main

I. Ventilation

None

J. Drainage

None

K. Emergency Communications

None

9B.2.20 MISCELLANEOUS ANALYSIS AREAS

The miscellaneous analysis areas described in item 9B.2.20 (figure 9B-3) contain components located in the turbine building, the corridor building and in the yard area. These analysis areas include Zones 79, 80, 81, the turbine building, the corridor building and the breezeway (engineering drawing 13-A-ZYD-021). These zones are found within each of the three PVNGS units. They contain some components (as noted in item C, Safe Shutdown Related Components and Cables), which may require operator actions for fires postulated in the control building or other safety-related areas. However, for fires that may occur in the following miscellaneous analysis areas, safe shutdown can be achieved and maintained from the control room, in conjunction with operator action, outside these analysis areas to achieve the shutdown function. Therefore, the fire barriers and fire protection equipment serving these miscellaneous areas are not required to be included in the fire protection quality assurance program. The portable fire extinguishers and hose stations located in the corridor building adjacent to the control building

have been classified as quality augmented (QAG) as they may be credited for use on fires in the control building.

9B.2.20.1 Turbine Building

A. Location

The analysis area is located to the east of the auxiliary building and main steam support structure.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of metal siding

South: Nonrated exterior wall of metal siding

2-hour rated exterior wall of masonry block construction at the turbine switchgear room

East: Nonrated exterior wall of metal siding

2-hour rated exterior wall of masonry block construction at the turbine switchgear room

West: Nonrated exterior wall of metal siding

2-hour rated exterior wall of concrete block construction at the turbine building battery room

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of built-up roofing on rigid insulation on metal decking

2. Analysis Area Access

One nonrated door in the nonrated north wall to the exterior at elevation 100 feet

One nonrated door in the nonrated north wall to the exterior at elevation 100 feet

Two nonrated doors in the nonrated east wall to the maintenance facility at elevation 100 feet

One Class B door in the 2-hour rated east wall of the turbine building switchgear room to the exterior at elevation 100 feet

One nonrated door in the nonrated east wall to the exterior at elevation 100 feet

Two nonrated doors in the nonrated south wall to the exterior at elevation 100 feet

One Class B door in the 2-hour rated west wall of the turbine building battery room to the exterior at elevation 100 feet

One nonrated door in the nonrated exterior west wall of stairway T112 at elevation 100 feet

One nonrated door in the nonrated east wall to the exterior at elevation 100 feet

One nonrated door in the nonrated west wall to the exterior at elevation 140 feet

One nonrated door in the nonrated west wall to the exterior at elevation 176 feet

3. Protected Raceways

   None

4. Protected Structural Members

   Two-hour rated fireproofing on beams and columns in the turbine building battery room

C. Safe Shutdown Related Components and Cables

- Nontrain related cables associated with the following system:

  Reactor coolant

- Train A auxiliary steam to auxiliary feedwater turbine isolation valve

D. Safety-Related Components and Cables Not Required for Safe Shutdown

   None

E. Nonsafety-Related Equipment and Components

- Balance-of-plant equipment
- Auxiliary feedwater pump and motor

F. Radioactive Material

   None

G. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation

- Oil, grease
- Fyrquel
- Resin
- Battery casing
- Hydrogen
- Charcoal
- Plastic (polyurethane and polisocyanurate foam, vinyl floor tile and cove molding)
- Wood

2. Transient Combustible Load Type

   - Cable insulation
   - Oil, grease
   - Fyrquel
   - Ordinary combustibles

3. Total Combustible (Fire) Loading

   High

H. Fire Detection

Smoke detectors in the feedwater pump area, at motor control centers, and in the switchgear and battery rooms at elevation 100 feet provide early warning. Smoke detectors near load and motor control centers at elevation provide early warning. Heat detectors in the lube oil room at elevation 140 feet actuate

the deluge system. Heat detectors in the hydrogen seal oil unit at elevation 140 feet actuate the deluge system and provide early warning. Thermal detectors at turbine bearings at elevation 176 feet provide early warning and preactivate the sprinkler system.

I. Fire Suppression

1. Primary

Automatic wet pipe sprinkler systems on elevations 100 feet and 140 feet. Automatic preaction sprinkler system covering the main turbine bearings at elevation 176 feet. Automatic deluge systems covering the feedwater pumps and lube oil centrifuge at elevation 100 feet. Automatic deluge system covering the lube oil room and hydrogen seal oil unit at elevation 140 feet. Manual deluge system covering the oil lines at the turbine bearings at elevation 176 feet.

2. Secondary

Hose stations and portable extinguishers are located throughout the area.

J. Ventilation

Manually controlled smoke venting to the outside.

K. Drainage

Numerous 4-inch drains

L. Emergency Communications

Telephones and sound powered telephone jacks throughout the area.

M. Summary and Conclusions

Safe shutdown capability will be provided by utilizing redundant systems available from the control room, in conjunction with operator action, outside this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function

One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.20.2 Corridor Building

A. Location

The analysis area consists of the corridor building abutting the east side of the control building and auxiliary building.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of metal siding

South: Nonrated exterior wall of metal siding

East: Nonrated exterior wall of metal siding at column line JF and open to operations support building

West: 3-hour rated wall of the control building and the auxiliary building

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

One Class A door in the 3-hour rated west wall to Fire Area II, Zone 5B at elevation 100 feet

One nonrated door in the nonrated east wall to the exterior at elevation 100 feet

Open to the operations support building at the south wall of stairway A at 110 feet

One nonrated missile door in the 3-hour rated west wall to Fire Area II, Zone 14, at elevation 120 feet

One nonrated missile door in the 3-hour rated west wall to Fire Area XV, Zone 54, at elevation 120 feet

Open to the operations support building at the south wall of stairway A at 130 feet

One nonrated missile door in the 3-hour rated west wall to Fire Area III, Zone 17, at elevation 140 feet

One Class A door in the 3-hour rated west wall to Fire Area XV, Zone 57J, at elevation 140 feet

One nonrated door in the nonrated north wall to the exterior at elevation 140 feet

One Class C door in the 1-hour rated east wall of stairway A at elevation 140 feet

One nonrated door in the nonrated east wall to the operations support building at elevation 140 feet

Open to the operations support building at the south wall of stairway A at elevation 150 feet

One nonrated missile door in the 3-hour rated west wall to Fire Area I, Zone 20 at 160 feet

3. Protected Raceways

None

4. Protected Structural Members

1-hour fireproofing on all beams and columns between column line JE and column line JH

C. Safe Shutdown Related Components and Cables

- Nontrain related cables associated with the following systems:

Control building HVAC

Reactor coolant

D. Safety-Related Components and Cables Not Required for Safe Shutdown

None

E. Nonsafety-Related Equipment and Components

- Offsite power circuits
- Balance-of-plant cables
- Radio transmitter (160 feet)
- Preaction system valves for cable spreading rooms (120 feet and 160 feet)

F. Radioactive Material

None

G. Combustible Loading

1. In Situ Combustible Load Type
    - Cable insulation
    - Plastic, paper, wood
2. Transient Combustible Load Type
    - Cable insulation
    - Ordinary combustibles
3. Total Combustible (Fire) Loading

    Moderate

H. Fire Detection

Smoke detectors in balance-of-plant cable shaft for early warning

I. Fire Suppression

1. Primary

Hose stations

2. Secondary

Portable extinguishers

J. Ventilation

Manually controlled smoke venting to the outside

K. Drainage

None

L. Emergency Communications

Telephones

M. Summary and Conclusions

The following system is affected for a fire in this analysis area:

Control building HVAC

The following nontrain related system is affected for a fire in this analysis area:

Reactor Coolant

One train of systems necessary to achieve and maintain hot standby and cold shutdown, has been demonstrated to remain available for use based on

fire barriers provided. Either train A or train B systems will remain available from the control room, in conjunction with operator action, outside of this analysis area to prevent or overcome the consequences of spurious operation of components or to establish equipment lineups required to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.20.3 Fire Zone 79, Reactor Makeup Water Tank

A. Location

Analysis Area 79 consists of Fire Zone 79.

Fire Zone 79 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to the yard

South: Open to the yard north of the holdup tank (Zone 80)

East: Adjacent to the nonrated west wall, of heavy concrete construction, of the fuel building (Fire Area VI)

West: Open to the yard

NOTE

The reactor makeup water tank is constructed of austenitic stainless steel.

2. Zone Access

Open to the yard (north, south, and west)

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safe Shutdown Related Components and Cables

- Nontrain related reactor makeup water tank and associated components

D. Safety-Related Components and Cables Not Required for Safe Shutdown

None

E. Nonsafety-Related Equipment and Components

- 5-kW heaters
- Conduit

F. Radioactive Material

Radioactive material in the tank

G. Combustible Exposure Fire Loading

1. In Situ Combustible Load Type

   Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible Exposure (Fire) Loading

   Low

H. Fire Detection

None

I. Fire Suppression

Manual hose stream from hydrants on the yard fire main

J. Ventilation

Natural convection

K. Drainage

None

L. Emergency Communications

None

M. Summary and Conclusions

No safe shutdown systems are affected for a fire in this analysis area.

Safe shutdown capability will remain available from the control room. One train of systems necessary to achieve hot standby and cold shutdown has been evaluated to remain available for safe shutdown in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.20.4 Fire Zone 80, Holdup Tank, Pump House, and Essential Pipe Tunnel

A. Location

Fire Zone 80 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet. The essential pipe tunnel is at elevation 86 feet.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

NOTE

The holdup tank is located to the southwest of the fuel building which is of heavy concrete construction. The holdup tank is constructed of reinforced concrete with an austenitic stainless steel liner plate.

North: Holdup tank is open to the yard south of the reactor makeup water tank (Zone 79). Essential pipe tunnel common to nonrated concrete south wall of fuel building, Fire Area VI

South: Open to the yard

East: Open to the yard west of the refueling water tank (Zone 81). Essential pipe tunnel common to nonrated concrete west wall of Auxiliary Building, Fire Area XV.

West: Open to the yard

2. Zone Access

The essential pipe tunnel is accessed through the pump house at the west end.

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safe Shutdown and Safety-Related Equipment and Components

Train A and B piping

D. Nonsafety-Related Equipment and Components

- Holdup tank
- Conduit

- Heaters
- Sump pumps

E. Radioactive Material

Radioactive material in the tank and process piping

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

Manual hose streams from hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

None

K. Emergency Communications

None

L. Summary and Conclusions

Normal shutdown is credited for a fire in this area. One train of safe shutdown equipment is expected to remain available due to fire barriers and spatial separation in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.20.5 Fire Zone 81, Refueling Water Tank

A. Location

Analysis Area 81 consists of Fire Zone 81.

Fire Zone 81 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Adjacent to the nonrated south wall, of heavy concrete construction, of the fuel building (Fire Area VI)

South: Open to the yard north of the radwaste building and carbon dioxide storage unit

East: Adjacent to the nonrated west wall, of heavy concrete construction, of the auxiliary building

West: Open to the yard east of the holdup tank (Zone 80)

NOTE

The refueling water tank is constructed of reinforced concrete with an austenitic stainless steel liner plate.

2. Zone Access

   Open to the yard (south and west)

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safe Shutdown Related Components and Cables

- Train A and train B cables associated with the following system:

  Chemical and volume control

  Engineered safety feature actuation

- Refueling water tank, level transmitters, and associated components

D. Safety-Related Components and Cables Not Required for Safe Shutdown

None

E. Nonsafety-Related Equipment and Components

- Holdup pumps
- Heaters
- Conduit

F. Radioactive Material

Radioactive material in the tank

G. Combustible Loading

1. In Situ Combustible Load Type

   None

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

H. Fire Detection

None

I. Fire Suppression

Manual hose streams from hydrants on the yard fire main

J. Ventilation

Natural convection

K. Drainage

None

L. Emergency Communications

None

M. Summary and Conclusions

The following systems are affected for a fire in this analysis area:

Chemical and volume control and engineered safety feature actuation.

Based on other component losses for this analysis area, the loss of refueling water tank level indication will not adversely affect safe shutdown capability.

One train of systems necessary to achieve and maintain hot standby and cold shutdown has been demonstrated to remain available for use based on fire barriers provided. Either train A or train B systems will remain available from the control room to achieve the shutdown function, in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.20.6 Breezeway

A. Location

Along north side of the corridor building, the east side of the auxiliary and main steam support structure, and the west side of the turbine building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to the yard area

South: Adjacent to the nonrated north wall of the corridor building

East: Adjacent to the nonrated west wall of the turbine building

West: Adjacent to the 3-hour rated east wall of the auxiliary building and the nonrated east wall of the main steam support structure

Floor: Nonrated slab of concrete construction

Ceiling: Open

2. Zone Access

Open to yard (north and east)

3. Protected Raceways

None

4. Protected Structural Members

None

C. Safe Shutdown Related Components and Cables

- Nontrain related cables associated with the following system:

  Reactor coolant

- Heater drain pumps

- Condensate pumps
- Nuclear cooling water pumps

D. Safety-Related Components and Cables Not Required for Safe Shutdown

None

E. Nonsafety-Related Equipment and Components

None

F. Radioactive Material

None

G. Combustible Loading

1. In Situ Combustible Load Type

   Ordinary combustibles

2. Transient Combustible Load Type

   Ordinary combustibles

3. Total Combustible (Fire) Loading

   Low

H. Fire Detection

None

I. Fire Suppression

None

J. Ventilation

Natural convection

K. Drainage

None

L. Emergency Communications

Telephone

M. Summary and Conclusions

The following nontrain related system is affected for a fire in this analysis area:

Reactor coolant.

Safe shutdown capability will be provided by utilizing redundant systems available from the control room, in conjunction with manual actions, outside of this analysis area to prevent or overcome the consequences of spurious operation of components.

This area is in accordance with 10CFR50, Appendix R, Section III.G.

9B.2.21 MISCELLANEOUS FIRE ZONES

The miscellaneous fire zones (figure 9B-3) contain nonsafe shutdown related components found outside of the power block, in the yard area; this includes Zones 75A, 75B, 76, 77, 85A, 85B, 91A, 91B, 91C, 91D, 92A, 92B, 92C, 92D, 99A, 99B, 99C and 99D (engineering drawing 13-A-ZYD-021). The zones are found with each of the three PVNGS units, except for two facilities shared by all three units. These facilities are the decontamination and laundry facility (Zones 91A, 91B, 91C, and 91D), which is located south of the Unit 1 radwaste building,

and the fire pump house (Zones 92A, 92B, 92C, and 92D), which is located in the northeast section of the station.

9B.2.21.1 Fire Zone 75A, Main Transformers and Bus

A. Location

Fire Zone 75A (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Zone 75B at column line 3

South: Open to the yard

East: Nonrated exterior wall of heavy concrete construction at column line P

West: Nonrated exterior wall of heavy concrete construction at column line F

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the atmosphere

NOTE

The three main transformers are separated by two 2-hour rated walls, one each at column lines J and N.

2. Zone Access

Open to the south (yard)

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   Main transformers and bus

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Transformer oil
      - Grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Heat-actuated detectors to activate the automatic water spray systems

H. Fire Suppression

1. Primary

Automatic water spray systems

2. Secondary

Manual hose streams from the hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

The main transformers are connected to sump drains.

K. Emergency Communications

None

9B.2.21.2 Fire Zone 75B, Auxiliary Transformer

A. Location

Fire Zone 75B (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall adjacent to the turbine building at column line 1

South: 2-hour rated wall common to Zone 75A at column line 3

East: Open to the yard

West: Nonrated wall of heavy concrete construction at column line H

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the atmosphere

2. Zone Access

Open to the east (yard)

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Auxiliary transformer and bus
- Neutral grounding resistors

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
    - Transformer oil
    - Grease
2. Transient Combustible Load Type
    - Ordinary combustible
    - Oil and grease
3. Total Combustible (Fire) Loading

    High

G. Fire Detection

Heat actuated detectors to actuate the automatic water spray systems

H. Fire Suppression

1. Primary

    Automatic water spray system

2. Secondary

    Manual hose streams from the hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

The auxiliary transformer is connected to a sump drain

K. Emergency Communications

None

9B.2.21.3 Fire Zone 76, ESF Service Transformers and Switchgear

A. Location

Fire Zone 76 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

NOTE

There are two ESF service transformers with related 13.8 kV switchgear, one located to the west of the normal service transformers (Zone 77), the other to the east.

North:	Both transformers	-	2-hour rated wall common to the switchgear building at column line T7

South:	Both transformers	-	Open to the yard
East:	Western transformer	-	2-hour rated wall common to Zone 77 at column line B
	Eastern transformer	-	Open to the yard
West:	Western transformer	-	2-hour rated wall common to the yard at column line A
	Eastern transformer	-	2-hour rated wall common to Zone 77 at column line D
Floor:	Nonrated basemat of heavy concrete construction		
Ceiling:	Open to the atmosphere		

2. Zone Access

   Open to the yard (south and east)

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

- ESF service transformers and 13.8 kV switchgear
- Neutral grounding resistors

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Transformer oil
   - Grease
   - Rubber
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil and grease
3. Total Combustible (Fire) Loading

   High

G. Fire Detection

   Heat actuated detectors to actuate the automatic water spray system

H. Fire Suppression

1. Primary

Automatic water spray system (for ESF service transformer area)

2. Secondary

Manual hose streams from the hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

The ESF service transformers connected to sump drains

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.21.4 Fire Zone 77, Normal Service Transformers

A. Location

Fire Zone 77 (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated barrier common to the switchgear building at column line T7

South: Open to the yard

East: 2-hour rated barrier common to Zone 76, eastern ESF service transformer, at column line D

West: 2-hour rated barrier common to Zone 76, western ESF service transformer, at column line B

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Open to the atmosphere.

NOTE

Within Zone 77 the two normal service transformers are separated by a 2-hour rated barrier at column line C.

2. Zone Access

Open to the yard (south)

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Neutral grounding resistors
- Normal service transformers

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Transformer oil
   - Grease
   - Rubber
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil and grease
3. Total Combustible (Fire) Loading

   High

G. Fire Detection

Heat actuated detectors to actuate the automatic water spray systems.

H. Fire Suppression

1. Primary

   Automatic water spray systems

2. Secondary

Manual hose streams from the hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

The normal service transformers are connected to sump drains.

K. Emergency Communications

Sound powered phone jack(s) is provided.

9B.2.21.5 Fire Zone 85A, Common Auxiliary Boilers (Abandoned)

A. Location

Fire Zone 85A (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Open to the yard

South: Open to the yard north of the condensate water storage tank

East: Open to the yard

West: Open to the yard

2. Zone Access

   Open to the yard

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   - Conduit
   - Common auxiliary boilers (abandoned)
   - Feed pumps
   - Force draft vents

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      None

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Burner front is protected by manual hose streams from hydrants on the yard fire main. Boiler does not contain or expose safety related equipment.

G. Fire Detection

None

H. Fire Suppression

1. Primary

   Manual hose streams from hydrants on the yard fire main

2. Secondary

   None

I. Ventilation

Natural convection

J. Drainage

None

K. Emergency Communications

None

9B.2.21.6 Fire Zone 85B, Lube Oil Storage Tanks

A. Location

Fire Zone 85B (engineering drawing 13-A-ZYD-021) is located in the outside areas at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Concrete dike common to the yard

South: Concrete dike common to the yard, north of the turbine building

East: Concrete dike common to the yard

West: Concrete dike common to the yard

NOTE

The concrete dike surrounding the two lube oil storage tanks is sized to contain the oil from a tank rupture. Each tank is constructed of carbon steel.

2. Zone Access

- Ladder access over the dike wall at the southeast corner
- Ladder access over the dike wall at the northwest corner

3. Sealed Penetrations

None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

- Dirty lube oil storage tank
- Clean lube oil storage tank
- Lube oil transfer pump
- Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

   Oil and grease

2. Transient Combustible Load Type

   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

High

G. Fire Detection

Heat-actuated detectors to actuate the automatic water spray system

H. Fire Suppression

1. Primary

Automatic water spray system

2. Secondary

Manual hose streams from hydrants on the yard fire main

I. Ventilation

Natural convection

J. Drainage

One 1-inch drain (normally capped) to remove rain water from inside the dike

K. Emergency Communications

None

9B.2.21.7 Fire Zone 91A, Clean Clothing Storage Area

A. Location

Fire Zone 91A (engineering drawing 13-A-ZYD-021) is located in the decontamination and laundry facility at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line L1

Nonrated wall of heavy concrete construction common to Zone 91D at column line L5

South: Nonrated wall of heavy concrete construction common to Zone 91B at column line L1.2

East: Nonrated exterior wall of heavy concrete construction at column line LC.

West: Nonrated walls of heavy concrete construction common to Zone 91D at column lines LB.1 and LB.3

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One nonrated door in the nonrated west wall to Zone 91D
- One nonrated door in the nonrated south wall to Zone 91B

- One open pass-through window in the nonrated south wall to Zone 91B
- One nonrated door (pair) in the nonrated east exterior wall

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   - Clean clothing
   - Protective clothing
   - Clothing radiation monitor
   - Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type

- Paper and fabric
- Plastic
- Rubber
- Cable insulation
- Lubricating oil

2. Transient Combustible Load Type

Ordinary combustible

3. Total Combustible (Fire) Loading

High

G. Fire Detection

None

H. Fire Suppression

1. Primary

One pressurized water fire extinguisher

2. Secondary

Manual hose stream from a hydrant on the yard fire main is available.

I. Ventilation

Flow through air filtration unit to outside

J. Drainage

None

K. Emergency Communications

None

9B.2.21.8 Fire Zone 91B, Bagged Contaminated Clothing Hold Area

A. Location

Fire Zone 91B (engineering drawing 13-A-ZYD-021) is located in the decontamination and laundry facility at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 91A at column line L1.2

Nonrated wall of heavy concrete construction common to Zone 91D at column line L1.3

South: Nonrated exterior wall of heavy concrete construction at column line L2

East: Nonrated exterior wall of heavy concrete construction at column line LC

West: Nonrated wall of heavy concrete construction common to Zone 91C at column line LB

Nonrated wall of heavy concrete construction common to Zone 91D at column line LB.1

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

- One nonrated door in the nonrated north wall to Zone 91A
- One open pass-through window in the nonrated north wall to Zone 91A
- One nonrated door (pair) in the nonrated east exterior wall

3. Sealed Penetrations

None

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Bagged contaminated clothing
- Protective clothing
- Drycleaning machines
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Paper and fabric
   - Cable insulation
   - Plastic
   - Wood
   - Rubber
   - Oil and grease
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil and grease
3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

1. Primary

One portable CO_2 and one pressurized water fire extinguisher

2. Secondary

Manual hose stream from a hydrant on the yard fire main is available.

I. Ventilation

Flow through air filtration unit to outside

J. Drainage

Five 4-inch drains

K. Emergency Communications

None

9B.2.21.9 Fire Zone 91C, Tools and Supplies Storage

A. Location

Fire Zone 91C (engineering drawing 13-A-ZYD-021) is located in the decontamination and laundry facility at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of heavy concrete construction common to Zone 91D at column line L1.3

South:	Nonrated exterior wall of heavy concrete construction at column line L2
East:	Nonrated wall of heavy concrete construction common to Zone 91B at column line LB
West:	Nonrated wall of heavy concrete construction common to Zone 91D at column line LA.4
Floor:	Nonrated basemat of heavy concrete construction
Ceiling:	Nonrated roof of heavy concrete construction

2. Zone Access

   One nonrated door in the nonrated north wall to Zone 91D

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Tools and supplies
- Conduit

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Paper and fabric
   - Oil and grease
   - Plastic
   - Rubber
   - Wood
   - Cable insulation

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

None

H. Fire Suppression

Two portable CO_2 and two pressurized water fire extinguishers are located in adjacent Zone 91D. Manual hose stream from a hydrant on the yard fire main is available.

I. Ventilation

Flow through air filtration unit to outside

J. Drainage

None

K. Emergency Communications

None

9B.2.21.10 Fire Zone 91D, Contaminated and Clean Parts Laydown and Disassembly Areas

A. Location

Fire Zone 91D (engineering drawing 13-A-ZYD-021) is located in the decontamination and laundry facility at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of heavy concrete construction at column line L1

South: Nonrated exterior wall of heavy concrete construction at column line L2

Nonrated wall of heavy concrete construction common to Zone 91A at column line L5

Nonrated wall of heavy concrete construction common to Zones 91B and 91C at column line L1.3

East: Nonrated wall of heavy concrete construction common to Zone 91A at column line LB.3

Nonrated wall of heavy concrete construction common to Zones 91A and 91B at column line LB.1

Nonrated wall of heavy concrete construction common to Zone 91C at column line LA.4

West: Nonrated exterior wall of heavy concrete construction at column line LA

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of heavy concrete construction

2. Zone Access

   - One nonrated door in the nonrated north exterior wall
   - One nonrated door in the nonrated east wall to Zone 91A
   - One nonrated door in the nonrated south wall to Zone 91C
   - One nonrated door in the nonrated west exterior wall
   - One nonrated rollup door in the nonrated west exterior wall

3. Sealed Penetrations

   None

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Turbulator

- Stainless steel tanks
- Ultrasonic clean system
- Decontamination spray booth
- Steamerette
- Pressure washer
- Two-ton monorail
- Sump and pump
- Conduit

E. Radioactive Material

Area designed to clean contaminated parts and equipment.

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Paper and fabric
   - Oil and grease
   - Plastic
   - Rubber
   - Wood

2. Transient Combustible Load Type

   Ordinary combustible

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   Two portable CO_2 and two pressurized water fire extinguishers

2. Secondary

   Manual hose stream from a hydrant on the yard fire main is available.

