COOK NUCLEAR PLANT SIMULATOR CERTIFICATION

U.S. Nuclear Regulatory Commission
Attn: Document Control Desk
Washington, D. C. 20555

Attn: T. E. Murley

August 24, 1990

Dear Dr. Murley:

The purpose of this letter is to submit information pursuant to 10CFR55.45.(b)(5) to certify the Cook Nuclear Plant Simulator Facility. Our submittal for certification addresses both units at Cook Nuclear Plant with Unit 2 serving as the reference plant. The requirements for dual unit simulation facilities were evaluated and the results demonstrate that the Cook Nuclear Plant simulator performance compares favorably with each unit. In addition, steady state and transient testing per ANSI/ANS 3.5-1985 Appendix B, was performed and compared the simulator performance to Cook Nuclear Plant Unit 1 performance with favorable results. We have discussed the certification requirements and the contents of Attachments 1 and 2, for Cook Nuclear Plant Units 1 and 2, respectively, with members of your staff on several occasions.

Both attachments contain the NRC Simulator Facility Certification Form 474, one for each docket number, and two copies of the Initial Certification Report, dated August 24, 1990, and a list of exceptions from ANSI/ANS 3.5-1985.

00293

U.S. NUCLEAR REGULATORY COMMISSION

APPROVED BY OMB: NO. 3150-0138
EXPIRES: 9-30-92

ESTIMATED BURDEN PER RESPONSE TO COMPLY WITH THIS INFORMATION COLLECTION REQUEST: 120 HRS. FORWARD COMMENTS REGARDING BURDEN ESTIMATE TO THE INFORMATION AND RECORDS MANAGEMENT BRANCH (MNBB 7714), U.S. NUCLEAR REGULATORY COMMISSION, WASHINGTON, DC 20555, AND TO THE PAPERWORK REDUCTION PROJECT (3150-0138), OFFICE OF MANAGEMENT AND BUDGET, WASHINGTON, DC 20503.

SIMULATION FACILITY CERTIFICATION

INSTRUCTIONS. This form is to be filed for initial certification, recertification (if required), and for any change to a simulation facility performance testing plan made after initial submittal of such a plan. Provide the following information, and check the appropriate box to indicate reason for submittal.

FACILITY	DOCKET NUMBER
COOK NUCLEAR PLANT	50- 315
LICENSEE	**DATE**
INDIANA MICHIGAN POWER COMPANY	8/24/90

This is to certify that:

1. The above named facility licensee is using a simulation facility consisting solely of a plant-referenced simulator that meets the requirements of 10 CFR 55.45.
2. Documentation is available for NRC review in accordance with 10 CFR 55.45(b).
3. This simulation facility meets the guidance contained in ANSI/ANS 3.5, 1985, as endorsed by NRC Regulatory Guide 1.149.

If there are any exceptions to the certification of this item, check here [X] and describe fully on additional pages as necessary.

NAME *(or other identification)* AND LOCATION OF SIMULATION FACILITY

COOK TRAINING CENTER
ONE COOK PLACE
BRIDGMAN, MI 49106

[X] SIMULATION FACILITY PERFORMANCE TEST ABSTRACTS ATTACHED. *(For performance tests conducted in the period ending with the date of this certification)*

DESCRIPTION OF PERFORMANCE TESTING COMPLETED *(Attach additional page(s) as necessary, and identify the item description being continued)*

See attached Transient, Steady State, Malfunction and Operability tests.

[X] SIMULATION FACILITY PERFORMANCE TESTING SCHEDULE ATTACHED. *(For the conduct of approximately 25% of performance tests per year for the four year period commencing with the date of this certification.)*

DESCRIPTION OF PERFORMANCE TESTING TO BE CONDUCTED. *(Attach additional page(s) as necessary, and identify the item description being continued)*

See attached test schedule of Cook Plant Simulator Unit 2 certification package.

[ ] PERFORMANCE TESTING PLAN CHANGE. *(For any modification to a performance testing plan submitted on a previous certification)*

DESCRIPTION OF PERFORMANCE TESTING PLAN CHANGE *(Attach additional page(s) as necessary, and identify the item description being continued)*

Not Applicable. Initial submittal.

[ ] RECERTIFICATION *(Describe corrective actions taken, attach results of completed performance testing in accordance with 10 CFR § 55.45(b)(5)(iv). Attach additional page(s) as necessary, and identify the item description being continued.)*

Not Applicable. Initial submittal.

Any false statement or omission in this document, including attachments, may be subject to civil and criminal sanctions. I certify under penalty of perjury that the information in this document and attachments is true and correct.

SIGNATURE — AUTHORIZED REPRESENTATIVE	TITLE	DATE
M R Allen	Vice President	8/24/90

In accordance with 10 CFR § 55.5, Communications, this form shall be submitted to the NRC as follows:

BY MAIL ADDRESSED TO: Director, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555

BY DELIVERY IN PERSON TO THE NRC OFFICE AT: One White Flint North, 11555 Rockville Pike, Rockville, MD

COOK PLANT SIMULATOR

EXCEPTIONS TO ANS 3.5 AND/OR REG GUIDE 1.149

1. (ANS 3.5 - 3.2.1) Currently the reference plant process computer is not replicated on the simulator. The Unit 2 plant process computer is being replaced during the 1991 refueling outage. The replacement plant process computer hardware is on site and being integrated into the simulator at this time. Scheduled implementation is by the last quarter of 1991.

2. (ANS 3.5 - 3.2.3) The reference plant wireless telephone equipment is not currently replicated in the simulator. A facsimile of this equipment has been ordered and will be integrated into the simulator during the last quarter of 1990.

3. (ANS 3.5 - 3.2.1) The degree of panel simulation is slightly different between the simulator and Cook Nuclear Plant Unit 1. Both units of the Cook Plant are essentially the same with minor differences, mainly on the Unit 1 secondary systems and secondary system control room displays. These minor differences have been reviewed by a team of consultants experienced in human factors and found not to cause negative training errors. The simulator software for Unit 1 training has been modified to functionally replicate Cook Plant Unit 1 systems and operating conditions.

COOK PLANT SIMULATOR

COOK PLANT UNIT 1 REFERENCE PLANT INFORMATION

1) Plant

Owner: Indiana Michigan Power Company
One Summit Square
P.O. Box 60
Fort Wayne, IN 46801

Operator: Indiana Michigan Power Company

8895 McGaw Road
Columbia, MD 21045

3) Date Available For Training: May 16,. 1988

4) Type of Report: Initial

COOK PLANT SIMULATOR

GENERAL INFORMATION

The Cook Plant reference plant simulator functions to provide training for both Units of the Cook Plant. Unit 2 certification is provided in a separate report. The simulator is modelled to the Cook Plant Unit 2 and modified to support training on Cook Plant Unit 1.

NRC Regulatory Guide 1.149 states that a utility wishing to utilize a simulator for more than one nuclear power plant, it must demonstrate in it's certification that the differences between the plants are not so significant that they have an impact on the ability of the facility to meet the requirements of ANSI/ANS 3.5 - 1985.

The demonstration includes:

1) Facility design and systems relevant to control room personnel;

2) Technical Specifications;

3) Procedures, primarily abnormal and emergency operating procedures;

4) Control room design and instrumentation/control locations; and

5) Operational characteristics.

All differences between Cook Plant Unit 1 and the simulator, assuming that the simulator only replicated Cook Plant Unit 2, were identified and a human factor analysis was performed to determine if training operators that operate Cook Plant Unit 1 were likely to make an error that resulted in a critical safety function (CSF) being challenged. This analysis (see attached "Human Factor Study") indicated that an operator trained on the simulator was not likely to cause an error that would result in a critical safety function being challenged.

Differences are summarized in the Human Factor Study.

Both units of the Cook Plant use the same systems and system designations.

Technical specifications are virtually identical for both units, with the exception that setpoints vary for each unit.

Procedures and procedure numbering scheme is the same for both units. However, procedures referencing turbine control, feedwater and condensate and main generator systems differ due to physical differences in equipment.

However, to enhance and support Cook Plant Unit 1 simulator training, a Unit 1 "training load" has been developed to replicate Cook Plant Unit 1 as a reference plant.

Transient and steady state testing has been conducted on the Unit 1 "training load" to verify system stability and operating characteristics.

Training with the Unit 1 training load fully supports training and examinations with respect to Cook Plant Unit 1, with the exception that training will not be conducted on the main turbine, feedwater (including condensate) and main generator systems. This training will be conducted in the classroom as difference training.

Marked up procedures will be used as applicable to substitute appropriate controls that are different between the units.

The Unit 1 training load will be modified to maintain dynamic replication of Cook Plant Unit 1 as the reference plant, however, the hardware configuration will only replicate Cook Plant Unit 2.

The Unit 1 "training load" uses the same models as Unit 2 and replicates all operating conditions per Unit 2 certification package.

COOK PLANT SIMULATOR

SIMULATOR ENVIRONMENT

I. Degree of Panel Simulation (ANS 3.5 - 3.2.1)

This section of the standard requires that the simulator shall contain sufficient operational panels, controls, instrumentation, alarms and other man-machine interfaces to conduct normal plant evolutions and respond to malfunctions.

The simulator contains sufficient panels, controls, instrumentation and alarms to conduct reference plant control room training on the Cook Plant Simulator (see Human Factor Study).

All panels are duplicated in size, color, shape, configuration, arrangement, and functionality as the reference plant, with few exceptions.

Those exceptions are:

1) Instrument bezel color may not be the same, as there isn't any exact method in the reference plant to control bezel color.

2) The containment RCP camera controls are not simulated, however, half loop level indication is provided during reactor coolant system half loop operations (which is the main purpose of the containment camera).

3) Two recorders on the main generator panel have been substituted for the original recorders which are slightly different and do not detract from training.

4) Back panels without controls have been simulated for spacial relationships, however they do not contain wiring, relays,etc. Additionally, the following simulator back panels are an approximate mirror image to the reference plant control room back panels:

1)	CW	Circulating Water
2)	RMS	Radiation Monitoring System
3)	APDMS	Axial Power Difference Monitoring System
4)	MFX	Movable Incore Flux Cabinet
5)	FFC	Failed Fuel Cabinet
6)	RMS-CT	Radiation Monitoring System Control Terminal
7)	FI	Fixed Incore
8)	Auxiliary Relay Panels	

II. Controls on Panels (ANS 3.5 - 3.2.2)

This section states that controls, panels and consoles shall be designed to replicate the size, shape, color and configuration of the functionally simulated hardware of the reference plant.

Most reference plant information is displayed in the same form and units on the simulator.

Most controls are located in the same location of the panels.

Differences in the control room panel configuration are maintained per the reference plant by comparing photographs taken that are biennially to verify the simulator configuration control process.

III. Control Room Environment (ANS 3.5 - 3.2.3)

This section states that consideration shall be given to simulating the reference plant control room environment to a degree reasonably possible and practical.

The Cook Plant simulator replicates lighting (both normal and emergency), obstructions (desks, bookcases, etc.), floor covering, communication systems(with the exception of the two way radio) and ceiling height the same as the reference plant.

Plant and/or reference plant control room noise has been simulated as listed below:

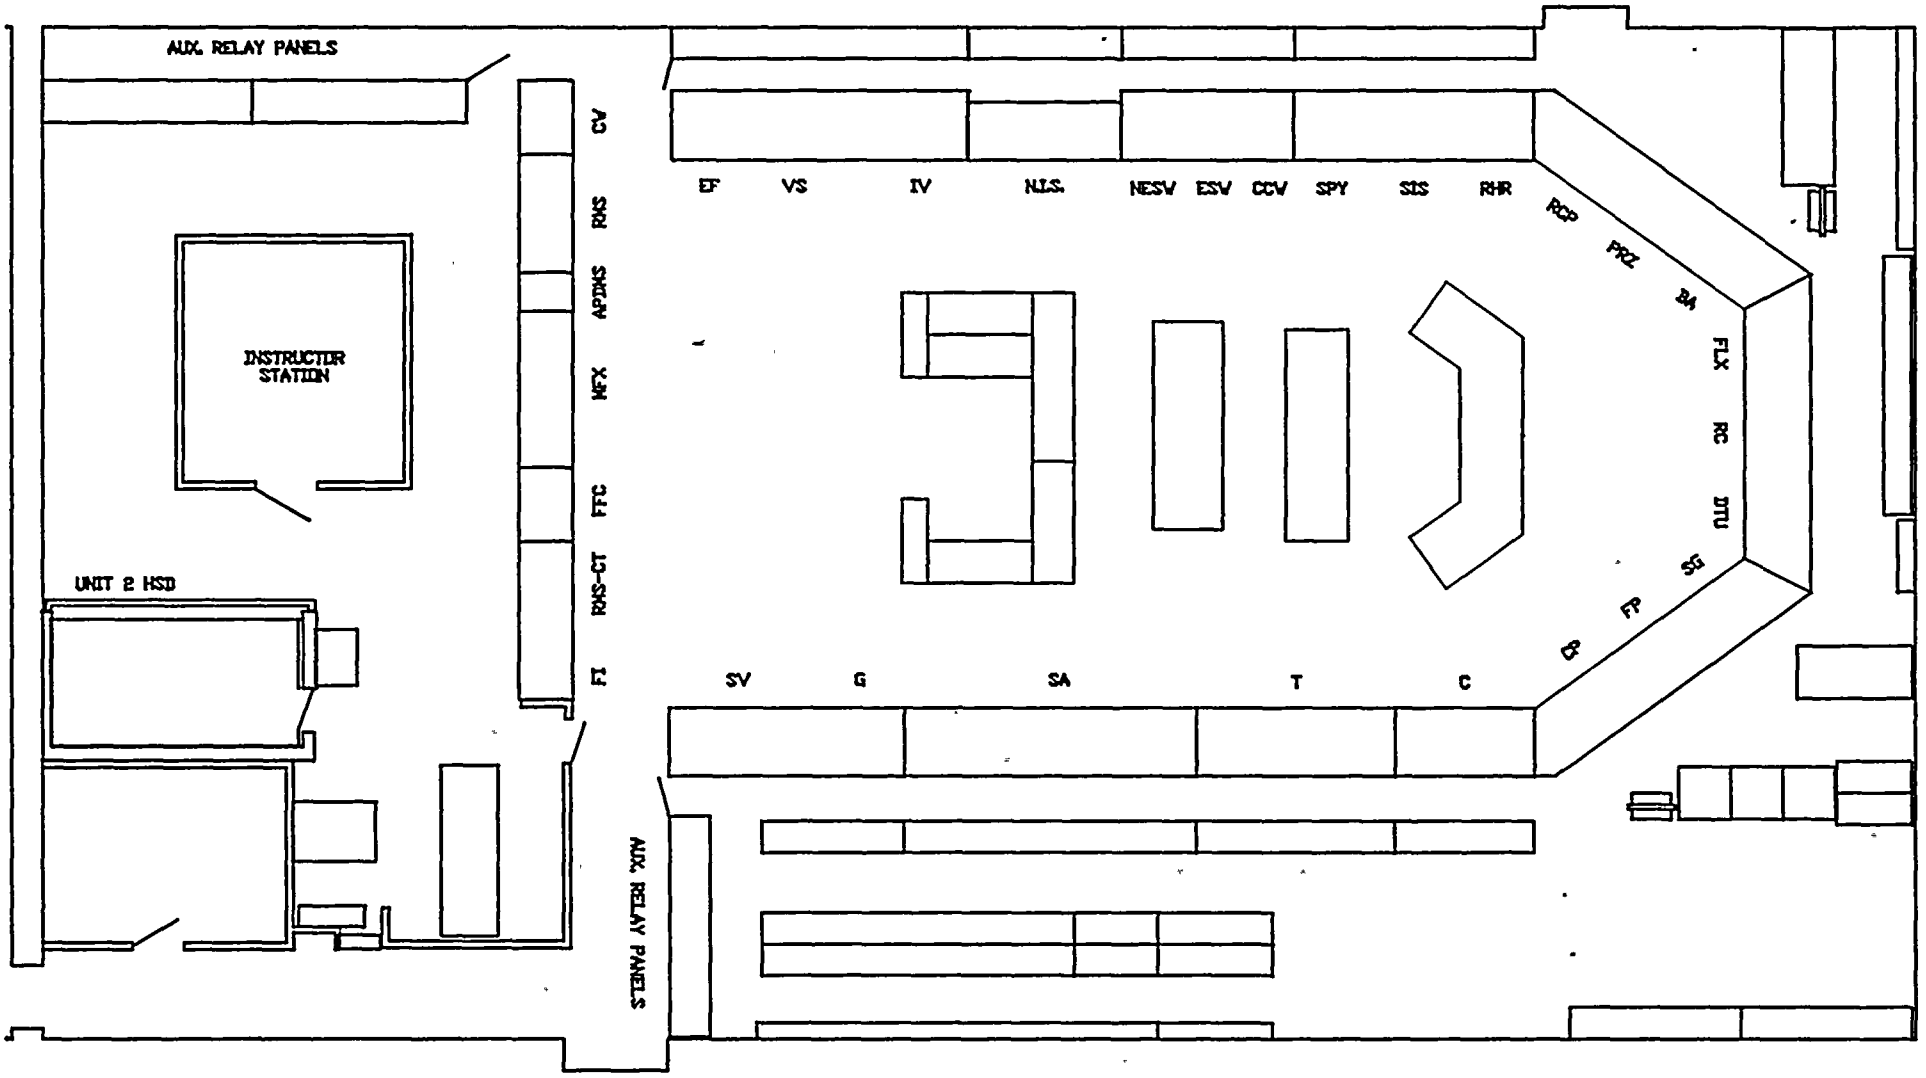
- Turbine room noise
- Pneumatic controllers
- Various relay noises
- Control room pressurization fan
- Some plant noises on the PA system

IV. Control Room Documentation (ANS 3.5 - A1.4)

All procedures, drawings and data used in the simulator control room are controlled in accordance with plant document control and do not deviate from the reference plant.

