U.S. Nuclear Regulatory Commission  
Attention: Document Control Desk  
Mail Station P1-37  
Washington, DC 20555-0001

REFERENCE: Docket 50-186  
University of Missouri-Columbia Research Reactor  
Renewed Facility Operating License No. R-103

SUBJECT: Written communication as specified by 10 CFR 50.4(b)(1) regarding responses to the  
"University of Missouri at Columbia - Request for Additional Information RE: License  
Amendment Request to Implement Selective Gas Extraction Target Experimental  
Facility at the University of Missouri Research Reactor (CAC No. MF9524)," dated  
September 7, 2017

By letter dated May 3, 2017, the University of Missouri Research Reactor (MURR) submitted a license amendment request (LAR) to the U.S. Nuclear Regulatory Commission (NRC) in order to conduct an experiment that would produce molybdenum-99 (Mo-99) in large quantities as part of its role in supplying critical medical radioisotopes to the domestic and international community. The experiment would utilize General Atomics' (GA) Selective Gas Extraction (SGE) process, which consists of irradiating target rods containing low-enriched uranium (LEU) pellets in the reactor graphite reflector region in order to produce fission product Mo-99. The Mo-99 would then be extracted from the LEU in dedicated hot cells using the SGE technology. Included with the LAR submittal was eight (8) attachments, six (6) of which contained proprietary information which was withheld from public disclosure pursuant to 10 CFR § 2.390.

By letter dated June 19, 2017, MURR submitted two (2) attachments (Attachment 9 – GA Design Report No. 30441R00038, "Computational Fluid Dynamics Analysis of Target Housing Design Calculation Report," and Attachment 10 – GA Design Report No. 30441R00041, "Critical Heat Flux Testing at the University of Wisconsin Final Report,") to supplement the May 3, 2017 submittal to further assist the NRC in review of the LAR. One version of each attachment contained proprietary information which was withheld from public disclosure pursuant to 10 CFR § 2.390.

By letter dated September 7, 2017, the NRC requested additional information and clarification regarding the proposed LAR in the form of thirty-eight (38) questions (numbered 1 through 38).

A020  
NRK

By letter dated October 17, 2017, MURR submitted one (1) attachment (Attachment 11 – GA Design Report No. 30441R00045, “Target Cooling System Flow Test Report”) to supplement the May 3, 2017 submittal to further assist the NRC in review of the LAR. One version of the attachment contained proprietary information which was withheld from public disclosure pursuant to 10 CFR § 2.390.

By letter dated November 1, 2017, the NRC requested additional information and clarification regarding the proposed LAR in the form of eighteen (18) questions (numbered 39 through 57).

Below are MURR’s responses to the September 7, 2017 request for additional information, including enclosures of supporting documentation.

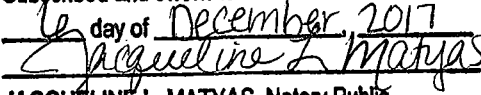

If there are questions regarding these responses, please contact me at (573) 882-5118. I declare under penalty of perjury that the foregoing is true and correct.

Sincerely,

  
Bruce Meffert  
Reactor Manager

9. Supplement 27.2 – Flux Trap Sample Materials
10. Supplement 28 – Control Blade Depletion Zones

## LAR Attachment 1

1. LAR, Attachment 1, Section 1.1, "Proposed Experiment Description," states, in part, that "The SGE Target Experimental Facility (TEF) will be operated by MURR staff in concert with MURR's routine reactor operations." The LAR provides changes to the facility that include the addition of a target cooling system (TCS), and associated reactor trips and TSs. Additionally, LAR, Section 5.2.3, states, in part, that "Loading two TAs [target assemblies] in the MURR graphite reflector region causes perturbations in neutronic and thermal performance of the MURR core as follows: The MURR core excess reactivity will increase slightly, which will be compensated by the reactivity control devices." During its review, the NRC staff could not find any information in the LAR discussing training requirements associated with the TEF, or the operators' requalification training in response to a malfunction of an automatic control system affecting reactivity; and thus, it is not clear to the NRC staff how the operator training will satisfy the requirements associated with 10 CFR 55.45, "Operating tests," and 10 CFR 55.59, "Requalification," as described below.

*The regulations in 10 CFR 55.59(a)(2)(ii) require an operating test that ensures the operator or senior operator demonstrate an understanding of and the ability to perform the actions necessary to accomplish a comprehensive sample of items specified in 10 CFR 55.45(a)(2) through (13) inclusive to the extent applicable to the facility. The regulations in 10 CFR 55.45(a)(8) require the operating test to demonstrate that the operators can "[S]afely operate the facility's auxiliary and emergency systems, including operation of those controls associated with plant equipment that could affect reactivity or the release of radioactive materials to the environment."*

*The regulations in 10 CFR 55.59(c)(3)(i)(W) require licensed operators to demonstrate that they can manipulate controls in response to a "[M]alfunction of an automatic control system that affects reactivity."*

*Provide a description of the operator training applicable to the proposed changes implemented with this LAR, or justify why no additional information is needed.*

1. Documented training will occur with every licensed operator prior to irradiating any target rod in the Selective Gas Extraction (SGE) Target Experimental Facility (TEF). At a minimum, the following topics/exercises will be covered in the pre-irradiation training:
  - a. SGE TEF system training, including detailed TEF component and instrumentation training;
  - b. Normal SGE TEF operating conditions, controls, and procedures;
  - c. Abnormal SGE TEF indications including abnormal parameters, alarms, and protective functions; and proper operator response to abnormal indications;
  - d. Emergency procedures; and
  - e. Each operator will be tested on items a. through d. to ensure the operators can operate the SGE TEF controls correctly and properly manipulate controls in response to TEF abnormal and emergency conditions. This testing and the testing results for each operator will be documented.

2. The SGE TEF will be added to the list of "Auxiliary Systems" in the "Topics of Operating Tests," Attachment 1 to the NRC-approved MURR Operator Requalification Program.
3. SGE TEF scenarios will be added to the list of "MURR Operational Task Index" used to conduct "Annual Operating Tests" in accordance with the MURR Operator Requalification Program.
4. Questions about the SGE TEF and TEF normal/emergency procedures will be developed and added to the Biennial Requalification Examination bank to satisfy the MURR Operator Requalification Program.

2. *LAR, Attachment 1, Section 1.2, "Normal Operation," states that, following irradiation, the reactor is shutdown and the TA is cooled by forced flow from the TCS for a specified time period to remove fission product decay heat, after which direct conduction with the pool water is sufficient to maintain the temperature of the target rods in a safe condition. However, the NRC staff is not clear as to the resulting condition of the TA should the TCS fail, or fail to remain in service for the specified time period.*

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. The regulations in 10 CFR 50.90 require that the applicant submit an application fully describing the changes desired, and following as far as applicable, the form prescribed for original applications. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 13, "Accident Analysis," indicates that the LAR should also describe how equipment will work when needed in potential accident situations.*

*Describe or reference the result of an analysis, which provides the results of the TA temperature during a loss of forced flow prior to the specified time period where direct conduction is sufficient to maintain the TA in a safe condition, or justify why no additional information is needed.*

There is no safety issue should the Target Cooling System (TCS) fail to operate for less than the specified period of time after a reactor shutdown. After shutdown, the effects of TCS failure on the Target Assembly (TA) are bounded by the loss of target flow accident described in LAR Attachment 1, Section 10.7, "Loss of Target Flow." As shown in Section 10.7, a 2 °C (3.6 °F) rise in peak cladding temperature will occur during a loss of flow accident. The reactor will scram when TCS flow reaches 85% of nominal 0.14 seconds after pump failure. For the case of a TCS failure after shutdown following irradiation of the target rods, the reactor has already been shut down which results in reduced TA heat generation and temperatures. The reduced starting heat generation and temperatures upon failure of the TCS will lead to decreased peak temperatures when compared to the results found in Section 10.7. Therefore, a post-reactor shutdown LOPF is bounded by the analyzed LOPF during operation.

3. LAR, Attachment 1, Section 3.3.1, "Target Flow Assembly Design," provides a description of the Target Flow Assembly Design, including the inlet piping, and states that there is a single inlet suction line pipe that is fitted with a replaceable screen to prevent any flow blockage caused by debris. The NRC staff review identified that additional information was needed to accurately model the target flow assembly.

The regulations in 10 CFR 50.90 require that the applicant submit an application fully describing the changes desired, and following as far as applicable, the form prescribed for original applications. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 13, indicates that the LAR should also describe how equipment will work when needed in accident situations (e.g., loss of coolant flow). Provide the following information, or justify why no additional information is needed.