I. Ventilation

   Flow through air filtration unit to outside

J. Drainage

   Nine 4-inch drains

K. Emergency Communications

   None

9B.2.21.11 Fire Zone 92A, Fire Pump Room No. 1 and Fuel Oil Day Tank

A. Location

   Fire Zone 92A (engineering drawing 13-A-ZYD-021) is located in the fire pump house at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Zone 92D

South: Nonrated exterior wall of concrete block construction at column line 1

East: Nonrated exterior wall of concrete block construction at column line A

West: 2-hour rated wall common to Zone 92C at column line B

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of Built-Up construction

NOTE

Fire Zone 92A includes the fuel day tank located to the southeast of the fire pump house.

2. Zone Access

- One Class B door in the 2-hour rated north wall to Zone 92D
- One nonrated door in the nonrated east exterior wall
- One nonrated rollup door in the nonrated east exterior wall
- One nonrated louver-damper in the nonrated south exterior wall

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   - Fuel oil day tank
   - Fire water pump (diesel-driven)
   - Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil and grease
      - Diesel oil
      - Polycarbonate battery casing

2. Transient Combustible Load Type

- Oil and grease
- Ordinary combustible

3. Total Combustible (Fire) Loading

Moderate

G. Fire Detection

None

H. Fire Suppression

1. Primary

Automatic wet pipe sprinkler system

2. Secondary

One portable CO_2 fire extinguisher

I. Ventilation

Flow to outside

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.21.12 Fire Zone 92B, Fire Pump Room No. 3 and Fuel Oil Day Tank

A. Location

Fire Zone 92B is located in the fire pump house at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated wall common to Zone 92D

South: Nonrated exterior wall of concrete block construction at column line 1

East: 2-hour rated wall common to Zone 92C at column line C

West: Nonrated exterior wall of concrete block construction at column line D

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of Build-Up construction

NOTE

Fire Zone 92B includes the fuel day tank located to the southwest of the fire pump house.

2. Zone Access

- One Class B door in the 2-hour rated north wall to Zone 92D
- One nonrated door in the nonrated west exterior wall
- One nonrated rollup door in the nonrated west exterior wall
- One nonrated louver damper in the nonrated south exterior wall

3. Sealed Penetrations

   Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   - Fire water pump (diesel-driven)
   - Fuel oil day tank
   - Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Oil and grease
      - Diesel fuel
      - Polycarbonate battery casing

2. Transient Combustible Load Type

   - Oil and grease
   - Ordinary combustible

3. Total Combustible (Fire) Loading

   Moderate

G. Fire Detection

None

K. Emergency Communications

None

9B.2.21.13 Fire Zone 92C, Fire Pump Room No. 2

A. Location

Fire Zone 92C (engineering drawing 13-A-ZYD-021) is located in the fire pump house at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated wall of concrete block construction common to Zone 92D

South: Nonrated exterior wall of concrete block construction at column line 1

East: 2-hour rated wall common to Zone 92A at column line B

West: 2-hour rated wall common to Zone 92B at column line C

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of Built-Up construction

2. Zone Access

- One nonrated door in the nonrated north wall to Zone 92D

- One nonrated louver damper in the nonrated south exterior wall

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

   - Jockey pump
   - Fire water pump (electric motor-driven)
   - Conduit

E. Radioactive Material

   None

F. Combustible Loading

   1. In Situ Combustible Load Type

      Oil and grease

   2. Transient Combustible Load Type

      - Ordinary combustible
      - Oil and grease

   3. Total Combustible (Fire) Loading

      Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

One portable CO_2 fire extinguisher

2. Secondary

Manual hose stream from a hydrant on the yard fire main is available. One portable CO_2 fire extinguisher is located in each of adjacent Zones 92A, 92B, and 92D.

I. Ventilation

Flow to outside

J. Drainage

One 4-inch drain

K. Emergency Communications

None

9B.2.21.14 Fire Zone 92D, Domestic Water Pump Room

A. Location

Fire Zone 92D (engineering drawing 13-A-ZYD-021) is located in the fire pump house at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: Nonrated exterior wall of concrete block construction at column line 3

South: 2-hour rated walls common to Zones 92A and 92B

Nonrated wall of concrete block construction common to Zone 92C

East: Nonrated exterior wall of concrete block construction at column line A

West: Nonrated exterior wall of concrete block construction at column line D

Floor: Nonrated basemat of heavy concrete construction

Ceiling: Nonrated roof of Built-Up construction

2. Zone Access

- One Class B door in the 2-hour rated south wall to Zone 92A
- One Class B door in the 2-hour rated south wall to Zone 92B
- One nonrated door in the nonrated south wall to Zone 92C
- One nonrated rollup door in the nonrated east exterior wall
- Two nonrated louver dampers in the nonrated north exterior wall

3. Sealed Penetrations

Seals equal or exceed fire barrier ratings.

4. Fire Dampers

   None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

- Domestic water transfer pumps
- Well water booster pumps
- Conduit

E. Radioactive Material

   None

F. Combustible Loading

1. In Situ Combustible Load Type
   - Oil and grease
   - Plastic
2. Transient Combustible Load Type
   - Ordinary combustible
   - Oil and grease

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

   None

H. Fire Suppression

1. Primary

   One portable CO_2 fire extinguisher

2. Secondary

   Manual hose stream from a hydrant on the yard fire main is available. One portable CO_2 fire extinguisher is located in each of adjacent Zones 92A, 92B, and 92C.

I. Ventilation

   Flow to outside

J. Drainage

   Three 4-inch drains

K. Emergency Communications

   None

9B.2.21.15 Low Level Radioactive Materials Storage Facility (LLRMSF)

A. Location

   The LLRMSF is located approximately 500 feet northeast of the Unit 1 cooling towers.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North:

South:

East:

West: All are non-rated exterior walls of heavy precast concrete construction.

Floor: Non-rated basemat of heavy concrete construction.

Roof: Non-rated roof of precast concrete construction.

2. Zone Access

- Non-rated personnel access doors in the non-rated east and south walls.
- Non-rated roll-up doors in the non-rated east and south walls.

3. Sealed Penetrations

Non-fire rated seals are provided for radiation shielding.

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

   All precast concrete construction.

C. Safety-Related Equipment and Components Not Required for Safe Shutdown

   None

D. Nonsafety-Related Equipment and Components

   Area radiation monitors

E. Radioactive Material

   Area containing radioactive material

F. Combustible Loading

   1. In Situ Combustible Load Type

      - Ordinary combustibles (rack storage to 16 feet)
      - Paper, plastic, rubber, resin
      - Wood pallets

   2. Transient Combustibles

      - Ordinary combustibles including radioactive materials
      - Vehicles in truck bay

   3. Total Combustible (Fire) Loading

      High

G. Fire Detection

   Photoelectric detector in the HVAC duct

H. Fire Suppression

1. Primary

Wet pipe sprinkler system

2. Secondary

One manual hose station

I. Ventilation

Manually controlled smoke exhaust venting to the outside portable smoke removal equipment.

J. Drainage

Retention within building

K. Emergency Communications

None

9B.2.21.16 Fire Zone 99A, Power Potential Transformer (PPT) "A" (In those units with DMWO 3771114 implemented)

A. Location

Fire Zone 99A (engineering drawing 13-A-ZYD-021) is located in the outside areas, adjacent to the plant southeast corner of the Turbine Building at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 2-hour rated exterior refractory composite removable wall at column line 7

Note that the height of this wall (facing the Turbine Building) is extended to 24 feet above grade in order to ensure the spatial separation (line of sight) requirements of NFPA 850.

South: 2-hour rated exterior wall of concrete construction at column line 8

East: 2-hour rated wall of concrete construction common to Zone 99B at column line S

West: 2-hour rated exterior wall of concrete construction at column line R

Note that the height of this wall (facing the Turbine Building) is extended to 24 feet above grade in order to ensure the spatial separation (line of sight) requirements of NFPA 850.

Floor: Non-rated basemat of concrete construction with a 12” layer of rock over a sump pit

Ceiling: Open to the atmosphere

2. Zone Access

- One non-rated security gate in the 2-hour rated south exterior wall at column line 8
- One 3’ by 7’ opening in the 2-hour rated east wall to Fire Zone 99B at column line S

3. Sealed Penetrations

Sealed equal or exceed fire barrier rating

4. Fire Dampers

None

5. Protected Raceways

None

6. Protected Structural Members

None

C. Safety-Related Equipment and Components

None

D. Nonsafety-Related Equipment and Components

- Power Potential Transformer and bus

E. Radioactive Material

None

F. Combustible Loading

9B.2.21.19 Fire Zone 99D, Power Control Room (PCR) (In those units with DMWO 3771114 implemented)

The PCR is an unoccupied NEMA type 3S outdoor enclosure to provide a degree of protection to personnel against access to hazardous parts; to provide a degree of protection for the equipment inside the enclosure against ingress of solid falling objects (falling dirt and windblown dust); and to provide a degree of protection with respect to harmful effects on the equipment due to ingress of water (rain, sleet, snow).

The PCR enclosure is constructed of two compartments. The lower compartment will house the plenum, risers, diffusers, and support structures. The upper compartment, divided into three rooms, will house all cables & wiring, the PCR building and all internal PCR equipment. The interior walls are 18ga (minimum) G90 galvanized or galvannealed sheet metal. The two interior walls each contain two doors for egress between rooms. The floors of the PCR will be covered with a rubber-like floor mat.

A. Location

Fire Zone 99D (engineering drawing 13-A-ZYD-021) is located in the outside areas, adjacent to the plant southeast corner of the Turbine Building, plant south of Fire Zone 99C, at elevation 100 feet 0 inch.

B. Fire Prevention Features

1. Zone Boundaries and Rated Fire Barriers

North: 18ga (minimum) G90 galvanized or galvannealed sheet metal wall panels with minimum R13 level insulation

South: 18ga (minimum) G90 galvanized or galvannealed sheet metal wall panels with minimum R13 level insulation

East: 18ga (minimum) G90 galvanized or galvannealed sheet metal wall panels with minimum R13 level insulation

West: 18ga (minimum) G90 galvanized or galvannealed sheet metal wall panels with minimum R13 level insulation

Floor: Basemat of concrete construction

Ceiling: 18ga (minimum) G90 galvanized or galvannealed sheet metal with minimum R19 level insulation

2. Zone Access

- Two locked 1.5 hour (min) 3′ x 6′-8″ Emergency Exit doors in the east exterior wall
- Two locked 1.5 hour (min) 3′-6″ x 6′-8″ personnel egress doors in the west exterior wall

3. Sealed Penetrations

Sealed equal or exceed fire barrier rating

4. Fire Dampers

None

5. Protected Raceways

   None

6. Protected Structural Members

   None

C. Safety-Related Equipment and Components

   None

D. Nonsafety-Related Equipment and Components

- EX2100e Panel
- BOP / Mark VI
- Rectifier Cabinets (4)
- Remote Server Panel
- 480V Distribution Panels (3)
- 120V Distribution Panels (2)
- Marshaling Panel
- Relay Panel
- Air Handling Units (3)
- Control Power Transformers (2)
- VESDA Panel
- Fire Protection Panel
- vNSA Icon Panel
- Heaters (3)
- Lights and Receptacles

E. Radioactive Material

None

F. Combustible Loading

1. In Situ Combustible Load Type

   - Cable insulation
   - Paper
   - Cloth
   - Plastics
   - Rubber

2. Transient Combustible Load Type

   - Ordinary Combustibles

3. Total Combustible (Fire) Loading

   Low

G. Fire Detection

- Equipped with a VESDA VLI Aspirating Smoke Detection System with detectors with signal output
- Smoke detection system with an alarm contact tied to electrical equipment control system alarm
- Three internal fire alarm strobes and two outside strobes with two outside horns

H. Fire Suppression

1. Primary

- Manually initiated Stat-X fire suppression system with two remote manual pull stations to initiate system

- Four external PCR mounted Halotron clean agent fire extinguishers, one per exterior door

2. Secondary

Manual hose streams from the hydrants on the yard fire main

I. Ventilation

Self-contained with HVAC units

J. Drainage

None

K. Emergency Communications

9B.2.22 ISFSI FIRE ZONES

The ISFSI Facility fire zone and the ISFSI Route fire zone are both located outside the power block on the 100’-0” elevation. The ISFSI Facility fire zone is located approximately 1,000 feet Southeast of the Unit 1 turbine building. The ISFSI Route fire zone consists of the cask transport path from outside the Unit 1, 2, and 3 fuel building railcar bay rollup doors to the ISFSI Facility.

Refer to the ISFSI 72.212 Evaluation Report and the PVNGS ISFSI fire hazards analysis for detailed requirements related to DFS operations in these fire zones.

There is no safe shutdown equipment within the ISFSI Facility fire zone or the ISFSI Route fire zone.

This page intentionally left blank

9B.3 COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1

9B.3.1 COMPLIANCE SUMMARY

The review of the fire protection program at PVNGS against the guidelines set forth in Appendix A to BTP APCSB 9.5-1 has played an integral part in the overall evaluation.
Table 9B.3-1 provides a detailed comparison of the Appendix A guidelines for plants under construction and operating plants against the PVNGS position. For each case of noncompliance, the bases constituting justification for the deviation are also provided.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 1 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Personnel Responsibility for the overall fire protection program should be assigned to a designated person in the upper level of management. This person should retain ultimate responsibility even though formulation and assurance of program implementation is delegated. Such delegation of authority should be to staff personnel prepared by training and experience in fire protection and nuclear plant safety to provide a balanced approach in directing the fire protection programs for nuclear power plants. The qualification requirements for the fire protection engineer or consultant who will assist in the design and selection of equipment, inspect and test the completed physical aspects of the system, develop the fire protection program, and assist in the firefighting training for the operating plant should be stated. Subsequently, the FSAR should discuss the training and the updating provisions such as fire drills provided for maintaining the competence of the station firefighting and operating crew, including personnel responsible for maintaining and inspecting the fire protection equipment. The fire protection staff should be responsible for: (a) coordination of building layout and systems design with fire area requirements, including consideration of potential hazards associated with postulated design basis fires	1. Personnel Same	1. Personnel The architect/engineer (A/E) for PVNGS utilized fire protection engineers to assist in the design and selection of equipment and the development of the fire protection program in general. These fire protection engineers had/have the following qualifications: • Registered as Professional Engineers (fire protection discipline) • Qualified for Members of Society of Fire Protection Engineers Current responsibilities, qualifications and administrative controls for the fire protection program are discussed in UFSAR paragraph 9.5.1.5. Training for the station firefighting and operating crews, including personnel responsible for maintenance, is discussed in UFSAR paragraph 9.5.1.5 or section 13.2.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 2 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Personnel (Continued) (b) design and maintenance of fire detection, suppression, and extinguishing system (c) fire prevention activities, (d) training and manual firefighting activities of plant personnel and the fire brigade (NOTE: NFPA 6, Recommendations for Organization of Industrial Fire Loss Prevention, contains useful guidance for organization and operation of the entire fire loss prevention program.)	1. Personnel (Continued)	1. Personnel (Continued)
2. Design Bases The overall fire protection program should be based upon evaluation of potential fire hazards throughout the plant and the effect of postulated design basis fires relative to maintaining ability to perform safety shutdown functions and minimize radioactive releases to the environment.	2. Design Bases Same	2. Design Bases The evaluation of applicable fire hazards has been performed. (See section 9B.2.)
3. Backup Total reliance should not be placed on a single automatic fire suppression system. Appropriate backup fire suppression capability should be provided.	3. Backup Same	3. Backup Backup fire suppression capability is provided for each automatic fire suppression system by the installation of manual hose stations, portable fire extinguishers and/or hose streams from hydrants on the yard fire main.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 3 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Single Failure Criterion A single failure in the fire suppression system should not impair both the primary and backup fire suppression capability. For example, redundant fire water pumps with independent power supplies and controls should be provided. Postulated fires or fire protection system failures need not be considered concurrent with other plant accidents or the most severe natural phenomena. However, in the event of the most severe earthquake, i.e., the safe shutdown earthquake (SSE), the fire suppression system should be capable of delivering water to manual hose stations located within hose reach of areas containing equipment required for safe plant shutdown. The fire protection systems should, however, retain their original design capability for (1) natural phenomena of less severity and greater frequency (approximately once in 10 years) such as tornadoes, hurricanes, floods, ice storms, or small intensity earthquakes which are characteristic of the site geographic region and (2) for potential man-created, site-related events such as oil barge collisions, aircraft crashes which have a reasonable probability of occurring at a specific plant site.	4. Single Failure Criterion A single failure in the fire suppression system should not impair both the primary and backup fire suppression capability. For example, redundant fire water pumps with independent power supplies and controls should be provided. Postulated fires or fire protection system failures need not be considered concurrent with other plant accidents or the most severe natural phenomena.	4. Single Failure Criterion PVNGS complies with the "single failure criterion" based on the definition of "backup" fire suppression being interpreted as follows for each specific hazard: NOTE: Postulated fires or fire protection system failures are not considered concurrent with other plant accidents or the most severe natural phenomena. • For hazards which depend upon water as both primary and backup suppression, PVNGS has redundant fire water pumps with independent power supplies. Piping between fire pumps and any of the several buildings within the plant is routed such that two separate flow paths exist, with sectional valves located such that a failure in either flow path can be isolated. • For any building which loses internal fire water protection due to a single failure of the fire water piping within the building, backup suppression capability is available from outside hydrants and/or inside portable extinguishers. • Specifically for the auxiliary and control buildings a single failure of the internal fire water piping does not impair both automatic sprinkler/spray systems and all of the internal fire water hose stations for any fire zone; i.e., if the failure for any specific hazard impairs the automatic sprinkler systems, at least one Class 2 hose station is still available in the fire zone. Specifically for the turbine building, a single failure of any fire water piping still allows full coverage of any location by either automatic sprinkler systems or by internal fire water hose stations.
The effects of lightning strikes should be included in the overall plant fire protection program.	The effects of lightning strikes should be included in the overall plant fire protection program.	PVNGS minimizes the effects of lightning strikes by providing lightning protection for the structure in accordance with the Underwriter's Laboratory Standard UL96A, 1964. All startup transformers, main transformers, and 13.8 kV switchgear are protected with appropriate lightning arrestors. (See appendix 9A response to Question 9A.66.)

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 4 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
5. Fire Suppression Systems Failure or inadvertent operation of the fire suppression system should not incapacitate safety-related systems or components. Fire suppression systems that are pressurized during normal plant operation should meet the guideline specified in APCSB-1, Protection Against Postulated Piping Failures in Fluid Systems Outside Containment.	5. Fire Suppression Systems Same	5. Fire Suppression Systems PVNGS complies. Inadvertent operation of a fire suppression system will not incapacitate safety-related systems due to the following reasons. • Preaction sprinkler systems are used in safety-related areas. These systems are not pressurized with water during normal operation. • Electrical cables are insulated and not subject to water damage. • Mechanical equipment such as heat exchangers, tanks, and piping will not be damaged by wetting due to sprinkler actuation. To obviate the possibility of damage to safety-related systems due to failure of a fire suppression system, all of the normally pressurized fire suppression systems have been analyzed to meet the guidelines specified in BTP APCSB 3-1. The fire suppression piping, in the fire zones where safety-related equipment or components are located, meet the project Seismic Category IX criteria stated below. Seismic Category IX structures and components are those non-Seismic Category I structures and components whose failure due to SSE loads could impact adjacent Seismic Category I structures or components. Seismic Category IX structures and components have been designed to experience no structural failure that might result in the malfunction of adjacent seismic Category I structures or components when subjected to the vibratory motions of the SSE in combination with the normal operating loads. A dynamic or equivalent static analysis has been performed using the relevant building response spectra to demonstrate structural integrity. Seismic Category IX requirements are an addition to any Seismic Category II or III requirements.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 5 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
6. Fuel Storage Areas The fire protection program (plans, personnel, and equipment) for buildings storing new reactor fuel and for adjacent fire zones which could affect the fuel storage zone should be fully operational before fuel is received at the site.	6. Fuel Storage Areas Schedule for implementation of modifications, if any, will be established on a case-by-case basis.	6. Fuel Storage Areas PVNGS complies. The fire protection program for the fuel building, where the new reactor fuel is stored, was fully operational prior to the receipt of fuel. The fire protection program for the adjacent fire zones to the fuel storage area (Zone 29A at elevation 140 feet 0 inch) was also implemented prior to the receipt of fuel at Unit 1. The combustible loading in the adjacent fire zones is low. Ionization smoke detectors are installed, for early warning, in the new fuel storage area and also in the following adjacent fire zones. • Zone 27 at elevation 100 feet 0 inch • Zone 28 at elevation 100 feet 0 inch • Zone 29 at elevation 120 feet 0 inch Hose stations and fire extinguishers are provided at elevations 100 feet 0 inch, 120 feet 0 inch, and 140 feet 0 inch. (See section 9B.2, Fire Hazards Analysis, for more details.)
7. Fuel Loading The fire protection program for an entire reactor unit should be fully operational prior to initial fuel loading in that reactor unit.	7. Fuel Loading Schedule for implementation of modifications, if any, will be established on a case-by-case basis.	7. Fuel Loading PVNGS complies.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 6 of 69)

A. OVERALL REQUIREMENTS OF NUCLEAR PLANT FIRE PROTECTION PROGRAM (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
8. Multiple-Reactor Sites On multiple-reactor sites where there are operating reactors and construction of remaining units is being completed, the fire protection program should provide continuing evaluation and include additional fire barriers, fire protection capability, and administrative controls necessary to protect the operating units from construction fire hazards. The superintendent of the operating plant should have the lead responsibility for site fire protection.	8. Multiple-Reactor Sites Same	8. Multiple-Reactor Sites Construction of Units 1, 2, and 3 is complete. The PVNGS fire protection program provides continuing evaluation of the fire protection/prevention measures to protect the operating unit(s) from construction fire hazards. Fire barriers between operating plants are not deemed necessary. Each unit complex is separated from any other unit complex by a distance of approximately 500 feet. Responsibilities for the fire protection program are discussed in section A.1 of this table.
9. Simultaneous Fires Simultaneous fires in more than one reactor need not be postulated, where separation requirements are met. A fire involving more than one reactor unit need not be postulated except for facilities shared between units.	9. Simultaneous Fires Same	9. Simultaneous Fires PVNGS does not postulate simultaneous fires in more than one reactor since no facilities, except for the fire water pumps, the water supply tanks, and the underground fire water main loop, are common. A separation distance of approximately 500 feet exists between units. The failure of the shared facilities will not affect the safe shutdown capability of the units. The two diesel-driven fire water pumps (50% capacity each) are protected by a wet pipe sprinkler system. (See section E.2.C of this table for more details).