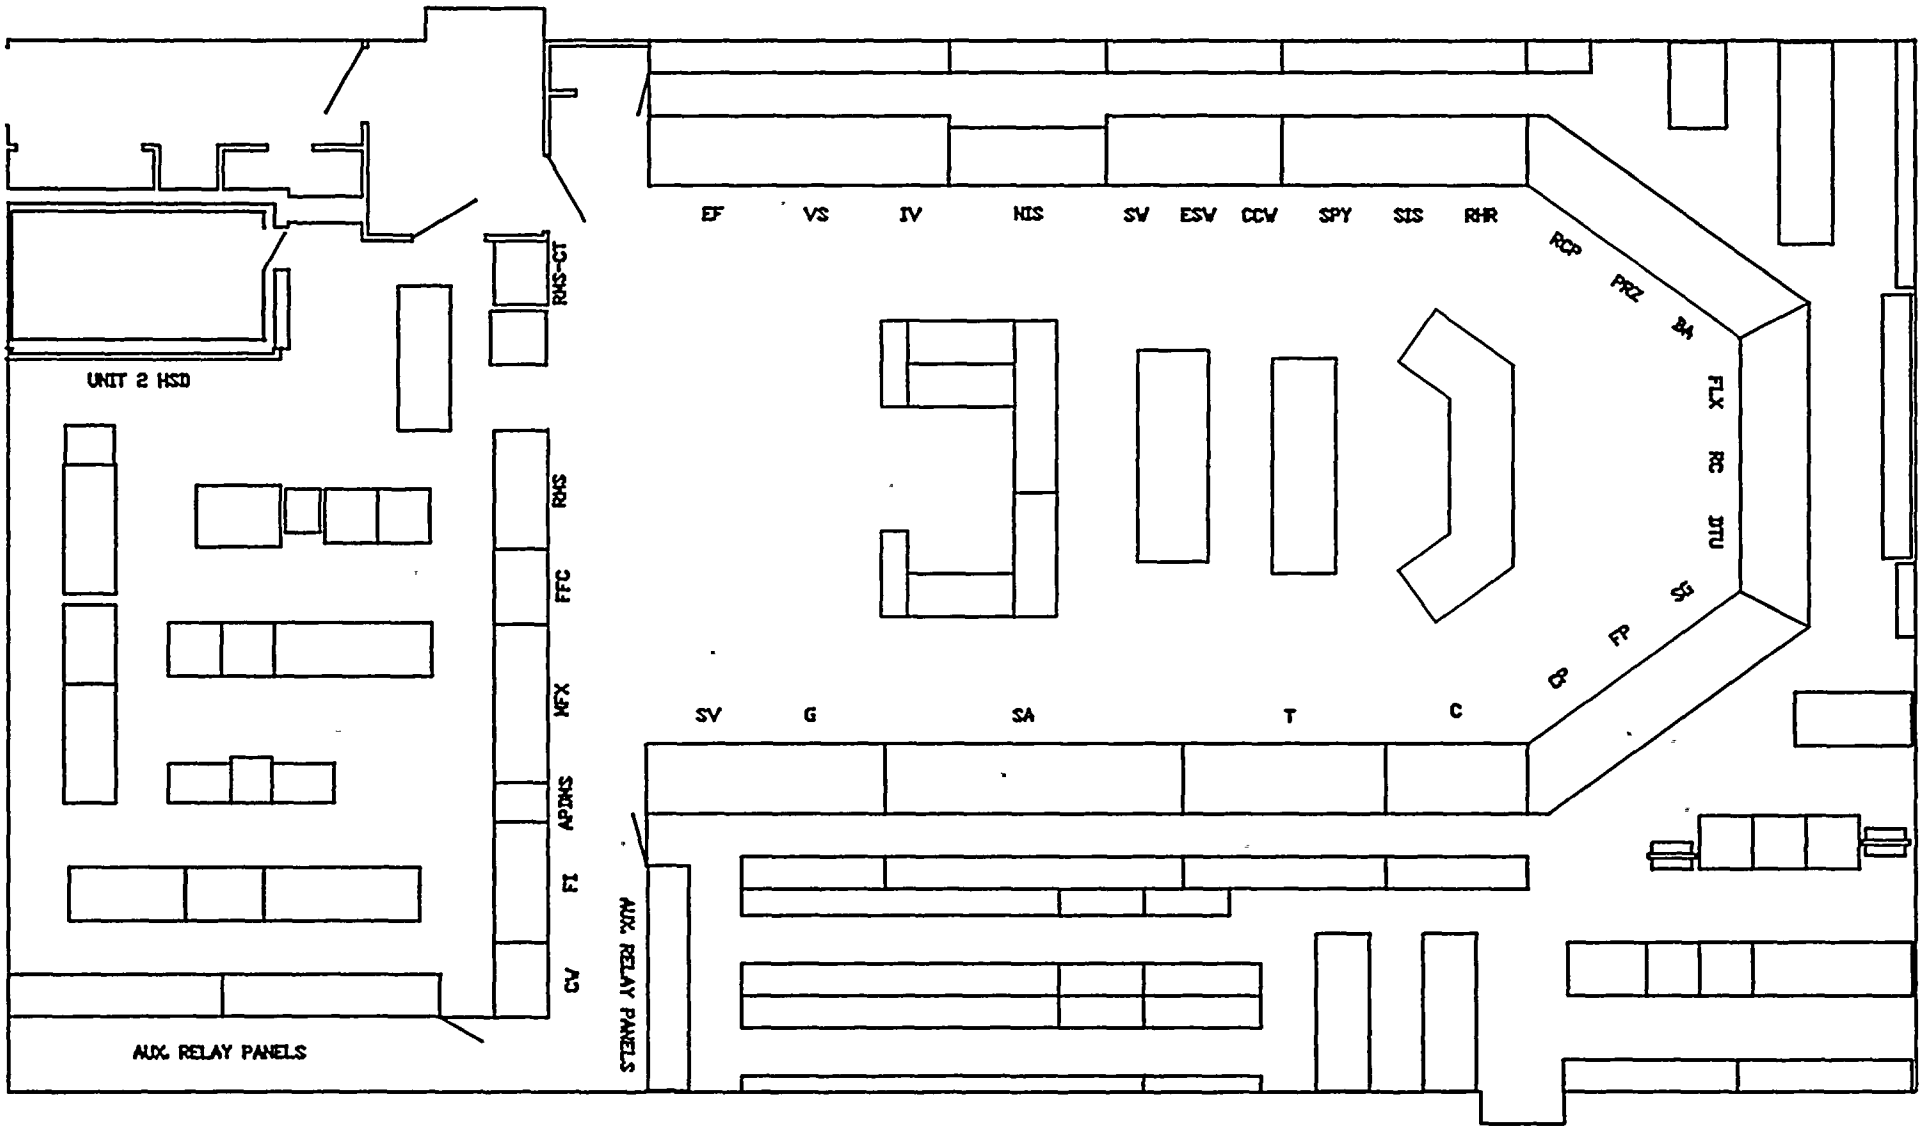
SIMULATOR CONTROL ROOM

SCALE: 1" = 9'0"



UNIT ONE CONTROL ROOM

SCALE: 1" = 9'0"



List of Panel Abbreviations for Control Room

SV	Plant Service
G	Generator
SA	Station Auxiliary
T	Turbine
C, CP.	Condensate
FP	Main Feedpump
SG	Steam Generator & Auxiliary Feedpump
DTU	Delta T & Unit
RC	Rod Control
FLX	Flux
BA	Boric Acid
PRZ	Pressurizer
RCP	Reactor Coolant Pump
RHR	Residual Heat Removal
SIS	Safety Injection System
SPY	Containment Spray
CCW	Component Cooling Water
ESW	Essential Service Water
NESW	Nonessential Service Water
N.I.S.	Nuclear Instrumentation System
IV	Isolation Valves
VS	Ventilation System
EF	Emergency Fire
CW	Circulating Water
RMS	Radiation Monitoring System
APDMS	Axial Power Difference Monitoring System
MFX	Movable Incore Cabinet
FFC	Failed Fuel & Communications
RMS-CT	Control Terminal for Rad. Monitoring System
FI	Fixed Incore
HSD	Hot Shutdown Panel

COOK PLANT SIMULATOR

SIMULATOR TESTS

I. Introduction (ANS 3.5 - A.3)

Appendix A.3 addresses simulator testing to demonstrate compliance with the documentation requirements of the standard by comparison of simulator performance with the data base where applicable.

II. Implementation

The following four areas of testing were performed to demonstate compliance with the standard:

1) Computer Real Time Test (Tab Computer) (ANS 3.5 - A3.1)

2) Normal Plant Evolutions (Tab 1) (ANS 3.5 - A3.2)

3) Simulator Transient Tests (ANS 3.5 - A3.3)

TAB

1 Reactor Vessel Head Void Formation
2 Anticipated Transient Without Scram
3 Steam Generator Tube Rupture
4 Unit Two Reactor Trip on November 13, 1985

SEE COOK PLANT SIMULATOR UNIT 2 CERTIFICATION PACKAGE

COOK PLANT SIMULATOR

NORMAL OPERATIONS TESTS

I. Introduction (ANS 3.5 - 3.1.1)

The Cook Plant Simulator is capable of simulating continuously, and in real time, plant operations of the reference plant. The simulator calculates plant system parameters corresponding to all selected plant operating plant conditions, displays those parameters on appropriate instrumentation and provides proper alarm and/or protective actions.

The simulator responds to operator action, improper operator action and no operator action in a realistic manner such that there is no observable difference between the reference plant control room indications and the simulator indications to the extent possible.

II. Implementation

The Cook Plant Simulator simulates plant operations from, and including, operations at Cold Shutdown at half loop (Mode 5) to full reactor power as specifically listed below:

1) Operations at Reactor Coolant System half loop (1-OHP-4021.017.001)

2) Filling and Venting the Reactor Coolant System (1-OHP-4021.002.001)

3) Plant Heatup From Cold Shutdown to Hot Standby (1-OHP-4021.001.001)

4) Reactor Startup (1-OHP-4021.001.002)

5) Power Escalation (1-OHP-4021-001.006)

6) Power Reduction (2.-OHP-4021.001.003)

7) Plant Cooldown From Hot Standby to Cold Shutdown (1-OHP-4021.001.004)

8) RCS Draining (1-OHP-4021.002.005)

9) Turbine Startup and Generator Synchronization (1-OHP-4021.050.001)

10) Load Changes (1-OHP-4021.001.003 OR 1-OHP-4021.001.006)

11) Reactor Trip Followed by Recovery to Rated Power (1-OHP-4021.001.002)

12) Power Operation at Less Than Full Reactor Coolant Flow (supported by the simulator, however, not allowed by Technical Specifications)

13) Core Performance Testing

A) Plant Thermal Power Calculation
B) Determination of Shutdown Margin (1-OHP-4021.001.012)
C) Determination of Critical Conditions (1-OHP-4021.001.011)
D) Low Power Physics Testing, including rod worth, temperature coefficient and flux distribution.

14) Operator Conducted Surveillance Testing

No effort has been made to single out operator conducted surveillance tests for certification. All surveillance tests that interface the operator and control room can be performed.

SEE COOK PLANT SIMULATOR UNIT 2 CERTIFICATION PACKAGE

SEE .COOK PLANT SIMULATOR UNIT 2 CERTIFICATION PACKAGE

COOK PLANT SIMULATOR

STEADY STATE OPERATION GENERAL INFORMATION

I. Steady State Operation (ANS 3.5 - 4.1)

To ensure compliance with the standard in regards to simulator steady state operation, the simulator has been operated at one hour intervals without operator action and compared to reference plant data for four different power levels (30%, 70%, 90% and 100%).

All simulator controls were aligned the same as the reference plant (all controls in AUTO).

Computed values were collected at one second intervals over a one hour period for each power level, graphed and compared to reference plant data, with the exception that non critical data points were not compared at power levels less than 100%.

Plant data was not available for Reactor Coolant System Hot Leg and Cold Leg temperature in the time frame during which the Steady State tests were performed for 30% and 90% power. These temperatures will be compared during performance of the next scheduled 30% and 90% Steady State tests.

All simulator instruments are calibrated on regular intervals and verified not to have errors greater than the reference plant. Instrument error was included in the allowable error range for each parameter.

Simulator discrepancy reports have been written for all data points designated by an '*'.

COOK PLANT SIMULATOR

TRANSIENT TEST ABSTRACT

I. Introduction (ANS 3.5 - 4)

Section 4 of the standard addresses simulator tests to ensure that simulator response:

1) Is the same as plant startup test data

2) Observable change in the parameters correspond in direction to those expected from best estimate of the simulated transient and do not violate the physical laws of nature

3) Does not fail to cause an alarm or automatic action if the reference plant would not cause an alarm or automatic action.

II. Transient Operation (ANS 3.5 - 4.2.1)

All transient tests in accordance with Appendix B section B.2.2 were conducted on the simulator and compared to data where existing data was available. In all other cases, the tests were reviewed by a team of subject matter experts (attachment 1) to ensure that the criteria of the standard were met.

All data was collected at a minimum resolution of every one half second.

All discrepancies identified from the test results will be corrected by the end of 1991.

COMPOSITION OF SUBJECT MATTER EXPERT PANEL

LAST NAME	FIRST NAME	RO DATE	SRO DATE	PRESENT POSITION

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MANUAL REACTOR TRIP

I. Introduction (ANS 3.5 - B.2.2(1))

The purpose of this test is to:

1) Test the simulator response to a manual reactor trip per ANS 3.5 - B.2.2(1).

2) Ensure that the simulator functions properly to a manual reactor trip and all parameters respond in a timely manner.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Pressurizer safety valves shall not lift.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted the following discrepancies:

a) Pressurizer surge line temperature drops lower than hot leg temperature during initial cooldown.

b) Steam generator #2 level increases significantly prior to the other steam generators.

Discrepancy reports have been initiated to investigate and correct these conditions.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULTANEOUS TRIP OF ALL MAIN FEEDWATER PUMPS

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a simultaneous trip of all main feedwater pumps per ANS 3.5 - B2.2.

2) Ensure that the simulator's auxiliary feedwater system functions properly to restore steam generator level in a timely manner following the reactor trip.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer level
4) Pressurizer pressure
5) Pressurizer temperature
6) Feedwater flow
7) Steam flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Pressurizer safety valves shall not lift.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULTANEOUS CLOSURE OF ALL MAIN STEAM ISOLATION VALVES

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a simultaneous closure of all main steam isolation valves per ANSI 3.5 - B2.2.

2) Ensure that the simulator's steam generator safety and power operated relief valves (PORV) function properly to limit steam generator pressure and that steam generator PORVs in conjunction with the auxiliary feedwater system control RCS average temperature.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Steam generator safeties and PORVs limit steam generator pressure.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The following discrepancies were noted by the team of subject matter experts:

a) Steam Generator #11 PORV (2-MRV-213) did not appear to have operated. The team ran the test on the simulator and determined that the lack of response of 2-MRV-213 was attributable to the setpoint dial (operator controlled) being slightly out of position. The team concluded that the response was correct for the condition.

b) Pressurizer surge line temperature response was incorrect for the condition.

c) Number four (4) steam generator steamed significantly more than the other steam generators.

Discrepancy reports have been written to investigate and correct conditions b and c.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULTANEOUS TRIP OF ALL REACTOR COOLANT PUMPS

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a simultaneous trip of all Reactor Coolant Pumps per ANSI 3.5 - B2.2.