3.1. A detailed description and drawings of the pipe inlet and screen.

Figure 3-1 shows the 3D model of the inlet piping assembly that transports cooling water from the MURR reactor pool to the pump suction in the Target Cooling System Module (TCSM). The inlet piping assembly consists of 3-inch schedule 40 pipe made from both aluminum (inside the pool) and stainless steel (outside the pool) with a total length of 52 feet (15.8 m). This section of piping contains an inline strainer purchased from a qualified supplier that is installed upstream of the pump suction. The strainer has a straining element with a 3/16-inch mesh size that has a 5/32-inch flow opening to protect the pump (Appendix 3-1 shows the detailed layout of the proposed strainer and its internal components). Figure 3-2 shows the location of the inlet pipe relative to the TCSM assembly.

## Appendix 3-1

3.2. The dimensions of the smallest piece of debris that could cause a rapid reduction in flow worse than what is assumed in the RELAP accident analysis.

RELAP assumes that the reactor scrams at 85% of nominal flow; therefore, any introduction of debris into the flow path reducing flow will cause a reactor scram at this flow rate. More severe reductions in flow, from events such as debris blocking the flow or a locked pump rotor, are provided in the response to RAI No. 33.

### 3.2. The dimensions of the largest piece of debris that could flow through the inlet screen.

The largest piece of debris that could flow through the inlet screen upstream of the TCSM pump suction is 0.221 inches (Figure 3-3). This is a rough screen to prevent damage to the pump. The TCSM contains a secondary fine mesh screen with a maximum particle size of 0.045 inches that could flow through it and into the target housing. The pump can tolerate a maximum particle size of 0.375 inches per the manufacturer's datasheet (see Appendix 3-2).

Appendix 3-2

*3.3. A description if there is any protection from debris entering the target decay heat removal valves when they are open.*

Currently, there is no protection from debris entering the Target Decay Heat Removal Valves when they are open as they take in clean water from the reactor pool. Additionally, natural convection flow is upward and out through the valves when they are open to remove decay heat from the Target Assemblies when shut down. Reactor Operations administrative procedure AP-RO-110, "Conduct of Operations," contains strict guidance regarding "Foreign Material Exclusion" when working on or near systems where foreign material could be introduced, especially around the reactor pool.

*3.4. Any design consideration given to minimize or prevent the introduction of air into TCS lines.*

To minimize or prevent the introduction of air into TCS lines, the cooling system piping will utilize flanges that meet ASME/ANSY B16.5 standards outside the pool. The piping system will implement V-Flanges inside the pool with metallic c-seals near high radiation areas. A pressure test will be conducted to ensure all flanges are watertight.

4. LAR, Attachment 1, Section 4.1, "Summary Description," provides a description of the the TEF I&C systems which include the following seven subsystems: (a) TCS Control System; (b) TCS Protection System; (c) TCS Parameter Indication, Recording and Alarm system; (d) TCS Secondary Coolant Control System; (e) TCS Secondary Coolant Parameter Indication, Recording, and Alarm System; (f) N-16 Reactor Power Monitoring System; and (g) Pool Coolant Monitoring System. For each of these systems, the NRC staff review was not able to completely identify sufficient design information to complete its review. Therefore, as described in RAIs 4.1 through 4.9 below, additional information is needed in order for the NRC staff to determine the adequacy of the design basis of the TEF I&C systems and subsystems.

The regulations in 10 CFR 50.90 require that the applicant submit an application fully describing the changes desired, and following as far as applicable, the form prescribed for original applications. The regulations in 10 CFR 50.34 require information related to design bases and the principal design criteria of the I&C systems. NUREG-1537, Part 1, Chapter 7, "Instrumentation and Control Systems," and Section 7.1, "Summary Description," provides guidance that the applicant should describe the I&C systems of the reactor, including block, logic, and flow diagrams showing major components and subsystems, and connections among them. The draft ISG augmenting Chapter 7 to NUREG-1537, Part 1, Section 7.2.1, "Design Criteria," provides additional design criteria for I&C systems (specific draft ISG sections are provided in [brackets] for reference).

- 4.1. For each of the systems listed above, (a) through (g), provide an overall block logic, and process flow diagrams showing major components and subsystems, and connections for the I&C, or justify why no additional information is needed.

(g) *Pool Coolant Monitoring System*

4.2. For each of the systems listed above, (a) through (g), provide more detail for the implementation of "Hardwired isolated interface with MURR SCRAM loop," (LAR, Attachment 1, Figure 30, page 54, "Target Cooling System Control System Architecture") used to describe the independent hard-wired safety function with regard to specific means of providing isolation or justify why no additional information is needed [draft ISG 7.1, 7.3, 7.4, 7.6, and 7.7].

Figure 4-2.a depicts all seven (7) sub-systems and shows that the critical process instruments are connected to the TCS protection system and MURR scram loop, which is independent from the process instruments for the other six (6) sub-systems, including the TCS control panel display as described above.

*(a) TCS Control System*

The TCS control system is a hardwired system that relies on relays, pushbuttons, switches, and light indicators. The TCS control system has no interface with the MURR SCRAM loop. The only connection between the TCS protection system, which de-energizes a signal to the MURR SCRAM loop, and the TCS control system is a signal from the TCS protection system that allows the Target Decay Heat Removal Valves (TDHRVs) to stay closed and the TCS pumps to operate. Malfunction of any part of the TCS control system or failure of the entire TCS control system will not prevent the TCS protection system from causing a reactor scram, when required.

*(b) TCS Protection System*

The TCS protection system contains flow rate and temperature transmitters that provide hardwired 4 to 20mA control signals to analog trip alarm units. Normally open contacts on the trip alarm units are hardwired between a power supply and the solenoids of two (2) redundant, independent, and fail-safe trip relays (TCS-1 and TCS-2). The TCS-1 contact is in line with the "Yellow Leg" of the MURR Scram Circuit, and the TCS-2 contact is in line with the "Green Leg" of the MURR Scram Circuit. When a transmitter signal passes a set point in an analog trip alarm unit, the trip unit normally open contacts will de-energize the relay solenoid (TCS-1 or TCS-2) of its respective MURR Scram Circuit. The MURR Scram Circuit will then de-energize causing a reactor scram. A loss of signal in any control loop or scram circuit will cause a reactor scram (see Figure 4-2.b).

The TCS Protection System also provides annunciation for a TCS Flow Scram or TCS Temperature Scram. The annunciations are activated by a loss of signal from the associated analog trip alarm unit that initiated the reactor scram.

Keyed bypass switches 2S42 and 2S43 have contacts as shown in Figure 4-2.b. The function and operation of these keyed bypass switches are explained in the response to RAI No. 4.7.

*(c) TCS Parameter Indication, Recording and Alarm System*

The TCS parameter indication, recording and alarm system has no interface with the MURR SCRAM loop.

*(d) TCS Secondary Coolant Control System*

The TCS secondary coolant control system has no interface with the MURR SCRAM loop.

*(e) TCS Secondary Coolant Parameter Indication, Recording, and Alarm System*

The TCS secondary coolant parameter indication, recording, and alarm system has no interface with the MURR SCRAM loop.

*(f) N-16 Reactor Power Monitoring System*

The N-16 reactor power monitoring system has no interface with the MURR SCRAM loop.

*(g) Pool Coolant Monitoring System*

The pool coolant monitoring system has no interface with the MURR SCRAM loop.