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 7 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Administrative procedures consistent with the need for maintaining the performance of the fire protection system and personnel in nuclear power plants should be provided. Guidance is contained in the following publications: NFPA 4 - Organization for Fire Services NFPA 4A - Organization for Fire Department NFPA 6 - Industrial Fire Loss Prevention NFPA 7 - Management of Fire Emergencies NFPA 8 - Management Responsibility for Effects of Fire on Operation NFPA 27 - Private Fire Brigades	1. Same	1. Administrative procedures consistent with the need for maintaining the performance of the fire protection system and personnel in nuclear power plants are provided.
2. Effective administrative measures should be implemented to prohibit bulk storage of combustible materials inside or adjacent to safety-related buildings or systems during operation or maintenance periods. Regulatory Guide 1.39, Housekeeping Requirements for Water-Cooled Nuclear Power Plants, provides guidance on housekeeping, including the disposal of combustible materials.	2. Same	2. PVNGS complies by providing administrative "Control of Combustibles" procedure.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 8 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Normal and abnormal conditions or other anticipated operations such as modifications (e.g., breaking fire stops, impairment of fire detection, and suppression systems) and refueling activities should be reviewed by appropriate special actions and procedures such as fire watches or temporary fire barriers implemented to assure adequate fire protection and reactor safety. In particular:	Same	3. PVNGS complies. Normal and abnormal conditions or other anticipated operations/modifications and refueling activities are covered by administrative control procedures, and appropriate compensatory measures will be implemented to assure adequate fire protection and reactor safety.
(a) Work involving ignition sources such as welding and flame cutting should be done under closely controlled conditions. Procedures governing such work should be reviewed and approved by persons trained and experienced in fire protection. Persons performing and directly assisting in such work should be trained and equipped to prevent and combat fires. If this is not possible, a person qualified in fire protection should directly monitor the work and function as a fire watch.		(a) PVNGS complies by providing administrative control of "hot work".
(b) Leaktesting, and similar procedures such as air flow determination, should use one of the commercially available aerosol techniques. Open flames or combustion generated smoke should not be permitted.		(b) PVNGS complies by prohibiting open flames and combustion generated smoke from being used for leaktesting or air flow tests.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 9 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
(c) Use of combustible material, e.g., HEPA and charcoal filters, dry ion exchange resins, or other combustible supplies, in safety-related areas should be controlled. Use of wood inside buildings containing safety-related systems or equipment should be permitted only when suitable noncombustible substitutes are not available. If wood must be used, only fire-retardant treated wood (scaffolding, lay down blocks) should be permitted. Such materials should be allowed into safety-related areas only when they are to be used immediately. Their possible and probable use should be considered in the fire hazard analysis to determine the adequacy of the installed fire protection systems.		(c) PVNGS complies by controlling the use of combustible material in safety-related areas. Use of wood inside buildings containing safety-related systems or equipment is permitted only when suitable noncombustible substitutes are not available. If wood is to be used, only fire-retardant treated wood (scaffolding, lay down blocks) is permitted. Such materials are allowed into safety-related areas only when they are to be used immediately. Transient combustibles are considered in section 9B.2 to determine the adequacy of the installed fire protection system. Exceptions allowed are furniture and fixtures of wood, wood components, or composite materials of pressed wood with plastic laminate surfaces, e.g., desks, cabinets, shelves, tables, counter tops, bulletin boards, etc., and miscellaneous wood articles in safety-related areas such as control, computer, and office areas which are included in the fire hazard analysis. The combustible loading in each fire zone has been estimated and protection described in the fire hazard analysis. Redundant safe shutdown equipment is protected such that one train will remain free of fire damage, or alternate shutdown capability is provided.
4. Nuclear power plants are frequently located in remote areas, at some distance from public fire departments. Also, first response fire departments are often volunteer. Public fire department response should be considered in the overall fire protection program. However, the plant should be designed to be self-sufficient with respect to firefighting activities and rely on supplemental or backup capability.	4. Same	4. PVNGS complies by providing a plant fire protection system and program that is designed to be self-sufficient. The Phoenix Fire Department provides backup assistance when requested.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 10 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
5. The need for good organization, training, and equipping of fire brigades at nuclear power plant sites requires effective measures be implemented to assure power discharge of these functions. The guidance in Regulatory Guide 1.101, Emergency Planning for Nuclear Power Plants, should be followed as applicable.	5. Same	5. PVNGS complies by implementing effective measures to insure proper organization, training, and equipping of the plant fire department. The guidance in Regulatory Guide 1.101, Emergency Planning for Nuclear Power Plants, is followed where applicable.
(a) Successful firefighting requires testing and maintenance of the fire protection equipment, emergency lighting, and communication, as well as practice as brigades for the people who must utilize the equipment. A test plan that lists the individuals and their responsibilities in connection with routine tests and inspections of the fire detection and protection systems should be developed. The test plan should contain the types, frequency, and detailed procedures for testing. Procedures should also contain instructions on maintaining fire protection during these periods when the fire protection system is impaired or during periods of plant maintenance, e.g., fire watches or temporary hose connections to water systems.	(a) Same	(a) PVNGS complies by developing a test plan that lists the individuals and their responsibilities in connection with routine plant tests and inspections of the plant fire protection system. The test plan contains the types, frequency, and detailed procedures for testing. The procedures contain instructions on maintaining fire protection during those periods when the fire protection system is impaired or during periods of plant maintenance. Section D.5 describes the emergency lighting and communication equipment credited for addressing postulated fires.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 11 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
(b) Basic training is a necessary element in effective firefighting operation. In order for a fire brigade to operate effectively, it must operate as a team. All members must know what their individual duties are. They must be familiar with the layout of the plant, equipment location, and operation in order to permit effective firefighting operations during times when a particular area is filled with smoke or is insufficiently lighted. Such training can only be accomplished by conducting drills several times a year (at least quarterly) so that all members of the fire brigade have had the opportunity to train as a team testing itself in the major areas of the plant. The drills should include the simulated use of equipment in each area and should be preplanned and post-critiqued to establish the training objective of the drills and determine how well these objectives have been met. These drills should periodically (at least annually) include local fire department participation where possible. Such drills also permit supervising personnel to evaluate the effectiveness of communications within the fire brigade and with the on scene fire team leader, the reactor operator in the control room, and the offsite command post.	(b) Same	(B) PVNGS complies by providing appropriate training of the plant fire department. All members are instructed in what their individual duties are. They are familiar with the layout of the plant and equipment location and operation. This permits effective firefighting operations during times when a particular area is filled with smoke or is insufficiently lighted. Drills are conducted on a quarterly basis and include the simulated use of equipment in each area. Drills are pre-planned and critiqued to establish the training objective and to determine how well the objectives, including communications, have been met. PVNGS includes offsite fire department participation in drills annually. The offsite fire department is the Phoenix Fire Department.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 12 of 69)

B. ADMINISTRATIVE PROCEDURES, CONTROLS, AND FIRE BRIGADE (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
(c) To have proper coverage during all phases of operation, members of each shift crew should be trained in fire protection. Training of the plant fire brigade should be coordinated with the local fire department so that responsibilities and duties are delineated in advance. This coordination should be part of the training course and implemented into the training of the local fire department staff. Local fire departments should be educated in the operational precautions when fighting fires on nuclear power plant sites. Local fire departments should be made aware of the need for radioactive protection of personnel and the special hazards associated with a nuclear power plant site.	(c) Same	(c) PVNGS complies by providing courses in fire protection training for members of each shift crew. Training is coordinated with the offsite fire department (Phoenix Fire Department).
(d) NFPA 27, Private Fire Brigade, should be followed in organization, training, and fire drills. This standard also is applicable for the inspection and maintenance of fire-fighting equipment. Among the standards referenced in this document, the following should be utilized: NFPA 194, Standard for Screw Threads and Gaskets for Fire Hose Couplings; NFPA 196, Standard for Fire Hose; NFPA 197, Training Standard on Initial Fire Attacks; NFPA 601, Recommended Manual of Instructions and Duties for the Plant Watchman on Guard. NFPA booklets and pamphlets listed on page 27-11 of Volume 8, 1971-72, are also applicable for good training references. In addition, courses in fire prevention and fire suppression which are recognized and/or sponsored by the fire protection industry should be utilized.	(d) Same	(d) PVNGS complies. The following documents are utilized where applicable: NFPA 601 (1975), Recommended Manual of Instructions and Duties for the Plant Watchman on Guard; NFPA 1001 (1987), Firefighter Professional Qualifications Level I; NFPA 1201 (1989), Developing Fire Protection Services for the Public; NFPA 1410 (1988), Training Standard on Initial Fire Attack; NFPA 1961 (1987), Fire Hose; NFPA 1963 (1985), Screw Threads and Gaskets for Fire Hose Connections. Courses in fire prevention and fire suppression which are recognized and/or sponsored by the fire protection industry are utilized as appropriate.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 13 of 69)

C. QUALITY ASSURANCE PROGRAM

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
Quality assurance (QA) programs of applicants and contractors should be developed and implemented to assure that the requirements for design, procurement, installation, and testing and administrative controls for the fire protection program for safety-related areas as defined in this Branch Position are satisfied. The program should be under the management control of the QA organization. The QA program criteria that applies to the fire protection program should include the following: 1. Design Control and Procurement Document Control Measures should be established to assure that all design-related guidelines of the Branch Technical Position are included in design and procurement documents and that deviations therefrom are controlled. 2. Instructions, Procedures, and Drawings Instructions, tests, administrative controls, fire drills, and training that govern the fire protection program should be prescribed by documented instructions, procedures, or drawings and should be accomplished in accordance with these documents. 3. Control of Purchased Material, Equipment, and Services Measures should be established to assure that purchased material, equipment, and services conform to the procurement documents.	Same	Implementation of the quality assurance program for fire protection is consistent with NRC Branch Technical Position APCSB 9.5-1, Appendix A, Section C, "Quality Assurance Program." Fire protection features required to protect safety-related structures, systems, and components are within the scope of the PVNGS Quality Assurance Program for the operational phase. APS implements the fire protection QA program through approved procedures, instructions, and drawings in accordance with the requirements of the PVNGS Operations Quality Assurance Program Description.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 14 of 69)

C. QUALITY ASSURANCE PROGRAM

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Inspection A program for independent inspection of activities affecting fire protection should be established and executed by, or for, the organization performing the activity to verify conformance with documented installation drawings and test procedures for accomplishing the activities. 5. Test and Test Control A test program should be established and implemented to assure that testing is performed and verified by inspection and audit to demonstrate conformance with design and system readiness requirements. The tests should be performed in accordance with written test procedures; test results should be properly evaluated and acted upon. 6. Inspection, Test, and Operation Status Measures should be established to provide for the identification of items that have satisfactorily passed required tests and inspections.		

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 15 of 69)

C. QUALITY ASSURANCE PROGRAM

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
7. Nonconforming Items Measures should be established to control items that do not conform to specified requirements to prevent inadvertent use of installation.		
8. Corrective Action Measures should be established to assure that conditions adverse to fire protection, such as failures, malfunctions, deficiencies, deviations, defective components uncontrolled combustible material and non-conformances are promptly identified, reported, and corrected.		
9. Records Records should be prepared and maintained to furnish evidence that the criteria enumerated above are being met for activities affecting the fire protection program.		
10. Audits Audits should be conducted and documented to verify compliance with the fire protection program including design and procurement documents, instructions, procedures and drawings, and inspection and test activities.		

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 16 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design	1. Building Design	1. Building Design
(a) Plant layouts should be arranged to:		(a) Plant layouts:
(1) Isolate safety-related systems from unacceptable fire hazards, and	(1) Same	(1) Safety-related systems are isolated from unacceptable fire hazards. For detailed descriptions of the protection and isolation of safety-related systems, see section 9B.2.
(2) Separate redundant safety-related systems from each other so that both are not subject to damage from a single fire hazard.	(2) Alternatives: (a) Redundant safety related systems that are subject to damage from a single fire hazard should be protected by a combination of fire retardant coatings and fire suppression systems, or (b) a separate system to perform the safety function should be provided.	(2) Redundant safety-related equipment required to shut down the unit per the design bases of section A.2 of this table are separated per the requirements of 10CFR50, Appendix R, with the exception of deviations as noted in appendix 9B.
(b) In order to accomplish 1.(a) above, safety-related systems should be identified throughout the plant. Therefore, a detailed fire hazard analysis should be made. The fire hazards analysis should be reviewed and updated as necessary.	(b) Same - Additional fire hazards analysis should be done after any plant modification.	(b) PVNGS complies and the detailed fire hazards analysis is provided by section 9B.2. The fire hazards analysis identifies safety-related systems and fire hazards. The fire hazards analysis is reviewed and updated after plant modification as necessary.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 17 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued) (c) For multiple reactor sites, cable spreading rooms should not be shared between reactors. Each cable spreading room should be separated from other areas of the plant by barriers (walls and floors) having a minimum fire resistance of 3 hours. Cabling for redundant safety divisions should be separated by walls having 3-hour fire barriers.	1. Building Design (Cont.) (c) Alternative guidance for constructed plants is shown in section F.3 of this table.	1. Building Design (Continued) (c) Cable spreading rooms are not shared between reactors. PVNGS complies by providing two separate cable spreading rooms for each reactor. The cables in each room are protected by a preaction sprinkler system, and are separated from other areas of the plant by 3-hour rate barriers (walls and floors) except as follows: Lower cable spreading room (Zone 14, control building, elevation 120 feet 0 inch) • A portion of the south exterior wall is of heavy concrete construction. The wall is not required to separate redundant shutdown related systems, and as such it is deemed not necessary to qualify it as a rated barrier. • Common walls with HVAC chases and a stairwell are 2-hour rated. There are no combustibles in the HVAC chases nor the stairwell, and the combustible (fire) loading of the lower cable spreading room is moderate. Therefore, a 2-hour fire resistance rating is considered adequate. • Common walls with the Halon protected communication and inverter rooms (Zones 12 and 13) are 1-hour rated. All three fire zones have a suppression system and smoke detectors for both suppression system actuation as well as early warning. The combustible (fire) loading in Zone 12 is moderate and in Zone 13 is low. 1-hour rated fire walls separating the three fire zones will provide the necessary protection. Upper cable spreading room (Zone 20, control building, elevation 160 feet 0 inch) • A portion of the south exterior wall is of heavy concrete construction. The wall is not required to separate redundant shutdown related systems, and as such it is not deemed necessary to qualify it as a rated barrier. The north exterior wall is of heavy concrete construction. The wall is not required to separate redundant shutdown related systems, and as such it is not deemed necessary to qualify it as a rated barrier.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 18 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (Continued)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued)	1. Building Design (Continued)	1. Building Design (Continued) • Common walls with HVAC chases and a stairwell are 2-hour rated. There are no combustibles in the HVAC chases nor the stairwell, and the combustible (fire) loading of the upper cable spreading room is moderate. Therefore, a 2-hour fire resistance rating is considered adequate. • Common walls with the normal smoke exhaust room are 2-hour rated. The combustible (fire) loading in this room is low. Therefore, a 2-hour fire resistance rating is considered adequate. • The ceiling, which is the roof of the control building, is nonrated and of heavy concrete construction. There are no penetrations in the ceiling of the upper cable spreading room and the barrier is not required to separate redundant shutdown related systems, and as such a fire resistance rating is not required.
(d) Interior wall and structural components, thermal insulation materials, and radiation shielding materials and sound-proofing should be noncombustible. Interior finishes should be noncombustible or listed by a nationally recognized testing laboratory, such as Factory Mutual or Underwriter's Laboratory, Inc. for flame spread, smoke, and fuel contribution of 25 or less in its use configuration (ASTM E84 test, Surface Burning Characteristics of Burning Materials).	(d) Same	(d) PVNGS complies except that surfacing is considered noncombustible when it is not over 1/8 inch thick, it has a spread rating not higher than 50 when measured using ASTM E84 test Surface Burning Characteristics of Building Materials or consists of surface coatings or paint and it has a structural base of noncombustible material. (See Appendix 9A response to Question 9A.68.) • Interior walls and structural components, thermal insulation materials, and radiation shielding materials and sound-proofing are noncombustible. • Interior finishes are listed by Underwriter's Laboratory Inc. for flame spread, smoke, and fuel contribution of 25 or less in its use configuration (ASTM E84 test), except for paint.
(e) Metal deck roof construction should be noncombustible (see the building materials directory of the Underwriter's Laboratory, Inc.) or listed as Class 1 by Factory Mutual System Approval Guide.	(e) Same. Where combustible material is used in metal deck roofing design, acceptable alternatives are (1) replace combustibles with noncombustible materials, (2) provide an automatic sprinkler system, or (3) provide ability to cover roof exterior and interior with adequate water volume and pressure.	(e) PVNGS complies by employing noncombustible buildup roof construction which meets the requirements of the Underwriter's Laboratory Class A rating.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 19 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (Continued)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued) (f) Suspended ceilings and their supports should be noncombustible construction. Concealed spaces should be devoid of combustibles.	1. Building Design (Continued) (f) Same. Adequate fire detection and suppression systems should be provided where full implementation is not practicable.	1. Building Design (Continued) (f) PVNGS complies. Suspended ceilings and their supports are noncombustible. Concealed spaces are devoid of combustibles except for the following: • Control room (Zone 17, control building, elevation 140 feet 0 inch). Cable trays are routed above the suspended ceiling. Ionization smoke detectors are provided for early warning in the cable tray area above the suspended ceiling. (See appendix 9A response to Question 9A.82.) • The raised platform in the control room is a concealed space. The cables routed below the raised floor are all non-safety related and classified as low-level signal instrumentation and control cables. The cables below the platform ternminate in the platform workstations. The cables do not control plant equipment. The cables are IEEE 383 or equivalent qualified. Fire detection is not provided in the raised platform. The control room is continuously manned location. There is no ignition source or other combustible material installed below the raised platform. The raised platform is provided with floor openings and louvered sides. This will allow any potential smoke to be detected by the control room personnel. The floor openings and louvers will allow for control room personnel to apply CO2 to the underside of the platform. • Computer room (Zone 16, control building, elevation 140 feet 0 inch). Ribbon cable between two computer cabinets is routed above the suspended ceiling utilizing access to the top of each cabinet. VESDA smoke detection tubing (CPVC) is routed above suspended ceiling in Unit 1 Room J-307 Fire detection and manual suppression is provided as detailed in section 9B.2. • Auxiliary building (elevation 140 feet 0 inch). Acetylene, helium, nitrogen, hydrogen, methane, (P-10 gas), and oxygen piping is routed above the suspended ceiling from the cylinder storage area (Zones 57B and 57P) to the hot laboratory (Zone 57A), RP Island (Zone 57J), cold laboratory (Zone 57K), and counting room (Zone 57D). In addition, cable trays are routed above the suspended ceiling. Fire detection is provided as indicated in section 9B.2. (See appendix 9A response to Question 9A.132.) • Corridor building (elevation 140 feet 0 inch). Cable trays are routed above the suspended ceiling. Fire detection is not provided in the corridor building. Damage to any cables or equipment located in this building will have no adverse effect on the ability to achieve and maintain safe shutdown.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 20 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued)	1. Building Design (Continued)	1. Building Design (Continued)
(g) High-voltage, high-amperage transformers installed inside buildings containing safety-related systems should be of the dry type or insulated and cooled with noncombustible liquid.	(g) Same. Safety-related systems that are exposed to flammable oil filled transformers should be protected from the effects of a fire by: • replacing with dry transformers or transformers that are insulated and cooled with noncombustible liquid; or • enclosing the transformer with a three-hour fire barrier and installing automatic water spray protection.	(g) PVNGS complies by employing dry type high voltage-high amperage transformers inside buildings containing safety-related systems.
(h) Buildings containing safety-related systems should be protected from exposure or spill fires involving oil filled transformers by: • locating such transformers at least 50 feet distant; or • ensuring that such building walls within 50 feet of oil filled transformers are without openings and have a fire resistance rating of at least 3 hours.	(h) Buildings containing safety-related systems, having openings in exterior walls closer than 50 feet to flammable oil filled transformers should be protected from the effects of a fire by: • closing of the opening to have fire resistance equal to 3 hours, • constructing a 3-hour fire barrier between the transformers and the wall openings; or	(h) PVNGS complies by locating all oil filled transformers at least 50 feet from any building containing safety-related systems with the exception of the west ESF transformer, which is located approximately 48 feet from the 3-hour-rated auxiliary building exterior wall.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 21 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued)	1. Building Design (Continued) • closing the opening and providing the capability to maintain a water curtain in case of a fire.	1. Building Design (Continued)
(i) Floor drains, sized to remove expected firefighting water flow should be provided in those areas where fixed water fire suppression systems are installed Drains should also be provided in other areas where hand hose lines may be used if such firefighting water could cause unacceptable damage to equipment in the area. Equipment should be installed on pedestals, or curbs should be provided as required to contain water and direct it to floor drains. (See NFPA 92M, Waterproofing and Draining of Floors.) Drains in areas containing combustible liquids should have provisions for preventing the spread of the fire throughout the drain system. Water drainage from areas that may contain radioactivity should be sampled and analyzed before discharge to the environment.	(i) Same. In operating plants or plants under construction, if accumulation of water from the operation of new fire suppression systems does not create unacceptable consequences, drains need not be installed.	(i) Failure (clogging) of the floor drain system during firefighting activities will not create unacceptable consequences nor prevent the ability to achieve safe shutdown of the plant. PVNGS has floor drains for areas having fixed sprinkler and spray systems. Drains are also provided in areas where hand hoses are the primary source of fire protection, except for the control room (Zone 17) where portable CO_2 and pressurized water fire extinguishers are provided for fire fighting. Floor drain systems, 4 inches or larger, with some degree of redundancy and separation are provided. All equipment is installed on pedestals with the exception of electrical switchgear and control room equipment. The drain lines for the turbine-generator lube oil storage room and the diesel fuel oil day tank rooms are equipped with shutoff valves to prevent the spread of fire through the drain system. Potentially radioactive drains from the auxiliary, containment, fuel, and radwaste buildings are routed to the liquid radwaste system (LRS) which is described in section 11.2. Evaporative losses from the liquid waste systems are filtered and monitored by the plant ventilation systems prior to discharge to the plant vent. Radioactive wastes unsuited for plant recycle are shipped offsite in accordance with NRC and DOT regulations. The radioactivity of the solid radwaste is monitored prior to disposal.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A
OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 22 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued) (i) Floors, walls, and ceilings enclosing separate fire areas should have minimum fire rating of 3 hours. Penetrations in these fire barriers, including conduits and piping, should be sealed or closed to provide a fire resistance rating at least equal to that of the fire barrier itself. Door openings should be protected with equivalent rated doors, frames, and hardware that have been tested and approved by a nationally recognized laboratory. Such doors should be normally closed and locked or alarmed with alarm and annunciation in the control room. Penetrations for ventilation system should be protected by a standard fire door damper where required. (Refer to NFPA 80, Fire Doors and Windows.)	1. Building Design (Continued) (i) Same. The fire hazard in each area should be evaluated to determine barrier requirements. If barrier fire resistance cannot be made adequate, fire detection and suppression should be provided, such as: • water curtain in case of fire, • flame-retardant coatings, • additional fire barriers	1. Building Design (Continued) (i) Fire hazards in each safety-related fire zone have been evaluated to determine fire barrier requirements. Where this analysis does not substantiate a need for a 3-hour rated barrier, 2-hour, 1-hour, or nonrated construction separates adjacent fire zones. See section 9B.2 and fire barriers depicted in engineering drawings 13-A-ZYD-029, 031, 030, 024, 026, 022 and 021. Each fire area may consist of one or more fire zones. For separation of the fire areas, see Section 9B.2 and figures 9B-1 through 9B-6 and engineering drawing 13-P-00B-005. In general, exterior walls, basements, and roofs on the power buildings are not rated but meet the following requirements: (1) They are not required to separate a safe shutdown related train inside the fire area from a significant fire hazard outside the fire areas. (2) They do not separate safety-related areas from nonsafety-related areas that present a significant fire threat to the safety-related areas. Additionally, all stairwells in safety-related areas are protected by barriers of 2-hour fire resistance rating in accordance with NFPA 101 (1976). Also, cable chases in the control building are separated from other parts of the building by fire barriers of 3-hour fire resistance rating. For all rated barriers in safety-related areas, the penetrations and doors, including ventilation systems, at a minimum, will carry a rating appropriate to that of the barrier itself. Three-hour barriers use a 3-hour Class A door; 2-hour barriers use a 1-1/2 hour Class B door; 1-hour barriers use a 3/4 hour class C door. A complete description of each zone and the barriers, detection, and suppression provided is contained in section 9B.2. (See appendix 9A response to Questions 9A.68, 9A.73, 9A.84, 9A.106, and 9A.121.)

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A
OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 23 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Building Design (Continued)	1. Building Design (Continued)	1. Building Design (Continued) PVNGS complies by locking and alarming fire-rated doors that are designated as part of the plant security system. Other fire-rated doors that are not part of the plant security system are normally closed, but not locked closed. Reliance has been placed upon administrative procedures to deep all fire doors in their normally closed position. Duct penetrations for ventilation through fire-rated walls or floors are equipped with fire-rated dampers equal to or greater than the rating of the wall or floor penetrated. NFPA 80 (1975) has been referred to as necessary. (See Appendix 9A response to Question 9A.68)
2. Control of Combustibles (a) Safety-related systems should be isolated or separated from combustible materials. When this is not possible because of the nature of the safety system or the combustible material, special protection should be provided to prevent a fire from defeating the safety system function. Such protection may involve a combination of automatic fire suppression and construction capable of withstanding and containing a fire that consumes all combustibles present. Examples of such combustible materials that may not be separable from the remainder of its systems are: (1) Emergency diesel generator fuel oil day tanks (2) Turbine-generator oil and hydraulic control fluid systems (3) Reactor coolant pump lube oil system		2. Control of Combustibles (a) For the diesel generator system, PVNGS complies by providing separate enclosures for the diesel generator day tanks, each with 3-hour rated barriers. (See appendix 9A response Question 9A.86.) For the turbine-generator lube oil storage and conditioning system, a separate 2-hour rated enclosure with automatic deluge system is provided. (It should be noted that the turbine-generator is not considered a "safe shutdown" or "safety-related" system.) Also, the turbine-generator lube oil storage is not a hazard to safe shutdown equipment. For hydraulic control fluid systems, no provisions are made for separation, as this fluid has a high auto-ignition point of 1150F. For safety-related systems within the containment, a reactor coolant pump oil collection system has been provided to prevent a fire from defeating the safety system functions. (See Appendix 9A responses to Question 9A.98 and 9A.126) For other safety-related systems where it is not possible to isolate the combustibles from the equipment, the fire hazards analysis in section 9B.2 has shown that: • A postulated fire will not prevent safe shutdown. (See Appendix 9A response to Question 9A.73.)