2) Ensure that the simulator will establish natural circulation conditions upon loss of forced Reactor Coolant System flow.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, with pressurizer level in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Natural Circulation conditions established as indicated by constant or decreasing RCS Hot Leg Temperatures.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted that surge line temperature response was not correct for the condition. A discrepancy report has been written to investigate and correct the condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

TRIP OF REACTOR COOLANT PUMP #11

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a trip of Reactor Coolant Pump #11 per ANSI 3.5 - B2.2.

2) Ensure that the simulator will initiate Reactor Coolant Pump #11 flow coastdown and flow reversal.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level control in manual.

III. Data Collected

1) Neutron flux
2) RCS hot leg temperature
3) RCS cold leg temperature
4) Steam Generator pressure
5) Steam Generator level
6) Steam flow
7) Feedwater flow
8) RCS loop flow
9) RCS T average

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) RCS Loop 1 flow decreases to minimum then is re-established by flow reversal from the other RCS loops as indicated by Loop 1 T hot less than unaffected loops' T cold.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted that steam generator number four (4) steamed significantly more than the other steam generators. A discrepancy report has been initiated to investigate and correct this condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

TRIP OF MAIN TURBINE FROM 9% POWER WITHOUT REACTOR TRIP

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a trip of the Main Turbine from the maximum power level (9%) which does not result in an immediate reactor trip per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to permit a Main Turbine trip without tripping the reactor as a direct result of the turbine trip.

II. Initial Conditions

1) The simulator is operating at beginning of life core conditions, reactor power at approximately 9 percent, steam generator feedwater in automatic, steam dumps in steam pressure mode, main generator in parallel at approximately 85 MWE, and Tavg matched to Tref.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The plant stabilizes with a Tavg higher than initial and a differential temperature (Tavg - Tstm) which corresponds to the final power.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MAXIMUM RATE POWER RAMP (100% - 75% - 100%)

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum rate power ramp per ANSI 3.5 - B2.2.

2) Ensure that the simulator will maintain stability during a maximum rate power ramp.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level control in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MAXIMUM SIZE REACTOR COOLANT RUPTURE WITH LOSS OF ALL OFFSITE POWER

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum size reactor coolant system rupture with a loss of all offsite power per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to accurately replicate containment response to a large break LOCA.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level control in manual.

III. Data Collected

1) Pressurizer pressure
2) Narrow range pressurizer pressure
3) Pressurizer level
4) Containment pressure
5) Containment temperature

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

PWR SIMULATOR TRANSIENT TEST

MAXIMUM SIZE UNISOLABLE MAIN STEAM LINE RUPTURE

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum size unisolable main steam line rupture per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to accurately replicate containment response to a large main steam line break.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Pressurizer pressure
2) Narrow range pressurizer pressure
3) Pressurizer level
4) Containment pressure
5) Containment temperature

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted that lower containment temperature decreased while containment pressure increased. A discrepancy report has been initiated to investigate and correct this condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SLOW PRIMARY SYSTEM DEPRESSURIZATION TO SATURATION

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a slow primary system depressurization to saturated conditions with high pressure Emergency Core Cooling System inhibited using a pressurizer relief valve per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to establish localized saturated conditions in the RCS while liquid is maintained in the pressurizer.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits, and pressurizer level control in manual.

III. Data Collected

1) Pressurizer relief valve (PORV) flow
2) Pressurizer pressure
3) Pressurizer temperature
4) Surge line temperature
5) Pressurizer level
6) Loop flow rates
7) RCS hot leg temperature
8) Source range detector output
9) Reactor vessel level
10) RCS Saturation margin

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Localized saturated conditions are established in the RCS as indicated by:

   a) RCS saturation margin decreasing to zero (0)
   b) RCS wide range pressure decreases to approximately Psat for RCS hot leg temperature
   c) Decreasing wide range RVLIS indications with increasing pressurizer level indications

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted the following discrepancies:

a) Pressurizer surge line response was inconsistent with pressurizer level response.

b) Reactor vessel level indicating system indication leveled off at approximately eight minutes and thirty seconds while mass was still being lost from the system.

c) RCS loop flow rates were not consistent with the event.

Discrepancy reports have been initiated to investigate and correct these conditions.

COOK PLANT SIMULATOR

DIFFERENCES

I. Introduction

The Cook Plant Simulator Certification Submittal references two differences between the reference plant and the simulator specified as exceptions. They are:

1) Plant Process Computer

Presently the Cook Plant Simulator does not simulate the reference plant process computer system due to replacement of this equipment in the reference plant. Installation in the plant is scheduled for the 1991 refueling outage (last quarter of 1991).

The hardware is on site to replicate and simulate the plant process computer and is expected to implemented by the end of the last quarter of 1991.

2) Plant Hand Held Radio Communication System

Presently the Cook Plant Simulator does not simulate the reference plant hand held radio communication system due to replacement of this equipment in the reference plant.

Equipment to replicate and simulate reference plant equipment is on order and expected implementation date is by the end of the last quarter of 1990.

3) Main Turbine, Feedwater, Condensate and Main Generator Systems

Cook Plant Unit 1 secondary system (General Electric) differs from the Unit 2 secondary system (Brown Boveri). These differences are summarized in the Human Factor Study.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

A detailed analysis was made of the physical differences between the Simulator and the Unit One control room at the D.C. Cook Nuclear Plant. Detailed photographs were taken of each facility. These photographs and other materials were utilized to identify and document 1,684 physical discrepancies out of the approximately 13,000 components (controls, displays, labels, etc.) in each facility. The majority of these discrepancies concerned minor annunciator, label and bezel differences, leaving 348 remaining discrepancies. These remaining 348 discrepancies were judged to be either insignificant or to be of no consequence in producing possible training errors.

A series of 16 operator interviews was conducted to supplement judgements concerning the consequences of these physical discrepancies. The evaluation concentrated primarily on Emergency Operating Procedures (EOPs).

An Assessment Panel of experts in operations, training, engineering and human factors independently evaluated all 1,684 identified discrepancies. Their task was to determine whether any of these discrepancies could cause a possible negative transfer of training error. Such negative transfer of training errors could either (1) possibly challenge a Critical Safety Function (CSF), Attachment 16, at the plant, (2) possibly adversely affect plant operations, or (3) have no significant effect on either plant CSFs or operations. The Assessment Panel found no physical discrepancies that would be likely to challenge any CSFs, and only 5 discrepancies that would be likely to adversely affect plant operations.

By a program of modifications to enhance simulation fidelity and specialized instruction to reduce negative transfer of training, the Panel decided that any remaining negative impacts could be minimized.. Therefore, as far as physical differences between the two facilities are concerned, the overall conclusion of the present study is that the Simulator at D.C. Cook may be used adequately to train and examine operators on D.C. Cook, Unit One. However, specific training and/or examination on the Unit One turbine, turbine control feedwater (and condensate) and main generator systems would be difficult due to differences between the two units and the fact that high physical fidelity is maintained between the simulator and Unit Two./

1.0 INTRODUCTION

The present report summarizes an analysis of the physical differences between the Simulator and the Unit One control room at the D.C. Cook Nuclear Plant operated by the Indiana/Michigan Power Company. This analysis has been conducted as part of the process of certifying the Simulator for the conduct of operator training and examinations on Unit One procedures.

1.1 Background

1.1.1 Baseline

The Donald C. Cook Nuclear Plant is a two unit nuclear power plant. Both units use Westinghouse four-loop pressurized water reactors with ice condenser containments as the primary design. The differences between the two units on the primary side are minimal, and operators are licensed to operate both units.

The two units have different turbine generator systems, and have a limited number of other differences on the primary side. The differences between the two units on the secondary side are currently being addressed through training so that operators may receive dual licenses despite secondary side system and equipment differences.

To meet the present Simulator certification requirements, the Simulator is being certified as "plant reference" by the utility. Analysis to support the certification application is to include evaluation of the Simulator's fidelity and functionality as compared to the actual plant control room and plant responses, in accordance with criteria specified in regulatory guidance (Reg. Guide 1.149; ANSI/ANS-3.5, 1985; NUREG 1258; etc.).

1.1.2 Simulator Characteristics

The Indiana/Michigan Power Company procured the Simulator to be plant reference to the D.C. Cook Unit Two control room. The Simulator is to be used for the training of operators for both Unit One and Unit Two, with the operators being licensed to operate either unit (dual licensed).

1.1.3 Fidelity of Unit Two Control Room and Simulator

Both D.C. Cook control rooms were evaluated extensively within the scope of the Detailed Control Room Design Review (DCRDR), and all identified Human Engineering Discrepancies (HEDs) are being addressed and resolved in the context of the DCRDR. Considerable control room modifications, backfits, and enhancements resulted from the DCRDR to resolve significant HEDs. These modifications, backfits, and enhancements are being implemented consistently in both control rooms and in the Simulator. Thus the DCRDR work at D.C. Cook is an ongoing process. One of the goals of this process is to insure that the Unit Two control room and the Simulator are virtually identical with respect to control board fidelity.

1.1.4 Fidelity of Unit One Control Room and Simulator

The Simulator is also intended to represent a faithful simulation of the Unit One control room in all important respects, with a few exceptions. Since the Unit One and Unit Two control rooms were made to be as identical as possible through original design, DCRDR backfits, and operational enhancements, and since the Simulator has a high degree of fidelity to Unit Two, the Simulator also has a high degree of fidelity to Unit One, except for system differences and panel arrangement differences for some of the backpanels.

These system exceptions are related primarily to different turbine generator systems between Units One and Two, and other secondary side system design and piping differences between the Units. There are also a few minor differences on the primary side between the Simulator and the Unit One control room. To obtain certification of the Simulator as "plant reference" to Unit One, these differences were identified and evaluated to see whether or not such differences contribute to an increase in the probability of operator error in the actual Unit One control room.

1.1.5 Unit One RTP Program Differences

D.C. Cook has recently implemented a reduced temperature and pressure (RTP) program to extend steam generator life on Unit One. This RTP program has caused operating ranges, setpoints, etc., for some plant parameters on Unit One to differ from those on Unit Two. Several related modifications to procedures are being made to reflect these new parameter values. D.C. Cook is also developing a software module for Unit One Simulator training that will accurately model Unit One performance under the RTP program parameters.

1.2 Project Objective

To certify the Simulator as "plant reference" to Unit One, the Simulator was evaluated against Unit One in accordance with the requirements of Regulatory Guide 1.149 and ANSI/ANS-3.5, 1985. Other guidance (e.g., NUREG 1258) provides further direction on criteria for acceptability of the Simulator as "plant reference."

Because of the system differences between Unit One and Unit Two (and therefore between Unit One and the Simulator), and because of operational differences between Unit One and Two due to the Unit One RTP program, D.C. Cook decided to contract with AETA/SCI/Tech-U-Fit to conduct an assessment of the human factors implications of using the Simulator for Unit One operator training and examinations.

1.3 Regulatory Guidance

The following regulatory guidance and supporting documents were used in the present study:

- o 10 CFR Parts 50 and 55, Operator's Licenses and Conforming Amendments
- o NRC Reg. Guide 1.149, Nuclear Power Plant Simulation Facilities for Use in Operator Licensing Examinations
- o ANSI/ANS 3.5,1985, Nuclear Power Plant Simulators for Use in Operator Training
- o NRC Reg. Guide 1.8, Qualification and Training of Personnel for Nuclear Power Plants
- o NUREG 1258, Evaluation Procedure for Simulation Facilities Certified Under 10 CFR 55
- o NRC Form 474, Simulation Facility Certification.

2.0 PHYSICAL DIFFERENCES

Given the objective of identifying and documenting the physical differences between the Simulator and the Unit One control room, the principle methodological issue was to develop procedures to facilitate detailed comparisons between the two facilities.

The primary method of detecting Unit One and Simulator differences was through the comparison of recent photographs of the corresponding control room areas, primarily the control panel components. These photographs were taken in the Simulator on July 21, 1989, and in the Unit One control room on July 26,1989. When a difference was found between the photographs, it was recorded on a specific form as described later. In certain cases, such as with the annunciators, lettering was too small to be read from the photos. In this case, instead of photos, hardcopy diagrams of Unit One and Simulator annunciators were used for comparison. These hardcopy diagrams were validated against actual annunciator and status light tiles for about 200 out of the approximately 1200 entries on the diagrams for each facility. In Unit One, all 214 tiles examined were in exact correspondence with the printed layout. In the Simulator, three (3) minor discrepancies (abbreviations, word order, etc.) were found between the actual tiles and the printed layout in 245 comparisons. These discrepancies had been previously identified, and were immediately corrected.

In order to identify discrepancies which might impair Simulator effectiveness and produce possible negative transfer of training, virtually all discrepancies were documented and assessed. Major candidates for discrepancies included:

- o Displays
  - Meters: range, graduation marks, zone banding
  - Indicating Lights: color, size
- o Controls
  - J-handles, dials, knobs: size, shape
  - Pushbuttons: size, shape, color
  - Toggle Switches: type, size
- o Labels
  - Abbreviations, location relative to component, content differences
  - Size
  - Type of Font
  - Presence/absence of specific component
- o Component arrangement
  - Relative positions of components
  - Location of corresponding components on other panels
- o Miscellaneous Components
  - Phone
  - Alarms
- o Sequential arrangement of panels

2.1 Discrepancy Forms

The physical discrepancies between the Unit One control room and the Simulator were recorded on two types of forms. The first form was the General Component Discrepancy (GCD) Form. A copy of this form is given in Attachment 1. Discrepancies between components such as controls, displays, pen recorders, indicating lights, and a few miscellaneous items were recorded on this form. Basic information about the component (type, location, label, etc.) was recorded for its identification. Discrepancies were recorded in the spaces applicable to that particular component. Spaces which applied to the component but had no differences were left blank. In certain applications of the GCD form, several components were listed on the same form and total numbers of discrepancies were listed. Additional descriptions of the components were given in either the "Type" or "Comments" sections of the form.

The second form, the Discrepancy Form for Matrices, was used for documenting discrepancies only for annunciator panels, status lights and knife switches. A copy of this form is given in Attachment 2. Discrepancies for these components were recorded on these forms because of their matrix arrangement. The matrix form was designed to include information such as label, color, and location differences. As with the GCD form, information could be provided for several elements grouped together or for individual elements.

The GCD form and the matrix form were developed to accommodate the different types of components found in a nuclear control room. These two forms evolved from the forms suggested in NUREG 1258. They contain all the relevant information contained in the NUREG 1258 versions.

2.2 Evaluation Methodologies

2.2.1 Control Panels in Control Room

Materials. Large, color photographs (about 12" x 16") of the Simulator and the Unit One control room were prepared by D.C. Cook. Three types of photos were available:

- Overall view of the primary U-shaped space,
- Panel views from top to bottom usually showing several demarcated systems,
- Detailed panel views showing close-ups of components and labels.

The overall views served to locate and orient among the detailed panel views. Each photo was labeled with an identification number to serve as a reference on the discrepancy forms. The two forms were developed and executed on Q&A Version 3.0 (Symantec) software.

Procedures. To locate Simulator-Unit One differences, the photo of a Simulator panel area and the photo of the corresponding panel in the Unit One control room were placed side by side. Then the two photos were compared for differences in labels, components, etc. When a discrepancy was observed, it was recorded on the GCD form. This form could be used to record one or more discrepancies on one component, as well as one or more discrepancies which were shared by several components. In the latter case, for example, a group of J-handle controls in the Simulator was the same as a group of the J-handle controls in Unit One except that their identification labels were of a different size.

This form was also used to record more complex discrepancies. For instance, the Turbine panels in the Simulator and in the Unit One control room are very different from each other in terms of number of components and their arrangement. This situation did not allow a comparison based on the typical condition where all features of a component are the same except for just a few differences. A discrepancy on a panel such as the Turbine panel was often based on a comparison of component groups which had the same or similar function as determined by their labels. Such groups often had differing numbers of controls or displays. In addition, components with similar functions were often not in the same panel locations. The basic description of this type of discrepancy is sometimes located in the Comments section at the bottom of the discrepancy form.

With regard to recording physical differences on the General Component Discrepancy form, this form served two primary functions. The top portion of the form identified the component(s). The rest of the form identified the discrepant features of the components:

Discrepancy #: Discrepancy reports were recorded in serial order within each panel/system. Thus, the Reactor Coolant Pump panel (RCP) discrepancies proceed from 1 to 24 and the Turbine panel (T) discrepancies proceed from 1 to 62.

Panel: The panel being evaluated was indicated by an abbreviation. Thus, the Pressurizer panel was represented by "PRZ" and the Safety Injection System panel by "SIS". This abbreviation appears at the bottom of the actual panel in the control room. A detailed listing of the control panels and their abbreviations is shown in Attachment 3.