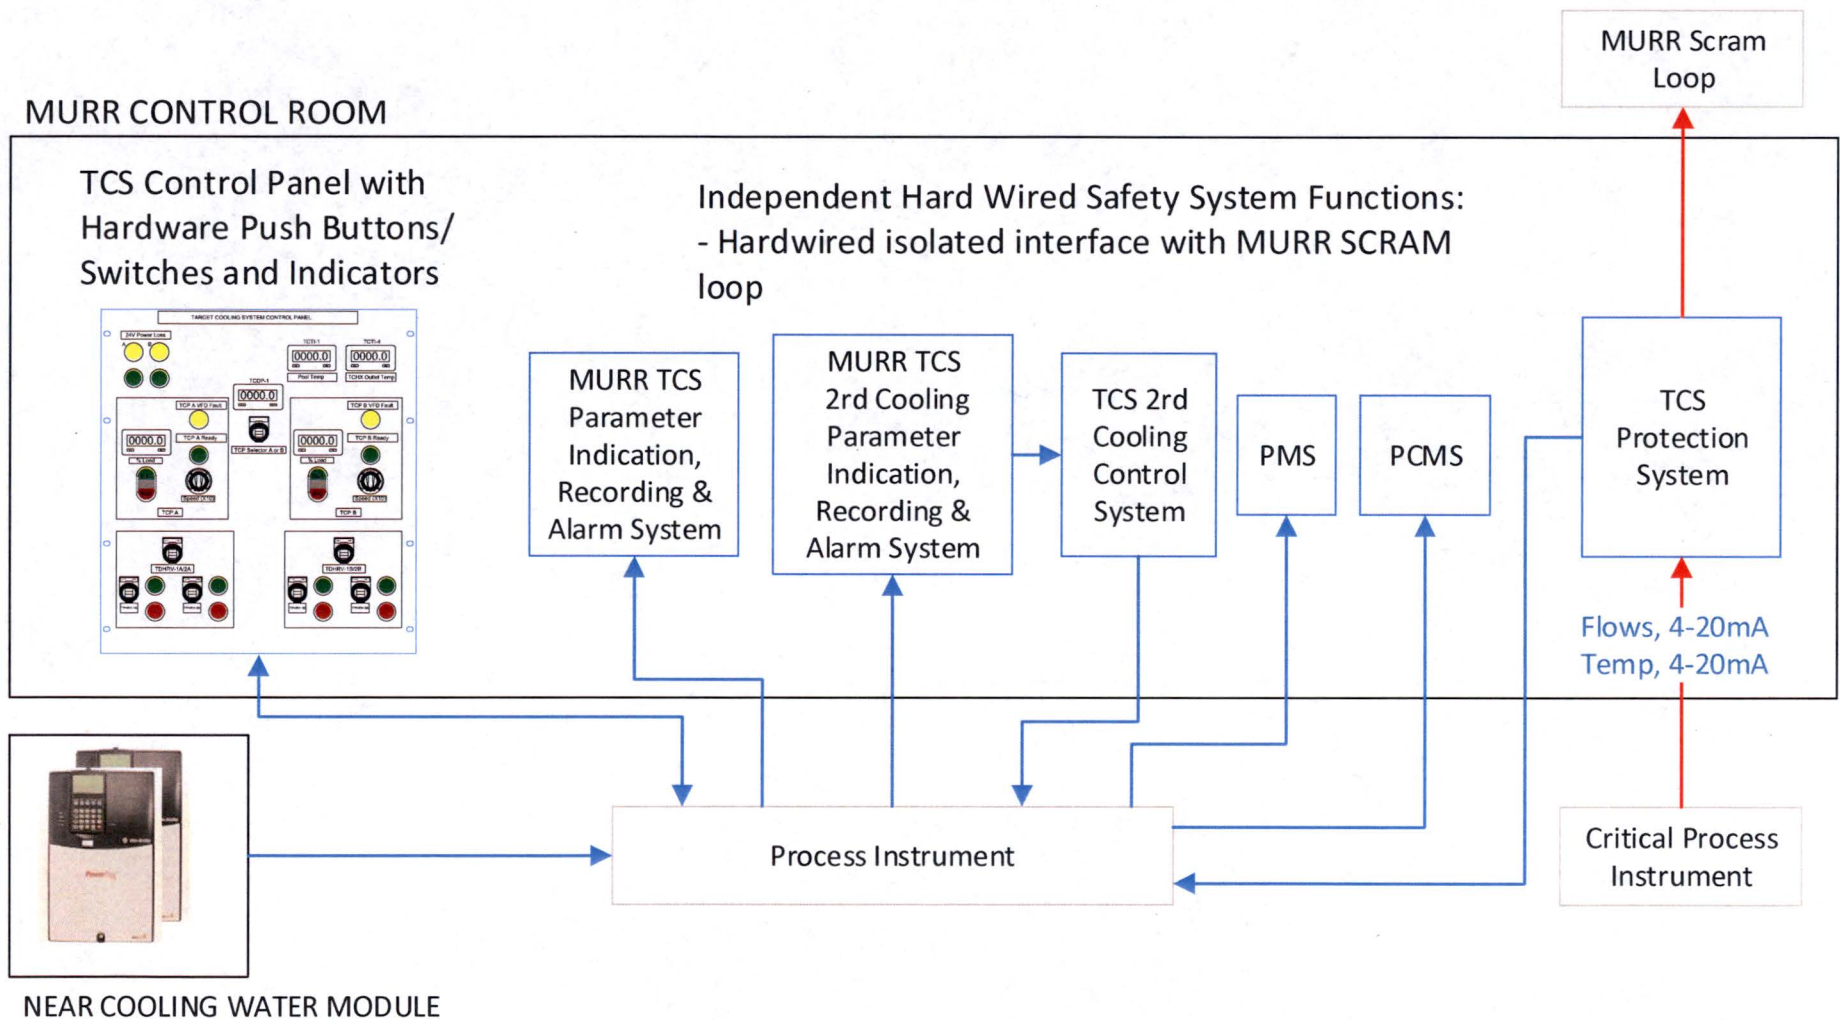

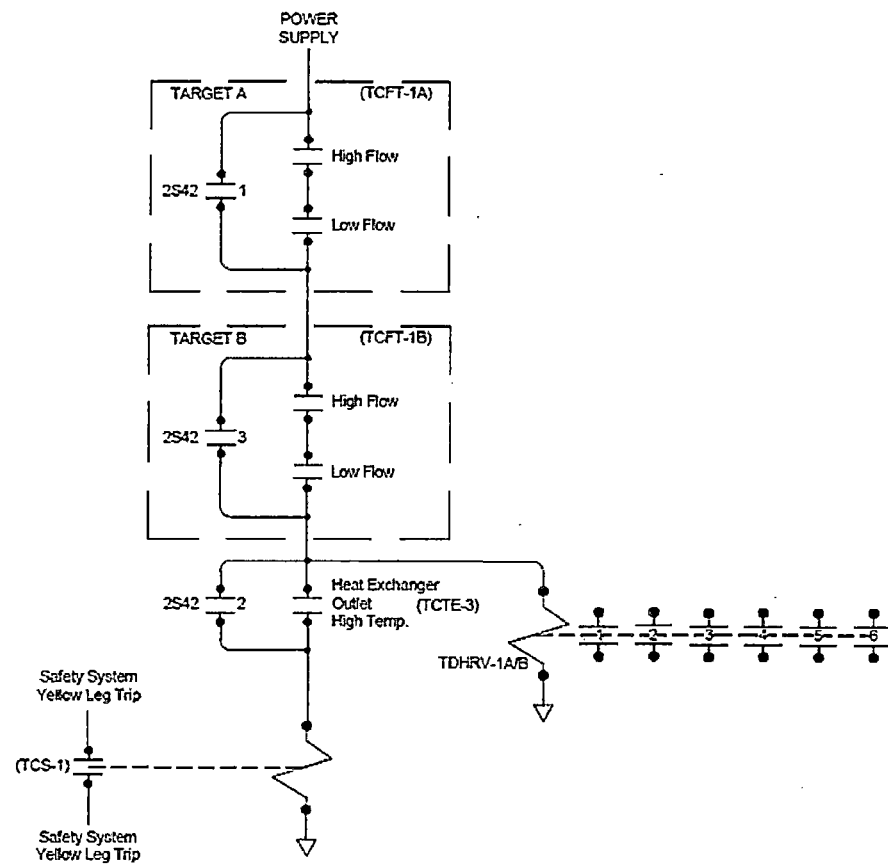

Figure 4-2.a  
Independent Hardwired Isolated Interface with MURR Scram Loop Block Diagram

4.3. *The LRA indicated that numerous indication and alarm systems will be added for the TEF I&C systems, but does not state how the operator will manage the additional task load successfully. For each of the systems listed above (a) through (g), provide a summary of the human-machine interface principles used in the location of the associated control console and other status display instruments for the TEF I&C systems, as listed below [draft ISG 7.6].*

4.3.1. *Explain how control, safety, and associated TEF position indication systems and alarm and warning lights are displayed and readily accessible and understandable to the reactor operator or justify why no additional information is needed.*

4.3.2. *Explain the other controls and displays of important parameters that the operator should monitor to keep TEF parameters within a limiting value, and those that can affect the reactivity of the core, are readily accessible and understandable to the reactor operator or justify why no additional information is needed.*

**NOTE:** Responses to RAI No. 4.3.1 and 4.3.2 are combined in the following TEF subsystem paragraphs below:

(a) *TCS Control System:*

The TCS control system is designed to control Target Cooling System (TCS) pump operation and the position of the Target Decay Heat Removal Valves (TDHRVs). From the TCS control system, the operator can start, stop, and change the speed of the TCS pumps during normal operations. In addition, the TCS control system contains an interlock between the TCS pumps and position of the TDHRVs that prevents the TCS pump from operating when any one of the TDHRVs are open. This interlock is actuated from a position indication switch located on each TDHRV actuator, which opens the contact that de-energizes both of the TCS pump control circuits.

The TCS control panel is shown in Figure 4-3.a. The indication lights on the TCS control panel are displayed based off the signals to the TCS control system.