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 24 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Control of Combustibles	2. Control of Combustibles	2. Control of Combustibles
(b) Bulk gas storage (either compressed or cryogenic) should not be permitted inside structures housing safety-related equipment. Storage of flammable gas, such as hydrogen, should be located outdoors or in separate detached buildings so that a fire or explosion will not adversely affect any safety-related systems or equipment. (Refer to NFPA 50A, Gaseous Hydrogen Systems.) Care should be taken to locate high-pressure gas storage containers with the long axis parallel to building walls. This will minimize the possibility of wall penetration in the event of a container failure. Use of compressed gases (especially flammable and fuel gases) inside buildings should be controlled. (Refer to NFPA 6, Industrial Fire Loss Prevention.)	(b) Same	(b) NFPA 50A (1973) was used as guidance in developing the PVNGS bulk gas storage control and systems. Bulk gas storage (either compressed or cryogenic) is located outside of buildings housing safety-related equipment. The bulk gas storage of hydrogen is located outdoors so that a fire or explosion will not adversely affect any safety-related systems or equipment. PVNGS complies with proper orientation of all high-pressure gas storage containers and by controlling the usage of compressed gases inside buildings, using the guidance of NFPA 6 (1974).
(c) The use of plastic materials should be minimized. In particular, halogenated plastics such as polyvinyl chloride (PVC) and neoprene should be used only when substitute noncombustible materials are not available. All plastic materials, including flame and fire-retardant materials, will burn with an intensity and Btu	(c) Same	(c) PVNGS complies by minimizing the use of smoke generating halogenated plastic (e.g., PVC) materials. Total usage of halogenated plastics (PVC) materials within power block buildings is limited. Applications of PVC are as follows: • Approximately 300 feet of 2-inch and 3-inch diameter PVC are used in the control building, elevation 100 feet 0 inch and below as vent and drain lines. (See appendix 9A response to Question 9A.123). • Approximately 50 feet of 1- and 2-inch diameter PVC is used in each radwaste building at elevation 100 feet 0 inch as a fill and drain line from a chemical addition tank and skid.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 25 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Control of Combustibles (Continued) production in a range similar to that of ordinary hydrocarbons. When burning, they produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA. The halogenated plastics also release free chlorine and hydrogen chloride when burning which are toxic to humans and corrosive to equipment.	2. Control of Combustibles (Continued)	2. Control of Combustibles (Continued) • Approximately 25 feet of 0.75 inch diameter CPVC is used as smoke detection sample piping for VESDA detector in Unit 1 Computer Room Storage Closet (J-307). • PVC conduits are used in the intake structure at the cooling towers and in the communications room in the Unit 3 turbine building. • PVC jacketed cable is found in some vendor panels and field installed cable. (Reference Table 9B.3-1, Section D.3.(g) for additional information.) • PVC jacket on flexible conduits. • An Electro-Static Dissipating (ESD) carpet material is installed on the raised platform and on the vinyl resilient flooring in the control room. The backing of the ESD carpet tiles are made of a PVC base material. It is identified as static dissipative PVC with conductive filler. The carpet properties are: critical radiant flux, $\geq$0.45 w/cm^2 (ASTM E-648) as required by UFSAR section 9.5.1, and smoke density, <450 (ASTM E-662). • PVC moisture eliminators in the Unit 1 Fuel Building Air Washers located on the roof of the Unit 1 Auxiliary Building (560 lbs. total). Other applications of plastics in the power block are: • One 260-gallon polypropylene tank for chemical addition located in each radwaste building at elevation 100 feet 0 inch (Zone 59). • Four safety-related battery rooms containing plastic battery casings in each control building at elevation 100 feet 0 inch (Zones 8A, 8B, 9A, and 9B - battery rooms). • The emergency lighting has plastic battery casing. • The security UPS has plastic battery casing. • Identification labels and equipment tags. • One Habitation Enclosure (8’ x 10’ x 6’6” H) in each Unit Turbine Building composed of all steel construction, steel sidieng and roof with various insulation materials (fiberglass, polyurethane foam and polyisocyanurate foam and drywall finish. Internal flooring consist of polyurethane foam insulation, vinyl tile and cove molding. A fire sprinkler is installed in each enclosure placed inside the Turbine Building.
(d) Storage of flammable liquids should, as a minimum, comply with the requirements of NFPA 30, Flammable and Combustible Liquids Code.	(d) Same	(d) PVNGS utilizes NFPA 30 (1976) as guidance in the storage of flammable liquids.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 26 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Electric Cable Construction, Cable Trays, and Cable Penetrations	3. Electric Cable Construction, Cable Trays, and Cable Penetrations	3. Electric Cable Construction, Cable Trays, and Cable Penetrations
(a) Only noncombustible materials should be used for cable tray construction.	(a) Same	(a) PVNGS complies by using only metal cable trays.
(b) See section F.3 of this table for fire protection guidelines for cable spreading rooms.	(b) Same	(b) (See section F.3 of this table for PVNGS position.)
(c) Automatic water sprinkler systems should be provided for cable trays outside the cable spreading room. Cables should be designed to allow wetting down with the deluge water without electrical faulting. Manual hose stations and portable hand extinguishers should be provided as backup. Safety-related equipment in the vicinity of such cable trays, that does not itself require water fire protection, but is subject to unacceptable damage from sprinkler water discharge, should be protected from sprinkler system operation of malfunction.	(c) Same. When safety-related cables do not satisfy the provisions of Regulatory Guide 1.75, all exposed cables should be covered with an approved fire-retardant coating and a fixed automatic water fire suppression system should be provided.	(c) PVNGS provides automatic preaction sprinkler systems in the auxiliary building areas which have significant cable concentrations. These protected areas are in the auxiliary building corridors at the 100 feet 0 inch and 120 feet 0 inch elevations and in the auxiliary building cable penetration rooms at the 100 feet 0 inch, 120 feet 0 inch elevations. Cable trays in the containment building are monitored by line type thermal detectors and ionization detectors. The detectors will alarm and annunciate in the control room and alarm locally. Manual hose stations and portable hand extinguishers are provided in fire zones as indicated in section 9B.2. Cables will allow wetting without faulting. Safety-related equipment is protected from sprinkler system malfunction by the use of preaction systems which prohibit inadvertent discharge (see section A.5 of this table). Manual hose stations are provided as indicated in section 9B.2. Safety-related cables that do not satisfy the provisions of Regulatory Guide 1.75 are provided with metal covers or protective envelopes. (See appendix 9A responses to Questions 9A.92, 9A.94, and 9A.102.)
(d) Cable and cable tray penetration of fire barriers (vertical and horizontal) should be sealed to give protection at least equivalent to that fire barrier. The design of fire barriers for horizontal and vertical cable trays should, as a minimum, meet the requirements of ASTM E119, Fire Test of Building Construction and Materials, including the hose stream test.	(d) Same. Where installed penetration seals are deficient with respect to fire resistance, these seals may be protected by covering both sides with an approved fire-retardant material. The adequacy of using such material should be demonstrated by suitable testing.	(d) PVNGS complies. Cable tray penetrations of rated fire barriers are sealed to provide a fire barrier rating at least equal to the barrier. (See appendix 9A response to Question 9A.110.)

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 27 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)	3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)	3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)
(e) Fire breaks should be provided as deemed necessary by the fire hazards analysis. Flame or flame-retardant coatings may be used as a fire break for grouped electrical cables to limit spread of fire in cable ventings. (Possible cable derating owing to use of such coating materials must be considered during design.)	(e) Same	(e) For cable trays which pass through rated walls, floors or ceilings, fire barriers that equal or exceed the rating of the wall or floor penetrated are provided. (See appendix 9A response to Question 9A.84.) Where PVNGS used IEEE 383 cable rated at 210,000 BTU/hr during construction, its regulatory commitment to cable fire retardancy is IEEE 383 at 70,000 BTU/hr. As such, PVNGS now procures power block cable to IEEE 383 fire retardancy requirements, other nationally recognized standards (e.g., UL 1581 Vertical Tray Flame Test, UL 910, or UL 1666) which have been evaluated to meet or exceed IEEE 383 fire retardancy requirements, or other criteria (e.g., new standards) evaluated by Design (Electrical) Engineering for fire retardant equivalency. There are 27 cables installed at PVNGS that do not meet the IEEE 383 flame test. These 27 cables have been evaluated, for both electrical and fire protection properties, and "Accepted-As-Is" by Material Engineering Evaluation (MEE) 02480. Safety-related areas outside containment which have significant concentrations of cable are provided with automatic water suppression systems. The above active and passive protection features will minimize the spread of fire in cable trays within a fire zone. No additional "fire breaks" are deemed necessary by the Fire Hazards Analysis nor by current NRC guidelines.
(f) Electric cable constructions should as a minimum pass the current IEEE 383 flame test. (This does not imply that cables passing this test will not require additional fire protection.)	(f) Same. For cable installation in operating plants and plants under construction that do not meet the IEEE 383 flame test requirements, all cables must be covered with an approved flame-retardant coating and properly derated.	(f) PVNGS meets or exceeds the requirement of IEEE-383. There are 27 cables installed at PVNGS that do not meet the IEEE 383 flame test. These 27 cables have been evaluated, for both electrical and fire protection properties, and "Accepted-As-Is" by Material Engineering Evaluation (MEE) 02480. During construction most scheduled cable construction was required to pass IEEE 383 (1974) requirements at 210,000 BTU/hr. Both Class 1E and non-Class 1E cable is now required to meet the standard's 70,000 BTU/hr requirement, other nationally recognized standards which have been evaluated to meet or exceed IEEE 383 requirements, or other criteria (e.g., new standards) evaluated by Design (Electrical) Engineering for fire retardant equivalency.
(g) To the extent practical, cable construction that does not give off corrosive gases while burning should be used.	(g) Applicable to new cable installations.	(g) PVNGS complies to the extent practical by providing cable construction that does not give off significant gases while burning. This is accomplished by minimizing the release of free chlorine and hydrogen chloride from power block cables. This is accomplished by restricting the use of PVC or PVC jacketed cable which meet or exceed the smoke generating requirements of UL 910 or UL 1685, or of cables which have been evaluated by Design (Electrical) Engineering for fire protection design applicability.
(h) Cable trays, raceways, conduit, trenches, or culverts should be used only for cables. Miscellaneous storage should not be permitted, nor should piping for flammable or combustible liquids or gases be installed in these areas.	(h) Same. Installed equipment in cable tunnels or culvert need not be removed if they present no hazard to the cable runs as determined by the fire hazards analysis.	(h) Conduit is run through the essential pipe tunnel and the condensate tunnel. Installed water piping in the pipe tunnels does not present a hazard to the conduit in those tunnels.
(i) The design of cable tunnels, culverts, and spreading rooms should provide for automatic or manual smoke venting as required to facilitate manual firefighting capability.	(i) Same	(i) PVNGS complies by providing for manual smoke venting for cable spreading rooms. PVNGS does not utilize any underground cable tunnels or cable culverts for safety-related cabling. However, safety-related conduits run through the condensate tunnel. Manual smoke venting is provided.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 28 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)	3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)	3. Electric Cable Construction, Cable Trays, and Cable Penetrations (Continued)
(j) Cables in the control room should be kept to the minimum necessary for operation of the control room. All cables entering the control room should terminate there. Cables should not be installed in floor trenches or culverts in the control room.	(j) Same. Existing cable installed in concealed floor and ceiling spaces should be protected with an automatic total flooding Halon system.	(j) PVNGS complies. The raised platform in the control room is a concealed space. The cables below the platform terminate in the platform workstations. The cables below the platform are non-safety related and are IEEE 383 or equivalent qualified. There is no ignition source or other combustible material installed below the raised platform. The control room is continuously manned location. Fire detection is not provided in the raised platform. The raised platform is provided with floor openings and louvered sides. This will allow any potential smoke to be detected by the control room personnel. The floor openings and louvers will allow for control room personnel to apply CO^2 to the underside of the platform. Cable trays are routed above and vertical raceways penetrate the corners of the suspended ceiling in the control room. Ionization smoke detectors are installed above the suspended ceiling for early warning and also below the suspended ceiling (see sections D.1.f and F.2 of this table). Fire suppression capability is provided by hose stations and portable fire extinguishers. All cables that enter the control room are terminated in the control room. No cabling is routed through the control room from one area to another. • Installation of an automatic total flooding Halon system is not deemed necessary due to the fact that the control room is manned all the time, the combustible (fire) loading is low and adequate fire suppression and detection is provided. • See appendix 9A response to Question 9A.82 and also section D.1(f) of this table.
4. Ventilation	4. Ventilation	4. Ventilation
(a) The products of combustion that need to be removed from a specific fire area should be evaluated to determine how they will be controlled. Smoke and corrosive gases should generally be automatically discharged directly outside to a safe location. Smoke and gases containing radioactive materials should be monitored in the fire area to determine if release to the environment is within the permissible limits of the plant Technical Specifications.	(a) Same. The products of combustion which need to be removed from a specific fire area should be evaluated to determine how they will be controlled.	(a) The products of combustion are removed manually using portable smoke removal equipment. See responses to Questions 9A.70, 9A.79, 9A.80, and 9A.96.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 29 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
(b) Any ventilation system designed to exhaust smoke or corrosive gases should be evaluated to ensure that inadvertent operation or signal failures will not violate the controlled areas of the plant design. This requirement includes containment functions for protection of the public and maintaining habitability for operations personnel.	(b) Same	(b) PVNGS compliance is described in detail in the appendix 9A response to Question 9A.70 (also see section D.4.(a) of this table.) The control building has a common smoke exhaust system which is not credited for removing smoke. Portable smoke removal equipment will be used to exhaust smoke to the outside. The existing smoke removal system can be used to exhaust smoke, if available. The existing smoke removal system is manually controlled from the control room. The existing smoke removal system has safety class isolation dampers to isolate the system during emergency conditions. Therefore, inadvertent operation or signal failure will not violate the controlled areas of the control building. Also, smoke intrusion into the outside air intake of the control building is monitored and alarmed in the control room. The containment, auxiliary, fuel, and radwaste buildings are continuously monitored for radioactivity and are equipped with isolation dampers. With the exception of the containment building and large open areas of the fuel building, the smoke from safety-related buildings of the plant is removed manually by use of portable smoke removal equipment. Normal plant ventilation system, if available, may also be used under manual control to remove smoke. Only portable equipment, however, is relied on for smoke removal capability. Smoke is vented manually from the affected fire zone to outside. Inadvertent operation or a single failure will not violate the controlled areas of the plant.
(c) The power supply and controls for mechanical ventilation systems should be run outside the fire areas served by the system.	(c) Same	(c) PVNGS does not meet this requirement with respect to the normal ventilation systems. However, smoke ejectors will be utilized in the event of fire. The power supply and controls for the essential air cooling units are run outside the fire zones served by the system.
(d) Fire suppression systems should be installed to protect charcoal filters in accordance with Regulatory Guide 1.52, Design Testing and Maintenance Criteria for Atmospheric Cleanup Air Filtration.	(d) Same	(d) High temperature alarms will alert operator in the control room. All charcoal filters are provided with internal spray nozzles with an outside connection to facilitate manual firefighting with hose attachments. The internal spray nozzles are not considered part of the required fire protection system. Compliance to the Regulatory Guide 1.52, Section C.3.k, is not required due to the fact that adsorbent auto-ignition will not result from radioactivity-induced heat in the adsorbent. The temperature will not exceed 200F (see section 1.8).
(e) The fresh air supply intakes to areas containing safety-related equipment or systems should be located remote from the exhaust air outlets and smoke vents of other fire areas to minimize the possibility of contaminating the intake air with the products of combustion.	(e) Same	(e) PVNGS complies by locating fresh air supply intakes of the following buildings remote from the exhaust air outlets – containment, control, auxiliary, diesel generator, fuel, radwaste, and turbine buildings.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 30 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Ventilation (Continued) (f) Stairwells should be designed to minimize smoke infiltration during a fire. Staircases should serve as escape routes and access routes for fire fighting. Fire exit routes should be clearly marked. Stairwells, elevators, and chutes should be enclosed in masonry towers with minimum fire rating of 3 hours and automatic fire doors at least equal to the enclosure construction, at each opening into the building. Elevators should not be used during fire emergencies.	4. Ventilation (Continued) (f) Same. Where stairwells or elevators cannot be enclosed in 3-hour fire-rated barrier with equivalent fire doors, escape and access routes should be established by prefire plan and practiced in drills by operating and fire brigade personnel.	4. Ventilation (Continued) (f) Stairwells with fire-rated enclosures are designed to minimize smoke infiltration during a fire by providing rated fire doors with door closure mechanisms. Staircases serve as escape routes and access routes for fire-fighting. All fire exits are clearly marked. PVNGS stairwells have 2-hour rated enclosures with Class B doors. PVNGS provides multiple access/egress points for all areas, except the following, to facilitate alternate routes or either access or escape. • The diesel generator shall have a centrally located stairwell with 2 and 3-hour rated walls and Class A doors separating Train A and Train B. Access to the diesel generator building is available through the control building at elevations 100 feet 0 inch and 120 feet 0 inch. • The fuel building has one stairwell, at the southeast end of the building, with 2-hour rated walls on three sides and one Class B door at each level. The wall toward the auxiliary building is 3-hour rated. Access to the safety-related area, at elevation 100 feet 0 inch, is available through the auxiliary building or from the western end of the fuel building. • The radwaste building has one stairwell, at the southeast end of the building with 2-hour rated walls on three sides with Class B doors. The wall toward the control building is 3-hour rated. Access to the radwaste building is available through the west end of the building at elevation 100 feet 0 inch or through the auxiliary building at elevation 120 feet 0 inch and 140 feet 0 inch. There are no safety-related systems in the radwaste building. The stairwell in the corridor building is 1-hour rated. The elevator shaft in the corridor building is not rated. The elevator shaft near the turbine building is not an integral part of any building and, therefore, is not rated. In addition, elevators are not to be used for exiting during fire emergencies.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 31 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Ventilation (Continued)	4. Ventilation (Continued)	4. Ventilation (Continued)
(g) Smoke and heat vents may be useful in specific areas such as cable spreading rooms and diesel fuel oil storage areas and switchgear rooms. When natural-convection ventilation is used, a minimum ratio of 1 square foot of venting areas per 200 square feet of floor area should be provided. If forced convection ventilation is used, 300 cubic feet per minute should be provided for every 200 square feet of floor area. See NFPA No. 204 for additional guidance on smoke control.	(g) Same	(g) PVNGS will use portable smoke removal equipment to remove smoke from upper and lower cable spreading rooms in the control building. The existing portable smoke ejectors will be used to remove smoke from the cable spreading rooms. No credit is taken for existing smoke removal systems in the control building as it may not be available. The portable smoke removal equipment does not meet the stated 300 cfm/200 ft^2 criteria. Standard NFPA 204M (1985) does not have specific reference to 300 cubic feet per minute per 200 square feet of floor area. The standard provides guidance for the venting of the buildings and is geared towards non-spinklered, single-story buildings. The standard discusses its reservation about the combined use of vents/sprinklers in the building and raises a concern that automatic roof venting may be detrimental to the performance of automatic sprinklers. As the cable spreading rooms are provided with fire-action sprinkler systems and the switchgear rooms are provided with CO_2 flood system, the recommended guidance is not used. Instead of recommended guidance, existing portable smoke removal equipment capacity is used. The smoke and heat removal from the diesel fuel oil storage area, in the diesel generator building, will be through the use of portable smoke removal equipment. Normal or essential ventilation systems may also be used if available. For the diesel fuel oil storage area, portable smoke removal equipment capacity meets the recommended ventilation of 300 cfm/200 ft^2. Only portable equipment, however, is relied on for smoke removal capability. See Appendix 9A response to Question 9A.86. Natural-convection ventilation is not used in any power block building.
(h) Self-contained breathing apparatus, using full face positive pressure masks, approved by NIOSH (National Institute for Occupational Safety and Health - approval formerly given by the U.S. Bureau of Mines) should be provided for fire brigade, damage control and control room personnel. Control room personnel may be furnished breathing air by a manifold system piped from a storage reservoir if practical. Service or operating life should be a minimum of 1/2 hour for the self-contained units.	(h) Same	(h) PVNGS complies. Only "bottled air" will be used with full face positive pressure masks approved by NIOSH. • Fire department and control room personnel are provided with self-contained breathing apparatus. • The service life of the self-contained breathing apparatus is a minimum of 1/2 hour.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 32 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Ventilation (Continued)	4. Ventilation (Continued)	4. Ventilation (Continued)
At least two extra air bottles should be located onsite for each self-contained breathing unit. In addition, an onsite 6-hour supply of reserve air should be provided and arranged to permit quick and complete replenishment of exhausted supply air bottles as they are returned. If compressors are used as a source of breathing air, only units approved for breathing air should be used. Special care must be taken to locate the compressor in areas free of dust and contaminants.		PVNGS complies by using only "bottled air" for self-contained breathing units. An additional 1-hour air supply is provided for each self-contained breathing unit. Additionally, a minimum 6-hour supply of reserve air is provided and arranged to permit quick and complete replenishment of exhausted air supply bottles.
(i) Where total flooding gas extinguishing systems are used, area intake and exhaust ventilation dampers should close upon initiation of gas flow to maintain necessary gas concentration. (See NFPA 12, Carbon Dioxide Systems, and 12A, Halon 1301 Systems.)	(i) Same	(i) Electrothermally actuated dampers are provided for CO_2 total flooding systems in the ESF switchgear room and the battery rooms. Electrothermally actuated dampers are provided for the Halon 1301 total flooding system in the communication, computer, and inverter rooms. With the exception of the battery room exhaust dampers, which are on a time delay to prevent overpressurization, for both total flooding gas extinguishing systems, the intake and exhaust dampers close upon initiation of gas flow to maintain the necessary gas concentration. (Also see sections E.4 and E.5 of this table.) See appendix 9A response to Question 9A.83.
5. Lighting and Communication	5. Lighting and Communication	5. Lighting and Communication
Lighting and two-way voice communication are vital to safe shutdown and emergency response in the event of fire. Suitable fixed and portable emergency lighting and communication devices should be provided to satisfy the following requirements:	Same	Lighting is provided. See subsection 9.5.3 and Appendix 9A response to Question 9A.125. Two-way voice communications are provided. See appendix 9A response to Question 9A.76.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 33 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
5. Lighting and Communication (Cont)	5. Lighting and Communication (Cont)	5. Lighting and Communication (Continued)
(a) Fixed emergency lighting should consist of sealed beam units with individual 8-hour minimum battery power supplies.		(a) Fixed emergency lighting with 8-hour battery backed power supplies are provided in all areas needed for the local manual operation of safe shutdown equipment and in access and egress routes, thereto. Exceptions to this are described in 5(b). Emergency lighting for personnel egress from other plant areas is provided by 1-1/2 hour battery units. See section 9.5.3.2.1 for specific locations containing 8-hour emergency lighting.
(b) Suitable sealed beam battery powered portable hand lights should be provided for mergency use.		(b) Sealed beam battery-powered portable lanterns will be readily available to the operators for the following: when access/egress or manual actions are required in the yard area (i.e., condensate storage tank pumphouse, reactor make-up water tank, alternate entrances to the diesel generator building); and when actions are necessary beyond 8 hours or to serve as a compensatory measure for nonfunctional emergency lights.
(c) Fixed emergency communication should use voice-powered head sets at preselected stations.		(c) Fixed emergency voice-powered headsets are provided at preselected stations. See section 9B.2 for specific zones containing voice-powered headset phone jacks.
(d) Fixed repeaters installed to permit use of portable radio communication units should be protected rom exposure to fire damage.		(d) The room which houses the repeaters and other major components of the plant two-way radio system is protected by a wet pipe sprinkler system and a remotely-monitored smoke detector. The redundant ac power feeds for the radio system are from independent MCCs in different fire zones. The power cables maintain separate routings and do not both pass through the same fire zone. The interior antenna system for the radio system is fault tolerant. Loss of the antennas and antenna cables in one fire zone will not significantly impact radio system performance in other fire zones. See also the response to Question 9A.129 in UFSAR Appendix 9A.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 34 of 69)

E. FIRE DETECTION AND SUPPRESSION

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Fire Detection	1. Fire Detection	1. Fire Detection
(a) Fire detection systems should as a minimum comply with NFPA 72D, Standard for the Installation, Maintenance and Use of Proprietary Protective Signaling Systems.	Same. Deviations from the requirements of NFPA 72D should be identified and justified.	(a) NFPA 72D (1975) was used as guidance in the design of the fire detection systems as described in the appendix 9A responses to Questions 9A.71, 9A.113, and 9A.128.
(b) Fire detection system should give audible and visual alarm and annunciation in the control room. Local audible alarms should also sound at the location of the fire.		(b) PVNGS complies by providing audible and visual alarm in the control room. Control room annunciation is provided by means of a visual display, which will display a printout description of any encountered alarm condition. Local audible alarms are provided in the areas of the fire.
(c) Fire alarms should be distinctive and unique. They should not be capable of being confused with any other plant system alarms.		(c) PVNGS complies. All signals from the fire protection system are received at the central alarm station (CAS) host computer. The fire alarm signal is then transmitted from CAS to each units' control room and annunciated at the fire protection display. The fire protection alarm signals received in the control rooms are distinctive and unique from all other trouble and alarm signals. A backup annunciator is available at the Fire Department if needed. See appendix 9A response to Question 9A.114.
(d) Fire detection and actuation systems should be connected to the plant emergency power supply.		(d) Fire detection and suppression systems for PVNGS have two sources of ac power. If failure of the primary source occurs, switching to the secondary power source will be automatic. The primary source of power is from the emergency lighting panels, with an UPS as a secondary source. However, the only power source under the fire protection quality assurance program is the local battery backups.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 35 of 69)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (a) An underground yard fire main loop should be installed to furnish anticipated fire water requirements. NFPA 24, Standard for Outside Protection, gives neccessary guidance for such installation. It references other design codes and standards developed by such organizations as the American National Standards Institute (ANSI) and the American Water Works Association (AWWA). Lined steel or cast iron pipe should be used to reduce internal tuberculation. Such tuberculation deposits in an unlined pipe over a period of years can significantly reduce	2. Fire Protection Water Supply Systems (a) Same. Visible location marking signs for underground valves is acceptable. Alternative valve position indicators should also be provided.	2. Fire Protection Water Supply Systems (a) PVNGS complies by installing underground yard main loop for the fire water requirements using the guidance of NFPA 24 (1973) and NFPA 24 (1995). A combination of cement mortar-lined (ductile) case iron pipe and reinforced fiberglass pipe is used for the underground yard main loop. Portions of the underground yard main loop piping which are cement mortar-lined (ductile) cast iron pipe follow the guidance of NFPA 24 (1973). Those portions which are reinforced fiberglass pipe follow the guidance of NFPA 24 (1995). The reinforced fiberglass piping is intended to meet all of the requirements of the cement mortar-lined (ductile) specific cast iron pipe (e.g., structural integrity, pressure boundary integrity, hydraulic performance and minimization of internal tuberculation) with the exception of those requirements that are uniquely related to the selection of the specific underground piping material. Cement-lined, cast iron pipe is used for the underground yard main loop. Flushing of the fire protection water system piping is performed using the guidance of NFPA 24 (1973). Post indicator valves are installed to isolate portions of the yard fire main for maintenance or repair without shutting off the entire system. Post-indicator valves that do not have above grade post-indicators, are provided with position indicators located below grade and access covers to allow verification of valve position and are intended to comply with the requirements of NFPA 24 (1995).