Photo ID: The Photo ID number refers to the photo on which the discrepancy was observed. The form provides a place for the Unit One (often referred to as "Reference" or "Ref") photo ID as well as the Simulator (or "Sim") photo ID. When both of these photos are accessed, the photos normally show very similar panel layouts. Differences in the photos were recorded as discrepancies. Occasionally, a photo ID space was not completed on the form. This occurred when a component was not present ("Does not exist") on one system panel, but was present on the other panel. If necessary, more than one photo ID would be placed in this space or additional photo IDs would be indicated in the Comments space.

Component Type: This field indicated whether the component being described was a light (indicating light), pen recorder, control, display or relay. A miscellaneous category was also included (phone circuit, clock, alarm, etc.). When more than one component of a given type was documented on a form, this field also indicated the number of such components. For instance, if six (6) displays were each discrepant, they would be indicated as:

Component Type: display(6)

In a few cases, a group of elements on a panel were considered as one component. This mostly occurred when indicating lights were placed directly above a J-handle or pushbutton.

Label and Identifier: This information provides the primary identification of the component. The label describes the plant system equipment and indicates the words and terms which are found near or on the component (e.g., MAIN GEN MW OUT). The label may also describe a system parameter (e.g., SPEED GOVERNOR PRESS). Note that capital letters are used to represent the actual label as found on the component. The identifier refers to the alpha-numeric description of equipment and its power supply (e.g., 1-SPI-300). When more than one component was being described on a single form, the first component and the last component in a sequence are indicated in these Label or Identifier fields. More detailed labeling and ID descriptions were indicated as space allowed.

The rest of the page provides for specific features about the components being evaluated (Parameter,...Legends/Symbols). These features were used in two ways. First, they can be used to further identify a component. Thus "Type" can further elaborate the component type as a "J-handle". The primary use of this feature, however, was to describe the discrepancy. On the same row as this feature are two fields, "Ref Type" and "Sim Type". When the type feature was used to document a discrepancy, the different type of component was indicated as:

Ref Type: J-handle
Sim Type: pushbutton

This system allows the reviewer to rapidly isolate the discrepant feature and to refer to the photo if further clarification is required.

To discriminate between the two uses of the features (i.e., further component identification vs. discrepancy identification), a "Y" (yes) or an "N" (no) was inserted after the colon following the name of the feature:

Type: Y
or
Label: N

The "Y" means that a discrepancy exists, in this case, in the type of component. With regard to the label, the "N" indicates that additional terminology was provided for component identification, but there is no discrepancy between the two labels.

The last category is "Comments". This field was used to describe non-typical discrepancies for which there were no identified features provided above. For instance, when a component on one panel did not have a corresponding component on the other panel, this condition was indicated in the "Comments" field. In addition, this particular comment about component absence was preceded and followed by three asterisks:

Comments: ***This control exists in the sim.
but not in the ref.***

Because the Simulator was modeled after Unit Two and being evaluated against Unit One, there were certain systematic differences in the labeling of equipment for which discrepancies were not identified. These conditions are listed below:

- Label differences specifying Unit One vs. Unit Two
- Label differences specifying North vs. South

- Same text on a label, but broken up differently from line to line:

  example: FUEL HLDG AREA EXHAUST FAN 2 / FUEL HLDG AREA EXHAUST FAN 2

- Manufacturing logos and/or labels

- Punctuation differences (presence/absence of periods, hyphens, parentheses)

- Slight difference in color shade which could be due to photo technique (e.g., as in color of bezels of a component).

The components on the relay panels (panels A-1 through A-15) were less complex and more amenable to a summary description. In recording relay panel discrepancies, the photos of the panels were laid side by side and observed for discrepancies in labeling and location of corresponding components. Also, any differences in the total number of components on each panel was examined. All of the discrepancies were recorded on the General Component Discrepancy form.

The Discrepancy # field contained the discrepancy number. All discrepancies on a relay panel were recorded on one form. Thus each panel had its own discrepancy number if it had one or more discrepancies. The Panel field contained the panel abbreviation. The Photo ID fields list one photo ID number for each unit, followed by an "*". The asterisk indicates that a complete listing of the photo ID numbers for the panel is found in the Comments field. All relay panels were of the "relay" Component Type. The Label field contains the name of the entire relay panel. The total number of labeling discrepancies was given in the Sim Com Labl field, and the total number of location differences was given in the Sim Location field. The total number of components found on each panel was indicated in the Comments field.

2.2.2 Annunciator Panels and Status Light Panels

Materials. The basis of comparison for the annunciator and status light panels were layout diagrams depicting their two-dimensional matrix arrangement. Each matrix window was identified by a drop number in the upper left hand corner of the window. The color of the window (Red, White, Amber) was indicated in the upper right corner. Each window presented the message shown on the annunciator window.

Procedure. The annunciator layout diagrams were provided by D.C. Cook. The revision dates ranged from 2/2/89 to 9/16/89. The hard copies were validated against the actual panel as described above. As in the comparison of panels, the corresponding matrix sheets for the Simulator and Unit One were placed side by side and examined for discrepancies in message content and terminology, window color, and window location. These discrepancies were then entered in the Discrepancy Form for Matrices.

The layout diagrams were used as worksheets. Discrepancies were indicated on both the Simulator and Unit One layout forms to identify the location of discrepancies. Discrepancies were documented in the following manner:

- o A circle was drawn around the drop number to flag any discrepancy in label content or color.
- o A square was drawn around the color indication of R, W, or A for a color discrepancy.
- o A square was drawn in the center-top of the window for a location discrepancy in which the same message had migrated to a different place on the corresponding panel. The new drop number was indicated inside this square.
- o A discrepancy in both the label and the color was indicated by a triangle around the color indication.

Text differences included a difference in wording, abbreviation or word order. A text difference also included the condition in which a message occurs only on one annunciator panel, but not on the corresponding annunciator panel in the other facility. A copy of the completed annunciator worksheets may be found in Appendix A.

The discrepancies were entered on the Discrepancy Form for Matrices. This form had space to enter 10 discrepancies. If more than 10 discrepancies were found, they were entered on a continuation form, labelled with an alphabetic suffix after the discrepancy number (e.g., "6A", "12B", etc.). At the top of the form, the discrepancy number was indicated. Following the discrepancy number and semi-colon is a number indicating the number of the annunciator. The status light panel is indicated by an alpha-numeric of varying length. This form has ten sets of repeated fields, each of which are identified by a drop number. The drop number is copied from the reference panel, not from the simulator. The presence of a discrepancy was indicated by a "Y" (yes) following one of the four characteristics of Label, Color, Param/Units and Location listed under the Drop #. Further description of the discrepancy is provided to the right for each of the four characteristics. For example, a label discrepancy can be described by the following item pair:

Ref Labl: EAST FPT OVERSPEED TRIP
Sim Labl: EAST FPT PRESS SETTER FAILURE

The label in the Unit One (reference) panel was always located on top and the Simulator label below. It was not necessary to use the Param/Units field.

To the far right are the terms RC and SC representing Reference plant color and Simulator color. Thus, an R following RC means that the particular tile in question is a red tile in Unit One.

R# and S# represent the drop number in the Reference and Simulator panels. If a number follows S#:, that number represents the location in that annunciator matrix to which the message has migrated. Thus migration or transposition of tiles is indicated by the presence of a number in this section.

The above description applies to the situation in which each drop number on the discrepancy form is dedicated to a drop number on the actual annunciator panel. Thus, if there were nine (9) windows with discrepancies on an annunciator panel, the matrix form would show nine sets of fields with indications. Individualized documentation for each annunciator tile was written for specific panels selected by D.C. Cook. These panels are shown below:

SIS	RHR	RCP	PRZ
FLX	RC	DTU	SG
FP	CP	SA	

The remaining panel annunciators were described in a more summary fashion on the same discrepancy form for matrices. According to this approach, the report lists the total number of label discrepancies found on a given annunciator or status light panel instead of specifying each label discrepancy. Similarly for the color and location features, only the total number of discrepancies is listed.

There is no difference in the manner of entry for Discrepancy # and annunciator ID. The ten sets of fields are used differently, however. If there are any label discrepancies, they are recorded in the first set of fields. The next type of discrepancy (e.g., color) would be located in the next set of fields. Location discrepancies are recorded in the third set of fields. In this format for grouped discrepancies, the number of differences are indicated in the simulator field, because the Unit One configuration is the reference condition. Since there were no "Param/Unts" discrepancies, only three sets of fields are used on the matrix form when annunciator/status light discrepancies are summarized or grouped. Status/monitor light panels were evaluated and documented in the same fashion as the annunciator panels. A copy of the completed worksheets for status/monitor lights is included in Appendix A.

2.2.3 Knife Switches

Materials. Knife switches are located on a variety of control room panels. Several switches are located or grouped together in one box. A layout diagram was developed directly from the control boards for each group. The main function of the diagram was to present the label for each switch and to indicate its relative position.

Procedure. Discrepancy identification proceeded by comparing corresponding forms for the Simulator and Unit One. The knife switches were examined for label content and terminology as well as for switch location. The discrepancies were then entered on the Discrepancy Form for Matrices. The comparison and documentation process was similar to the process used for the annunciators and status light boxes. The layout diagrams were developed specifically to record labeling and location information about the knife switches. This information was copied directly from the actual knife switch boxes in the Simulator and Unit One control room. Each knife switch in a box was assigned a number to allow for easier identification, and the boxes were placed into rows and columns on the layout diagrams to create a Matrix which preserved their actual order on the panels. On the layout diagram, each window represented one knife switch in a box and the number of the knife switch was indicated in the upper right hand corner.

Discrepancies were first recorded on the layout diagrams and were documented with the following symbols on each discrepant knife switch window:

- A line drawn diagonally through the number box indicated that the label text was different
- A circle drawn around the number indicated that a knife switch with the same message had migrated to a different location in the other unit. The corresponding location was indicated below the circle with the format: (row number, column number (e.g., 2,4 means the window in the second row in column four).

Individual knife switch labels were not considered to be different if their wording terminology were slightly different but the meaning was obviously the same. Abbreviation and punctuation differences were ignored. The main label difference, then, occurred when the text on one label appeared in one facility, but not in any recognizable form in the other. A copy of the completed knife switch worksheet layout diagrams may be found in Appendix B.

The Discrepancy Form for Matrices was used to record all knife switch differences. As the knife switch boxes were usually grouped together on a panel, each group was recorded on one form. At the top of the form, the Discrepancy # field gives the discrepancy number followed by the panel abbreviation and the numbers of the boxes recorded on the form or a brief description of the group location (B:bottom; L:left; R:right). Each of the ten sets of data fields on the form was used to record the discrepancies for one knife switch box. The Drop # field received the number of the knife switch box. This number was found on the label above the actual boxes in the two facilities. A "Y" (yes) in the label field indicated that there was at least one labeling discrepancy. The total number of discrepancies for that particular box could be found in the "Sim labl" field. A "Y" in the Location field indicated that at least one knife switch label had migrated to a different location between the two units. The actual number of location differences was recorded in the S # (Simulator location) field. The corresponding locations for the individual knife switches were not recorded on the form, but could be found on the layout diagrams. The two other fields on the form, Color and Param/Unts, were never used. The Comments field

was used to give further identification of the location of the knife switch boxes on the panel and also to give any information which was not specified in any of the other fields.

2.2.4 Hot Shut Down Panel

Materials. The materials consisted of photographs and diagrams. For this panel, a photomosaic was made for evaluation of larger characteristics such as component arrangement. To compare labels, a diagram of the Unit One panel was developed to include label names which could then be compared to the Simulator panel. For certain details which could not be determined from the photographs (e.g., scale markings) a special diagram was prepared.

Procedure. The photomosaics were compared for the presence/absence of components, component arrangement, large labels and other large features. The Unit One diagrams were compared against the Simulator panel for label and scale discrepancies. Discrepancies were recorded on the General Component Discrepancy Form in the same manner as the other control panels in the control room.

2.2.5 Consoles and Desks

The items evaluated were the Operator Console, the Computer Operator's Console and a large, U-shaped desk used for storage of documents and CRT use. The computer printer station was not evaluated because it will soon be replaced.

Materials. The operator consoles/stations/desks in the center of the horseshoe panel were photographed in the Simulator and Unit One. The photos presented several views of the desks.

Procedure. The photos were evaluated for discrepancies concerning such items as number location of telephones, CRTs, and labels.

2.3 Results

The basic output for the identification of physical differences in this study were discrepancy report forms documenting all differences observed in the comparison of the Simulator with the Unit One control room. Note that the discrepancy report form allows the entry of more than one discrepancy for any given component and that the form allows more than one component to be described. Consequently, the number of actual discrepancies is greater than the number of discrepancy report forms. Thus it may be difficult to say that one panel has more discrepancies than another panel based solely on the total number of discrepancy reports for those panels.

The numbers of discrepancy reports executed for each panel are shown in Attachments 3 & 4. Attachment 3 indicates the number of discrepancies for controls and displays for each of the system panels in the Simulator. The panels are listed in sequential order by panel name and panel abbreviation. The total number of discrepancy reports was 738 for all of the panels, excluding

discrepancies for annunciators, status lights, monitor lights and knife switches. This number of discrepancy reports was from a total of 5,242 control and display components counted on all of the panels listed (exclusive of annunciators and labels). Attachment 4 indicates that there are 2,523 annunciator/status/monitor light tiles in the Simulator, for a total of 7,765 controls, displays and lighted tiles in the facility. To this number must be added at least an equal number of labels as there are controls and displays (5,242), for a grand total of about 13,007 components in the Simulator.

The number of discrepancies for the annunciator tiles, status lights and monitor lights is shown in Attachment 4. The annunciator tile, status light, and monitor light matrices are listed in numerical order and by name and number. Separate columns show the number of discrepancies associated with each matrix. The total number of annunciator/status light/monitor light discrepancies was 604. Knife switches were counted separately, as shown in Attachment 5. The total number of knife switch discrepancies was 113.

The distribution of the types of discrepancies found on the controls and displays (exclusive of annunciators/lights/knife switches) around the system panels may be found in Attachment 6. Inspection of the types of discrepancies indicated that a very large portion of the actual discrepancies were written concerning differences in various kinds of labels including component labels, identification labels, system labels, and unit labels (514 total). Also many discrepancies reports concerned minor differences in the color and shape of bezels (105 incidences) There were altogether 619 of these labeling and minor bezel discrepancies. The fact that the total number of discrepancies listed in Attachment 6 (967) exceeds the total number of discrepancy report forms found in Attachment 3 (738) merely indicates that more than one discrepancy was often noted on a single discrepancy report form. If all noted discrepancies for the entire Simulator are lumped together, the total number is 967 for controls and displays and 712 for annunciators (lights) knife switches, for a grand total of 1,684 noted discrepancies. These 1,684 discrepancies are from a total of 13,007 identified components in the control facility.

2.4 Summary of Physical Differences

From the above results of the survey of physical differences between the Simulator and the Unit One control room a total of 1684 discrepancies was found. Annunciators/status lights/monitor lights and labels could be lumped together as textual displays whose differences could be considered relatively minor, since the operator can always read the meaning. If this is done, 1118 discrepancies may be subtracted from the total of 1684, leaving 566. From this total minor differences in bezels and knife switch notations can produce a further reduction by 218, to a total of 348 discrepancies. Thus, after such an *a priori* elimination process, only 348 discrepancies remain which might be considered candidates for producing training and/or transfer of training problems. Furthermore, the vast majority of these discrepancies represent minor and trivial differences. Nevertheless, all of the noted discrepancies (1,684 instances) were considered in the Assessment phase of the present study, not just the 348 most likely candidates.

3.0 ENVIRONMENTAL MEASUREMENTS

The environmental parameters in the Unit One control room and in the Simulator were assessed by means of physical measurements. The major environmental parameters measured in the present study were lighting, acoustics and temperature/humidity.

3.1 Lighting Measurements

Lighting measurements consisted of two basic quantities: (1) illuminance, the light falling on objects, and (2) luminance, the light coming from objects, either by reflection or directly from an extended luminous source. Illuminance measurements were taken in foot-candles (fc) by a Photo Research, Lite Mate III Photometer, Model 504, with a cosine-corrected illuminance probe. Luminance measurements were taken in foot-Lamberts (fL) by the same Photometer with a Photo Research, Spot Mate, Model 502, 1-degree spot luminance probe. For illuminance measurements the probe was positioned on the center of the surface being measured, facing away from the surface. Luminance measurements were made from a small surface area subtending about 1 degree of visual angle at a distance of about 2 feet. All instruments were calibrated according to the manufacturer's recommendations.