In the upper left hand corner of the control panel, there are illuminated lights for the 24VDC redundant power supplies. Two (2) green lights under the 24V power loss label displayed on the TCS control panel means that both of the 24 VDC power supplies are operating properly. A yellow light under the 24V power loss label informs the operator that a redundant power supply has failed and needs to be replaced. In other words, a green light means normal operation and a yellow light means abnormal operation.

The TCS control panel also includes indications of TCS pump load, differential pressure of the coolant (TCDP-1) across the Target Cooling System Module (TCSM), pool temperature (TCTI-1) and TCS heat exchanger (TCHX) coolant outlet temperature (TCTI-4). The pump load (%) indications show the ratio of TCS pump motor operating current (A) to the TCS pump motor maximum current (A) at 100% speed. The differential pressure (psid) (TCDP-1) indication

shows the pressure drop between the TCSM coolant inlet and outlet. The TCSM pressure drop provides maintenance information on the HX train in the TCSM. The pool temperature (TCTI-1) shows the temperature of TCSM coolant inlet (or the pool temperature). The TCHX coolant output temperature (TCTE-4A/B) provides data on TCSM performance. This temperature is also used as a feedback for the temperature control in the secondary coolant loop via control valves (S-3A or S-3B) in the TCS secondary coolant control system.

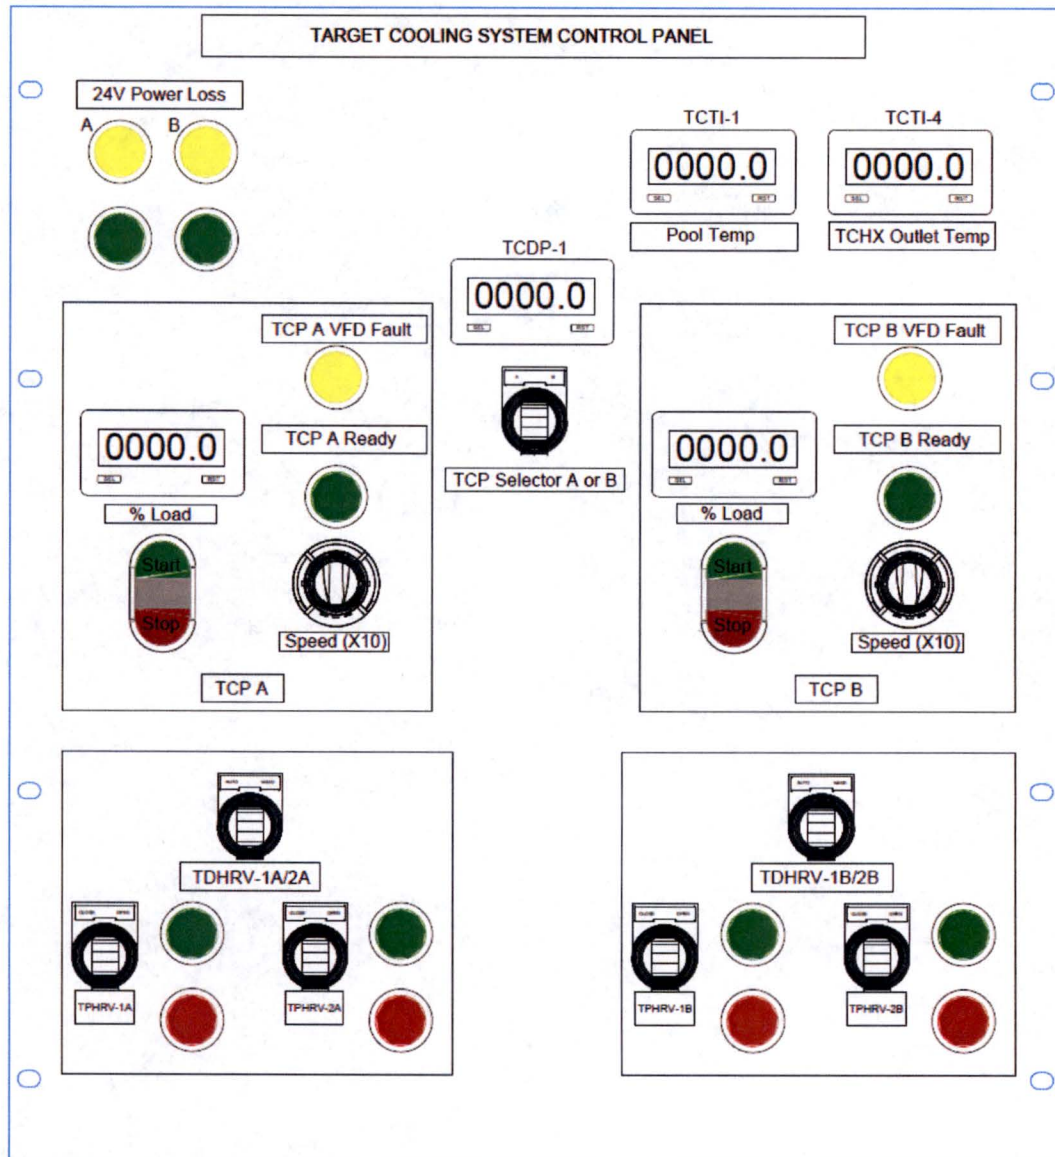

Figure 4-3.a  
Target Cooling System Control Panel Layout

The temperature measurement (TCTI-4) located between the HX outlet from the TCSM and the Target Assemblies is displayed on the upper right hand corner of the TCS control panel. Reactor pool temperature (TCTI-1, also the TCS pump inlet temperature) is also displayed in the upper right corner of the panel. In the middle of the control panel is the differential

pressure measurement of the inlet and outlet of the TCSM. The selector switch is underneath the differential pressure measurement, which allows the operator to switch between controlling the TCS pump TCP-A or TCP-B.

TCP-A and TCP-B are the pumps for the TCS. One will be operated while the other is secured. The operator will know if pump TCP-A or TCP-B is operating normally by the illuminated lights. A green light indicates the pump is ready for use, and a yellow light indicates the variable frequency drive (VFD) has faulted. When the green light is not illuminated, this indicates that the TCS pump is interlocked or the VFD is faulted whereas a yellow light indication only appears if the VFD has faulted. The TCS pump is interlocked when one (or more) TDHRVs are open, and this will result in the green light not being illuminated. TCP-A controls and indications are located on the left side of the TCS control panel, whereas TCP-B controls and indications are located on the right side of the panel. The VFD, which controls the TCS pump, is electrically wired to the TCS control system and is controlled from the TCS control panel. On the panel, the operator can use the on/off pushbuttons to activate/deactivate the VFD, and use the speed dial to vary the VFD frequency. The VFD then controls the speed to the TCS pump. The percentage load indication on the TCS control panel describes the percentage of electric current in use by the pump over the current of the maximum speed.

'Auto/Manual' switches for the TDHRVs are found on the TCS control panel. During normal operation, 'Auto/Manual' switches are locked to 'Auto' mode in which the TDHRVs are closed. When the TDHRVs are in 'Manual' mode, the operator can individually change the position for each of the TDHRVs from the TCS control panel as needed for maintenance or troubleshooting purposes without the effects from the interlock between the TCS pump and the TDHRVs. The 'Manual' mode is used only for system maintenance or testing when the reactor is shutdown. In order for the TDHRVs to be switched to manual mode, maintenance key(s) must be inserted into a selector switch(es) on the TCS control panel. The use of these keys will require Reactor Manager's permission to perform maintenance or testing.

Indications and controls on the control panel for TDHRV-1A/2A for Target Assembly A are on the left side and for TDHRV-1B/2B for Target Assembly B are on the right side. The limit switches for the TDHRVs send a signal to the TCS control system for the status of the valve, which is displayed on the control panel by an indication light. On the TCS control panel, a green light means normal operation of the valve and a red light means abnormal operation of the valve. The valves are closed in normal operation and open in abnormal operation. If the red light is indicated on the TCS control system, the TDHRVs are open to allow the pool water to enter the Target Assemblies by natural convection for cooling of the Target Assembly.

Each individual light bulb can be tested by push-to-test. A burnt out lightbulb will not light up during the push-to-test. In addition, the push-to-test has no other functions or real device actuation other than testing to indicate whether the lightbulb is working properly.

Table 4-3.a below provides a list of all possible alarms for the TCS and the corresponding alarm indication colors. The table also provides the actions and steps that the operator must perform after the indication or alarm has signaled.