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 36 of 69)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Continued)
water flow through the combination of increased friction and reduced pipe diameter. Means for treating and flushing the systems should be provided. Approved visually indicating sectional control valves, such as post-indicator valves, should be provided to isolate portions of the main for maintenance or repair without shutting off the entire system.		
The fire main system piping should be separate from service or sanitary water system piping.	For operating plants, fire main system piping that can be isolated from service or sanitary water system piping is acceptable.	PVNGS complies by utilizing separate piping for fire protection and domestic water.
(b) A common yard fire main loop may serve multiunit nuclear power plant sites, if cross-connected between units. Sectional control valves should permit maintaining independence of the individual loop around each unit. For such installations, common water supplies may also be utilized. The water supply should be sized for the largest single expected flow. For multiple reactor sites with widely separated plants (approaching 1 mile or more), separate yard fire main loops should be used.	(b) Same. Sectionalized systems are acceptable.	(b) PVNGS complies by utilizing a cross-connected yard main loop with appropriate sectional control valves to serve all three units, which are approximately 500 feet apart from each other. The flow capacity is sized for the largest expected flow for any one unit (see section E.(2).(e) of this table.) All units can be supplied considering a single failure in any part of the loop.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 37 of 69)

D. GENERAL GUIDELINES FOR PLANT PROTECTION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (Continued) (c) If pumps are required to meet system pressure or flow requirements, a sufficient number of pumps should be provided so that 100% capacity will be available with one pump inactive (e.g., three 50% pumps or two 100% pumps). The connection to the yard fire main loop from each fire pump should be widely separated, preferably located on opposite sides of the plant. Each pump should have its own driver with independent power supplies and control. At least one pump (if not powered from the emergency diesels) should be driven by nonelectrical means, preferably diesel engine. Pumps and drivers should be located in rooms separated from the remaining pumps and equipment by a minimum 3-hour fire wall. Alarms indicating pump running, driver availability, or failure to start should be provided in the control room.	2. Fire Protection Water Supply Systems (Continued) (c) Same	2. Fire Protection Water Supply Systems (Continued) (c) PVNGS has three fire pumps capable of supplying 1500 ± 10% (1,350 minimum) gallons per minute each at 125 psi. Two are diesel-driven and one has an electric motor driver. With one pump inactive, adequate capacity is available for all plant areas. With two pumps inactive, adequate capacity (1,350 gpm) is available for all safety related areas. Minimum pumping capacity of 1,350 gpm is based on 500 gallons per minute for manual hose streams plus the hydraulically calculated demand for the largest safety-related area sprinkler or deluge system. Each fire pump is separately connected to the yard fire main loop. Each fire pump is provided with its own driver, with independent power supplies and control. Pumps and drivers are located in rooms separated from the remaining pumps and equipment by 2-hour walls. Wet pipe sprinkler systems are provided in the two diesel-driven pump rooms. The following alarms are provided in the control room for the diesel-driven pumps. • Engine running [Class A signal] • Controller switch to "off" or "manual" position [Class A signal] • Controller trouble [Class B signal] common for - Loss of battery charger - Failure of engine to start automatically - Shutdown from overspeed - Low oil pressure - High engine jacket water temperature - Battery failure - Fuel oil day tank low level The following alarms are provided in the control room for the motor-driven pump. • Motor running [Class A signal] • Loss of the line power on line side of motor starter in any phase [Class A signal]

Table 9B.3-1

OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 38 of 69)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (Cont) Details of the fire pump installation should as a minimum conform to NFPA 20, Standard for the Installation of Centrifugal Fire Pumps.	2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Continued) NFPA 20 (1976) was used as a guide for the fire pump installation. Diesel fire pump skid components (pump, diesel engine and controller) installed in 2005, were installed using the guidance of NFPA 20, 2003. Exceptions include the following: • NFPA 20 (1976), Section 8-4.2: A guard or protection pipe is not installed for all exposed fuel lines. The diesel fuel supply tanks are located near the fire pumphouse with approximately 6 feet of exposed piping between the aboveground fuel tank and the fire pumphouse. • NFPA 20 (1976), Section 8-4.5: Diesel fuel supply tanks of steel construction are located aboveground, outside the fire pumphouse, in concrete dikes. These dikes are not considered part of the required fire protection system. The tanks and fuel piping are exposed. Freeze protection is provided by insulating the fuel piping and by using No. 2 diesel fuel specifications with appropriate winterized properties. See appendix 9A response to Question 9A.72. • NFPA 25 (2002), Section 8.3.1: The fire protection diesel driven pumps are started once per month and run for not less than 60 minutes to ensure normal operating temperatures are attained and diesels run smoothly. This change is consistent with prior technical specification commitments on the fire protection system that allowed the diesels to start from ambient conditions and operate for at least 30 minutes on recirculation flow at least once per 31 days.
(d) Two separate reliable water supplies should be provided. If tanks are used, two 100% (minimum of 300,000 gallons each) system capacity tanks should be installed. They should be so interconnected that pumps can take suction from either or both. However, a leak in one tank or its piping should not cause both tanks to drain. The main plant fire water supply capacity should be capable of refilling either tank in a minimum of 8 hours. Common tanks are permitted for fire and sanitary or service water storage. When this is done, however, minimum fire water storage requirements should be dedicated by means of a vertical standpipe for other water services.	(d) Same	(d) Two separate, reliable water supply tanks are provided. Each tank has a capacity of 500,000 gallons. Of the 500,000 gallons stored within each tank, 300,000 gallons are dedicated for fire protection. The remaining 200,000 gallons are available for other uses by means of suction piping that penetrates each tank above the 300,000-gallon level. Both tanks are interconnected and the pumps can take suction from either or both. A significant leak in one tank or its piping will initiate a low level alarm alerting operators in the Unit 1 Control Room.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A
OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 39 of 69)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Continued) This design feature will ensure timely operator action to isolate the tank or the pipe section from where the leak is occurring. The main plant water supply pumps are normally capable of refilling either tank in 8 hours but are not considered part of the required fire protection system.
(e) The fire water supply (total capacity and flowrate) should be calculated on the basis of the largest expected flowrate for a period of 2 hours, but not less than 300,000 gallons. This flowrate should be based (conservatively) on 1000 gpm for manual hose streams plus the greater of: (1) all sprinkler heads opened and flowing in the largest designed fire area; or (2) the largest open head deluge system(s) operating.	(e) Same	(e) PVNGS complies. Underground fire protection water lines are sized to accommodate the largest plant site fire protection water demand for automatic systems plus simultaneous flow of 1000 gpm for hose streams for the turbine building and 500 gpm for other areas of the power block. To achieve the maximum line flowrate for the turbine building (non-safety-related area) for 2 hours, the multiple use water supply in the tank will supplement the fire protection supply. Each tank has a nominal volume of 500,000 gallons. The fire protection water supply (lower 3/5 of the storage tanks) is combined with the multiple use water supply (upper 2/5) for a maximum total of 1,000,000 gallons. The reserved fire water capacity is a total of 600,000 gallons, 300,000 gallons minimum per tank for two tanks. The minimum reserved fire water capacity of 300,000 gallons is greater than the calculated largest expected safety-related area sprinkler flowrate for a period of 2 hours plus an allowance for manual hose streams of 500 gpm (reference Safety Evaluation Report, NUREG-0857,Item 9.5.1.2, page 9-31).
(f) Lakes or fresh water ponds of sufficient size may qualify as sole source of water for fire protection, but require at least two intakes to the pump supply. When a common water supply is permitted for fire protection and the ultimate heat sink, the following conditions should also be satisfied: (1) The additional fire protection water requirements are designed into the total storage capacity; and		(f) Not applicable to PVNGS

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 40 of 69)

E. FIRE DETECTION AND SUPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Fire Protection Water Supply Systems (Cont) (2) Failure of the fire protection system should not degrade the function of the ultimate heat sink.	2. Fire Protection Water Supply Systems (Cont)	2. Fire Protection Water Supply Systems (Continued)
(g) Outside manual hose installation should be sufficient to reach any location with an effective hose stream. To accomplish this hydrants should be installed approximately every 250 feet on the yard main system. The lateral to each hydrant from the yard main should be controlled by a visually indicating or key-operated (curb) valve. A hose house, equipped with hose and combination nozzle, and other auxiliary equipment recommended in NFPA 25, Outside Protection, should be provided as needed but at least every 1000 feet. Threads compatible with those used by local fire departments should be provided on all hydrants, hose couplings, and standpipe risers.	(g) Same	(g) PVNGS complies with exceptions noted. • The lateral to each hydrant from the yard main is controlled by key-operated (curb) valve. • The PVNGS Fire Department has emergency response vehicle(s) which carry an assortment of hose, nozzles and auxiliary equipment in lieu of hose houses which can reach any location about the power block with an effective hose stream. • National standard hose thread is provided on all hydrants, hose couplings and standpipe risers. Local fire departments carry adapters to allow use of national standard thread.

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Water Sprinklers and Hose Standpipe Systems (a) Each automatic sprinkler system and manual hose station standpipe should have an independent connection to the plant underground water main. Headers fed from each end are permitted inside buildings to supply multiple sprinkler and standpipe systems. When provided, such headers are considered an extension of the yard main system. The header arrangement should be such that no single failure can impair both the primary and backup fire protection system.	3. Water Sprinklers and Hose Standpipe Systems (a) Same	3. Water Sprinklers and Hose Standpipe Systems (a) PVNGS complies by providing headers that are fed from each end for the control, auxiliary, and turbine buildings. These headers serve multiple sprinkler systems and also the hose rack/reel stations for each respective building, and no single failure will result in any of the following situations: • For the auxiliary and control buildings, primary water spray systems and all hose stations for any specific fire zone impaired at once. • For the turbine building, primary sprinkler system and backup hose stations impaired at once. • For the diesel generator building, no single failure can impair both trains or both primary and backup fire protection system. Separate headers from the control building feed the automatic preaction sprinkler systems. Each diesel generator train is fed separately. The hose stations, connected to each header, are located in the control building. • For the main steam support structure, no single failure can impair both the primary and backup suppression capability. The backup hose streams are available from hydrant on the yard main and hose station No. 63 in the turbine building adjacent to the main steam support structure. (See appendix 9A response to Question 9A.100.) In the fuel building, sprinkler system and manual hose stations are fed from a single header connected to the plant underground yard main. In the containment building, all of the hose stations and the sprinklers for the charcoal filters are fed from a single header from the auxiliary building. The supply header piping is Seismic Category I. (See appendix 9A response to Question 9A.97.)

Table 9B.3-1

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Water Sprinklers and Hose Standpipe Systems (Continued) Each sprinkler and standpipe system should be equipped with outside screw and yoke (OS&Y) gate valve, or other approved shut off valve, and water flow alarm. Safety-related equipment hat does not itself require sprinkler water fire protection, but is subject to unacceptable damage if wetted by sprinkler water discharge should be protected by water shields or baffles.	3. Water Sprinklers and Hose Standpipe Systems (Continued)	3. Water Sprinklers and Hose Standpipe Systems (Continued) Each sprinkler and standpipe system is equipped with an OS&Y gate valve or approved shut off valve. Water flow alarms are provided for the sprinkler systems. See section A.5 of this table for discussion of inadvertent operation of fire suppression systems not incapacitating safety-related systems.
(b) All valves in the fire water systems should be electrically supervised. The electrical supervision signal should indicate in the control room and other appropriate command locations in the plant (see NFPA 26, Supervision of Valves.)	(b) Same. When electrical supervision of fire protection valves is not practicable, an adequate management supervision program should be provided. Such a program should include locking valves open with strict key control; tamper proof seals; and periodic, visual check of all valves.	(b) All valves controlling (isolating) Automatic Fire Protection Water Suppression Systems, and all sectional and header isolation valves, are locked in their proper position, and are supervised by inspection, per NFPA 13, 1976, section 3.13. Additionally: Supervision of the following valves is provided by inspection. • Valves located on laterals from the yard main to each hydrant. These are key-operated (curb) valves, normally open, and cannot be closed without the key. • All post-indicator valves which are locked open. • The header isolation valves for standpipes and hose stations. • Valves for the automatic water sprinkler heads over two missile doors.

NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 43 of 69)

E. FIRE DETECTION AND SUPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Water Sprinklers and Hose Standpipe Systems (Continued) (c) Automatic sprinkler systems should as a minimum conform to requirements of appropriate standards such as NFPA 13, Standard for the Installation of Sprinkler Systems, and NFPA 15, Standard for Water Spray Fixed Systems.	3. Water Sprinklers and Hose Standpipe Systems (Continued) (c) Same	3. Sprinklers and Hose Standpipe Systems (Continued) (c) PVNGS uses as guidance NFPA 13 (1976), Standard for the Installation of Sprinklers, and NFPA 15 (1973), Standard for Water Spray Fixed Systems, as follows: • In the auxiliary, control, fuel, radwaste, and turbine buildings and also in the main steam support structure the spacing, location, and position of the sprinklers are dictated by the type of construction. The ceilings in all these buildings are of noncombustible construction and the beam epth exceeds that which is indicated in NFPA 13 (1976). NFPA guidance is provided only for those buildings with beams of less than 18 inches in depth. The actual sprinkler spacing as measured from ceiling or beam is more than the spacing recommended in NFPA 13 (1976) Section 4.3.4. However, in order to protect the structural steel, sprinklers have been provided in bays formed by beams. These sprinklers are located 16 inches to 22 inches from the ceiling. Conformance to the applicable NFPA standards required per Section 4020 of NFPA 15 (1973) is addressed separately in this report. • See E.(3).(b) for conformance to NFPA 26 (1976) • See E.(3).(d) for conformance to NFPA 14 (1976) • See E.(2).(a) and E.(2).(g) for conformance to NFPA 24 (1973) • See E.(2).(c) for conformance to NFPA 20 (1976) • See E.(1).(a) for conformance to NFPA 72D (1975)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
(d) Interior manual hose installation shall be able to reach any location with at least one effective hose stream. To accomplish this, standpipes with hose connections, equipped with a maximum of 75 feet of 1-1/2-inch woven jacket-lined fire hose and suitable nozzles should be provided in all buildings, including containment, on all floors and should be spaced at not more than 100-foot intervals. Individual standpipes should be of at least 4-inch diameter for multiple hose connections and 2-1/2-inch diameter for single hose connections. These systems should follow the requirements of NFPA 14, Standpipe and Hose Systems, for sizing, spacing, and pipe support requirements.	(d) Interior manual hose installation should be able to reach any location with at least one effective hose stream. To accomplish this, standpipes with hose connections, equipped with a maximum of 75 feet of 1-1/2 inch woven jacket-lined fire hose and suitable nozzles, should be provided in all buildings, including containment, on all floors and should be spaced at not more than 100-foot intervals. Individual standpipes should be of at least 4-inch diameter for multiple hose connections and 2-1/2-inch diameter for single hose connections. These systems should follow the requirements of NFPA No. 14 for sizing, spacing, and pipe support requirements (NELPIA).	(d) PVNGS complies except that: • As indicted in section 9B.2, hose lengths of 75 feet, 100 feet, 125 feet, and 150 feet are used (see appendix 9A responses to Questions 9A.65 and 9A.115). • The following multiple hose connections are fed from a common 2-1/2-inch standpipe: Radwaste building: • Hose station No. 54 (elevation 120 feet 0 inch) and No. 56 (elevation 140 feet 0 inch) • Hose station No. 55 (elevation 120 feet 0 inch) and No. 57 (elevation 140 feet 0 inch) Turbine building: • Hose stations No. 79 and No. 101. Both hose stations are located close to each other at elevation 176 feet 0 inch

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Water Sprinklers and Hose Standpipe Systems (Continued) Hose stations should be located outside entrances to normally unoccupied areas and inside normally occupied areas. Standpipes serving hose stations in areas housing safety-related equipment should have shutoff valves and pressure-reducing devices (if applicable) outside the area. Provisions should be made to supply water at least to standpipes and hose connections for manual firefighting in areas within hose reach of equipment required for safe plant shutdown in the event of an SSE. The standpipe system serving such hose stations should be analyzed for SSE loading and should be provided with supports to assure system pressure integrity. The piping and valves for the portion of hose standpipe system affected by this functional requirement should at least satisfy ANSI Standard B31.1, Power Piping. The water supply for this condition may be obtained by manual operator actuation of valve(s) in a connection to the hose standpipe header from a normal Seismic Category I water system such as essential service water system. The cross-connection should be (a) capable of providing flow to at least two hose stations (approximately 75 gpm/hose station), and (b) designed to the same standards as the Seismic Category I water system; it should not degrade the performance of the Seismic Category I water system.	3. Water Sprinklers and Hose Standpipe Systems (Continued) Hose stations should be located outside entrances to normally unoccupied areas and inside normally occupied areas. Standpipes serving hose stations in areas housing safety-related equipment should have shutoff valves and pressure-reducing devices (if applicable) outside the area.	3. Water Sprinklers and Hose Standpipe Systems (Continued) Hose stations are provided at the entrances to fire zones as detailed in section 9B.2. PVNGS provides shutoff valves for standpipes and pressure reducing devices for hose stations in areas housing safety related equipment. The shutoff valves are located outside the zones, except for those zones noted in Table E.3.(d)-3. Table E.3.(d)-3 STANDPIPES SERVING HOSE STATIONS WITH SHUTOFF VALVES LOCATED INSIDE THE SAME FIRE ZONE

Fire Zone	Location	Safety-Related Equipment Within Zone/Justification
42D	Auxiliary building, El: 100 feet 0 inch	Train A cables and conduit/hose streams from nearby hose stations available. Redundant train available.
42C	Auxiliary building, El: 100 feet 0 inch	Train A and B cables and conduit/hose streams from nearby hose stations available. Redundant train available.
52D	Auxiliary building, El: 120 feet 0 inch	Train B conduit. Redundant train available.
66B	Containment building, El: 80 feet 0 inch through 140 feet 0 inch	Cables, control instrumentation, and piping/hose streams from nearby hose stations available. Redundant train available. Line type thermal detectors, installed in cable trays.

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Water Sprinklers and Hose Standpipe Systems (Continued)	3. Water Sprinklers and Hose Standpipe Systems (Continued)	3. Water Sprinklers and Hose Standpipe Systems (Continued)
(e) The proper type of hose nozzles to be supplied to each area should be based on the fire hazard analysis. The usual combination spray/straight-stream nozzle may cause unacceptable mechanical damage (for example, the delicate electronic equipment in the control room) and be unsuitable. Electrically safe nozzles should be provided at locations where electrical equipment or cabling is located.	(e) Same	(e) PVNGS selects the proper types of hose nozzles based upon the fire hazards analysis. See Section 9B.2 for details. Electrically safe nozzles are used in areas where electrical equipment or cabling is located.
(f) Certain fires such as those involving flammable liquids respond well to foam suppression. Consideration should be given to use of any of the available foams for such specialized protection application. These include the more common chemical and mechanical low expansion foams, high expansion foam, and the relatively new aqueous film forming foam (AFFF).	(f) Same	(f) Special extinguishing agents are available for use by the fire department as required.
4. Halon Suppression Systems The use of Halon fire extinguishing agents should as a minimum comply with the requirements of NFPA 12A and 12B, Halogenated Fire Extinguishing Agent Systems - Halon 1301 and Halon 1211. Only UL or FM approved agents should be used. In addition to the guidelines of NFPA 12A and 12B, preventative maintenance and testing of the systems, including check weighting of the Halon cylinders should be done at least quarterly.	4. Halon Suppression Systems Same	4. Halon Suppression Systems PVNGS complies by utilizing "Halogenated Fire Extinguishing Agent System - Halon 1301." NFPA 12A (1973) was used as a guide for the installation of Halon 1301 systems. PVNGS verifies the liquid quantity in, or weight of the Halon in the cylinders at least every 6 months.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 47 of 69)
E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Halon Suppression Systems (Continued)	4. Halon Suppression Systems (Cont.)	4. Halon Suppression Systems (Continued)
Particular consideration should also be given to:		The PVNGS design reflects these considerations:
(a) minimum required Halon concentration and soak time		(a) The minimum/maximum Halon concentration range used is 5% to 7% by volume in occupied hazard areas, and 5% to 10% by volume in unoccupied areas or areas evacuable within 1 minute as provided by NFPA Pamphlet 12A (1984), Section 2-1.1.3.
(b) toxicity of Halon		(b) The Halon concentration used is below the limits specified in NFPA 12A (1973). A 20-second time delay before system actuation is provided for evacuation of personnel.
(c) toxicity and corrosive characteristics of thermal decomposition products of Halon		(c) The low concentration of Halon 1301 with rapid extinguishment (less than 10 seconds) is provided to minimize production of thermal decomposition product.
5. Carbon Dioxide Suppression Systems	5. Carbon Dioxide Suppression Systems	5. Carbon Dioxide Suppression Systems
The use of carbon dioxide extinguishing systems should as a minimum comply with the requirements of NFPA 12, Carbon Dioxide Extinguishing Systems.	Same	NFPA 12 (1973) was used as a guide for the installation of carbon dioxide extinguishing systems.
Particular consideration should also be given to:		The PVNGS design reflects these considerations;
(a) minimum required CO_2 concentration and soak time;		(a) Design CO_2 concentration of 50% is used with a flooding factor of 0.083 lb CO_2/ft^3. (Section 2421, NFPA 12, 1973). Extended discharge protection of approximately 18 minutes is provided for the ESF switchgear rooms.
(b) toxicity of CO_2;		(b) Odorizing equipment is provided to alert personnel of system operation. Actuation of CO_2 to each protected area is delayed to allow evacuation of personnel. The actuation time delay is area - specific and based on the anticipated time to allow personnel egress. The time delay setpoint is adjustable and is controlled by plant procedures.
(c) possibility of secondary thermal shock (cooling) damage;		(c) Discharge nozzles are located away from equipment to avoid possibility of thermal shock damage.
(d) offsetting requirements for venting during CO_2 injection to prevent overpressurization versus sealing to prevent loss of agent.		(d) Damper is provided with time delay relay to prevent over-pressurization during CO_2 injection in the battery rooms, door cracks in the ESF switchgear rooms are utilized to prevent overpressurization.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 48 of 69)

E. FIRE DETECTION AND SUPPRESSION (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
5. Carbon Dioxide Suppression Systems (Continued)	5. Carbon Dioxide Suppression Systems (Continued)	5. Carbon Dioxide Suppression Systems (Continued)
(e) design requirements from overpressurization; and		(e) Provided as indicated above.
(f) possibility and probability of CO_2 systems being out-of-service because of personnel safety consideration. CO_2 systems are disarmed whenever people are present in an area so protected. Areas entered frequently (even though duration time for any visit is short) have often been found with CO_2 systems shut off.	(f) Same	(f) The status of the CO_2 suppression syst4em is monitored in the control room. When the CO_2 system is disarmed, this condition is annunciated in the control room except for the CO_2 manual valves which are locked/sealed open and administratively controlled.
6. Portable Extinguishers Fire extinguishers should be provided in accordance with guide lines of NFPA 10 and 10A, Portable Fire Extinguishers Installation, Maintenance and Use. Dry chemical extinguishers should be installed with due consideration given to cleanup problems after use and possible adverse effects on equipment installed in the area.	6. Portable Extinguishers Same	6. Portable Extinguishers PVNGS complies by providing portable extinguishers using the guidelines of NFPA 10 (1975). Listed below are zones where the travel distance between extinguishers exceeds the maximum travel distance of 75 feet required per Section 3.2 of NFPA 10 (1975). Zones 37A and 37B; Train A and B corridor zones, El: 70 feet 0 inch, auxiliary building Zones 39A and 39B: Train A and B pipeways, El: 88 feet 0 inch, auxiliary building

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 49 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Primary and Secondary Containment	1. Primary and Secondary Containment	1. Primary and Secondary Containment
(a) Normal Operation Fire protection requirements for primary and secondary containment areas should be provided on the basis of specific identified hazards. For example:	(a) Normal Operation Same except as noted.	(a) Normal Operation PVNGS complies with the fire protection requirements for the specific identified hazards for the primary containment areas. See section 9B.2. See F.1.(b) for portable fire extinguishers. Note: There are no secondary containment areas in PVNGS.
• Lubricating oil or hydraulic fluid system for the primary coolant pumps		• PVNGS complies by providing a design for the reactor coolant pumps which channels lube oil leakage away from the hot surfaces of the pump to an oil collection tank. See appendix 9A response to Question 9A.126.
• Cable tray arrangements and cable penetrations		• Cable tray arrangements and cable penetrations are protected. Line type temperature detectors as well as ionization smoke detectors are provided for early warning. Class A wiring is provided. The high temperature alarm is annunciated in the control room. Cable trays are also accessible from manual hose stations. PVNGS meets 10CFR50, Appendix R, Section III.G.2, separation criteria with the exception of the deviations called out in section 9B.2 of this report and the appendix 9A response to Question 9A.130.
• Charcoal filters		• For the fire protection provided for the charcoal filters, see section D.4(d) of this table.
Because of the general inaccessibility of these areas during normal plant operations, protection should be provided by automatic fixed systems. Automatic sprinklers should be installed for those hazards identified as requiring fixed suppression.	Fire suppression systems should be provided based on the fire hazards analysis. Fixed fire suppression capability should be provided for hazards that could jeopardize safe plant shutdown. Automatic sprinklers are preferred. An acceptable alternate is automatic gas (Halon or CO_2) for hazards identified as requiring fixed suppression protection.	PVNGS does not provide any automatic fixed suppression system within the containment based on the results of the fire hazards analysis in section 9B.2. The analysis has shown that any postulated fire occurring within the PVNGS containment will not restrict the capability of safe shutdown systems to accomplish a safe shutdown of the reactor.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 50 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Primary and Secondary Containment (Continued)	1. Primary and Secondary Containment (continued)	1. Primary and Secondary Containment (continued)
Operation of the fire protection systems should not compromise integrity of the containment or the other safety-related systems. Fire protection activities in the containment areas should function in conjunction with total containment requirements such as control of contaminated liquid and gaseous release and ventilation.	An enclosure may be required to confine the agent if a gas system is used. Such enclosure should not adversely affect safe shutdown, or other operating equipment in containment.	PVNGS does not utilize any fixed gas fire suppression systems within the containment building. Fire protection systems will not compromise the integrity of the containment or of the other safety-related systems. Fire protection activities will function in conjunction with total containment requirements such as the control of contaminated liquid and gaseous release and ventilation.
Fire detection systems should alarm and annunciate in the control room. The type of detection used and the location of the detectors should be most suitable to the particular type of fire that could be expected from the identified hazard. A primary containment general area fire detection capability should be provided as backup for the above described hazard detection. To accomplish this, suitable smoke detection (e.g., visual obscuration, light scattering, and particle counting) should be installed in the air recirculation system ahead of any filters.		Fire detection systems will alarm and annunciate in the control room. Line-type temperature detectors are installed on the cable trays, thermal detectors in the HVAC charcoal filters, and ionization detectors near the reactor coolant pumps. Primary general area fire detection capability is provided by ionization detectors as backup to the specific hazard detection identified above. Therefore, smoke detection ahead of the air filters is not provided. Special fire protection requirements during refueling and maintenance operations are addressed in section F.1.(b) of this table.
Automatic fire suppression capability need not be provided in the primary containment atmospheres that are inerted during normal operation. However, special fire protection requirements during refueling and maintenance operations should be satisfied as provided below.	Automatic fire suppression capability need not be provided in the primary containment atmospheres that are inerted during normal operation. However, special fire protection requirements during refueling and maintenance operations should be satisfied as provided below.	