The nineteen (19) locations at which lighting measurements were taken in the Simulator and in the Unit One control room are shown in Attachments 7 and 8 respectively. Two kinds of measurements are reported: (1) control panel or desk measurements of illuminance and luminance at the approximate middle of the panel or desk (looking straight ahead, standing or seated), designated "AHEAD"; and (2) measurements of illuminance falling on a hand-held writing pad oriented at about 30 degrees from the horizontal and about 4 feet above the floor, designated "PAD". Lighting measurements were conducted under normal and emergency lighting conditions. Not all measurement locations were utilized in making luminance measurements under emergency lighting conditions.

Attachments 9 and 10 show the illuminance measured for the "ahead" and "pad" orientations at each measurement location under the normal and emergency lighting conditions respectively. The average illuminance values reveal that the "pad" measurements are generally higher than the "ahead" measurements, and that the Simulator is always considerably brighter than the Unit One control room. Attachment 11 shows the magnitude of the differences in illuminance between the two facilities (about 10 to 20 foot-candles of incident light on the average). Attachment 12 and 13 show the panel luminance measurements for each location and the differences between the Simulator and Unit One. Once again, on the average, the panels in the Simulator are brighter than the panels in the Unit One control room, this time by about 5 to 7 foot Lamberts of reflected light.

When one takes into account the scale differences, the variability is generally greater for the "pad" as opposed to the "ahead" orientation. Individual locations near the desks at the center of the room (locations 1-5) and at the back panels (locations 15 and 16) show unusually large variation. Much of the diminished illumination observed in the Unit One control room was due to numerous lamps being burned out in that facility.

3.2 Acoustic Measurements

Acoustic measurements consisted of two basic quantities: (1) weighted sound levels that integrate acoustic energy from different frequencies in a specified manner, and (2) octave band levels which indicate the amount of acoustic energy in different parts of the frequency spectrum. Both types of measurements were made with a single instrument, the Ivie Model IE-10A Sound Level Meter and Octave Band Analyzer. This instrument was calibrated by means of a Burel & Kjaer Model BK 4230 Sound Level Calibrator. All measurements were made with an integral random-incidence microphone positioned at a height of about 5 feet above the floor (approximate ear height). C-weighted sound levels were taken to approximate the physical acoustic environment, with all audible frequencies equally weighted except extremely high and extremely low frequencies. A-weighted sound levels were taken to approximate how the human listener might perceive these sounds, with the various frequency components of the sound weighted according to the appropriate sensitivity of the human ear. Octave band pressure levels were measured to provide information on the shape of the acoustic frequency spectrum emanating form various sound sources. All measurements were expressed in decibels (dB) re 20 micro Pascals.

Sixteen (16) locations at which acoustic measurements were taken in the Simulator and in the Unit One control room. Complete data were collected only for locations 1 through 13. Acoustic measurements were made in Unit One under noisy conditions at the beginning of the day shift with a relatively large number of people in the control room (about 7:00 a.m. on August 19, 1989) and under quiet conditions during the backshift with a relatively small number of people in the control room (about 5:00 a.m. on the same day). Acoustic measurements were made in the Simulator only during relatively quiet conditions during the morning of August 18, 1989 (about 10:00 a.m.) Acoustic measurements were also made of auditory alarm signals in both Unit One and the Simulator.

There was very little difference in either the A-weighted or C-weighted sound level between noisy and quiet conditions (about 56 to 58 dBA and 73 to 74 dBC), despite the fact that the number of people in the facility was more than double during the noisy period. Acoustic measurements made in the Simulator under quiet conditions with virtually nobody present in the room. Under quiet conditions the Unit One control room is more noisy than the Simulator by about 8 dBA or 17 dBC.

The shapes of the sound spectra observed for the two facilities under quiet conditions revealed the minimum octave band measurement obtained in each facility. These measurements represent a sort of noise floor below which the ambient octave band levels are not likely to penetrate. On the other hand, the average sound spectrum reveals little difference between the minimum and average "quiet" sound spectrum for each facility.

In all cases the spectrum is dominated by low frequency building sounds below 250 Hz, rather than speech spectrum sounds in the region from 200 to 1000 Hz. However, the sound spectrum for Unit One has progressively more low frequency sound energy than the spectrum for the Simulator. The shapes of the spectra do not differ greatly from those for the average "quiet" spectra, except that slightly more acoustic energy can be observed in the speech range, showing the effect of intermittent human speech sounds.

Acoustic measurements of the sound levels produced by auditory alarms were taken at a location near the center of the room. In all cases except one, the alarm was considerably more intense in Unit One that in the Simulator (by about 9 to 18 dB). The only exception was the telephone, which was virtually the same in each facility. They all have a similar spectrum shape in both facilities, only four of the five alarms were considerably louder in Unit One than in the Simulator. Measurements were taken near the control room door in Unit One with the door open. The results of such measurements taken in the Simulator with the door open and the artificial, simulated external noise source generator turned on. In this case, not only is the sound level altogether too low in the Simulator, but the sound spectrum shape for the Simulator does not adequately model that for Unit One.

3.3 Temperature/Humidity Measurements

Measurements of temperature and humidity were made in the Unit One control room and in the Simulator. These measurements were made on the morning of August 19, 1989, by means of a Webster Instruments sling psychrometer. As concerns ambient dry bulb temperatures, both facilities were virtually the same. There was, however, a slight difference in the measured wet bulb and relative humidity values.

3.4 Summary of Environmental Measurements

The environmental measurements generally showed that the Simulator was brighter than the Unit One control room, that the Unit One control room was more noisy than the Simulator, and that the temperature was the same, but the relative humidity was slightly higher in Unit One. In addition, auditory alarms were generally louder in the Unit One control room than in the Simulator.

4.0 OPERATOR INTERVIEWS

4.1 Objective

The objective of the operator interviews was to obtain information and opinions from control room operators at the D.C. Cook Nuclear Plant regarding the physical hardware differences between the Unit One control room and the Simulator as well as the potential significance of these differences for control room operation and training.

The major differences of interest included the presence or absence of controls and displays, the arrangements of component groups and labeling. Potential issues of software fidelity or Simulator response dynamics were not in the scope of the present analysis.

4.2 Method

Operator responses were assessed through structured interviews by means of an Operator Interview Form. An example of this Operator Interview Form may be found in Appendix C. All of the operators interviewed had current licenses. They had varying degrees of experience. Except for three, all interviews were conducted in the Unit One or Unit Two control rooms or the Shift Supervisor's office. This feature allowed the operators to refer directly to a particular component, panel or item when desired. The other three interviews were conducted in the training building. The settings were quiet and comfortable. There was no time constraint except from the shift supervisors.

The interview began with a brief introduction stating the objective of the study and that the operator's responses would remain anonymous. The first section of the interview developed background information regarding experience as a dual licensed operator at D.C. Cook. Then the operator was asked a variety of questions designed to determine whether the Unit One vs. Simulator differences had any significant effect on training, examinations or control room operation, or whether these differences might be likely to have such an effect in the future. The questions were open-ended to allow flexibility in responses. Some questions asked the operators to estimate the intensity of their responses on a rating scale. Other questions asked about the operator's direct experience, while some questions asked the operator to speculate about certain hypothetical situations. At the end of the interview, operators were given an opportunity to propose modifications to resolve Unit One vs. Simulator differences. The operators were also encouraged to comment on differences that may not have surfaced during previous questions.

4.3 Results

4.3.1 Operator Characteristics

Seventeen (17) operators were interviewed. All interviews were with a single operator, except for paired interviews with Shift Supervisors and Assistant Shift Supervisors. The typical length of an interview was about one hour.

Results of the initial interviews indicated that for certain questions, when discussing the significance of Unit One vs. Simulator differences, it was important to specify whether normal procedures, emergency procedures or abnormal procedures were being practiced on the Simulator, and whether these procedures represented Unit One or Unit Two. The interview forms were later modified to more accurately indicate this sort of context (see Appendix D for an example of the modified form).

The average operating experience for the sample (after obtaining the license) was slightly over four years, with a range of three months to twelve years. Operators tended to equally divide their time in the plant between the two units. Most interviewees indicated that they will work on one unit for two weeks and then work on the other unit for two weeks. Only two of the interviewees had trained on the Simulator in preparation for their licenses. Nevertheless, the entire sample of operators had spent a number of hours working in the Simulator in the past 6 months. Operator estimates for the proportion of Simulator time spent on Emergency Operating Procedures (EOPs) ranged from 70% to 90%. The remaining time was devoted to normal and abnormal procedures. Of the total Simulator time, approximately two days had been spent on Unit One training.

Thus, the large majority of Simulator training up to the time of the present interviews had been devoted to Unit Two EOPs. A Background Questionnaire was filled out by all of the operators who were interviewed. The results of this questionnaire may be found in Appendix E.

4.3.2 Operator Comments

When asked to rate the similarity between the Simulator (Sim) and the Unit One (U1) control room on a seven-point scale (1=identical panels, 7=no similarity), operators responded with an average rating of 3.2. This rating represents a moderate degree of judged similarity. The operators also listed the control room panels which they felt exhibited the most U1-Sim differences. The panel areas mentioned most frequently were the Turbine Control/Turbine Aux. panel, Feedwater Heaters and the Main Feed Pumps. Little or no mention was made of panels on the primary side. Additional operator comments from different portions of the interview discuss the heaters:

- The switch positions on the heater drain panel have a high likelihood of causing an error, especially for new operators during a transient.
- The heater drain pumps were identified as requiring extra alertness to locate them after working on Unit Two.
- On Unit Two, the components for the heater pumps and discharge valves are on top of the panel; On Unit One the controls are on the bottom. After switching units, this can result in a delay of a few seconds.
- Concerning the Feedwater Heater panel and MSR section, some of the operators are glad that the Simulator duplicates Unit Two instead of Unit One - They feel that if one can operate Unit Two, then Unit One should not cause serious problems.

EOP Training. Operators were asked whether Unit One vs. Simulator differences would cause problems in EOP training. All of the operators answered "no". However, some qualifications were mentioned:

- o It would be necessary to be aware of RTP differences.

- o If a reactor trip were not completed, it might be necessary to trip feedpumps on the secondary side, which involves Unit One - Simulator differences.

- o If you don't get a turbine trip in an EOP, you need to trip the high pressure oil pumps and these vary between Units One and Two.

- o The crossover switches for the heater drains are in the EOPs and they vary between the Units.

Normal and Abnormal Procedures. Operators were also queried in regard to normal and abnormal procedures. Before the Simulator was available, an SRO would usually handle all of the secondary panels. When the Simulator became available, the SRO would allow some of these actions be handled by an RO. Ten out of ten operators indicated that it would be desirable to train on normal and abnormal procedures as well as on EOPs. However, eight of these operators predicted difficulty in training for Unit One normal and abnormal procedures on the Simulator because these procedures tend to require those secondary panels which exhibit U1-Sim differences. Several operators volunteered opinions on this item. They felt that training for start-up and shut-down would not be practical. Similar reactions were obtained for Turbine, MSR and Feedpump operations.

Although one operator thought that it would be possible to pretend to be in Unit One while performing normal procedures in the Simulator, several operators thought this would be difficult. One operator said that he doesn't want to go to (the Unit Two) Simulator and pretend he is in Unit One.

4.3.3 Additional Comments

- o There is no way to deal with this if one is trying to train specifically for Unit One.

- o If the Simulator is being used for Unit One training and some components are missing, the procedural sequence would be interrupted randomly. This would cause continuity to be broken in the procedure which would be bad for training.

- o It would be better to do "walkdowns" on Unit One normal procedures than to train on the Simulator for these procedures.

- o One operator thought it would only be possible to train on the primary side for normal procedures.

Operators also gave an indication of which panels were likely to cause difficulty in practicing Unit One normal procedures on the Simulator. Panels that would cause difficulty or would need to be modified for Unit One normal procedures included the Feedwater Heater panel, Feedpump panel, Electric panel and the Turbine and DTU panels. Additional comments about specific panels were also offered by the sample of operators:

- The heaters and MSR are so different, its hard to imagine training Unit One on the Simulator.
- The feedpumps require mental transformation of labels.
- A lot would have to be changed to make it work, i.e. the panels starting with DTU and proceeding to the Turbine panel would have to be changed appropriately.
- If the Simulator is used to simulate Unit One (e.g., Lube Oil pumps), then there would be confusion.
- One cannot train at all on the Simulator for the Turbine and MSR panels on Unit One.

4.4 Summary of Operator Interviews

The panels which are most different between the Unit One Control Room and the Simulator are on the secondary side. Since the panels on the primary side are more similar, and since the EOPs require mostly primary panels, the Simulator was judged by operators to be effective for training and examining on EOPs for both Units One and Two.

The operators would also like to train on the Simulator for normal procedures such as start-up and shut-down. Since these procedures heavily involve the secondary panels, operators expressed the opinion that training on normal procedures may not be practical due to the large number of Unit One vs. Simulator differences.

5.0 ASSESSMENT

Each of the 1684 discrepancies identified was assessed to determine whether the discrepancy would be corrected, or whether, if it were not corrected, the discrepancy might cause a significant problem for training or examination. If the discrepancy were not going to be corrected, an assessment was made to determine the probability that a specific discrepancy might cause a negative transfer of training error on the part of an operator, what kind of an error might be induced in the operator's behavior and what would be the possible consequences of such an error. A Simulator/Unit One Discrepancy Assessment form was developed for this purpose, and an Assessment Panel was convened to implement the assessment process.

5.1 Assessment Form

The Simulator/Unit One Discrepancy Assessment form was designed to formalize the process of assessment and provide a consistent format for the assessment portion of the physical discrepancy data base. A separate Assessment form was executed for each discrepancy form generated during the identification of physical differences. An example of this Assessment form is shown in Attachment 14. After identifying the Discrepancy Number and Panel name, the Assessment Panel answered the following questions:

1. Will D.C. Cook agree to take corrective action to make the Simulator match Unit One for this discrepancy? If so, the discrepancy would effectively disappear, and the Panel would skip to the Assessment Category section of the form. There category number three (3) "no significant effect" would be checked, and approval would be noted along with the approval date.

2. Could training with this discrepancy cause a negative transfer of training error? Here, a "negative transfer of training error (NTT)" was defined as an error committed by an operator while operating in the Unit One control room, such that a strongly indicated cause for that error could be training or examining of that operator on Unit One procedures administered in the Simulator. If the answer were "no", i.e. no negative transfer of training error could be identified, the Panel would once again skip to the Assessment Category section, check number 3, and approve the action. If the answer were "yes", the Panel would continue to fill out the rest of the form.

3. What is the possible behavioral error due to negative transfer of training? If a possible NTT error could be readily identified, what would be the worst such error that could occur? For example, the operator could misread or misinterpret the information contained on a given display. Or the operator could activate the wrong control.

4. What is the predicted likelihood of such a negative transfer of training (NTT) error occurring? Here the Panel used a seven-point rating scale from "definitely not" to "definitely" to indicate its judgment as to the likelihood of such an error.

5. What might be the worst consequences of such an NTT error? For example, the operator could act upon or transmit the wrong information. Or the operator could open instead of close a given valve.

6. What might be the effect of such an NTT error, if one assumes the worst consequence? For example, the operator could act as if there is sufficient core coolant when there really is not. Or the operator could close the valve to restore core coolant instead of opening it.

7. What is the assumed scenario for the determination of safety and/or operational consequences or effects? For example, the above consequences and effects could be assumed during a Loss of Coolant Accident (LOCA) scenario.

8. What is the possible effect of the identified NTT error on any Critical Safety Function (CSF) at the plant? A plant-specific definition of a "critical safety function" may be found in the Appendix F. First, it was decided whether any CSF at all was involved in operating a given panel, group of components or individual component. If a significant CSF could be identified, the Assessment Panel determined how the particular NTT could affect that or any other CSF at the plant. This determination was made on a seven-point rating scale from "no effect" to "prevents restoration" of the CSF.

9. What is the possible effect of the identified NTT error on plant operations? Here, it was assumed that no CSF was involved. The Assessment Panel used a different seven-point rating scale to estimate operational impact ranging from "no effect" to "extended loss of plant function".

The above nine (9) items completed the formal assessment of possible problems that could be caused by identified physical discrepancies between the Simulator and the Unit One control room. The remainder of the form was devoted to the disposition of each discrepancy. In this portion, the Assessment Panel assigned a category for each discrepancy depending upon its effect on plant safety or operations. The categories were:

1. Training with this discrepancy could directly challenge or cause a loss of CSF.

2. Training with this discrepancy could adversely affect normal plant operation.

3. Training with this discrepancy would have no significant effect on plant CSF or operation.

Any comments that were needed to explain the assessment action were noted, as well as any suggestions for corrective action which would lessen the possible negative consequences of a given discrepancy. Finally, approval of the assessment action was indicated by the Panel, along with the date of approval. For the purpose of entering the results of the assessment process into the computerized data base for the study a summary version of the Assessment form was developed.