Table 4-3.a  
Target Cooling System Alarms/Indications and Possible Faults

<b>Alarms</b>	<b>Alarm Indication</b>	<b>Possible Fault</b>
24V power supply A fault signal	Yellow light on	Power supply A may be faulted.
24V power supply B fault signal	Yellow light on	Power supply B may be faulted.
24V power supply A OK signal	Green light not on	(1) Power supply A may be faulted. (2) The green lightbulb may be burned out.
24V power supply B OK signal	Green light not on	(1) Power supply A may be faulted. (2) The green lightbulb may be burned out.
TCP A fault signal	Yellow light on	The VFD A may be faulted.
TCP B fault signal	Yellow light on	The VFD B may be faulted.
TCP A ready signal	Green light not on	(1) VFD A may be faulted. (2) The green lightbulb may be burned out.
TCP B ready signal	Green light not on	(1) VFD B may be faulted. (2) The green lightbulb may be burned out.

The TCP control system with its associated alarms and warning lights will be placed within easy view of the Console operator. It will be to the operator's left as the operator is sitting at the reactor control console. When the operator is standing near the TCS control panel, the switches of the panel are in easy reach of the operator. See the draft copy of the MURR Control Room Instrument Cabinet shown as Figure 4.f. During normal operation, the TCP control system will be started and flow rates adjusted prior to reactor startup so that during reactor startup and operation, the operator will have no need to adjust the TCP controls. The indication of all green lights and a lack of alarms will inform the operator that the TCP Control System is operating normally. The TCP control system is labeled 'D' on Figure 4.f.

*(b) TCS Protection System*

The TCS protection system has only two (2) indications available to the operator, which are both on the main MURR Annunciator. These indications are the "TCS Flow Scram" annunciation and the "TCS Temp Scram" annunciation. These scram annunciations are

activated by a loss of signal from the associated analog trip alarm unit that initiated the reactor scram and provide the operator with a red flashing light and a distinctive audible alarm indicating an abnormal condition. Table 4-3.b below illustrates the operation of all MURR Annunciations, and the “TCS Flow Scram” annunciation and the “TCS Temp Scram” annunciation will operate the same way. During normal TCS operations, the annunciator will be unlit and silent. The TCS protection system will only add operator task load in a TCS abnormal event. To identify where the MURR Annunciator is in the Control Room, see Figure 4.f where the MURR Annunciator is labeled ‘1’.

Table 4-3.b  
MURR Annunciator Alarm Sequence

Condition	Illumination	Audible Signal
Normal	Off	Off
Alarm Input	Flashing	On
Alarm Input Acknowledged	Steady-On	Off
Return to Normal	Dim Flashing	On
Reset	Off	Off
Operational Test	Flashing	On

*(c) TCS Parameter Indication, Recording and Alarm System*

Two (2) digital chart recorders will display and record all of the TCS flow rate and temperature parameters of the two (2) TCS cooling branches. One chart recorder will record and display Target Assembly A Cooling parameters, and Target Assembly B Cooling will have its own recorder. The operator will be able to select any of the parameters for display in either a real-time signal display or a historical trending display. The chart recorders will also provide alarms for abnormal TCS parameters as an operator aid. The chart recorders will be to the operator’s left as the operator is sitting at the reactor control console. These chart recorders are labeled ‘B’ and ‘C’ on Figure 4.f. During normal TCS operations, the only additional operator task will be taking logs on TCS process parameters once every two (2) hours.

*(d) TCS Secondary Coolant Control System*

The TCS secondary coolant control system consists of a pump control panel where the operator will be able to start/stop the TCS secondary coolant pump (SP-5), raise or lower the speed of SP-5, and monitor the percent speed and percent electrical current load of SP-5. It also consists of a programmable proportional-integral-derivative (PID) controller, which adjusts the secondary coolant flow rate to the TCS heat exchanger.

There are no lights or alarms associated with the TCS secondary coolant control system. However, the TCS secondary coolant pump control panel will be within two (2) feet of the TCS

secondary coolant paperless chart recorder where TCS secondary coolant flow rate and temperatures are available to the operator as the operator adjusts SP-5 speed. The SP-5 control panel is labeled 'G' on Figure 4.f whereas the TCS secondary coolant chart recorder is labeled 'I' on Figure 4.f. This pump control panel is in easy reach of a standing operator. The control room operator will start SP-5 before or during a reactor startup, as required, and adjust the speed of SP-5 as needed to maintain proper water temperature to the Target Assemblies. Once the reactor is at 10 MW, the operator will only need to adjust SP-5 speed as weather conditions significantly change the secondary coolant inlet water temperatures. Otherwise, the TCS secondary coolant control system will automatically control secondary coolant flow to the TCS heat exchanger as described in the next paragraph.

During normal operation, the TCS secondary coolant control system will automatically adjust the position of valve S-3A or S-3B to control the temperature of the water going to the Target Assemblies by changing the secondary coolant flow rate going through the TCS heat exchanger. A PID controller that is controlling the position of valve S-3A or S-3B displays a 0 to 100 percent indication of the position of either S-3A or S-3B. Controlling flow rate with valve S-3A or S-3B is a fine adjustment of flow rate used to compensate for small, short-term fluctuations in coolant temperature. The S-3A/S-3B PID controller is labelled 'A' on Figure 4.f.

*(e) TCS Secondary Coolant Parameter Indication, Recording, and Alarm System*

One (1) digital chart recorder will record and display the TCS secondary coolant flow rate and temperature parameters. The operator will be able to select any of the parameters for display in either a real-time signal display or a historical trending display. The chart recorders will also provide alarms for abnormal TCS secondary coolant temperature, flow rate, and valve S-3A/S-3B position. The chart recorder will be to the operator's right as the operator is sitting at the reactor control console. This chart recorder is labeled 'I' on Figure 4.f. During normal TCS operations, the only additional operator task will be taking logs on TCS process parameters once every two (2) hours.

*(f) N-16 Reactor Power Monitoring System*

The N-16 reactor power monitoring system has two (2) independent channels with two (2) independent indications (Rack Mounted Ratemeter – see Figure 4.3-b) in the Control Room labeled 'H' on Figure 4.f (there will also be a third installed spare). It is to the operator's right as the operator is sitting at the reactor control console. During normal reactor operation, the only additional operator task will be taking logs on the N-16 reactor power monitor once every two (2) hours.

Figure 4-3.b  
N-16 Reactor Power Monitoring System Indication (1 of 2)

(g) *Pool Coolant Monitoring System*

The pool coolant monitoring system has only one (1) bar graph indication showing a value between 1 and 100% and one (1) pool coolant high activity alarm which is audible and has a red light. Both the indication and alarm are labeled 'F' on Figure 4.f. It is to the operator's left as the operator is sitting at the reactor control console. During normal TCS operations, the only additional operator task will be taking logs on the pool coolant monitor level once every two (2) hours.

4.3.3. *Explain how displays and controls provided for manual system-level actuation and control of safety equipment will be functional under conditions that may require manual actions or justify why no additional information is needed.*

(a) *TCS Control System:*

The target cooling flows are designed for manual operations. The operators set cooling flow rate by varying TCS pump speed using the potentiometer on the TCS control panel to obtain a nominal flow rate. There are no other TCS control system manual actions required by the operator during either normal or abnormal conditions.

(b) *TCS Protection System*

There is no manual actuation of the TCS protection system. However, in the event something happened to the TCS where the operator needed to protect the TEF and/or reactor, the operator would push the reactor Manual Scram button located at the reactor control console. The Manual Scram button not only de-energizes both the "Yellow" and "Green" Legs of the MURR Safety System to cause a reactor scram by tripping the Trip Actuator Amplifiers (TAAs) of the MURR Safety Circuit, it also secures all electrical power to the electromagnets of all four (4) shim control blades.

*(c) TCS Parameter Indication, Recording and Alarm System*

There is no control function and no safety equipment associated with the TCS parameter indication, recording, and alarm system.

*(d) TCS Secondary Coolant Control System*

There is no safety equipment associated with the TCS secondary coolant control system.

*(e) TCS Secondary Coolant Parameter Indication, Recording, and Alarm System*

There is no control function and no safety equipment associated with the TCS secondary coolant parameter indication, recording, and alarm system.

*(f) N-16 Reactor Power Monitoring System*

There is no control function and no safety equipment associated with the N-16 reactor power monitoring system.

*(g) Pool Coolant Monitoring System*

There is no control function and no safety equipment associated with the pool coolant monitoring system.

*4.3.4. Provide diagrams that illustrate the various control panel layouts for controls and indicators, including labeling and color schemes (similar to Figure 31 for the TCS Control Panel). Additionally, provide a general depiction of where all of the system control and indicators are located in relation to the operator or justify why no additional information is needed.*

*(a) TCS Control System:*

The location of the indicators, alarms, and controls on the TCS control panel are described in the response to RAI No. 4.3.1 and are displayed in the TCS control panel layout in Figure 4-3.a. The TCS control system has a TCS control panel located in the MURR control room as shown on Figure 4.f, "MURR Control Room Instrument Cabinet." The entire MURR Control Room Instrument Cabinet, including all its components, is in easy view of the Console operator. The TCS control panel is labeled "D" on Figure 4.f.