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 51 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Primary and Secondary Containment (continued)	1. Primary and Secondary Containment (continued)	1. Primary and Secondary Containment (continued)
(b) Refueling and Maintenance	(b) Refueling and Maintenance	(b) Refueling and Maintenance
Refueling and maintenance operations in containment may introduce additional hazards such as contamination control materials, decontamination supplies, wood planking, temporary wiring, welding, and flame cutting (with portable compressed fuel gas supply). Possible fires would not necessarily be in the vicinity of fixed detection and suppression systems.	Same	
Management procedures and controls necessary to assure adequate fire protection are discussed in section 3a.		PVNGS complies, as described in section 3a of this table.
In addition, manual firefighting capability should be permanently installed in containment. Standpipes with hose stations, and portable fire extinguishers, should be installed at strategic locations throughout containment for any required manual firefighting operations.	Equivalent protection from portable systems should be provided if it is impractical to install standpipes with hose stations.	PVNGS complies by providing permanent hose stations within the containment building. Portable fire extinguishers are provided within the containment building during outages (modes 5 and 6). They are removed during operation (modes 1-4) to prevent potential adverse effects from radiation, heat, and other plant accidents and to permit periodic inspections.
Adequate self-contained breathing apparatus should be provided near the containment entrances for firefighting and damage control personnel. These units should be independent of any breathing apparatus or air supply systems provided for general plant activities.		PVNGS complies by providing the plant fire department with self-contained breathing apparatus for use as required.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 52 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Control Room	2. Control Room	2. Control Room
The control room is essential to safe reactor operation. It must be protected against disabling fire damage and should be separated from other areas of the plant by floors, walls, and roofs having minimum fire resistance ratings of 3 hours. Control room cabinets and consoles are subject to damage from two distinct fire hazards: (a) Fire originating within cabinet or console; and (b) Exposure fire involving combustibles in the general room area.	Same	PVNGS complies by providing 3-hour rated walls, floor, and ceiling for the control room complex except for the following: (i) The southeast exterior wall of the control room is non-rated. It is not required to separate redundant shutdown systems. (ii) The common walls to the three HVAC chases, located at three corners of the control room, are 2-hour rated. There are no combustibles in the HVAC chases and the combustible (fire) loading of the control room is low. (iii) The common walls between the control room and computer room are 2-hour rated. The computer room has a Halon suppression system. (See appendix 9A responses to Questions 9A.109 and 9A.118.)
Manual firefighting capability should be provided for both hazards. Hose stations and portable water and Halon extinguishers should be located in the control room to eliminate the need for operators to leave the control room. An additional hose piping shutoff valve and pressure-reducing device should be installed outside the control room. Hose stations adjacent to the control room with portable extinguishers in the control room acceptable.	Hose stations adjacent to the control room with extinguishers in the control room are acceptable.	PVNGS complies by providing a hose station adjacent to each entrance to the control room plus portable CO_2 and pressurized water fire extinguishers inside the control room. Portable Halon extinguishers are utilized in the computer room. The hose piping shutoff valves are installed outside the control room.
Nozzles that are compatible with the hazards and equipment in the control room should be provided for the manual hose station. The nozzles chosen should satisfy actual firefighting needs, satisfy electrical safety and minimize physical damage to electrical equipment from hose stream impingement.		PVNGS complies by providing Class C nozzles on the hose stations to satisfy electrical safety and minimize physical damage to electrical equipment from hose stream impingement.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 53 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
2. Control Room (continued)	2. Control Room (continued)	2. Control Room (continued)
Fire detection in the control room cabinets and consoles should be provided by smoke and heat detectors in each fire area. Alarm and annunciation should be provided in the control room. Fire alarms in other parts of the plant should also be alarmed and annunciated in the control room.		PVNGS complies by providing smoke detectors in the ventilation stream above each cabinet. Area smoke detectors are provided for the entire control room. All fire alarms in the plant are annunciated in the control room. The PVNGS design does not utilize smoke detectors inside control room cabinets.
Breathing apparatus for control room operators should be readily available. Control room floors, ceiling, supporting structure, and walls, including penetrations and doors, should be designed to a minimum fire rating of 3 hours. All penetration seals should be airtight.		PVNGS complies by providing readily available breathing apparatus for the control room personnel. The fire rating of the control room is described at the start of this section. Penetration seals are airtight.
The control room ventilation intake should be provided with smoke detection capability to automatically alarm locally and isolate the control room ventilation system to protect operators by preventing smoke from entering the control room. Manually operated venting of the control room should be available so that operators have the option of venting for visibility.	Manually operated ventilation systems are acceptable.	Smoke detectors are installed to provide area wide coverage in the control room and to alarm if smoke is detected. • Smoke detection is provided in the combined control building/control room ventilation intake shaft. • If smoke enters the control room, the Control Room Ventilation Isolation Actuation Signal (CRVIAS) will be manually initiated to protect the operators. • PVNGS complies with manually operated smoke removal ventilation system.
Cables should not be located in concealed floor and ceiling spaces. All cables that enter the control room should terminate in the control room. That is, no cabling should be simply routed through the control room from one area to another.	If such concealed spaces are used, however, they should have fixed automatic total flooding Halon protection	Cables to the control room operator workstations are routed below the raised platform. Some cable trays are routed above the suspended ceiling. See response to section D.1(f) of this table. All cables that enter the control room are terminated in the control room. No cabling is routed through the control room from one area to another.
Safety-related equipment should be mounted on pedestals or the control room should have curbs and drains to direct water away from such equipment. Such drains should be provided with means for closing to maintain integrity of the control room in the event of other accidents requiring control room isolation.	Not applicable.	Not applicable. Note: For information concerning mounting of control room equipment, see section D.1.(i) of this table.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 54 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Cable Spreading Room The primary fire suppression in the cable spreading room should be an automatic water system such as closed head sprinklers, open head deluge, or open directional spray nozzles. Deluge and open spray systems should have provisions for manual operation at a remote station; however, there should be provisions to preclude inadvertent operation. Location of sprinkler heads or spray nozzles should consider cable tray sizing and arrangements to assure adequate water coverage. Cables should be designed to allow wetting down with deluge water without electrical faulting. Open head deluge and open directional spray systems should be zoned so that a single failure will not deprive the entire area of automatic fire suppression capability. The use of foam is acceptable, provided it is of a type capable of being delivered by a sprinkler or deluge system, such as an AFFF. An automatic water suppression system with manual hoses and portable extinguisher backup is acceptable, provided: (a) At least two remote and separate entrances are provided to the room for access by fire brigade personnel: and (b) Aisle separation provided between tray stacks should be at least 3 feet wide and 8 feet high.	3. Cable Spreading Room (a) The preferred acceptable methods are: 1. Automatic water system such as closed head sprinklers, open head deluge, or open directional spray nozzles. Deluge and open spray systems should have provisions for manual operation at a remote station; however, there should also be provisions to preclude inadvertent operation. Location of sprinkler heads or spray nozzles should consider cable tray sizing and arrangements to assure adequate water coverage. Cables should be designed to allow wetting down with deluge water without electrical faulting. Open head deluge and open directional spray systems should be zoned so that a single failure will not deprive the entire area of automatic fire suppression capability. The use of foam is acceptable, provided it is of a type capable of being delivered by a sprinkler or deluge system, such as an AFFF.	3. Cable Spreading Room (a)1. PVNGS complies by utilizing automatic preaction sprinkler systems with closed head directional spray. In order to prevent a single failure from depriving the entire area of automatic protection, each cable spreading room is divided into zones and each zone is protected by a separate preaction system. The upper cable spreading room (elevation 160 feet 0 inch) is divided into five zones and the lower cable spreading room (elevation 120 feet 0 inch) is divided into six zones. Cables are designed to allow wetting without faulting.

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 55 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Cable Spreading Room (continued)	3. Cable Spreading Room (continued)	3. Cable Spreading Room (continued)
	(2) Manual hoses and portable extinguishers should be provided as backup.	(2) PVNGS complies by providing hose stations and portable CO_2 fire extinguishers as backup.
	(3) Each cable spreading room of each unit should have divisional cable separation, and be separated from the other and the rest of the plant by a minimum 3-hour rated fire wall (refer to NFPA 251 or ASTM E119 for fire test resistance rating).	(3) PVNGS complies by providing a design as described in section D.1.(c) of this table.
Drains to remove firefighting water should be provided with adequate seals when gas extinguishing systems are also installed. Redundant safety-related cable division should be separated by walls with a 3-hour fire rating.	(4) At least two remote and separate entrances are provided to the room for access by fire brigade personnel; and	(4) PVNGS complies by providing two remote and separate entrances for access by fire department personnel.
	(5) Aisle separation provided between tray stacks should be at least 3 feet wide and 8 feet high.	(5) Two cable spreading rooms are provided for divisional separation, one for train A and one for train B. PVNGS also complies with the intent of "aisle separation" within each cable spreading room, but actual separation is 2 feet 6 inches wide by 7 feet 6 inches high.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 56 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Cable Spreading Room (continued)	3. Cable Spreading Room (continued) (b) For cable spreading rooms that do not provide divisional cable separation of a(3), in addition to meeting a(1), (2), (4), and (5) above, the following should also be provided: (1) Divisional cable separation should meet the guidelines of Regulatory Guide 1.75, Physical Independence of Electric Systems. (2) All cabling should be covered with a suitable fire-retardant coating. (3) As an alternate to a(1) above, automatically initiated gas systems (Halon or CO_2) may be used for primary fire suppression, provided a fixed water system is used as a backup. (4) Plants that cannot meet the guidelines of Regulatory Guide 1.75, in addition to meeting a(1), (2), (4), and (5) above, an auxiliary shutdown system with all abling independent of the cable spreading room should be provided.	3. Cable Spreading Room (continued) (b) Not applicable to PVNGS, as divisional separation is provided.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 57 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
3. Cable Spreading Room (Continued)	3. Cable Spreading Room (Continued)	3. Cable Spreading Room (Continued)
Alternately, gas systems (Halon or CO_2) may be used for primary fire suppression if they are backed up by an installed water spray system and hose stations and portable extinguishers immediately outside the room and if the access requirements stated above are met.		Not applicable to PVNGS; preaction system is provided as primary system.
Electric cable construction should, as a minimum, pass the flame test in IEEE-383, IEEE Standard for Type Test of Class 1E Electric Cables, Field Splices and Connections for Nuclear Power Generating Stations.		Electric cable construction is discussed in section D.3.(f) of this table.
For multiple-reactor unit sites, cable spreading rooms should not be shared between reactors. Each cable spreading room of each unit should have divisional cable separation as stated above and be separated from the other and the rest of the plant by a wall with a minimum fire rating of 3 hours. (See NFPA 251, Fire Tests, Building Construction and Materials, or ASTM E119, Fire Test of Building Construction and Materials, for fire test resistance rating.)		PVNGS complies by providing two separate cable spreading rooms for each reactor. The cable spreading rooms of each unit have divisional cable separation, as described in section D.1.(c) of this table.
The ventilation system to the cable spreading room should be designed to isolate the area upon actuation of any gas extinguishing system in the area. In addition, smoke venting of the cable spreading room may be desirable. Such smoke venting systems should be controlled automatically by the fire detection or suppression system as appropriate. Capability for remote manual control should also be provided.		PVNGS does not utilize gas extinguishing systems for the cable spreading rooms. Smoke venting for the cable spreading rooms is manually operated from the control room.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 58 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Plant Computer Room Safety-related computers should be separated from other areas of the plant by barriers having a minimum 3-hour fire-resistant rating. Automatic fire detection should be provided to alarm and annunciate in the control room and alarm locally. Manual hose stations and portable water and Halon fire extinguishers should be provided.	4. Plant Computer Room Same	4. Plant Computer Room PVNGS computers are not safety-related. The computer room is separated from the control room by 2-hour rated barriers. The computer room is provided with a fixed Halon total flooding system. Detectors are provided for early warning and alarm locally.
5. Switchgear Rooms Switchgear rooms should be separated from the remainder of the plant by minimum 3-hour rated fire barriers, if practicable. Automatic fire detection should alarm and annunciate in the control room and alarm locally. Fire hose stations and portable extinguishers should be readily available.	5. Switchgear Rooms Switchgear rooms should be separated from the remainder of the plant by minimum 3-hour rated fire barriers to the extent practicable. Automatic fire detection should alarm and annunciate in the control room and alarm locally. Fire hose stations and portable extinguishers should be readily available.	5. Switchgear Rooms PVNGS safety-related switchgear rooms are separated primarily by 3-hour rated fire barriers, but some portions are 2-hour and 1-hour rated. The floors and ceilings are 3-hour rated. The train A and train B switchgear are located in separate fire zones and areas. (For details of barriers provided refer to section 9B.2.) The basis for this exception is that the PVNGS switchgear rooms are equipped with fixed CO_2 total flooding systems in addition to the fixed water hose stations and portable extinguishers, and by the fact that the fire hazards analysis has shown the combustible (fire) loading for this area to be low such that the existing barriers will contain a postulated fire.
Acceptable protection for cables that pass through the switchgear room is automatic water or gas agent suppression. Such automatic suppression must consider preventing unacceptable damage to electrical equipment and possible necessary containment of agent following discharge.	Acceptable protection for cables that pass through the switchgear room is automatic water or gas agent suppression. Such automatic suppression must consider preventing unacceptable damage to electrical equipment and possible necessary containment of agent following discharge.	PVNGS complies by providing fixed CO_2 total flooding systems for the ESF switchgear rooms. (See appendix 9A response to Question 9A.83.) The nozzles are located away from the electrical equipment in order to prevent unacceptable damage. The HVAC dampers will automatically close, following CO_2 discharge, to contain the agent.

Table 9B.3-1

NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 59 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
6. Remote Safety-Related Panels	6. Remote Safety-Related Panels	6. Remote Safety-Related Panels
The general area housing remote safety-related panels should be provided with automatic fire detectors that alarm locally and alarm and annunciate in the control room. Combustible materials should be controlled and limited to those required for operation. Portable extinguishers and manual hose stations should be provided.	Same	PVNGS complies. Automatic fire detectors are provided to alarm locally and to alarm and annunciate in the control room. Portable extinguishers and manual hose stations are available within the same fire area. Combustible materials are controlled and limited to those required for operation.
7. Station Battery Rooms	7. Station Battery Rooms	7. Station Battery Rooms
Battery rooms should be protected against fire explosions. Battery rooms should be separated from each other and other areas of the plant by barriers having a minimum fire rating of 3 hours inclusive of all penetrations and openings. (See NFPA 69, Standard on Explosion Prevention Systems.) Ventilation systems in the battery rooms should be capable of maintaining the hydrogen concentration well below 2 vol. % hydrogen concentration. Standpipe and hose and portable extinguishers should be provided.	Same	PVNGS complies by providing barriers having 3-hour fire ratings. In addition the battery rooms have CO_2 total flooding systems. The ventilation system is capable of maintaining the hydrogen concentration below 2 vol. %. Hose stations and portable extinguishers are located within the same fire area.
Alternatives:		Alternatives:
(a) Provide a total fire-rated barrier enclosure of the battery room complex that exceeds the fire load contained in the room.		Not applicable; PVNGS meets requirements above.
(b) Reduce the fire load to be within the fire barrier capability of 1-1/2 hours.		
OR		
(c) Provide a remote manual actuated sprinkler system in each room and provide the 1-1/2 hour fire barrier separation.		

Table 9B.3-1

NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 60 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
8. Turbine Lubrication and Control Oil Storage and Use Areas	8. Turbine Lubrication and Control Oil Storage and Use Areas	8. Turbine Lubrication and Control Oil Storage and Use Areas
A blank fire wall having a minimum resistance rating of 3 hours should separate all areas containing safety-related system and equipment from the turbine oil system.	Same. When a blank wall is not present, open head deluge protection should be provided for the turbine oil hazards and automatic open head water curtain protection should be provided for wall openings.	PVNGS has 2-hour fire barriers that separate the turbine lube oils reservoir from the rest of the turbine building. None of the equipment located in the turbine building is safety-related. The lube oil room is protected by an open head deluge system. The turbine building at elevations 100 feet and 140 feet are protected by a complete automatic wet pipe sprinkler system.
9. Diesel Generator Areas	9. Diesel Generator Areas	9. Diesel Generator Areas
Diesel generators should be separated from each other and other areas of the plant by fire barriers having a minimum fire resistance rating of 3 hours.	Same	PVNGS complies. The diesel generators are separated from each other and other areas of the plant by barriers having a fire resistance rating of 3 hours.
Automatic fire suppression such as AFFF foam or sprinklers should be installed to combat any diesel generator or lubricating oil fires. Automatic fire detection should be provided to alarm and annunciate in the control room and alarm locally. Drainage for firefighting water and means for local manual venting of smoke should be provided.		PVNGS complies by providing an automatic preaction sprinkler system for each diesel generator area. Ultraviolet and thermal detectors are installed for early warning and for system actuation. Drainage for firefighting water and means for local manual venting are provided. Automatic fire detection provided to alarm and annunciate in the control room and alarms locally.
Day tanks with total capacity up to 1100 gallons are permitted in the diesel generator area under the following conditions: (a) The day tank is located in a separate enclosure, with a minimum fire resistance rating of 3 hours, including doors or penetrations. These enclosures should be capable of containing the entire contents of the day tanks. The enclosure should be ventilated to avoid accumulation to oil fumes.	When day tanks cannot be separated from the diesel generator, one of the following should be provided for the diesel generator area. (a) Automatic open head deluge or open head spray nozzle system(s).	A fuel oil day tank of 1100 gallon nominal capacity is installed in each diesel generator area. Three-hour enclosures are provided for each of the day tanks. The enclosures are sized to contain the entire contents of the day tanks. (See appendix 9A response to Questions 9A.86.) The enclosures are protected by an automatic preaction sprinkler system. Thermal detectors are installed for early warning and system actuation. The enclosures are ventilated to avoid accumulation of oil fumes.

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 61 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
9. Diesel Generator Areas (continued) (b) The enclosure should be protected by automatic fire suppression systems such as AFFF or sprinklers.	9. Diesel Generator Areas (continued) (b) Automatic closed head sprinklers (c) Automatic AFF that is delivered by a sprinkler deluge or spray system (d) Automatic gas system (Halon or CO_2) may be used in lieu of foam or sprinklers to combat diesel generator and/or lubricating oil fires.	9. Diesel Generators Areas (continued)
10. Diesel Fuel Oil Storage Areas Diesel fuel oil tanks with a capacity greater than 1100 gallon should not be located inside the buildings containing safety-related equipment. They should be located at least 50 feet from any building containing safety related equipment, or if located within 50 feet, they should be housed in a separate building with construction having a minimum fire resistance rating of 3 hours. Buried tanks are considered as meeting the 3-hour fire resistance requirements. See NFPA 30, Flammable and Combustible Liquids Code, for additional guidance. When located in a separate building the tank should be protected by an automatic fire suppression system such as AFFF or sprinklers.	10. Diesel Fuel Oil Storage Areas Same	10. Diesel Fuel Oil Storage Areas PVNGS complies by providing an underground location for the diesel fuel oil storage tanks with capacities that are larger than 1100 gallons. The underground tanks are located more than 50 feet from any building containing safety-related equipment, except for the diesel generator building which is separated from the buried tanks by approximately 31 feet.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 62 of 69)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
10. Diesel Fuel Oil Storage Areas (continued)	10. Diesel Fuel Oil Storage Areas (continued)	10. Diesel Fuel Oil Storage Areas (continued)
Tanks, unless buried, should not be located directly above or below safety-related systems or equipment regardless of the firm rating of separating floors or ceilings.		
	In operating plants where tanks are located directly above or below the diesel generators and cannot reasonably be moved, separating floors and main structural members should, as a minimum, have fire resistance rating of 3 hours. Floors should be liquid tight to prevent leaking of possible oil spills from one level to another. Drains should be provided to remove possible oil spills and fire-fighting water to a safe location. One of the following acceptable methods of fire protection should also be provided: (a) Automatic open head deluge or open head spray nozzle system(s) (b) Automatic closed head sprinklers; or (c) Automatic AFFF that is delivered by a sprinkler system or spray system	PVNGS complies by providing 3-hour rated enclosures for the day tanks that are located directly above diesel generators, and day tank floors that are liquid tight with drains designed to remove oil and fire water to a safe location. The enclosures are adequately vented. The enclosures are protected by automatic preaction sprinkler systems.

Table 9B.3-1

OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 63 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
11. Safety-Related Pumps Pumphouses and rooms housing safety-related pumps or other safety-related equipment should be separated from other areas of the plant by fire barriers having at least 3-hour ratings. These rooms should be protected by automatic sprinkler protection unless a fire hazards analysis can demonstrate that a fire will not endanger other safety-related equipment required for safe plant shutdown. Early warning fire detection should be installed with alarm and annunciation locally and in the control room. Local hose stations and portable extinguishers should also be provided.	11. Safety-Related Pumps Pumphouses and rooms housing safety-related pumps should be protected by automatic sprinkler protection unless a fire hazards analysis can demonstrate that a fire will not endanger other safety-related equipment required for safe plant shutdown. Early warning fire detection should be installed with alarm and annunciation locally and in the control room. Local hose stations and portable extinguishers should also be provided.	11. Safety-Related Pumps PVNGS complies by demonstrating in the fire hazards analysis that a fire in any safety-related pump room will not endanger other safety-related equipment required for safe plant shutdown. The analyses for areas that contain safety-related pumps are included in section 9B.2 (see Zones 1, 2, 28, 30A, 30B, 31A, 31B, 32A, 32B, 34A, 34B, 46A, 46B, 46E, 72, 73, 51B, 63A, 63B, 78, 83, 84). An early warning fire detection system is installed in all zones listed above except Zone 78. The detection will alarm locally and alarm and annunciate in the control room. Automatic preaction water suppression systems are installed over the pumps in Zones 30A, 30B, 31A, 31B, 32A, 32B, 46A, 46B, 46E, and 72. Local hose stations and portable extinguishers are available at, or near, the areas that contain safety-related pumps (zones indicated above) except: Zone 78: Diesel fuel oil transfer pumps Zone 83: Condensate transfer pumps Zone 84: Essential spray pond pumps The above three zones are in the outside area and the PVNGS Fire Department has emergency response vehicle(s) which carry an assortment of hose, nozzles, and auxiliary equipment in lieu of hose houses. The diesel fuel oil transfer pumps (Zone 78) are located within the tanks and the tanks are installed underground. The condensate transfer pumps (Zone 83) are separated from each other by a nonrated reinforced concrete partition wall. The wall is of full height but not the full width of the building. It does, however, provide a radiant heat barrier between the pumps. The combustible (fire) loading in this zone is low and ionization detectors are provided with alarm and annunciation in the control room. (Refer to section 9B.2.9.1.8, Deviations from 10CFR50, Appendix R.) The essential spray pond pumps (Zone 84) are separated from each other by a nonrated reinforced concrete wall. The combustible (fire) loading in this zone is low and ionization detectors are provided with alarm and annunciation in the control room.
Equipment pedestals or curbs and drains should be provided to remove and direct water away from safety-related equipment.		Equipment pedestals and drains are provided to remove and direct water away from the equipment.
Provision should be made for manual control of the ventilation system to facilitate smoke removal if required for manual firefighting operation.		Manual control of ventilation system has been provided as discussed in section D.4 of this table.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 64 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
12. New Fuel Area Hand portable extinguishers should be located within this area. Also, local hose stations should be located outside but within hose reach of this area. Automatic fire detection should alarm and annunciate in the control room and alarm locally. Combustibles should be limited to a minimum in the new fuel area. The storage area should be provided with a drainage system to preclude accumulation of water. The storage configuration of new fuel should always be so maintained as to preclude criticality for any water density that might occur during fire water application.	12. New Fuel Area Same	12. New Fuel Area PVNGS complies by providing portable CO_2 extinguishers. A hose station is located within reach of this area. Ionization detectors are provided to alarm and annunciate in the control room and alarm locally. Drains are provided to preclude accumulation of water. The hose station in the new fuel fire zone is equipped with a Class A-B-C nozzle. The storage configuration of new fuel is such as to preclude criticality for any water density that might occur during fire water application. (See section 9.1.)
13. Spent Fuel Pool Area Protection for the spent fuel pool area should be provided by local hose stations and portable extinguishers. Automatic fire detection should be the control room and to alarm locally.	13. Spent Fuel Pool Area Same	13. Spent Fuel Pool Area PVNGS complies. A local hose station and a portable CO_2 extinguisher are provided. Automatic smoke detection system is provided in the area to alarm and annunciate in the control room and to alarm locally. Detectors are not provided directly over the spent fuel pool.
14. Radwaste Building The radwaste building should be separated from other areas of the plant by fire barriers having at least 3-hour ratings. Automatic sprinklers should be used in all areas where combustible materials are located. Automatic fire detection should be provided to annunciate and alarm in the control room and alarm locally. During a fire, the ventilation systems in these areas should be capable of being isolated. Water should drain to liquid radwaste building sumps.	14. Radwaste Building Same	14. Radwaste Building PVNGS complies by separating the radwaste building from the adjacent control and auxiliary buildings by fire barriers of 3-hour rating. Door A204, between the auxiliary building and the radwaste building, is protected by sprinklers located on both sides of the door. (See appendix 9A response to Question 9A.106.) A wet pipe sprinkler system has been provided in the waste compacting area (Zone 5B; section 9B.2). Automatic fire detection is provided to alarm and annunciate in the control room and alarm locally. Fire zones provided with ionization detectors are identified in section 9B.2.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 65 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
14. Radwaste Building (Continued) Accept alternative fire protection is automatic fire detection to alarm and annunciate in the control room, in addition to manual hose stations and portable extinguishers consisting of hand-held and large-wheeled units.	14. Radwaste Building (Continued)	14. Radwaste Building (Continued) Manual hose stations and portable extinguishers are provided. All drains are routed to the radwaste building sump except for the auxiliary drain from the shutdown cooling heat exchanger. The radwaste building ventilation systems are capable of being isolated during fire.
15. Decontamination Areas The decontamination areas should be protected by automatic sprinklers if flammable liquids are stored. Automatic fire detection should be provided to annunciate and alarm in the control room and alarm locally. The ventilation system should be capable of being isolated. Local hose stations and hand portable extinguishers should be provided as backup to the sprinkler system.	15. Decontamination Areas Same	15. Decontamination Areas The decontamination areas are as follows: • Personnel decontamination area - auxiliary building, elevation 140 feet, Zone 57F • Tool room and supply storage area - radwaste building, elevation 100 feet, Zone 60E • Decontamination and laundry facility area, elevation 100 feet, Zones 91A, 91B, 91C, and 91D. No flammable liquid storage is planned in Zones 57F and 60E. The decontamination and laundry facility area is located outside and is physically separated by more than 30 feet and by walls of heavy concrete construction from the radwaste building. Ionization detectors are provided in Zones 57F and 60E. Wet pipe sprinklers are provided in Zone 57H. The decontamination and laundry facility area are not provided with a detection system. It is not deemed necessary due to the physical separation from safety related structures. Portable extinguishers are provided in the decontamination and laundry facility area and the area is readily accessible for manual fire fighting. Ventilation isolation capability is provided.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 66 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
16. Safety-Related Water Tanks Storage tanks that supply water for safe shutdown should be protected from the effects of fire. Local hose stations and portable extinguishers should be provided. Portable extinguishers should be located in nearby hose houses. Combustible materials should not be stored next to outdoor tanks. A minimum of 50 feet of separation should be provided between outdoor tanks and combustible materials where feasible.	16. Safety-Related Water Tanks Same	16. Safety-Related Water Tanks Water for safe shutdown is supplied from the following tanks and reservoirs: (a) Condensate storage tank - Zone 83 (b) Refueling water storage tank - Zone 81 (c) Spray pond - Zone 84A and 84B PVNGS complies by protecting the above tanks and reservoir from the effects of fire, however: • Due to the low in situ combustibles in the above three fire zones, portable extinguishers are not provided. The nearby hydrants are available for firefighting. • Local standpipe hose stations are not provided due to the outdoor location. • The refueling water tank is located adjacent to the fuel building. The exterior wall of the fuel building, near the refueling tank, is of reinforced concrete and the area inside the building is protected by wet pipe sprinklers.
17. Cooling Towers Cooling towers should be of non-combustible construction or so located that a fire will not adversely affect any safety-related systems or equipment. Cooling towers should be of noncombustible construction when the basins are used for ultimate heat sink or for the fire protection water supply.	17. Cooling Towers Same. Cooling towers of combustible construction, so located that a fire in them could adversely affect safety-related systems or equipment, should be protected with an open head deluge system installation with hydrants and hose houses strategically located.	17. Cooling Towers A fire at the cooling towers will not adversely affect any safety-related systems or equipment.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 67 of 69)