5.2 Assessment Panel

The Assessment Panel met between November 13 and November 16, 1989. The composition of the Assessment Panel is given in Attachment 15. A permanent body of 4 to 5 individuals from the first group of names in the attachment was always present during Panel meetings. There were also always present one or two licensed reactor operators from the second rotating group of names in the attachment. The answers to each question were discussed openly among all members present on the panel at the time. The final wording for each entry on the form, as well as the final disposition for each discrepancy, was always arrived at by group consensus. Any disagreements were resolved or compromised through group discussion. Every member of the Panel present agreed with the outcome of every assessment.

5.3 Results of Assessment

Just as in the identification of discrepancies, for statistical purposes, the minimum divisible unit for assessment was a single discrepancy report form. Since more than one physical difference may be described on a single report form, statistical statements about numbers of discrepancies do not always accurately reflect the precise number of physical differences involved. Nonetheless, such statements can provide valuable comparative information.

Each of the 1684 discrepancies identified was assessed. Of these discrepancies, the majority were labelling differences and slight or insignificant color differences in bezels, needle pointers, etc. Labelling and minor color differences accounted for about two thirds of the total number of non-annunciator discrepancies. Of these 619 labelling and color differences, D.C. Cook has agreed to make the Simulator match Unit One in most cases. The remaining cases of labelling and minor color differences were all judged by the Assessment Panel not to cause any NTT error. They were all assigned to category 3, "no significant effect on plant CSF or operations." Other minor labelling differences that were summarily dismissed as category 3, having "no significant effect," were:

1. Singular vs. plural designations on labels
2. Size of lettering on eschutsion plates
3. Horizontal vs. arched vs. vertical lettering
4. Calibration stickers (all will be removed)
5. Operator aids, if in Unit 1 and not in Sim.
6. Power supply (identifier) label differences.

The detailed results of all of these judgments may be found in Appendix G, which constitutes the Book of Discrepancy Reports and Assessments, the main database produced by the present study.

Thus, many discrepancies were either slated to be fixed or summarily dismissed as insignificant based upon one of the rules stated earlier. The remaining discrepancy reports were each individually assessed by the Panel on a case by case basis. The first step was to determine whether any negative transfer of training (NTT) error could be readily associated with the discrepancy. If an NTT error could be identified, certain general rules were applied to assist in the process of determining the significance or consequence of each discrepancy and its associated possible error(s). The discrepancy and/or error was judged to be less important if:

1. No critical safety function (CSF) was involved.

2. The procedure was easier to execute on Unit One than on the Simulator.

3. There were no panel components in the Unit One control room that were not in the Simulator.

4. Physical differences stood out clearly and were easy to remember without confusion.

5. Unit One was less complicated than the Simulator.

6. No new procedures would be added when transferring procedures from the Simulator to Unit One.

7. Unit One procedures could be readily used on the Simulator without modification, only deletion of steps.

8. Mirror-imaged backpanels are highly varied and differences stand out between Unit One and the Simulator.

9. Rows or columns of components or tiles may be laterally shifted but logical arrangement is maintained.

10. Annunciator/status tiles must be individually touched to acknowledge.

11. Knife switches are basically functionally arranged in columns.

12. Two identically located controls for the same function are activated in the same direction in both facilities.

On the other hand, the discrepancy and/or its associated possible NTT error(s) were judged to be more important if:

1. One or more Critical Safety Functions (CSFs) were involved.

2. The procedure was harder to execute on Unit One than on the Simulator.

3. There were panel components in the Unit One control room that were not present in the Simulator.

4. Physical differences did not stand out clearly and were easily confused.

5. Logical order was not maintained in the shifting of rows and columns of components or tiles.

6. Two identically located controls for the same function are activated in opposite directions in Unit One and in the Simulator.

Each of the remaining discrepancies or group of discrepancies was judged panel by panel according to the above criteria in order to determine the final category of assessment. For the total of 1684 discrepancies, the following assessment categories were assigned:

Category Number	Number of Cases
1	0
2	5
3	1679.

The 5 discrepancies that were judged to be in category 2 were all found on only two control panels: Feedwater Heaters/MSR (C-3) and Turbine Auxiliaries (T-2). Although these 5 category-2 discrepancies were judged to be capable of adversely affecting normal plant operations, none of them were judged to be capable of directly challenging or causing a loss of any Critical Safety Functions (CSFs) at the plant.

The situation portrayed above only holds if a large number of minor modifications are made to the Simulator and a few modifications are made to the Unit One control room. All of these modifications were committed to by the D.C. Cook Nuclear Plant. Besides large numbers of label changes and minor color changes on bezels and pointer needles, the following are some significant corrective actions that will be taken to make the Simulator match the Unit One control room:

1. Add dimmers to the Simulator lighting system

2. Reverse QRV 171 switches on the BA panel to operate in the same direction.

5.4 Summary of the Assessment Process

Although 1684 physical discrepancies were identified between the Simulator and the Unit One control room, the overall assessment process showed no discrepancies that would be likely to directly challenge or cause the loss of a CSF in Unit One due to training on the Simulator. Only 5 discrepancies might adversely affect normal plant operations in Unit One due to Simulator training. These adverse effects can be minimized or eliminated by specialized, separate training to sensitize operators to their presence. The majority of discrepancies would have no significant effect on plant CSFs or operations.

6.0 OVERALL CONCLUSIONS

The overall conclusions that may be drawn from the present study are the following:

1. A methodology was developed to identify and document the physical differences between the Simulator and the Unit One control room. This methodology was based upon detailed photographs of each facility, careful scrutiny of the photographs and a system of computerized discrepancy report forms.

2. The results of this methodology yielded the identification and documentation of 1684 discrepancies between the two facilities. The vast majority of these discrepancies concerned annunciators, labels, and minor bezel differences, leaving 348 remaining discrepancies.

3. Environmental measurements demonstrated that the Unit One control room was somewhat darker, noisier and more humid than the Simulator. These discrepancies were all either judged to be minor or were agreed to be corrected by the utility.

4. Operators who were interviewed as a part of the study indicated that the Simulator was effective for training on Unit One Emergency Operating Procedures (EOPs), since the primary sides were quite similar between the two facilities. However, since the secondary sides were somewhat different, operators felt that training on certain Unit One normal procedures might not be practical in the Simulator.

5. The 1684 discrepancies uncovered in the course of the study were all evaluated by an Assessment Panel of experts in operations, training, engineering and human factors. The panel employed a formal assessment algorithm which revealed no challenges to Critical Safety Functions (CSFs) by training on the Simulator, and only 5 adverse effects upon plant operations. This situation only holds if the utility makes a significant number of minor corrections in the Simulator.

6. A program of modifications to enhance simulation fidelity, specialized instruction to minimize negative transfer of training and sensitivity to physical and functional differences can minimize the negative impact of those discrepancies that remain.

7. Therefore, as far as physical differences between the two facilities are concerned, the overall conclusion of the present study is that the Simulator at D.C. Cook may be used adequately to train and examine on EOPs for the Unit One control room. The Simulator may also possibly be used to train and examine on normal operating procedures for Unit One, provided that such procedures do not depend heavily upon functions located on the Secondary Side of the plant.

SIMULATOR/UNIT 1 DISCREPANCY ASSESSMENT

Discrepancy #: _____

Panel : _____

Corrective action will make simulator match Unit 1: Y N

Training with this discrepancy could cause a negative transfer error: Y N

Possible behavioral error due to negative transfer of training (NTT):

Likelihood of error:

Cat. 3 | Cat. 1 or 2

Def. not	Very unlikely	Unlikely	Maybe	Likely	Very Likely	Definitely

Consequences of NTT error:

Effect of NTT error:

Assumed scenario:

Effect of NTT on Critical Safety Function (CSF):

Cat. 2 or 3				Cat. 1		
No Effect	Potential Reduction to CSF Maint. Resource	Reduced CSF Maint. Resource Capability	Loss of CSF Maint. Resource	Challenge to CSF	Loss of CSF	Prevents Restoration

Effect of NTT Error on plant operations:

Cat. 3					Cat. 2	
No Effect	Requires Additional Steps	Reduction in Oper. Perform.	Loss of Component Function	Loss of System Function	Extended Loss of System Function	Extended Loss of Plant Function

Assessment Category:

_____ 1. Training with this discrepancy could directly challenge or cause a loss of CSF.

_____ 2. Training with this discrepancy could adversely affect normal plant operation.

_____ 3. Training with this discrepancy would have no significant effect on plant CSF or operations.

Comments:

Approved by Committee: Y N

Approval Date: _____

CRITICAL SAFETY FUNCTION DEFINITION

Critical Safety Function (CSF) Controls and Indication:

Any control or indication which is used in identifying or mitigating a challenge to the Critical Safety Functions as defined by the Westinghouse Owners Group (WOG) Emergency Operating Procedures. Additionally CSF controls and indications are any controls or indications which through misinterpretation or misoperation could lead to a transient which would challenge the WOG CSFs.

WOG Critical Safety Functions:

Subcriticality
Core Cooling
Heat Sink
Integrity
Containment
Inventory

SIMULATION FACILITY CERTIFICATION

Accession # 9009050394

INSTRUCTIONS. This form is to be filed for initial certification, recertification (if required), and for any change to a simulation facility performance testing plan made after initial submittal of such a plan. Provide the following information, and check the appropriate box to indicate reason for submittal.

FACILITY	DOCKET NUMBER
COOK NUCLEAR PLANT	50- 316
LICENSEE	**DATE**
INDIANA MICHIGAN POWER COMPANY	8/24/90

This is to certify that:

1. The above named facility licensee is using a simulation facility consisting solely of a plant-referenced simulator that meets the requirements of 10 CFR 55.45.
2. Documentation is available for NRC review in accordance with 10 CFR 55.45(b).
3. This simulation facility meets the guidance contained in ANSI/ANS 3.5, 1985, as endorsed by NRC Regulatory Guide 1.149.
   If there are any exceptions to the certification of this item, check here [X] and describe fully on additional pages as necessary.

NAME *(or other identification)* AND LOCATION OF SIMULATION FACILITY

COOK TRAINING CENTER
ONE COOK PLACE
BRIDGMAN, MI 49106

[X] SIMULATION FACILITY PERFORMANCE TEST ABSTRACTS ATTACHED. *(For performance tests conducted in the period ending with the date of this certification)*

DESCRIPTION OF PERFORMANCE TESTING COMPLETED *(Attach additional page(s) as necessary, and identify the item description being continued)*

BY DELIVERY IN PERSON TO THE NRC OFFICE AT: One White Flint North
11555 Rockville Pike
Rockville, MD

COOK PLANT SIMULATOR

EXCEPTIONS TO ANS 3.5 AND/OR REG GUIDE 1.149

1. (ANS 3.5 - 3.2.1) Currently the reference plant process computer is not replicated on the simulator. The Unit 2 plant process computer is being replaced during the 1991 refueling outage. The replacement plant process computer hardware is on site and being integrated into the simulator at this time. Scheduled implementation is by the last quarter of 1991.

2. (ANS 3.5 - 3.2.3) The reference plant wireless telephone equipment is not currently replicated in the simulator. A facsimile of this equipment has been ordered and will be integrated into the simulator during the last quarter of 1990.

COOK PLANT SIMULATOR

GENERAL INFORMATION

The Cook Plant reference plant simulator functions to provide training for both Units of the Cook Plant. Unit 1 certification is provided in a separate report. The simulator is modelled to the Cook Plant Unit 2 and modified to support training on Cook Plant Unit 1.

The simulator incorporates several advanced models to increase simulator functional fidelity as listed below:

The reactor coolant system thermal hydraulic model is the Singer Link RETACT (Real Time Advanced Core and Thermohydraulic Code) model that provides best estimate prediction capability for the analysis of normal and abnormal operating conditions.

The RETACT code will predict parameters not only observable from the control room, but also key parameters such as fuel center line temperature, peak cladding temperature, DNB ratio, coolant mixture level and generation of non-condensable gases, including fuel melt with generation of hydrogen.

The reactor core neutronic model, Singer Link's Space-Time Kinetics (STK) code, is an advanced three dimensional multi-node model which calculates the reactor power distribution using a one-group, adiabatic space-time kinetics model. The core is divided into six axial meshes and 25 azimuthal meshes for a total of 150 regions (nodes).

The core model fidelity was further increased by AEPSC nuclear fuel engineers, Cook Simulator Software and Singer Link engineers after delivery to include each fuel assembly exposure and to increase the number of fuel types from 6 to 13. This provided better neutron flux and delta flux distribution and rod worth.

Cook Simulator software engineers increased the feedwater system fidelity by complete modelling of the feedwater level control system and transmitter noise. This has greatly enhanced the operator responses to feedwater transients in the plant.

Plant operations from cold shutdown and the Reactor Coolant System drained to half loop conditions (Mode 5) to 100% power, including reactor coolant system fill and vent, heatup, cooldown and drain down, are supported by the simulator.

The electrical distribution system is modelled to include 120 volt AC breakers, including any breakers operated inside the control room, plus all higher AC voltages and all DC voltages.

The radioactive transport model is presently being upgraded to predict accurate radiation and activity levels that would be present in the various plant systems following the 4 classes of fuel damage due to loss of cooling transients and iodine spiking phenomena in the reactor coolant system.

The Cook Plant Simulator also has a fully functional Simulated Technical Support Center (STSC) to support Plant Emergency Plan drills and exercises. This includes transmission of appropriate data to the Emergency Operations Facility (EOF), Operations Staging Area (OSA) and Initial Assessment Group (IAG) to support real time simulation of Emergency Plan exercises.

COOK PLANT SIMULATOR

SIMULATOR ENVIRONMENT

I. Degree of Panel Simulation (ANS 3.5 - 3.2.1)

This section of the standard requires that the simulator shall contain sufficient operational panels, controls, instrumentation, alarms and other man-machine interfaces to conduct normal plant evolutions and respond to malfunctions.

All panels, controls, instrumentation and alarms located in the reference plant control room are duplicated and functional in the Cook Plant Simulator, with the exception of the containment camera controls.

All panels are duplicated in size, color, shape, configuration, arrangement, and functionality as the reference plant, with few exceptions.

Those exceptions are:

1) Instrument bezel color may not be the same, as there isn't any exact method in the reference plant to control bezel color.

2) The containment RCP camera controls are not simulated, however, half loop level indication is provided during reactor coolant system half loop operations (which is the main purpose of the containment camera).

3) Two recorders on the main generator panel have been substituted for the original recorders which are slightly different and do not detract from training.

4) Back panels without controls have been simulated for spacial relationships, however they do not contain wiring, relays, etc.

II. Controls on Panels (ANS 3.5 - 3.2.2)

This section states that controls, panels and consoles shall be designed to replicate the size, shape, color and configuration of the functionally simulated hardware of the reference plant.

All controls, panels and consoles with functional hardware that is used by the reactor operator of the reference plant are replicated in size, shape, color and configuration, with the exception that the simulator Unit 2 Hot Shutdown Panel is in the position of the reference plant Unit 1 Hot Shutdown Panel. Students are routed out of the control room and back to the Hot Shutdown Panel to simulate a different location.

All reference plant information is displayed in the same form and units on the simulator.

All simulator controls are located in the same location of the reference plant panels.

All changes to control room panels are maintained per the reference plant and photographs are taken biennially to verify the simulator configuration control process.

III. Control Room Environment (ANS 3.5 - 3.2.3)

This section states that consideration shall be given to simulating the reference plant control room environment to a degree reasonably possible and practical.

The Cook Plant simulator replicates lighting (both normal and emergency), obstructions (desks, bookcases, etc.), floor covering, communication systems(with the exception of the two way radio) and ceiling height the same as the reference plant.