*(b) TCS Protection System*

See Figure 4.f in response to RAI No. 4.3.1 and 4.3.2.

*(c) TCS Parameter Indication, Recording and Alarm System*

Figure 4-3.c is a photo of a working chart recorder from a Yokogawa brochure and is similar to the chart recorders that will be used. Therefore, it is not displaying exactly how the TCS parameter indication, recording, and alarm chart recorder displays will be configured. However, it can be seen that many color and display options are available.

These chart recorders are labeled 'B' and 'C' on Figure 4.f.

Figure 4-3.c  
Yokogawa Chart Recorder  
(similar to chart recorders used for the TCS  
and TCS secondary cooling parameter indication, recording, and alarm systems)

(d) *TCS Secondary Coolant Control System*

Figure 4-3.d.1 is a photo of a MURR variable speed pump control panel. The TCS secondary coolant pump (SP-5) control panel will be similar, but not exactly, like the control panel shown below.

The SP-5 pump control panel location is labeled 'G' on Figure 4.f and is to the right of the operator sitting at the reactor control console.

Figure 4-3.d.1  
Existing MURR Variable Speed Drive Pump Control Panel

Figure 4-3.d.2 is a photo of an existing MURR valve PID controller. The PID controller for valve S-3A/S-3B is the exact same controller as shown.

The valve S-3A/S-3B PID controller location is labeled 'A' on Figure 4.f and is to the left of the operator sitting at the reactor control console.

Figure 4-3.d.2  
Valve S-3A/S-3B PID Controller

(e) *TCS Secondary Coolant Parameter Indication, Recording, and Alarm System*

Figure 4-3.c is a photo of a working chart recorder from a Yokogawa brochure and is similar to the chart recorder that will be used. Therefore, it is not displaying exactly how the TCS secondary coolant parameter indication, recording, and alarm chart recorder display will be configured. However, it can be seen that many color and display options are available.

This chart recorder is labeled 'T' on Figure 4.f.

(f) *N-16 Reactor Power Monitoring System*

See Figure 4-3.b in response to RAI No. 4.3.1 and 4.3.2. It will be configured to read out in % reactor power.

(g) *Pool Coolant Monitoring System*

Figure 4-3.g is a photo of the pool coolant monitor indication located in the MURR Control Room.

The pool coolant monitor indication location is labeled 'F' on Figure 4.f and is to the left of the operator sitting at the reactor control console.

Figure 4-3.g  
Pool Coolant Monitor Indication in the MURR Control Room

4.4. The NRC staff review did not find a complete a description of the TEF I&C system instruments by type [e.g., hardwired analog, computerized digital that uses stored programs (software, which includes firmware), or combinations of these], and there was no discussion or identification of digital systems. The NRC staff review found that some systems are hardwired analog, but not all systems. Provide a description of the TEF I&C system instruments by type, or justify why no additional information is needed.

Table 4-4 provides a list of the sensor measurements in the SGE TEF with their corresponding specifications such as measurement type, sensor designation and location(s), sensor details, and measurement specification.

Table 4-4  
SGE TEF Control Instrumentation Specifications

Measurement Type	Sensor Designation & Location(s)	Sensor Details	Measurement Specifications
Temperature	TC TE-1 for the pool water entering the TCSM inlet	Dual-element platinum RTD(s) in a thermowell. Signal conditioners are used to convert RTD signal to 4 to 20 mA analog signals.	<ul style="list-style-type: none"> <li>• Range: 32-500 °F</li> <li>• Accuracy: Class A</li> <li>• 4 to 20 mA analog output</li> </ul>
Temperature	TC TE-2, TC TE-3, TC TE-4A/B at the TCSM outlet	Dual-element platinum RTD(s) in a thermowell. Signal conditioners are used to convert RTD signal to 4 to 20 mA analog signals.	<ul style="list-style-type: none"> <li>• Range: 32-500 °F</li> <li>• Accuracy: Class A</li> <li>• 4 to 20 mA analog output</li> </ul>

\* NOTE: Accuracy as stated in manufacturer's brochure compared with small test source. The N-16 reactor power monitoring system will be calibrated in place against a thermal power calculation at full reactor power to increase the accuracy of the system to within 1% of the thermal power calculation.

(a) *TCS Control System:*

Figure 4-1.a shows the TCS control system block diagram and includes the interfaces with the TCS protection system, which is used to initiate a reactor scram. In this figure, the two (2) subsystems shown in the MURR control room are the TCS control system and the TCS protection system. The TCS control panel is also displayed in the MURR control room. The left side of Figure 4-1.a lists all of the field process instruments in the TCS control system and includes designations. The process instruments are listed by digital inputs, analog inputs, digital outputs, and analog outputs for normal devices, and analog inputs for critical devices.

The following digital input signals are sent directly to the TCS control system for display on the TCS control panel as a normal or abnormal condition: 24 VDC power supplies, VFD's for the TCS pumps, and TDHRVs position status. The TCS differential transmitter signal is also displayed on TCS control panel. Reactor pool temperature and TCHX temperature sensor are converted into 4 to 20 mA output signals by the signal conditioners in the cooling system junction box and then displayed on the TCS control panel. The VFDs in the target cooling junction box control the speed for the TCS pumps. The heat exchanger outlet temperature sensors are also converted to 4 to 20 mA output signals by the signal conditioners in the cooling system junction box and then electrically wired to the TCS protection system. The inlet flow sensors for the Target Assemblies are directly wired to the TCS protection system.

The field process equipment in Figure 4-1.a provide the TCS control system and the TCS protection system with the sensor information and data as described above. The electrical wired dashed line shows that the TCS control system controls the field process equipment for the speed and on/off capability of the TCS pump and open/closed capability of the TDHRVs.

The TCS protection system de-energizes an analog, electrical signal to scram the reactor in the event of abnormal condition for flow or temperature. In the event of abnormal flow condition, the TCS protection system also de-energizes an electrical interlock signal to the TCS control system to open the TDHRVs and secure the TC pumps.

Both the TCS and TCS secondary coolant parameter indication, recording, and alarm systems use digital chart recorders to provide indication of all parameters, recording of all parameters, and alarms on some of the parameters. The indication, recording, and alarm functions of these digital recorders are operator aids and are not required for TEF or reactor safety.

The pool coolant monitoring system uses a digital, programmable multi-channel analyzer (MCA) to allow only gamma energies associated with I-132 to be processed as a signal. The MCA includes adjustable 4 to 20 mA readings to the calibrate control room indication to known test sources.

The N-16 reactor power monitoring system uses a digital rate meter to process the output of the ion chamber into a usable signal and provides indication in the control room. The rate meter includes adjustable outputs to the calibrate control room indication to a thermal power calculation.

4.5. *The NRC staff review did not find a discussion of any additional area and effluent radiation detection systems to be installed to facilitate the TFE system that monitor and alarm to provide indication of potentially hazardous radiation levels, including alarms or signals to other subsystems, as applicable. Provide information on any additional area and effluent radiation monitors, or justify why no additional information is needed.*

No additional area or effluent radiation detection systems are required for TEF operation. The MURR facility already has sufficient area radiation monitors at the reactor pool surface, radiation monitors in the reactor containment building ventilation exhaust plenum, and a facility exhaust stack radiation monitoring system. The existing facility radiation monitors have the proper range and

sensitivity and are capable of detecting and protecting against any radiation hazard potential of TEF operation.

- 4.6. *The NRC staff review did not find a discussion of access control features (e.g., variable frequency drives with accessible control pads for local maintenance control shown in LAR, Attachment 1, page 54, Figure 30), to includes both preventing unauthorized access and allowing authorized access for both analog and digital systems (as applicable). Provide information on access controls such as alarms and locks on panel doors, or administrative control of access to rooms, and the protection of any networked systems (if applicable) or justify why no additional information is needed [draft ISG 7.2.5].*

During normal operation, the TCS pump remote on/off and TCS pump speed are controlled by the operator at the TCS control panel located in the MURR control room. For maintenance, diagnostic, and troubleshooting purposes, the TCS pumps can be controlled directly from the variable frequency drives (VFDs) in their enclosure cabinet. This local control of the VFDs requires Reactor Manager's approval because it involves changing the VFD program to stop receiving control inputs from the TCS control panel and instead receive control inputs from the keypad on the VFD. After maintenance, the TCP control inputs are reset to come from the TCS control panel.