F. GUIDELINES FOR SPECIFIC PLANT AREAS (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
18. Miscellaneous Areas Miscellaneous areas such as records storage areas, shops, warehouses, and auxiliary boiler rooms should be so located that a fire or effects of a fire, including smoke, will not adversely affect any safety-related systems or equipment. Fuel oil tanks for auxiliary boilers should be buried or provided with dikes to contain the entire tank contents.	18. Miscellaneous Areas Same	18. Miscellaneous Areas PVNGS considers that any exposure fire in these miscellaneous areas will not affect safety-related equipment or systems. A fire hazards analysis has been performed on fire areas in or adjacent to safety-related equipment. This includes the records storage area (adjacent to the computer room (Zone 16)) and the shop area (Zone 60E). The auxiliary boiler area (Zone 85A) and the warehouse areas are not located at or adjacent to safety-related equipment. The fuel oil tanks that supplied the now abandoned auxiliary boiler are remote from the power block and safety-related equipment. In addition, any exposure fire in the dry active waste processing system (DAWPS) facility is not considered to affect safety-related, safe-shutdown, or result in a significant radiological release due to administrative control of the contents of this facility.

Table 9B.3-1

COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 68 of 69)

G. SPECIAL PROTECTION GUIDELINES

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
1. Welding and Cutting, Acetylene - Oxygen Fuel Gas Systems This equipment is used in various areas throughout the plant. Storage locations should be chosen to permit fire protection by automatic sprinkler systems. Local hose stations and portable equipment should be provided as backup. The requirements of NFPA 51 and 51B are applicable to these hazards. A permit system should be required to utilize this equipment. (Also refer to 2f herein.)	1. Welding and Cutting, Acetylene - Oxygen Fuel Gas Systems Same	1. Welding and Cutting, Acetylene - Oxygen Fuel Gas Systems NFPA 51 (1974) and NFPA 51B (1976) are used as guidelines for handling of these processes. A permit system is in place to use this equipment. Reserve inventory of acetylene-Oxygen is stored at the chemical storage facility, near the WRF, and on the south side of Unit 3 Ops Support Building, welding shop. Both locations utilize outdoor storage. Control of Oxy-Acetylene use within structures is in accordance with the permit system and site procedures and/or the safety manual.
2. Storage Areas for Dry Ion Exchange Resins Dry ion exchange resins should not be stored near essential safety-related systems. Dry unused resins should be protected by automatic wet pipe sprinkler installations. Detection by smoke and heat detectors should alarm and annunciate in the control room and alarm locally. Local hose sta tions and portable extinguishers should provide backup for these areas. Storage areas of dry resin should have curbs and drains. (Refer to NFPA 92M, Waterproofing and Draining of Floors.)	2. Storage Areas for Dry Ion Same	2. Storage Areas for Dry Ion Exchange Resins Dry ion exchange resins are stored in the warehouse which is approximately 400 feet from Unit 2 power block areas and is, therefore, remote from essential safety-related system. Automatic wet pipe sprinkler protection is provided in the warehouse as well as hose stations and portable extinguishers. Detection by smoke and heat detectors is not provided.
3. Hazardous Chemicals Hazardous chemicals should be stored and protected in accordance with the recommendations of NFPA 49, Hazardous Chemicals Data. Chemicals storage areas should be well ventilated and protected against flooding conditions since some chemicals may react with water to produce ignition.	3. Hazardous Chemicals	3. Hazardous Chemicals For the storage of hazardous chemicals, the recommendations of NFPA 49 (1975) are used as guidance.

Table 9B.3-1
COMPARISON OF PALO VERDE NUCLEAR GENERATING STATION TO APPENDIX A OF
NRC BRANCH TECHNICAL POSITION APCSB 9.5-1 (Sheet 69 of 69)

G. SPECIAL PROTECTION GUIDELINES (CONTINUED)

APPLICATION DOCKETED BUT CONSTRUCTION PERMIT NOT RECEIVED AS OF 7/1/76	PLANTS UNDER CONSTRUCTION AND OPERATING PLANTS	PVNGS POSITION AND BASIS FOR NONCOMPLIANCE ITEMS
4. Materials Containing Radioactivity Materials that collect and contain radioactivity such as spent ion exchange resins, charcoal filters, and HEPA filters should be stored in closed metal tanks or containers that are located in areas free from ignition sources or combustibles. These materials should be protected from exposure to fires in adjacent areas as well. Consideration should be given to requirements for removal of isotopic decay heat from entrained radioactive materials.	4. Materials Containing Same	4. Materials Containing Radioactivity Materials that contain radioactivity are collected in the radwaste systems and stored in 55-gallon drums at 100-foot elevation of the radwaste building. Spent resins are temporarily stored in a steel tank at the 110-foot elevation of the radwaste building. Spent charcoal filters are directly processed through the radwaste system. HEPA filter waste is sent through the baler system and then placed in the drums. PVNGS complies with the protection of drum storage area Zone 58, and the spent resin tanks, Zone 62. (See section 9B.2.) At PVNGS the level of radiation in the entrained radioactive materials is not high enough to generate heat due to isotropic decay.

TABLES (cont)

FIGURES

10. STEAM AND POWER CONVERSION SYSTEM

10.1 SUMMARY DESCRIPTION

The steam and power conversion systems for each unit at PVNGS are identical. Therefore, the summary description provided in this section is on a per-unit basis.

10.1.1 DESIGN BASES

The steam and power conversion system is designed to remove heat energy from the reactor coolant in two steam generators and to convert it to electric power via the turbine-generator. The main condenser transfers heat that is not utilized in the cycle to the circulating water system and deaerates the condensate. The closed regenerative turbine cycle heats the condensate and returns it as feedwater to the steam generators.

A full-flow condensate demineralizer system is available to maintain feedwater quality. A blowdown system operates to maintain steam generator water chemistry. The condenser air removal system provides a filter and charcoal adsorber and is monitored for radioactive contamination. The Seismic Category I redundant auxiliary feedwater pumps, one motor-driven and one steam turbine-driven, provide feedwater during loss of offsite power and during design basis accident conditions. A non-Seismic Category I, motor-driven auxiliary feedwater pump provides feedwater for startup, hot standby, and normal shutdown.

10.1.2 SYSTEM DESCRIPTION

Components of the steam and power conversion system are of types that have been extensively used in fossil fuel plants and in other nuclear power plants. Instruments, controls, and protective devices are provided to ensure reliable and safe operation, as described in paragraph 10.2.2.3.

A system flow diagram is shown in figure 10.1-1. A summary of design basis information and performance specifications is given in table 10.1-1. Also, the cycle heat balances, at turbine rated (guaranteed) power and at stretch power (valves wide open-VWO), are shown on figures 10.1-2 and 10.1-3, respectively, and are summarized in table 10.2-2. Safety-related components include the main steam isolation valves, the atmospheric steam dump valves, the feedwater isolation valves, the Seismic Category I portion of the auxiliary feedwater system, and the main steam safety valves. The steam and power conversion system provides steam for the feedwater pump turbines, the turbine gland sealing system, condensate and feedwater heating, and main turbine reheat steam as required.

The condenser air removal system is described in subsection 10.4.2. The condensate cleanup system is described in subsection 10.4.6. The auxiliary feedwater system is described in subsection 10.4.9.

10.1.3 SAFETY-RELATED FEATURES

10.1.3.1 Loss of External Electrical Load and/or Turbine Trip

Upon loss of load the turbine control system provides for fast closing of turbine valves. Depending on the magnitude of the

load reduction, a turbine bypass system will dump excess steam into the condenser and, if required, to atmosphere. If the load reduction is large, i.e., greater than approximately 55% of full load, an automatic reactor power cutback will be initiated provided the turbine power level is greater than 75%. The turbine control and bypass equipment is not safety grade.

In the event the condenser is not available to receive steam, ASME Code safety and atmospheric dump valves are provided on the main steam piping.

The atmospheric dump valves are remotely operated from the control room and can be modulated to control the steam flow.

The power/load unbalance circuit is capable of controlling the speed of the turbine generator upon full load rejection so as to not exceed 110% of rated turbine speed. After a power/load unbalance circuit actuation, a positive turbine trip occurs with no subsequent re-opening of the control valves and intercept valves.

10.1.3.2 Overpressure Protection

Safety valves are provided on the main steam lines in accordance with the ASME Boiler and Pressure Vessel Code, Section III. The pressure relief capacity of all safety valves is such that the flow capacity is equal to 19 x 10^6 lb/hr (105% of maximum calculated steam generator stretch power mass flow, 18.0 x 10^6 lb/hr) at setpoint pressure.

Table 10.1-1

STEAM AND POWER CONVERSION SYSTEM DESIGN AND PERFORMANCE SPECIFICATIONS (Sheet 1 of 4)

Design and Performance Characteristics	Original Design Value(1)	Power Uprate/Rotor Replacement Value(2)
Main steam system minimum required design pressure/temperature, psia/F	1270/575	1270/575
Main steam system operating pressure/temperature, at 100% power, psia/F (at guar. load 3817/3990 MWt)	1070/552.9	1012/546.1
Main steam system operating pressure/temperature, at 100% power, psia/F (VWO)	1000/544.6	1007/545.4
Main steam flow, guar./VWO, 10^6 lb/h	17.2/18.1	17.96/18.36
Main turbine throttle flow, guar./VWO, 10^6 lb/h	15.9/17.05	16.87/17.28
Main condenser pressure, in.Hg abs	3.5	3.5
Feedwater temperature, guar./VWO, F	442.5/449.5	448.5/450.9
Main turbine-generator output, guar./VWO, MWe	1304/1375	1411/1443
Guaranteed generator rating, MVA	1559.1	1559.1
No./normal capacity/runout capacity at 65% of each feedwater pump, lb/hr x 10^6 at VWO	2/9.2/11.3	2/9.2/11.3
No./design capacity/runout capacity of each condensate pump, lb/hr x 10^6	3/4.4/6.2	3/4.4/6.2
Turbine gland seal system, normal flow air/steam, lb/h	2855/9025	2855/9025
Steam generator blowdown system, flowrate, normal/abnormal/high rate	0.2%/1%/8% of maximum steam rate	0.2%/1%/8% of maximum steam rate

Table 10.1-1

STEAM AND POWER CONVERSION SYSTEM DESIGN AND

PERFORMANCE SPECIFICATIONS (Sheet 2 of 4)

System Component	Performance Characteristics
Main steam system (section 10.3)	
Main steam piping	From each steam generator up to and including the main steam isolation valves: ASME III, Code Class 2. (design pressure 1255 psig, design temperature 600F, Seismic Category I) Balance of the main steam piping: ANSI B31.1
Main steam isolation valves (one per steam line)	Maximum closing time 4.6 seconds after receipt of signal. ASME III, Code Class 2 valves. (design pressure 1270 psia, design temperature 575F, Seismic Category I)
Main steam safety valves (five per steam line)	Required flow capacity equal to 19 x 10^6 lb/hr (105% of the maximum calculated steam generator stretch power flow 18.0 x 10^6 lb/hr) at setpoint pressure: ASME III, Code Class 2 valves. (design pressure 1375 psig, design temperature 575F, Seismic Category I) (See CESSAR Table 5.4.13-2).
Atmospheric dump valves (one per steam line)	Required flow capacity equal to 950,000 lb/hr (min): ASME III, Code Class 2 valves. (design pressure 1333 psia, design temperature 575F, Seismic Category I)
Turbine bypass system (subsection 10.4.4)	
Bypass valves downstream of main steam isolation valves (six piped to condenser, two piped to atmosphere)	Flow capacity equal to at least 55% of design steam flow: Piping ANSI B31.1 (design pressure 1255 psig, design temperature 600F, non-Seismic Category I)

Table 10.1-1

STEAM AND POWER CONVERSION SYSTEM DESIGN AND

PERFORMANCE SPECIFICATIONS (Sheet 3 of 4)

System Component	Performance Characteristics

STEAM AND POWER CONVERSION SYSTEM DESIGN AND PERFORMANCE SPECIFICATIONS (Sheet 4 of 4)

System Component	Performance Characteristics
	All piping from the condensate storage tank to the Seismic Category I auxiliary feedwater pumps and containment isolation valves is ASME III, Code Class 3; piping from and including the isolation valves to the steam generators is ASME III, Code Class 2, design pressure 1255 psig, design temperature 600F, Seismic Category I All piping associated with the non-Seismic Category I motor-driven auxiliary feedwater pump, excluding upstream of the condensate tank isolation valve and downstream of the containment isolation valves, is ANSI B31.1 Code for pressure piping.
Secondary chemistry control system (subsection 10.4.6)	Full flow condensate demineralization. Continuous hydrazine additions for oxygen scavenging and continuous ammonia additions for pH control. Continuous monitoring of significant chemical parameters. Steam generator blowdown at a rate up to 8% of the maximum steaming rate

<u>NOTE 1</u>: The parameters listed in Table 10.1-1 for Original Design are nominal parameters obtained from GE Heat Balance 449HB673 (13-M400-0301-00029) and Specification 13-MM-0004/010 for the original rated performance at 3800 MWt and VWO conditions of the plant secondary system, respectively. The Heat Balance and specification are applicable for original operation, stretch power to 3876 MWe and T_{hot} Reduction. For the actual design parameters and predicted performance at various power levels see calculation 13-MC-MT-0200.

<u>NOTE 2</u>: The parameters listed in Table 10.1-1 for Power Uprate are nominal parameters obtained from GE Thermal Kit 91LR0297 (13-M400-0303-01058) to determine the effect of Replacement Steam Generators, Power Uprate to 3990 MWt and Low Pressure Turbine Rotor Replacement on the plant secondary system. For the actual design parameters and predicted performance at various power levels see calculation 13-MC-MT-0200.

10.1.3.3 Loss of Normal Electric Power

The auxiliary feedwater system is designed to provide feedwater to the steam generators for the removal of decay heat when the feedwater pumps are not available following a loss of normal electric power. In the event of reactor trip with loss of offsite power, two Seismic Category I auxiliary feedwater pumps, one motor-driven and one steam turbine-driven, are available to provide feedwater to the steam generators. The motor-driven pump and its associated isolation valves receive power from a separate standby diesel generator bus. In addition, the steam turbine-driven auxiliary feedwater pump with dc powered controls is available. Refer to subsection 10.4.9.

10.1.4 TESTS AND INSPECTIONS

Pumps and controls are given preoperational tests. Functional operational checks are made on essential valves, control systems, and protective equipment.

10.1.5 INSTRUMENTATION APPLICATIONS

Operating instrumentation is provided to permit the operators to monitor equipment and plant performance. Equipment, instruments, and controls are inspected regularly and are monitored during operation to ensure proper functioning of systems.

Checking and recalibration of instruments and controls continue during operating periods as well as during standby and shutdown periods.

10.2 TURBINE-GENERATOR

The function of the turbine-generator is to convert thermal energy into electric power.

10.2.1 DESIGN BASES

10.2.1.1 Safety Design Bases

The turbine-generator serves no safety function and has no safety design bases.

10.2.1.2 Power Generation Design Bases

The following is a list of the principal design bases:

A. The turbine-generator load change characteristics are compatible with the restrictions imposed by or on the nuclear steam supply system (NSSS). The NSSS is capable of accepting a step load change of 10% and ramp load change of 5% per minute over the load range of 15 to 100%. These load change rates can be accomplished without the operation of the turbine bypass system (TBS) described in subsection 10.4.4. With operation of the TBS, the reactor can accept step load rejections of up to 55% of the rated power of 3817 MWt without causing a reactor trip by bypassing steam to the condenser and, if required, to atmosphere. With the reactor power cutback system and TBS, the reactor can accept a step load rejection of 100% without causing a reactor trip. However, the steam bypass control system (SBCS) and reactor power cutback system (RPCS) are not capable of handling step load rejections for turbine power level between 57% and 75% due to limitations on condenser pressure.

B. The turbine-generator is designed to trip automatically under abnormal conditions as designated in paragraph 10.2.2.4.

C. The turbine-generator is intended to operate base loaded.

10.2.1.3 Codes and Standards

System components are designed in accordance with the requirements of ANSI B31.1.0 Code for pressure piping, TEMA and HEI standards for heat exchangers, NEMA standards, IEEE standards, Hydraulic Institute standards, and regulations of the National Board of Fire Underwriters.

10.2.2 DESCRIPTION

The General Electric turbine-generator (engineering drawings 01, 02, 03-M-MTP-001, -002 and -003) is designated TC6F-43 and consists of turbines, a generator, moisture separator-reheaters, exciter, controls, and auxiliary subsystems. The major design parameters of the turbine-generator are presented in tables 10.2-1 and 10.2-2. Details of system components are presented in this section. The location of the turbine-generator is shown in engineering drawings 13-P-OOB-002 through -011.

10.2.2.1 Turbine-Generator Description

The turbine is an 1800 revolutions per minute, tandem-compound, six-flow, reheat unit with 43-inch, last-stage buckets (blades). The turbine includes one double-flow, high-pressure turbine; three double-flow, low-pressure turbines; and four

moisture separator-reheaters with two stages of reheating. The direct-driven generator is conductor-cooled and rated at 1559.1 MVA at 24 kV, three phase, 60 Hz. Other related system components include a complete turbine-generator bearing lubrication oil system, an electrohydraulic control (EHC) system with supervisory instrumentation, a turbine gland sealing system (refer to subsection 10.4.3), overspeed protective devices, turning gear, a generator hydrogen and seal oil system, a stator cooling system, an exciter cooler (for those units where DMWO 3286783 has been implemented, the exciter cooler has been removed), a rectifier section, and a voltage adjuster.

Table 10.2-1
TURBINE-GENERATOR DESIGN DATA

Supplier	General Electric
Unit designation	TC6F-43" LSB
Last-stage bucket length, in.	43
Design condenser backpressure (average for three shells), in. Hg abs	3.50
Stages of reheating	2
Stages of feedwater heating	7
Rotational speed, r/min	1,800
Guaranteed generator rating, MVA	1,559.1
Generator voltage, kV	24
Power factor	0.9
Short circuit ratio	0.5

10.2.2.2 Turbine-Generator Cycle Description

Steam from the main steam system enters the high-pressure turbine through four stop and governing control valves. Crossties are provided both upstream and downstream of the stop valves to provide pressure equalization with one or more stop valves closed. A portion of the main steam is used for second-stage reheat of the steam supply to the low-pressure turbines.

There are two steam extraction points in the high-pressure turbine. Steam from the first (higher pressure) extraction point is used for seventh-point feedwater heating and first-stage reheat of the two-stage reheater. Steam from the second

Table 10.2-2
TURBINE-GENERATOR PERFORMANCE DATA

Parameter	Guaranteed Load [(a)(b)] Original/Pur & Rotor Replacement	Valves Wide Open [(a)(b)] Original/Pur & Rotor Replacement
NSSS thermal output, MWt	3,911/4,013	4,030/4,030
Steam generator outlet pressure, psia	1,020/1,030	1,010/1,025

a. For turbine-generator design purposes only.

b. The parameters listed for Original Design are nominal parameters obtained from GE Heat Balance for the original rated performance and Valves Wide Open conditions of the plant secondary system. This data is applicable for original operation at 3800 MWt, stretch power to 3876 MWe and T_{hot} reduction. The parameters listed for Power Uprate (PUR) are nominal secondary system parameters based upon implementation of Replacement Steam Generators, Power Uprate to 3990 MWt and Low Pressure Turbine Rotor Replacement.

extraction point is used for sixth-point feedwater heating. (Refer to subsection 10.4.7 for discussion of the condensate and feedwater system.) After expansion in the high-pressure turbine, the steam flows through the moisture separator-reheaters to remove entrained moisture and to superheat the steam, thus improving cycle efficiency. A portion of the cold reheat steam is used for fifth-point feedwater heating. (Feedwater heaters are numbered sequentially in order of increasing extraction pressure.)

Hot reheat steam leaving the moisture separator-reheaters is used to power the feedwater pump turbine. Hot reheat steam also is distributed equally to the three low-pressure turbines through combined reheat stop and intercept valves. In each low-pressure turbine, there are four steam extraction points for the remaining four stages of feedwater heating (one heater train per low-pressure turbine). After expansion in the low-pressure turbines, the steam is discharged to the main condensers.

In addition to the external moisture separators, the last three low-pressure turbine stages are designed to remove any condensed moisture and drain it to the next lowest extraction. The moisture from the external moisture separators is drained to moisture separator drain tanks and from there to the high-pressure heater drain tank and subsequently is pumped into the feedwater system. Similarly, the condensate in the reheaters is drained to the heater drain tank and is pumped into the feedwater system.

10.2.2.3 Automatic Controls

Automatic controls provide control of turbine speed and acceleration through the entire speed range, with several discrete speed and acceleration rate settings. The automatic control system includes control of load and loading rate from no load to full load, with continuous load adjustments and discrete loading rates. Should it become necessary to remove the generating unit from the primary automatic controls, the standby manual control of speed and load takes over, thus allowing continued operation of the turbine generator.

10.2.2.3.1 Electrohydraulic Control Systems

The turbine-generator is equipped with an EHC system that combines the principles of solid-state electronics and high-pressure hydraulics to control steam flow through the turbine. The control system has three major subsystems: speed control unit, load control unit, and valve flow control units.

10.2.2.3.1.1 Speed Control Unit. The speed control unit produces the speed error signal for input to the load control unit. This error signal is determined by comparing the desired speed with the actual speed of the turbine at steady-state conditions, or the desired acceleration with the actual acceleration during startup. Because of the importance in safeguarding against overspeed, the speed control unit has two redundant channels. If the primary channel fails, the backup channel takes over automatically. If both channels should fail, the turbine-generator will trip.

The above two speed channels generate three error signals during the period between turbine roll and synchronization. Two of these error signals are from a deviation between the actual speed as measured by the primary and backup speed sensors and a reference speed. The third error signal is a deviation between the actual acceleration as measured by the primary and backup speed sensors and a reference acceleration. These signals combine with signals from the load control unit to generate a flow reference signal to the control valves and intercept valves.