Plant and/or reference plant control room noise has been simulated as listed below:

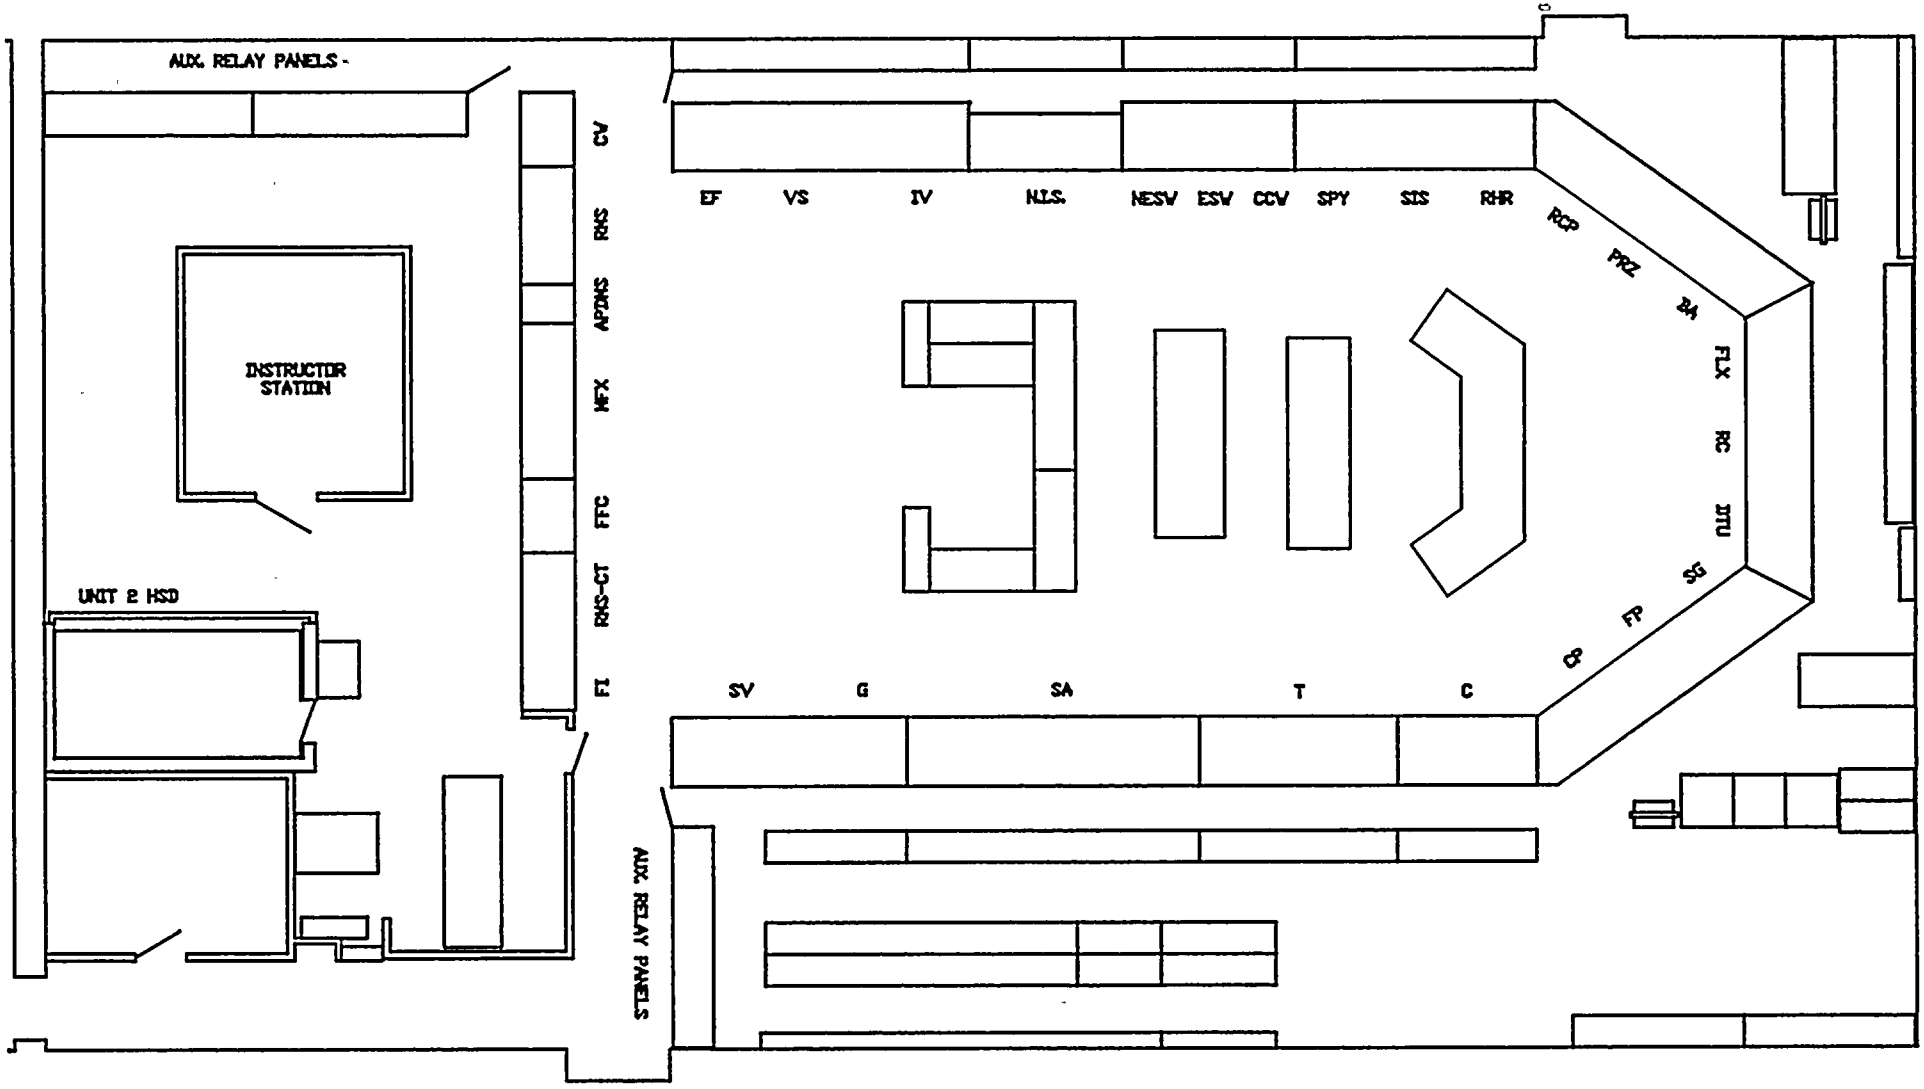
- Turbine room noise
- Pneumatic valve controllers
- Various relay noises
- Control room pressurization fan
- Some plant noises on the PA system

IV. Control Room Documentation (ANS 3.5 - A1.4)

All procedures, drawings and data used in the simulator control room are controlled in accordance with plant document control and do not deviate from the reference plant.

SIMULATOR CONTROL ROOM

SCALE: 1" = 9'0"



UNIT TWO CONTROL ROOM

SCALE: 1" = 9'0"

FI	Fixed Incore
HSD	Hot Shutdown Panel

COOK PLANT SIMULATOR

SIMULATOR TESTS

I. Introduction (ANS 3.5 - A.3)

Appendix A.3 addresses simulator testing to demonstrate compliance with the documentation requirements of the standard by comparison of simulator performance with the data base where applicable.

II. Implementation

The following four areas of testing were performed to demonstate compliance with the standard:

1) Computer Real Time Test (Tab Computer) (ANS 3.5 - A3.1)

2) Normal Plant Evolutions (Tab 1) (ANS 3.5 - A3.2)

3) Simulator Transient Tests (ANS 3.5 - A3.3)

TAB	
1	Reactor Vessel Head Void Formation
2	Anticipated Transient Without Scram
3	Steam Generator Tube Rupture
4	Unit Two Reactor Trip on November 13, 1985

COOK PLANT SIMULATOR

COMPUTER REAL TIME REQUIREMENT ABSTRACT

I. Introduction (ANS 3.5 - A3.1)

Section A3.1 addresses the requirement that the simulation computer complex must be verified for real time simulation. That is, the simulation dynamic performance is in the same time base relationships, sequences, durations, rates and accelerations as the dynamic performance as that of the reference plant.

II. Implementation

The Cook Plant Simulator uses Real Time Executive Tasks (RTEX) to ensure that the simulator remains in real time during all simulation. This task uses a frame counter routine that ensures that an overtime abort and simulator "freeze" condition occurs if the Real Time Executive Task fails to execute two frames in a 100 millisecond time period.

13) Core Performance Testing

A) Plant Thermal Power Calculation
B) Determination of Shutdown Margin (2-OHP-4021.001.012)
C) Determination of Critical Conditions (2-OHP-4021.001.011)
D) Low Power Physics Testing, including rod worth, temperature coefficient and flux distribution.

14) Operator Conducted Surveillance Testing

No effort has been made to single out operator conducted surveillance tests for certification. All surveillance tests that interface the operator and control room can be performed.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

NATURAL CIRCULATION COOLDOWN IN EXCESS OF RECOMMENDED COOLDOWN RATE

I. Introduction

The purpose of this test is to:

1) Test the simulator response to a natural circulation cooldown in excess of recommended cooldown rate (operator maloperation).

2) Ensure that the simulator functions to develop a steam void in the reactor vessel head if the control room operators either violate the recommended cooldown rate while performing a natural circulation cooldown in accordance with the Westinghouse Owners Group (WOG) emergency operating procedures (EOPs) or elect to perform the WOG EOP which allows intentional reactor vessel head void formation.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level
12) Reactor vessel level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) A void is formed in the reactor vessel head as indicated by decreasing Reactor Vessel Level Indication System (RVLIS) indication, increasing or steady Pressurizer level, and RCS wide range pressure greater than Psat for the RCS hot leg temperatures.

2) The observable change in parameters correspond in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts felt that the response of Steam Generator level was incorrect and a Discrepancy Report was initiated to investigate and correct the condition. Steam generator level response will be corrected by 3/91.

The team concluded that other system parameters were satisfactory for the transient.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

ANTICIPATED TRANSIENT WITHOUT SCRAM (ATWS)

I. Introduction

The purpose of this test is to:

1) Test the simulator response to a failure of the reactor to trip from full power.

2) Ensure that the simulator functions to provide proper response to a failure of the reactor to trip after a trip of one (1) main feedpump from one hundred percent power with the operators performing actions required per 2-OHP 4023.FR-S.1 (Response to Nuclear Power Generation/ATWS).

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters correspond in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

STEAM GENERATOR TUBE RUPTURE

I. Introduction

The purpose of this test is to:

1) Test the simulator response to a 600 gpm steam generator tube rupture.

2) Ensure that the simulator functions to provide proper response to a 600 gpm tube rupture and operator actions to mitigate the event using 2-OHP 4023.E-3 (Steam Generator Tube Rupture) and 2-OHP 4023.ES-3.1 (Post-SGTR Cooldown using Backfill).

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) A stratification layer is developed in the ruptured steam generator above the U-tubes after the ruptured steam generator is isolated as indicated by relatively constant ruptured steam generator pressure during initial cooldown.

2) Backfill through the ruptured tube is developed as indicated by increasing pressurizer level concurrent with decreasing ruptured steam generator level when RCS pressure is less than ruptured steam generator pressure.

3) The observable change in parameters correspond in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

4) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted the following discrepancies:

a) The #3 steam generator wide range level response (oscillation) after approximately 18 minutes was inappropriate for the condition.

b) The #3 steam generator steamed at a significantly higher rate than the other non-ruptured steam generators.

c) The pressurizer surge line response was not in the proper direction for the condition during RCS depressurization. The surge line showed no change or an outsurge when in fact pressurizer level was increasing. Data is currently being collected in the reference plant for surge line thermal stress studies which will be used to correct surge line flow response.

Discrepancy reports where written on these discrepancies to investigate and correct the condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

UNIT TWO REACTOR TRIP , NOVEMBER 13, 1985

I. Introduction

The purpose of this test is to:

1) Test the simulator response to an actual reference plant event.

2) Ensure that the simulator functions to provide proper response to a reactor trip from 80.5 percent power, initiated by a failure of MPP-221 (No. 22 steam generator, channel 2 steam pressure) transmitter.

Note: This transient was selected due to the minimal impact upon plant response by the operators.

II. Initial Conditions

1) The simulator is operating at 80.5 percent power steady state, control rod bank D positioned to maintain axial flux difference within limits, with rod control in manual.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters correspond in direction and magnitude to reference plant data.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed by comparison to actual plant data.

VI. Discrepancies

The following discrepancies were noted by the team of subject matter experts:

a) The #2 steam generator wide range level response was not consistent with expected, based upon narrow range level data.

b) The RCS average temperature response was not consistent with the data. The simulator did not cool down as far as the plant in the initial stage immediately following the trip.

Discrepancy reports have been written to investigate and correct the discrepancies.

COOK PLANT SIMULATOR

MALFUNCTION TEST ABSTRACT

I. Introduction (ANS 3.5 - 4.2.2)

Section 4 of the standard addresses conduct of simulator malfunction tests and section C.10 of the guide addresses frequency of malfunction testing.

The Cook Plant Simulator has 306 malfunctions, listed in the Instructor Station capability section, that are used to introduce transients and/or faults into the simulation for operator training.

These malfunctions were tested in their entirety during construction of the simulator (completed in May, 1988). Due to training requirements during 1989, twenty five percent of the malfunctions were tested in the first part of 1990 and another 25 percent will be tested in the last quarter of 1990 to meet the requirement that twenty five percent is to be tested each year and all malfunctions are to be tested in four years.

II. Malfunction Test Acceptance Criteria

All Cook Plant Simulator Malfunctions are compared to a Malfunction Cause and Effect Document which was prepared for acceptance testing during initial construction.

This document was prepared and approved by a team of five individuals possessing more than 30 man years of operation experience at Cook Nuclear Plant and approximately 6 man years of simulator operation experience.

This document is maintained up to date to reflect present plant conditions and is used as the base document for all malfunction tests.

COOK PLANT SIMULATOR

SYSTEMATIC REVIEW PROCESS

I. Items Reviewed (ANS 3.5 - 3.1.2)

The following documents are reviewed for the need to verify and create malfunctions for training:

1. Plant Licensee Event Reports
2. Plant Condition Reports
3. Plant Problem Reports
4. Other Plant Licensee Event Reports
5. Industry Events
6. INPO SOERs
7. INPO SERs

In addition, plant Probabilistic Risk Assessment results will be reviewed after completion.

COOK PLANT SIMULATOR

STEADY STATE OPERATION GENERAL INFORMATION

I. Steady State Operation (ANS 3.5 - 4.1)

To ensure compliance with the standard in regards to simulator steady state operation, the simulator has been operated at one hour intervals without operator action and compared to reference plant data for four different power levels (30%, 60%, 90% and 100%).

All simulator controls were aligned the same as the reference plant (all controls in AUTO).

Computed values were collected at one second intervals over a one hour period for each power level, graphed and compared to reference plant data, with the exception that non critical data points were not compared at power levels less than 100%.

Plant data was not available for Reactor Coolant System Hot Leg and Cold Leg temperature in the time frame during which the Steady State tests were performed for 60% and 90% power. These temperatures will be compared during performance of the next scheduled 60% and 90% Steady State tests.

All simulator instruments are calibrated on regular intervals and verified not to have errors greater than the reference plant. Instrument error was included in the allowable error range for each parameter.

Simulator discrepancy reports have been written for all data points designated by an '*'.

COOK PLANT SIMULATOR

TRANSIENT TEST ABSTRACT

I. Introduction (ANS 3.5 - 4)

Section 4 of the standard addresses simulator tests to ensure that simulator response:

1) Is the same as plant startup test data

2) Observable change in the parameters correspond in direction to those expected from best estimate of the simulated transient and do not violate the physical laws of nature

3) Does not fail to cause an alarm or automatic action if the reference plant would not cause an alarm or automatic action.

II. Transient Operation (ANS 3.5 - 4.2.1)

All transient tests in accordance with Appendix B section B.2.2 were conducted on the simulator and compared to data where existing data was available. In all other cases, the tests were reviewed by a team of subject matter experts (attachment 1) to ensure that the criteria of the standard were met.

All data was collected at a minimum resolution of every one half second.

All discrepancies identified from the test results will be corrected by the end of 1991.

COMPOSITION OF SUBJECT MATTER EXPERT PANEL

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MANUAL REACTOR TRIP

I. Introduction (ANS 3.5 - B.2.2(1))

The purpose of this test is to:

1) Test the simulator response to a manual reactor trip per ANS 3.5 - B.2.2(1).

2) Ensure that the simulator functions properly to a manual reactor trip and all parameters respond in a timely manner.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer level
4) Pressurizer pressure
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Pressurizer safety valves shall not lift.

2) The observable change in parameters correspond in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULATANEOUS TRIP OF ALL MAIN FEEDWATER PUMPS

I. Introduction (ANS 3.5 - B2.2(2))

The purpose of this test is to:

1) Test the simulator response to a simultaneous trip of all main feedwater pumps per ANS 3.5 - B2.2(2).

2) Ensure that the simulator's auxiliary feedwater system functions properly to restore steam generator level in a timely manner following the reactor trip.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer level
4) Pressurizer pressure
5) Pressurizer temperature
6) Feedwater flow
7) Steam flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Pressurizer safety valves shall not lift.

2) The observable change in parameters correspond in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI: Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULTANEOUS CLOSURE OF ALL MAIN STEAM ISOLATION VALVES

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a simultaneous closure of all main steam isolation valves per ANSI 3.5 - B2.2.