Additionally, each VFD is located in an enclosure with a locked door handle, as shown in Figure 4.6. The VFD enclosures are located near the TCS pumps. The door is interlocked with a handle mechanism to prevent the door from being opened without first turning off power via the fused disconnect. There are two (2) ways to operate this handle. The first method requires the operator or maintenance personnel to turn off the high power feed to the VFD enclosure from distribution panel HVP-4 (Section 3.4.9 of LAR Part 1 Attachment 1) prior to opening the door. A second way allows the maintenance personnel to troubleshoot the VFD while energized. The handle does have an override mechanism that allows maintenance personnel to open the enclosure door without disconnecting the power for troubleshooting purposes, if needed. The handle also has padlock provisions for lock out/tag out.

Figure 4.6  
Variable Frequency Drive Enclosure

- 4.7. *The NRC staff review finds that the keyed bypass switches to the TCS Protection System (LAR, Attachment 1, Section 4.3.3, "Target Cooling System Protection Bypass Capability"), allow for reactor operation with the TCS not operating, one TCS branch operating, or both TCS branches operating. The keyed bypass removes the protection signal inputs for any part of the TCS that is not operating. However, the following information was not provided. Provide the following information or justify why no additional information is needed:*

First of all, there has been a change to the bypass switch design to the TCS protection system since the license amendment for this project was first submitted. MURR staff realized that using one (1) keyed bypass switch allowed a potential for a single failure to affect both the "Yellow" and "Green" legs of the safety system of the TCS protection system. Therefore, the design has changed to have two (2) independent keyed bypass switches; one switch for the "Yellow" safety leg and the other for

the “Green” safety leg. The revised design has no physical connection between the “Yellow” and “Green” safety legs and is represented by Figure 4.7.

*4.7.1. The procedural administrative control of authorized use for the keys for the bypass switches (i.e., MURR standard operating procedure or TS).*

Similar to the NRC-approved use of bypasses for the safety system legs of the Flux-Trap Irradiations Reactivity Safety Trip (FIRST) device approved by MURR License Amendment No. 35 (dated February 9, 2012), the bypass switches of the TEF protection system will be controlled in the same manner. See current MURR Technical Specification 3.2.g.21., Center Test Hole, and associated note (5) that requires Reactor Manager's permission to bypass the safety function of the FIRST device.

The draft, proposed Technical Specifications, attached as Enclosure 1 to this submittal, state that the TEF protection system shall only be bypassed with the specific authorization of the Reactor Manager. During normal TEF TCS operations with both Target Assemblies operating, no keys will be inserted into the switches (2S42 and 2S43). However, if either one or both Target Assemblies will not be running, two (2) bypass keys with bright yellow tags will be inserted and required to be in the correct positions. Keys with the bright yellow tags inserted into 2S42 and 2S43 will be obvious to all operators in the control room. In addition, the operating procedure for starting up, operating, and shutting down the TCS will also have instructional steps reminding operators to receive Reactor Manager's specific permission to use the keys. This procedure will require two-person verification that the keyed bypass switches are in the correct positions prior to reactor startup.

*4.7.2. The location of the bypass keys on the reactor console, and specifically, if any visual indication is provided for the bypass status of the individual green and yellow safety legs.*

The keyed bypass switches will be left of the operator sitting at the reactor control console. The switches will be on the MURR Instrument Cabinet. The switches are labeled 'E' on Figure 4.f. The switches are purposely placed near the TCS control panel and at easy eye level to see when they are inserted. The presence of the keys with bright yellow tags will infer a bypass is being used because the keys will be locked in a cabinet when no bypass function is required.

*4.7.3. Electrical isolation of the relay inputs to the MURR Reactor Safety System (RSS) between the yellow and green safety legs and each leg and the MURR RSS.*

As stated earlier, the keyed bypass switch design submitted with the original license amendment request did not have electrical isolation between the TCS "Yellow" and "Green" safety legs. However, the revised two (2) bypass switch design as shown in Figure 4.7 eliminates all electrical connections between the TCS "Yellow" and "Green" safety legs. Therefore, there is electrical isolation between the TCS "Yellow" and "Green" safety legs, the TCS safety legs and the MURR reactor safety system, and the MURR reactor safety system "Yellow" and "Green" safety legs. The only interaction between a TCS safety leg and the MURR reactor safety system is the magnetic coupling inside the associated relay (TCS-1 or

TCS-2) between the relay solenoid and its normally open contact wired into the reactor safety system.

4.7.4. *LAR, Attachment 1, Section 4.3.3, discusses a failure or misuse of a single switch with two TAs operating, but does not fully discuss the single component failure criteria associated with the operating loop with the implications of the other loop being intentionally bypassed due to being non-operating. Discuss the single component failure criteria when only one TA loop is operational and the failure exists in that operating loop.*

The following example will be used to answer 4.7.4. In this example, Target Assembly A will be the operating assembly, and Target Assembly B will be non-operating.

Since Target Assembly B is non-operating, the operating procedure will have cooling isolation valves closed to the Target Assembly B branch of the TCS. Therefore, flow transmitters TCFT-1B and TCFT-2B will read zero (0) gpm, and the associated trip unit will have opened the Target B Low Flow contacts in both the TCS "Yellow" and "Green" safety legs. Refer to Figure 4.7 during this explanation. Therefore, to bypass the TCS low flow scram function for Target B, both switch contacts 2S42-3 and 2S43-3 must be closed, with Reactor Manager's approval. The TCS operating procedure will direct the operator to place both switches 2S42 and 2S43 to the 'Target B Bypass' position to make contacts 2S42-3 and 2S43-3 close.

In this configuration, only the TCS high and low flow protection contacts for Target Assembly B have been bypassed. All the contacts for Target Assembly A high and low flow protection and both of the heat exchanger outlet temperature contacts are still effective for causing a reactor scram.

In this configuration, Target Assembly A still has two (2) independent flow transmitters connected to two (2) independent analog trip units providing output to two (2) independent high flow safety contacts and two (2) independent low flow safety contacts which are located in two (2) independent TCS safety legs ("Yellow" and "Green") providing input to the two (2) existing independent reactor safety system safety legs ("Yellow" and "Green") via two (2) fail-safe relays (TCS-1 and TCS-2). Target Assembly A also has two (2) independent temperature detectors and transmitters connected to two (2) independent analog trip units providing two (2) independent heat exchanger outlet high temperature contacts which are located in two (2) independent TCS safety legs ("Yellow" and "Green") providing input to the two (2) existing independent reactor safety system safety legs ("Yellow" and "Green") via two (2) fail-safe relays (TCS-1 and TCS-2).

As stated in the response to RAI No. 4.7.3, the bypass switches are now also electrically isolated.

There is redundancy in every safety sensor transmitter, relay, contact, switch, and safety loop signal for the operating Target Assembly even when the other Target Assembly protection is

bypassed. In addition, the entire safety system is designed to scram the reactor on a loss of signal. Therefore, no single failure of sensor transmitter, relay, contact, switch, and safety loop signal will cause the operating target to lose scram protection.

- 4.8. *The NRC staff review did not find a complete description of the hardware detectors for the TCS Flow Elements, TCS Flow Transmitters, Pool Coolant Monitoring System detector, and the Target Cooling Automatic Temperature Control Valves (S-3A and S-38). Provide a description of the hardware detectors, or justify why no additional information is needed.*

The TCS target flow meters TCFE/TCFTs have been addressed in Table 4-4, "TEF Control Instrument Specifications."

The pool coolant monitoring system detector is a sodium iodide scintillation detector. The detector is inserted into a 2.7-liter housing in which pool coolant flows through at a rate of one (1) gallon per minute. Per Attachment 1 of the original LAR Part1, the pool coolant monitor was to detect the fission product I-131. The system's multi-channel analyzer was to be centered on I-131's 364 keV gamma. Due to excessive signal noise from other pool coolant isotopes in the energies around 364 keV, MURR has decided to change the pool coolant monitor's multi-channel analyzer to have a detection window centered on the 667 keV gamma of I-132, another fission product. Please note this important change. I-132 produces a 667 keV gamma 99% of the time when it decays and is produced in significant quantities during the fission of U-235. The energy range around 667 keV contains significantly less background noise from other radioisotopes in the pool coolant. In addition, the design change from detecting I-131 to I-132 allows the removal of the cation resin column of the pool coolant monitoring system piping. The cation resin was originally needed to reduce the Na-24 double escape peak noise in the 364 keV range. Removing the cation resin from the design reduces radiation dose to staff who would have to maintain the resin column over many years.