10.2.2.3.1.2 Load Control Unit. The load control unit develops flow reference signals that are used to proportion the steam flow to the control valves and intercept valves. Signal outputs are based on a proper combination of the speed error signals and load reference signals. The generator does not strictly follow load, but is controlled through a ramped, predetermined straight-line function. Power/load imbalance is discussed in paragraph 10.2.2.3.1.4.

10.2.2.3.1.3 Valve Flow Control Units. The valve flow control unit regulates the steam flows as directed by the load control unit. Compensation circuits are introduced to ensure linear steam flow response with respect to steam flow reference signals. The bypass valve in the No. 2 main stop valve, control valves, and the intercept valves each have a control loop which consists of electronic circuitry, an electrohydraulic servo valve, a hydraulic actuator, and a linear position transducer. By use of valve position feedback control, the valve control units position the bypass valve in

the No. 2 main stop valve, the control valves, and the intercept valves according to the flow demand signal from the load control unit, the standby control unit, or directly from the control panel (valve test).

Only the No. 2 main stop valve has an internal bypass valve. The control loop operates the internal bypass valve and is used only for prewarming the turbine.

The flow of the main steam entering the high-pressure turbine is controlled by four stop valves and four governing control valves. Each stop valve is controlled by an electrohydraulic actuator so that the stop valve is either fully open or fully closed. The function of the stop valves is to shut off the flow of steam to the turbine, when required. The stop valves are closed within 0.2 second or less when steam pressure is present, and are closed in 0.3 second or less when no steam pressure is present, by actuation of the emergency trip system devices. These devices are independent of the electronic flow control unit (see paragraph 10.2.2.3.1.5).

The turbine control valves are positioned by electrohydraulic servo-actuators in response to signals from their respective flow control unit. The flow control unit signal positions the control valves for long range speed control through the normal turbine operating range and for load control after the turbine-generator unit is synchronized.

The combined reheat valves located in the hot reheat lines are stop and intercept valves in one casing and control steam flow to the low-pressure turbines. During normal operation of the turbine, the stop and intercept valves are wide open. The

intercept valve flow control unit positions the valve during startup and normal operations and closes the valve rapidly on loss of turbine load. The reheat stop valves close completely on turbine overspeed and trip.

10.2.2.3.1.4 Power/Load Unbalance. Associated with the load control unit is a rate sensitive power/load unbalance circuit whose purpose is to initiate control valve fast closing action under load rejection conditions that might lead to rapid rotor acceleration and consequent overspeed.

Valve action will occur when the power exceeds the load by at least 40% and generator current is lost in a time span of 35 ms or less with an additional 150 ms time delay. Cold reheat pressure is used as a measure of power, and generator current is used as a measure of load to provide discrimination between loss of load incidents and occurrences of electric system faults.

The power/load unbalance circuitry includes an approximate 150 ms time delay between the detection of a power/load unbalance condition and actuation of turbine control. This time delay will allow the turbine control to ride out transient electrical transmission network disturbances. The 150 ms delay is based on a three-phase bolted fault at the Palo Verde 525 kv switchyard as a worst case scenario.

Following the detection of a power/load unbalance condition and the 150 ms time delay, all control valves are closed in 0.2 second or less when steam pressure is present, and are closed in 0.3 second or less when no steam pressure is present, by a fast acting solenoid for each control valve. Simultaneously,

the load reference signal is grounded and the load reference motor begins to run back toward the no-load flow point. Should the condition disappear quickly, the power/load unbalance circuit will reset automatically, and the load reference signal will be reestablished near its value prior to the loss of load. Should the condition persist and the load does not return within approximately 45 seconds, the load reference runback will be completed. The power/load unbalance circuit will clear automatically when the cold reheat pressure drops below 40%. However, after a power/load unbalance circuit actuation, a positive turbine trip occurs with no subsequent re-opening of the control valves and intercept valves.

10.2.2.3.1.5 Overspeed Protection. Two means of overspeed trip protection are provided; a mechanical overspeed trip (OST) and a backup overspeed trip (BOST). The OST is a conventional eccentric ring that actuates a trip latch to operate a pilot valve that operates the mechanical trip valve. The mechanical trip valve releases the hydraulic fluid pressure in the steam valve actuator, allowing the springs to close the steam valves.

The OST trip is set at 110% (+1%/-2.5%) of rated turbine speed. (Refer to protection system block diagram, figure 10.2-2.)

The BOST is an electric trip normally set to operate at a slightly higher speed than the OST. Three independent BOSTs are provided by magnetic pickups from toothed wheels on the turbine shaft. The signals are amplified through electronic circuitry and are compared to trip speed reference voltage signals. Exceeding the trip speed will cause each BOST voltage to energize its master trip relay. The master trip relays,

through a two-out-of-three logic, deenergize both pilot solenoids of the master (electric) trip solenoid valve. This releases the hydraulic fluid pressure in the steam valve actuators, causing the turbine main valves to close. The overspeed trip logic is shown in figure 10.2-1.

The BOST electric trip also results in a "cross trip" by actuating, also through two-out-of-three relay logic, the mechanical trip, the mechanical trip solenoid, and the trip latch system described above. The BOST trip is set at 111% of rated turbine speed.

When in the standby mode, the automatic speed control and load control subsystems are out of service. If it is necessary to operate the turbine in the standby mode, added overspeed protection is provided by automatically lowering the setpoint of the backup overspeed governor to 105% of rated turbine speed. The mechanical governor then becomes the backup governor since its trip setpoint remains at 110% (+1%/-2.5%) of rated speed. (See table 10.2-3 for turbine overspeed sensors and trip signals.) Each of the two means of overspeed tripping may be independently tested online at any desired load. During these tests, overspeed protection will be provided by the device not being tested.

Finally, because the turbine-generator overspeed protection system is not a safety system (other than for equipment protection), a single failure analysis per IEEE-279 is not required.

Table 10.2-3
TURBINE OVERSPEED SENSORS AND TRIP SETPOINTS (Sheet 1 of 2)

Sensors	Type	Function	Setpoints in Percent of Turbine Rated Speed			
			HP Stop Valve	HP Throttle Valve	LP Stop Valve	LP Intercept Valve

a. Turbine supplier identification number.

b. Control valves and intercept valves all close in 0.2 second or less following a 150 ms delay when power/load unbalance detects loss of generator load. This could occur before turbine speed starts to increase. This is not a trip.

10.2.2.4 Turbine Protective Trips

Turbine protective trips are independent of the electronic control system and, when initiated, cause tripping of all turbine stop and control valves. The protective trips are:

- Overspeed trip (mechanical): 110% (+1%/-2.5%) of normal
- Backup overspeed trip (electrical): 111% of normal
- Low vacuum trip
- Excessive thrust bearing wear trip
- Electric solenoid trip actuated by:
  - Reactor trip
  - Generator trip
  - Manual trip from control room
- Excessive vibration trip
- Manual trip handle located at the turbine front standard
- High exhaust hood temperature trip
- Moisture separator drain system high level trip
- Prolonged loss of stator coolant trip
- Low hydraulic fluid pressure trip
- Loss of both speed signals or backup overspeed trip
- Low bearing oil pressure trip
- Loss of main shaft oil pump discharge pressure trip

The EHC system employs five electric and one mechanical speed inputs. Signals are redundantly processed in both electronic and hydraulic logic channels. Valve opening actuation is provided by a 1600 psig hydraulic system that is totally independent of the bearing lubrication system. Valve closing actuation is provided by springs and steam forces upon the reduction or relief of fluid pressure. The system is designed so that loss of fluid pressure for any reason leads to valve closing and consequent shutdown.

To help prevent turbine overspeed, a sequential tripping system isolates all steam to the high-pressure turbine and low-pressure turbines, and must detect no load on the generator before the main generator breaker is opened. (See figure 10.2-3.) This system provides for an orderly shutdown from a single tripping signal and prevents a rapid rise in speed that would occur if the generator breaker were opened before the turbine valves closed. All turbine protective trips are done by sequential tripping logic including the manual trip from the control room or by the trip handle at the turbine front standard. In a sequential trip, the interval between the closure of the turbine valves and the opening of the generator breaker is at least 3 seconds. Refer to calculation 13-EC-MA-232. In some electrical faults which would do serious damage to the generator, sequential tripping is not permissible. In these cases the generator and turbine are tripped simultaneously.

It is possible for the operator, in an emergency, to open the main generator breaker from the control room switch instead of using the turbine trip button. This action at or near full

load, coupled with transient steam conditions from the steam generator, could cause serious turbine damage and excessive overspeed. To help prevent the above, the operator is required to hold a breaker bypass switch in "trip" as a permissive before operating the main breaker switch to trip the generator. Limit switches on the main stop valves, control valves, reheat stop valves, and intercept valves are used in the sequential tripping logic. A reverse power relay is used to detect reverse current flow for the no load condition on the generator. A time delay, which is adjustable in the reverse power relay, is credited for a portion of the 3 second interval between a turbine trip and the loss of power to the RCPs assumed in certain accident analyses. Refer to section 8.3.4 and table 15.0-0. In a sequential trip, the unit auxiliary transformer continues to supply power to the non-Class 1E distribution system during the relay timeout period. Refer to section 8.3.5 and calculation 13-EC-MA-232.

All steam valves are arranged in series pairs such as a main stop valve and associated control valve or a reheat stop and associated intercept valve. There are four pairs of valves for the high-pressure turbine and two pair of valves for each low-pressure turbine making a total of ten pairs of steam admission valves. Each stop valve, control valve, and intercept valve (20 total) is actuated by either of two overspeed trip systems. Four control valves on the high-pressure turbine and one intercept valve on each low-pressure turbine is modulated by the speed governing system. Closure of either valve in a pair stops the steam flow from that source and therefore a single valve failure would not disable the

turbine overspeed trip from functioning. The backup overspeed trip and the trip caused by loss of the primary and backup speed signals are initiated by the 24 volt dc trip logic shown on figure 10.2-2.

The 24 volt trip system is used for turbine vital trips which includes the backup overspeed trip. A 125 volt dc trip system is also used for trips from related equipment and several turbine protective trips. As further protection, there is a "cross trip" logic employed which allows all trips originating in the 24 volt dc logic to initiate a trip by the 125 volt dc system. Conversely all trips originating in the 125 volt dc logic will initiate a trip in the 24 volt dc system. The output trip signals from these two voltage levels energize separate and individual solenoid valves which, in turn, dump the pressure off the high-pressure fluid connected to all the turbine steam admission valves.

10.2.2.5 Other Protective Systems

In addition to the previously mentioned devices, other protective features of the turbine and steam system are:

A. Safety valves on the moisture separator-reheater to protect the high-pressure turbine cylinder from overpressure in the event of a turbine trip

B. With the exception of the last two low-pressure heaters, each steam extraction line is equipped with a nonreturn valve to protect the turbine from overspeed due to reverse flow in case of a turbine trip. Each nonreturn valve will be exercised once per week using a

hand air test valve which is located at the nonreturn valve. Movement of the nonreturn valve shaft and counter weight extension will be noted during testing.

C. Exhaust casing rupture diaphragms to protect the low-pressure turbine cylinders from overpressure in case of loss of condenser vacuum.

10.2.2.6 Plant Loading and Load Following

The turbine-generator is intended to be base loaded, but is designed to match or exceed the transient load following capabilities of the NSSS. The reactor regulating system (RRS) automatically adjusts reactor power to follow turbine load transients. The RRS senses turbine first-stage pressure as a linear indication of load and generates signals that regulate control element assembly (CEA) drive direction and speed. As a combined unit consisting of turbine-generator and reactor, the system accepts step load changes of $\pm 10\%$ and ramp load changes of $\pm 5\%$/min over the range of 15 to 100% full power. It also accepts, with the aid of the turbine bypass system, a load rejection of approximately 55% of full load power without reactor trip. For load rejections greater than approximately 55% of full load, reactor power is cut back as described in subsection 10.4.4, and steam is dumped to the condenser as needed. In the event of complete loss of load, the system automatically runs back to house load. If the condenser is not available, concurrent with a load rejection, the reactor is tripped.

The turbine control system is designed to provide protection to the turbine by tripping the turbine for certain predetermined

conditions as discussed in paragraph 10.2.2.3. The turbine is tripped upon reactor trip. The reactor protective system provides two separate signals of reactor trip to the turbine control system.

10.2.2.7 Inspection and Testing Requirements

Major system components are readily accessible for inspection and are available for testing during normal plant operation. Controls and protective devices associated with each turbine-generator component will be tested on a regularly scheduled basis. Various turbine trips will be tested in sequence prior to unit startup.

The schedules for testing and inspection of the various system components are developed as part of the plant operating procedures presented in section 13.5.

10.2.3 TURBINE DISK INTEGRITY

10.2.3.1 Materials Selection

The originally installed General Electric turbine wheels and rotors are made from vacuum melted or vacuum degassed Ni-Cr-Mo-V alloy steel by processes that minimize flaw occurrence and provide adequate fracture toughness. Tramp elements are controlled to the lowest practical concentrations consistent with good scrap selection and melting practices, and consistent with obtaining adequate initial and long life fracture toughness for the environment in which the parts operate. The turbine wheel and rotor materials have the lowest fracture appearance transition temperatures (FATT) and highest

Charpy V-notch energies obtainable, on a consistent basis, from water quenched Ni-Cr-Mo-V material at the sizes and strength levels used. Since actual levels of FATT and Charpy V-notch energy vary depending upon the size of the part and the location within the part, etc., these variations will be taken into account in accepting specific forgings for use in turbines for nuclear application. Charpy tests essentially in accordance with Specification ASTM A370 are included.

The replacement General Electric Low Pressure Rotors are manufactured as a monoblock forging and do not have shrunk on wheels to preclude brittle failure at the wheel bore region. The monoblock forging material chemistry is optimally balanced to achieve high hardenability, good fracture toughness at the required tensile strength, low tramp elements to minimize temper embrittlement and low sulfur to minimize harmful segregation. This material is similar to ASTM 470 Class 6 but with more restrictive quality requirements.

The rotor forging is semi-machined to provide suitable surface for a periphery ultrasonic inspection. After final heat treatment a series of NDT testing is performed to ensure rotor structural integrity. Specimen testing of the rotors is performed to assure the rotors meet the supplier’s material specifications. Charpy tests essentially in accordance with Specifications ASTM A370 and ASTM A470 are included. A copy of all these test records and inspections for each rotor are submitted by GE and included in SDR log 13-M400-0303-1036.[1]

10.2.3.2 Fracture Toughness

Suitable material toughness is obtained through the use of materials described in paragraph 10.2.3.1 to produce a balance of adequate material strength and toughness to ensure safety while simultaneously providing high reliability, availability, and efficiency during operation. For the original General Electric turbines, bore stress calculations include components due to centrifugal loads, interference fit, and thermal gradients where applicable. The ratio of material fracture toughness, K_{IC} (as derived from material tests on each wheel or rotor) to the maximum tangential stress for wheels and rotors at speeds from normal to 115% of rated speed[a] will be at least $2\sqrt{\text{inches}}$. Adequate material fracture toughness needed to maintain this ratio is assured by destructive tests on material taken from the wheel or rotor using correlation methods which are more conservative than that presented in reference 1.

Turbine operating procedures are employed to preclude brittle fracture at startup by ensuring that the metal temperature of wheels and rotors (a) is adequately above the FATT, and (b) as defined above is sufficient to maintain the fracture toughness to tangential stress ratio at or above $2\sqrt{\text{inches}}$. For original General Electric turbines details of these startup procedures are contained in reference 2.

---

a. The highest anticipated speed resulting from a loss of load is 110%.

10.2.3.3 High-Temperature Properties

The operating temperatures of the high-pressure rotor in turbines operating with light-water reactors are below the creep rupture range. Creep rupture is, therefore, not considered to be a significant factor in assuring rotor integrity over the lifetime of the turbine. Basic data is obtained from laboratory creep rupture tests.

10.2.3.4 Turbine Disk Design

The original General Electric turbine assembly is designed to withstand normal conditions and anticipated transients including those resulting in turbine trip without loss of structural integrity. The design of the turbine assembly meets the following criteria:

A. The maximum tangential stress in wheels and rotors resulting from centrifugal forces, interference fit, and thermal gradients does not exceed 0.75 of the yield strength of the materials at 115% of rated speed.

B. Turbine shaft bearings are designed to retain their structural integrity under normal operating loads and anticipated transients, including those leading to turbine trips.

C. The multitude of natural critical frequencies of the turbine shaft assemblies existing between zero speed and 20% overspeed are controlled in the design and operation so as to cause no distress to the unit during operation.

GE, in the course of designing the new turbine for Palo Verde #1, 2 and 3, has evaluated tensile stresses in rotating

components. All of the rotating components have sufficient margin to tensile strength at design component temperatures to support operating speeds well in excess of 120% of normal. For example, the overspeed capability of the un-bucketed HP and LP rotors is over 200%. The most limiting components, per design, for the bucketed rotors are the LP L-0 buckets which have a minimum overspeed capability of 170%. The design of some of the most critical parts of the monoblock rotor assembly meet the following criteria:

A. The new monoblock rotors utilize tangential entry “pinetree” dovetails to attach the first five stages of buckets and radial entry “finger” dovetails to attach the last two stages. The wheel tangential entry dovetails are shot peened to introduce a compressive stress layer for protection against Stress Corrosion Cracking (SCC). In addition, the critical areas that are susceptible to SCC are designed such that the peak stresses do not exceed 55 percent of the material yield strength.

B. Turbine shaft bearings are designed to retain their structural integrity under normal operating loads and anticipated transients, including those leading to turbine trips.

C. The multitude of natural critical frequencies of the turbine shaft assemblies existing between zero speed and 20% overspeed are controlled in the design and operation so as to cause no distress to the unit during operation.

10.2.3.5 Preservice Inspection

The preservice inspection program is as follows:

A. The original wheel and rotor forgings and the new monoblock forgings are rough machined with minimum stock allowance prior to heat treatment.

B. Each original rotor and wheel forging and new monoblock forging is subjected to a 100% volumetric (ultrasonic) examination. Each finish-machined original rotor and wheel and new monoblock forging is subjected to a surface magnetic particle and visual examination. Results of the above examination will be evaluated by use of General Electric acceptance criteria. These criteria are most restrictive than those specified for Class 1 components in the ASME Boiler and Pressure Vessel Code, Sections III and V, and include the requirement that subsurface sonic indications are either removed or evaluated to assure that they do not grow to a size which compromises the integrity of the unit during the service life of the unit.

C. Finish-machined surfaces are subjected to a magnetic particle examination. No magnetic particle flaw indications are permissible in bores, holes, keyways, and other highly stressed regions.

D. Each fully bucketed turbine rotor assembly is spin tested at or above the maximum speed anticipated following a load rejection from full load.

10.2.3.6 Inservice Inspection

The inservice inspection program for the turbine assembly and valves includes the following:

A. Disassembly of the turbine is conducted during selected plant shutdowns. Inspection of parts that are normally inaccessible when the turbine is assembled for operation, such as couplings, coupling bolts, turbine shafts, low-pressure turbine buckets, low-pressure wheels, and high-pressure rotors, is conducted. This inspection consists of visual, surface, and volumetric examinations.

B. Dismantle at least one main steam stop valve, one main steam control valve, one reheat stop valve, and one reheat intercept valve during selected refueling or maintenance shutdowns, and conduct a visual and surface examination of valve seats, wheels, and stems. If unacceptable flaws or excessive corrosion are found in a valve, other valves of its type are inspected. Valve bushings are inspected and cleaned, and bore diameters are checked for proper clearance.

C. Main steam stop, control, reheat stop, and intercept valves will be exercised at least once per quarter by closing each valve and observing by direct observation that it moves smoothly to a fully closed position.

D. Extraction steam valves will be exercised once per week using a hand air test valve which is located at the nonreturn valve. Movement of the nonreturn valve shaft

and counterweight extension will be noted during testing.

10.2.4 EVALUATION

10.2.4.1 Power Generation

Components of the turbine-generator are conventional and are types that have been extensively used in other nuclear power plants. Instruments, controls, and protective devices are provided to ensure reliable and safe operation. Redundant, fast actuating controls are installed to prevent any damage resulting from overspeed and/or full load rejection. The control system ensures turbine trip upon reactor trip. Automatic low-pressure exhaust hood water sprays prevent excessive hood temperatures. Exhaust casing rupture diaphragms prevent low-pressure cylinder overpressure in the event of loss of condenser vacuum.

Since the steam generated in the steam generators is not normally radioactive, no radiation shielding is provided for the turbine-generator and associated components. Thus, radiological considerations do not affect access to system components during normal conditions. In the event of a primary-to-secondary system leak due to a steam generator tube leak, it is possible for the main steam to become radioactively contaminated. Discussions of the radiological aspects of primary-to-secondary leakage are presented in chapters 11 and 12.

10.2.4.2 CESSAR Interface Evaluation

Refer to subsections 5.1.5 and 7.2.4.

10.2.5 INSTRUMENTATION APPLICATIONS

The turbine-generator is provided with a full complement of turbine supervisory instruments mounted in the control room, complete with sensors and/or transmitters mounted on the associated equipment, which indicate and record the following:

- Speed
- Stop valve position
- Control valve position
- Intercept valve position
- Temperatures as required for controlled starting, including:
  - Steam chest
  - Nozzle bowl
  - First-stage steam and drain
  - High-pressure casing drain
  - High-pressure exhaust
  - First-stage reheater outlet
  - Second-stage reheater outlet
- Casing expansion
- Casing and shaft differential expansion

- Vibration at each bearing
- Shaft eccentricity
- Bearing oil drain, shaft bearing sleeve, and thrust bearing plate temperatures
- Shaft axial position

Control room alarms are provided to warn the operators of the following abnormal conditions:

- High vibration
- High eccentricity
- High differential expansion
- High bearing temperature
- High exhaust hood temperature alarm
- Turbine trip (for each independent redundant channel)
- Low vacuum
- Thrust bearing wear
- Low bearing oil pressure
- Low steam seal pressure
- High gland seal condenser pressure (or low vacuum)
- Overspeed trip (for each independent redundant channel)
- High-low level in moisture separator drain tank

Local and control room indication of the following miscellaneous parameters are provided:

- Main steam chest pressure
- Steam seal header pressure
- Gland seal condenser vacuum
- Bearing oil header pressure
- Hydraulic header pressure
- Crossover pressure
- Moisture separator drain tank level (local only)
- First-stage pressure
- High-pressure turbine exhaust pressure
- Extraction steam pressure, each extraction point (via computer)
- Exhaust hood spray water flow
- Exhaust hood temperature, each exhaust

Instrumentation and controls are provided in the control room for the generator equipment as follows:

A. Generator supervisory instruments with sensors and/or transmitters mounted on the associated equipment, indicating or recording the following:

   1. Multiple generator stator winding temperatures. The detectors are built into the generator, fully protected from the cooling medium, and suitably distributed around the circumference in positions having the highest temperature.

2. Multiple stator winding cooling coil outlet temperature detectors

3. Stator coolant inlet and discharge temperatures

4. Hydrogen cooler inlet gas temperature (two detectors at each point)

5. Field temperature

6. Hydrogen gas pressure

7. Hydrogen gas purity

8. Generator winding over temperature.

B. Alarms are provided for high stator, hydrogen, stator coil coolant, and field temperature. An alarm is provided from a core monitoring system to indicate a local core overheating condition.

10.3 MAIN STEAM SUPPLY SYSTEM

The function of the main steam supply system is to deliver steam from the steam generators to the high-pressure turbine over a range of flows and pressures covering the entire operating range from system warmup to valves-wide-open (VWO) conditions. The system also provides steam to the moisture separator/reheaters, the feedwater pump turbines, the auxiliary steam system, and the steam seal system for the main and the feedwater pump turbines.

Under certain conditions the Auxiliary Steam condensate cross connection header may be connected to the Secondary Chemistry Condensate Cleanup System in order to transfer water from the steam generators to the Chemical Waste Neutralization Tanks. This capability is discussed further in Section 10.4.6.

10.3.1 DESIGN BASES

10.3.1.1 Safety Design Bases

Pertinent safety design bases are as follows:

A. Safety Design Basis One

   The system provides a means of dissipating heat generated in the nuclear steam supply system (NSSS) during normal power operation, plant startup, hot shutdown, hot standby, and cooldown, even if the main condenser is unavailable. Atmospheric dump valves are provided to allow cooldown of the steam generator when the condenser is not available.

B. Safety Design Basis Two

The system is provided with automatically operated isolation valves on the main steam lines. These valves are located outside of and as close as possible to the containment in accordance with the requirements of Criterion 57 of 10CFR50.

C. Safety Design Basis Three

The system, from the secondary side of the steam generators and up to and including the main steam isolation valves (MSIVs) and the main steam isolation valve bypass valves, is designed to withstand the effects of a safe shutdown earthquake (SSE). The safety-related portions of the system are capable of withstanding the effects of natural phenomena.

D. Safety Design Basis Four

Main steam system components important to safety are designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, testing, and postulated accidents, including loss-of-coolant accidents (LOCAs), in accordance with 10CFR50, Appendix A, General Design Criterion 4.

E. Safety Design Basis Five

The main steam piping and supports are designed so that a single failure in the main steam system will have no contributory effects on:

- Initiation of a LOCA

- Integrity of other steam lines
- The capability of the engineered safety features system to effect a safe reactor shutdown
- Transmission of excessive loading to the containment pressure boundary

F. Safety Design Basis Six

The portion of the main steam system that is constructed in accordance with ASME Section III, Class 2, requirements is provided with access to welds and removable insulation as required for inservice inspection in accordance with ASME Section XI, Rules for Inservice Inspection of Nuclear Reactor Coolant Systems.

G. Safety Design Basis Seven

Flow restrictors are installed in the steam generator steam nozzles to limit flow in the event of a main steam line break.

H. Safety Design Basis Eight

Provide steam to the auxiliary feedwater pump turbine.

10.3.1.2 Power Generation Design Basis