2) Ensure that the simulator's steam generator safety and power operated relief valves (PORV) function properly to limit steam generator pressure and that steam generator PORVs in conjunction with the auxiliary feedwater system control RCS average temperature.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Steam generator safeties and PORVs limit steam generator pressure.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

The team did note that Steam Generator #24 PORV (2-MRV-243) did not appear to have operated. The team ran the test on the simulator and determined that the lack of response of 2-MRV-243 was attributable to the setpoint dial (operator controlled) being slightly out of position. The team concluded that the response was correct for the condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SIMULTANEOUS TRIP OF ALL REACTOR COOLANT PUMPS

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a simultaneous trip of all Reactor Coolant Pumps per ANSI 3.5 - B2.2.

2) Ensure that the simulator will establish natural circulation conditions upon loss of forced Reactor Coolant System flow.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Natural Circulation conditions established as indicated by constant or decreasing RCS Hot Leg Temperatures.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted the following conditions:

1) A Saftey Injection occurred just prior to the end of the transient. This was deemed to be an acceptable response based upon cooldown and auxiliary feedwater system flow.

2) An oscillation occurred which affected Steam Generator Wide Range/ Narrow Range Level and Steam Generator Pressure. A Discrepancy Report was written to investigate and correct the cause of the oscillation.

The team did note that Steam Generator #24 PORV (2-MRV-243) did not appear to have operated. The team ran the test on the simulator and determined that the lack of response of 2-MRV-243 was attributable to the setpoint dial (operator controlled) being slightly out of position. The team concluded that the response was correct for the condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

TRIP OF REACTOR COOLANT PUMP #21

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a trip of Reactor Coolant Pump #21 per ANSI 3.5 - B2.2.

2) Ensure that the simulator will initiate Reactor Coolant Pump #21 flow coastdown and flow reversal.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS hot leg temperature
3) RCS cold leg temperature
4) Steam Generator pressure
5) Steam Generator level
6) Steam flow
7) Feedwater flow
8) RCS loop flow
9) RCS T average

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) RCS Loop 1 flow decreases to minimum then is re-established by flow reversal from the other RCS loops as indicated by Loop 1 T hot less than unaffected loops T cold.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

TRIP OF MAIN TURBINE FROM 9% POWER WITHOUT REACTOR TRIP

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a trip of the Main Turbine from the maximum power level (9%) which does not result in an immediate reactor trip per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to permit a Main Turbine trip without tripping the reactor as a direct result of the turbine trip.

II. Initial Conditions

1) The simulator is operating at middle of life core conditions, reactor power at approximately 9 percent, steam generator feedwater in automatic, steam dumps in steam pressure mode, main generator in parallel at approximately 85 MWe, and Tavg matched to Tref.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The plant stabilizes at a lower power than initial with a Tavg higher than initial and a differential temperature (Tavg - Tstm) which corresponds to the final power.

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MAXIMUM RATE POWER RAMP (100% - 75% - 100%)

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum rate power ramp per ANSI 3.5 - B2.2.

2) Ensure that the simulator will maintain stability during a maximum rate power ramp.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Neutron flux
2) RCS average temperature
3) Pressurizer pressure
4) Pressurizer level
5) Pressurizer temperature
6) Steam flow
7) Feedwater flow
8) RCS hot leg temperature
9) RCS cold leg temperature
10) Steam generator pressure
11) Steam generator level

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MAXIMUM SIZE REACTOR COOLANT RUPTURE WITH LOSS OF ALL OFFSITE POWER

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum size reactor coolant system rupture with a loss of all offsite power per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to accurately replicate containment response to a large break LOCA.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Pressurizer pressure
2) Narrow range pressurizer pressure
3) Pressurizer level
4) Containment pressure
5) Containment temperature

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted that Narrow Range Pressurizer Pressure continued below 1700 psig and should not have. A discrepancy report has been initiated to correct this condition.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

MAXIMUM SIZE UNISOLABLE MAIN STEAM LINE RUPTURE

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a maximum size unisolable main steam line rupture per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to accurately replicate containment response to a large main steam line break.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Pressurizer pressure
2) Narrow range pressurizer pressure
3) Pressurizer level
4) Containment pressure
5) Containment temperature

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

2) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

The team of subject matter experts noted that:

a) Narrow Range Pressurizer Pressure continued below 1700 PSIG and should not have.

b) Lower containment temperature decreased while containment pressure increased.

Discrepancy reports have been initiated to investigate and correct these conditions.

COOK PLANT SIMULATOR

PWR SIMULATOR TRANSIENT TEST

SLOW PRIMARY SYSTEM DEPRESSURIZATION TO SATURATION

I. Introduction (ANS 3.5 - B2.2)

The purpose of this test is to:

1) Test the simulator response to a slow primary system depressurization to saturated conditions with high pressure Emergency Core Cooling System inhibited using a pressurizer relief valve per ANSI 3.5 - B2.2.

2) Ensure that the simulator will function to establish localized saturated conditions in the RCS while liquid is maintained in the pressurizer.

II. Initial Conditions

1) The simulator is operating at normal steady state, full power conditions with control rod bank D positioned to maintain axial flux difference within limits.

III. Data Collected

1) Pressurizer relief valve (PORV) flow
2) Pressurizer pressure
3) Pressurizer temperature
4) Surge line temperature
5) Pressurizer level
6) Loop flow rates
7) RCS hot leg temperature
8) Source range detector output
9) Reactor vessel level
10) RCS saturation margin

IV. Acceptance Criteria

The following acceptance criteria are to be used to determine acceptable simulator response:

1) Localized saturated conditions are established in the RCS as indicated by:

   a) RCS saturation margin decreasing to zero (0)
   b) RCS wide range pressure decreases to approximately Psat for RCS hot leg temperature
   c) Decreasing wide range RVLIS indications with increasing pressurizer level indications

2) The observable change in parameters corresponds in direction and magnitude to those expected from a best estimate analysis for the simulated transient and do not violate the physical laws of nature.

3) The simulator shall not fail to cause an alarm or automatic action if the reference plant would have caused an alarm and/or automatic action, and conversely, the simulator shall not cause an alarm and/or automatic action if the reference plant would not cause an alarm and/or automatic action.

V. Analysis

This transient was analyzed as a best estimate of expected actions.

VI. Discrepancies

No discrepancies were noted by the team of subject matter experts.

The team did request that Steam Generator parameters be plotted to clarify that a cooldown was initiated at the approximately eleven (11) minute mark and noted that the response was correct for the condition (cooldown).

COOK PLANT SIMULATOR

INSTRUCTOR STATION GENERAL INFORMATION

I. Overview (ANS 3.5 - 3.4)

The Cook Plant Simulator instructor station uses a Singer Link Advanced Man Machine Interface (AMMI) to allow the instructor to interface with the simulator training software.

The simulator instructor station serves as the main control center of the simulator complex. The instructor is provided with interactive color monitors featuring touch screen capabilities, video cameras connected to both a monitor and a video cassette recorder and communication equipment.

This equipment is used to establish simulator operating states, provide remote and local control, monitor student performance and obtain student exercise reports.

II. Simulator Operating Modes (ANS 3.5 - 3.4.3)

Freeze Mode

Freeze mode is the state of the simulator when all simulation is loaded, the panel I/O reflects the current conditions, but all simulation models have been suspended.

Run Mode

Run mode is the state of the simulator when all simulation is loaded, the panel I/O reflects the current conditions, the simulation models are executing and the simulator is responsive to student and/or instructor inputs.

Backtrack Mode

Backtrack mode is the state of the simulator when all simulation software is loaded, but the simulation models are suspended.

The Cook Plant Simulator stores 240 backtrack records at intervals of one tenth of a second to ten minutes (default is 1 minute) which provide the instructor the capability for replay and/or reinitialization of the simulator. Also, the instructor has the capability to preview backtrack conditions prior to resetting to a particular backtrack record.

Replay Mode

The Cook Plant Simulator has the capability to replay a given scenario from any backtrack record. The simulator is placed in the backtrack mode and then replay is selected from one of the 240 backtrack records.

When the simulator is placed in Replay Mode, the replay function will "stimulate" the simulator I/O and instructor station functions to drive the simulator software from the recorded operator/instructor actions.

Replay mode can be paused (freeze) and continued (run) to allow instructor comments during a scenario replay.

Snapshot Mode

The simulator has the capability to provide snapshots of simulator conditions at any given time in a training scenario. There are up to 100 snapshot records, with 40 snapshots being reserved for normal training scenarios.

Simulator Time Control

Real Time — Real time is the time mode in which each second of simulation corresponds to one second of actual plant operation.

Slow Time — Slow time allows close inspection of plant transients by expanding each second of simulation into several seconds of clock time. The slow time rate is variable by factors of 1/X, where X is an integer from 2 to 10.

Fast Time — Fast time mode allows slow, time consuming operations to be performed at an accelerated rate. Fast time rate is variable by a factor of X where X is an integer from 1 to N and N is a parameter dependent maximum rate as listed below:

Parameter	Maximum Rate
Xenon	60
Samarium	60
Turbine Metal Temperature	10
Reactor Coolant System Temperature	10
Condenser Vacuum	10
Containment Hydrogen	100
Decay Heat	200
Pressurizer Heater Power	10

III. Malfunctions (ANS 3.5 - 3.4.2)

The simulator has 306 malfunctions which can be used for various training scenarios. The instructor is provided the capability of selecting up to sixty active or pending malfunctions at one time. (The malfunctions are listed under the Malfunction Tab).

Each malfunction has the following capability:

Event Trigger - Triggers from any boolean event (allows for simultaneous insertion of malfunctions).

Initial Severity- Allows insertion of any malfunction at any initial severity from 0 to 100 %.

Ramp Time - Allows malfunctions to be ramped from an initial severity to a final severity with respect to time.

Final Severity - Allows determination of a final severity of any malfunction from 0 to 100%.

Delay Time - Allows for delay of malfunction from insertion to actuation with respect to time.

Global Malfunctions

Global malfunctions are provided to fail any motor operated valve by simulating a thermal overload condition and to fail any air operated valve by simulating a broken air line to the valve actuator.. Additionally all 4KV and 600 V breakers fail open by simulating a breaker latch failure.

Malfunctions can be inserted and/or deleted by either Malfunction Index Tableau, Simulation Diagram (P & ID) or expert mode command.

IV. Local Operator Actions (ANS 3.5 - 3.4.4)

Local operator actions allow the instructor to initiate remote auxiliary operator actions and other normal operations of equipment outside the control room. (Local operator actions are listed under Local Operator Action Tab). These actions allow the instructor to operate pertinent manual valves, breakers and equipment necessary for simulation located outside the control room from the instructor station.

Additionally, the instructor is provided the capability to communicate with the control room in a manner that the operator is accustomed to in the reference plant control room by page and/or telephone.

V. Overrides

Overrides allow the instructor to simulate failure of control room panel devices. Specifically, this includes lamps, switches, meters, pen recorders, relays and potentiometer.

VI. Initial Conditions (ANS 3.5 - 3.4.1)

The simulator provides up to 100 initial conditions for the instructor's use. Initial conditions 1 through 40 are protected and reserved for normal training scenarios. These 40 initial conditions contain various plant operating conditions, fission product concentrations and various times in core life as summarized below:

Core Life	-	BOL (0 MWD/MTU)	6
		MOL1(100 MWD/MTU)	3
		MOL2(9000 MWD/MTU)	24
		EOL1(17500 MWD/MTU)	4
		EOL2(18000 MWD/MTU)	4
Fission Product Poison	-	Xenon Free Startup	6
		Peak Xenon Startup	5
		Other Xenon Startup	4
Operating Conditions	-	Several	

VII. Exceeding Limits (ANS 3.5 - 4.3)

The simulator provides a method of alerting the instructor that the simulator is exceeding normal simulator operating limits (i.e., conditions that are unanalyzed). If one of the simulator operating limits is exceeded (Tab "Exceeding Limits"), the simulator is placed in a freeze condition and a "pop up" message is displayed on the instructor station that indicates which operating limit has been exceeded.

COOK PLANT SIMULATOR

SIMULATOR OPERATING LIMITS ABSTRACT

I. Introduction

Section 4 of the standard states that administrative controls shall be provided to alert instructors that the simulator is exceeding design and/or known operating conditions.

II. Implementation

The Cook Plant Simulator supports fuel damage (melt) and reactor coolant system two-phase flow conditions, therefore, there are no limits to alert the instructor of two phase flow or fuel melt conditions.

However, to provide the instructor with a means to determine if the simulator is approaching and/or exceeding design operating conditions, a Simulator Operations Limit (SOL) pop up screen on the instructor station is activated when limits, as described on the attached sheets, are exceeded.

This warning screen is activated when the assigned parameter is within ten percent of the limit, and if the limit is exceeded, the simulator is placed in a "freeze" condition.

COOK PLANT SIMULATOR

SIMULATOR EXCEEDING LIMITS SUMMARY

PARAMETER	LOW LIMIT	HIGH LIMIT	UNITS	DESCRIPTION
RCTHL1-4	32	10000	deg f	RCS HOT LEG TEMPERATURES
		BASIS:		lo - Freezing point of water hi - Point not reachable
RCTCL1-4	32	10000	deg f	RCS COLD LEG TEMPERATURES
		BASIS:		lo - Freezing point of water hi - Point not reachable
RCPHL1-4	0	3100	psia	RCS HOT LEG PRESSURE
		BASIS:		lo - Zero Pressure hi - Greater than Design Pressure
RCBORON	0	53000	ppm	RCS BORON CONCENTRATION
		BASIS:		lo - Zero Boron hi - Boron Saturation at 212 degrees
RCTNTA251	32	10000	deg f	PRESSURIZER LIQUID TEMP
		BASIS:		lo - Freezing point of water hi - Point not reachable
RCTNTA252	32	10000	deg f	PRESSURIZER VAPOR SPACE TEMP
		BASIS:		lo - Freezing point of water hi - Point not reachable
RCTNTA253	32	10000	deg f	PRESSURIZER SURGE LINE TEMP
		BASIS:		lo - Freezing point of water hi - Point not reachable
RCPPRZ	0	3086	deg f	PRESSURIZER PRESSURE
		BASIS:		lo - Zero Pressure hi - RCS Design Pressure
RCBORONPRZ	0	53000	ppm	PRESSURIZER BORON CONC.
		BASIS:		lo - Zero Boron hi - Boron Saturation at 212 degrees
CRQN	0	1.25		REACTOR POWER
		BASIS:		lo - Zero Power hi - Greater than any expected power level

COOK PLANT SIMULATOR

SIMULATOR EXCEEDING LIMITS SUMMARY

PARAMETER	LOW LIMIT	HIGH LIMIT	UNITS	DESCRIPTION
RCTCOREOUT	32	10000	deg f	CORE EXIT TEMP. BASIS: lo - Freezing point of water hi - Point not reachable
MSPSG[1-4]	0	1302	psia	STEAM GENERATOR PRESSURE BASIS: lo - Zero Pressure hi - Design Pressure + 20%
RCTSGDM[1-4]	32	2500	deg f	STEAM GENERATOR DOME TEMP BASIS: lo - Freezing point of water hi - Greater than any expected temperature
FWPCN[1-3]	0	22.7	psia	MAIN CONDENSER PRESSURE BASIS: lo - Perfect Vacuum hi - Rupture Disk pressure + 14.7 psi
FWPAFPTCNE/W	0	22.7	psia	MFP CONDENSER PRESSURE BASIS: lo - Perfect Vacuum hi - Rupture Disk pressure + 14.7 psi
CHPUC	10	28	psia	UPPER CONTAINMENT PRESSURE BASIS: lo - < -3 PSIG hi - > 12 PSIG
CHPLC	10	28	psia	LOWER CONTAINMENT PRESSURE BASIS: lo - < -3 PSIG hi - > 12 PSIG
CHTUC	32	240	deg f	UPPER CONTAINMENT TEMP. BASIS: lo - Freezing point of water hi - TSAT for 28 psia
CHTLC	32	240	deg f	LOWER CONTAINMENT TEMP. BASIS: lo - Freezing point of water hi - Tsat for 28 psia

COOK PLANT SIMULATOR

COOK PLANT SIMULATOR

DIFFERENCES

I. Introduction

The Cook Plant Simulator Certification Submittal references two differences between the reference plant and the simulator specified as exceptions. They are:

1) Plant Process Computer

Presently the Cook Plant Simulator does not simulate the reference plant process computer system due to replacement of this equipment in the reference plant. Installation in the plant is scheduled for the 1991 refueling outage (last quarter of 1991).

The hardware is on site to replicate and simulate the plant process computer and is expected to implemented by the end of the last quarter of 1991.

2) Plant Hand Held Radio Communication System

Presently the Cook Plant Simulator does not simulate the reference plant hand held radio communication system due to replacement of this equipment in the reference plant.

Equipment to replicate and simulate reference plant equipment is on order and expected implementation date is by the end of the last quarter of 1990.