The target cooling automatic temperature control valves (S-3A and S-3B) are 3-way valves, which will control the secondary coolant flow rate by passing coolant through the TCS heat exchanger and also bypassing coolant around the heat exchanger. The valve position will be controlled by an electric motor. Single loop programmable PID controllers, providing both automatic and manual control of the output signal, establish the valve position. In automatic mode, the process variable represented by an analog signal is input into the controller where it is compared to an established set point. The controller calculates the error between the process variable input and the set point and provides an analog output to position the control valve until the error between the analog input and the set point is eliminated. In manual mode, the output of the controller is driven between 0-100% allowing the operator to position the valve manually.

- 4.9. *LAR, Attachment 1, Section 3.4.9, "Electrical Power System Supporting the TCS," indicates that the new electrical system and power provided from MCC-4 is safety-related. The NRC staff review did not find information related to whether an electrical breaker coordination study was performed to ensure that downstream breakers do not trip breakers located upstream. Provide an analysis to ensure that the selected breaker and cable for electrical equipment is properly*

*sized (i.e., to ensure adequate voltage is available at the terminals of the equipment—e.g., cooling pumps), or justify why no additional information is needed.*

The sentence “Location of the new electrical wiring will ensure that no electromagnetic interference will exist between the electrical power service and any safety-related I&C circuits” did not mean to imply that there is safety-related equipment that requires electrical power in order to perform their function. As described in Section 10.12, “Loss of Offsite Electrical Power,” a loss of electrical power will cause the reactor to scram, the Target Cooling System (TCS) pumps to secure, and the redundant, parallel Target Decay Heat Removal Valves (TDHRV) to open. Electrical power is not required to safely shutdown the Target Experimental Facility (TEF) or for it to maintain a safe shutdown condition.

Additionally, the modification to the MURR electrical power system – addition of a new high voltage panel HVP-4, a new 112.5-kVA transformer and a new 120/208-V lighting panel – was designed by University of Missouri Planning, Design and Construction Services in compliance with all applicable electrical codes and standards, including proper sizing of breakers and conductors. The rules governing and controlling design and construction practices for the University have been established and approved by the Board of Curators in the Collected Rules and Regulations 70.060. The following codes and standards were used:

- International Building Code – 2015
- International Plumbing Code - 2015
- International Mechanical Code – 2015
- International Existing Building Code – 2015
- International Fire Code - 2015
- International Fuel Gas Code - 2015
- National Electric Code – 2014
- NFPA 110 Standard for Emergency and Standby Power Systems - 2013
- NFPA 101 Life Safety Code – 2015
- NFPA 99 Standard for Health Care Facilities – 2005
- NFPA 96 Standard for Ventilating Control and Fire Protection of Commercial Cooking Operations - 2014
- NFPA 90A Installation of Air Conditioning and Ventilating Systems - 2015
- NFPA 72 National Fire Alarm Code – 2013
- NFPA 45 Standard on Fire Protection for Laboratories Using Chemicals – 2015
- NFPA 20 Standard for the Installation of Stationary Fire Pumps for Fire Protection - 2013
- NFPA 14 Standard for the Installation of Standpipe, Private Hydrants and Hose Systems - 2013
- NFPA 13 Installation of Fire Sprinkler Systems – 2013
- ASHRAE 90.1 – Energy Standard for Buildings – 2013

- ASME A17.1 – Safety Code for Elevators and Escalators
- Americans with Disabilities Act – Standards for Accessible Design 2010

5. *LAR, Attachment 1, Section 8.3, "Solid Sources," provided general information on the SNM content for two target assemblies. However, the NRC staff was unable to find information relative to the total amount of SNM that would be used during the production process. As such, the NRC staff is unable to establish if the LAR would require any changes to the licensee's current license conditions, emergency plan, or PSP.*

*The regulations in 10 CFR 50.34(b)(6)(v) require research reactor licensees to develop and implement an emergency plan. RG 2.6, ANSI/ANS-15.16, and NUREG-0849, provides guidance for the development of emergency plans.*

*The regulations in 10 CFR Part 73 require each licensee who possesses, uses or transports SNM of moderate or low strategic significance to establish and maintain a physical protection system. RG 5.59 provides guidance for the development of the PSP.*

*Provide information on the quantity of SNM which is planned to be processed in the TEF, and indicate if this quantity will result in any changes to the current licensee conditions for SNM possession, or the emergency and/or PSPs, as a result of this LAR, or justify why no additional information is needed.*

Section 2.B.2.b of MURR Renewed Facility Operating License No. R-103 states, "Pursuant to the Act and 10 CFR Part 70, the following activities are included: ...b. to receive, possess, and use, in connection with the operation of the facility, up to 5 kilograms of contained uranium-235 of an enrichment less than 20 percent in the isotope uranium-235, for use in experiments;.."

As part of LAR Part 1 submission, MURR is not requesting a change to the possession limit of uranium-235 of an enrichment less than 20 percent in the isotope uranium-235. Therefore, no changes are required to the current MURR Emergency and Physical Security Plans as part of LAR Part 1 submission. However, an increase in the possession limit and the quantity of Special Nuclear Material (SNM) that will be processed and stored in the hot cells will be included in LAR Part 2 submission.

Additionally, irradiation of SNM under this project cannot be performed unless a take-back contract between MURR and DOE is executed. This restriction is documented in the MURR/DOE LEU Lease Agreement [Ref. 5-1]. The SNM in the target rods must be processed and placed in a form that DOE will eventually accept, most likely U<sub>3</sub>O<sub>8</sub> powder after the SGE process is performed on the UO<sub>2</sub> pellets to extract Mo-99.

Finally, as discussed during the NRC public meeting on February 2, 2017, MURR is not requesting irradiation of any target rods under LAR Part 1 unless LAR Part 2 is approved.

References:

- 5-1 "Lease Contract for the Supply of Low Enriched Uranium for Domestic Molybdenum-99 Production," Contract No. NNSA-LC16-Y12-1001, University of Missouri-Columbia, June 2016.

6. *LAR, Attachment 1, Section 9.3, "Material Control & Accounting," states, in part, that "Irradiated target rod material control will be discussed in the Part 2 License Amendment application." The LAR for Part 1 of the SGE experiment involves the necessary reactor and facility modifications, target fabrication, and all associated steps up to and including the irradiation of target rods. The LAR indicates that the remaining SGE process systems (i.e. the hot cells necessary to perform the target dissociation and the actual SGE process) and the associated safety analyses will be addressed in the future, when Part 2 of the SGE experiment is submitted for review and approval. The NRC staff notes that the possibility exists that the LAR Part 1 could be approved and the LAR Part 2 could be denied. Approval of Part 1 without the approval of Part 2 would leave the applicant with the ability to irradiate the target rods with no clear pathway as to how those target rods would be handled once irradiated. As such, the NRC staff finds that there is no discussion of what would happen to the irradiated target rods if the future LAR for Part 2 of the SGE experiment is not approved. This information is needed in order for the NRC staff to determine that the irradiated target rods are handled safely.*

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 11, "Radiation Protection Program and Radioactive and Waste Management," indicates that the LAR should provide information on radiation protection and waste management.*

*Provide a description of how all irradiated target rods will be handled in the instance that the Part 2 license amendment is denied. Also, provide all associated impacts (e.g., radiological, environmental, etc.) involved with the irradiated target rods in the instance that the Part 2 license amendment is denied, or justify why no additional information is needed.*

As explained in the response to RAI No. 5, irradiation of SNM under this project cannot be performed unless a take-back contract between MURR and DOE is executed. The SNM in the target rods must be processed and placed in a form that DOE will eventually accept, most likely  $\text{U}_3\text{O}_8$  powder. The  $\text{UO}_2$  pellets are converted to  $\text{U}_3\text{O}_8$  powder as the SGE process is performed to extract Mo-99.

Additionally, as discussed during the NRC public meeting on February 2, 2017, MURR is not requesting irradiation of any target rods under LAR Part 1 unless LAR Part 2 is approved.

7. LAR, Attachment 1, Section 10.1, "Target Experimental Facility Maximum Hypothetical Accident," provides a description of the maximum hypothetical accident (MHA) associated with the TEF (known as the TEF MHA versus the SAR MHA which results from the Failed Fueled Experiment accident). The NRC staff review of the TEF MHA has identified that the following items need additional information, for the NRC staff to ensure that radiation doses to the workers and public remain below the limit in 10 CFR Part 20.

*The regulations in 10 CFR Part 20 require that doses to workers and members of the public be limited. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 13, states the applicant should discuss and analyze a postulated accident scenario whose potential consequences are shown to exceed and bound all credible accidents. For non-power reactors, this accident is called the MHA.*

*Note: The methodology used to calculate the occupational and public doses in the LAR appears to include several assumptions and/or calculations that were previously used in the MHA analysis provided by the licensee in its responses to RAIs for the license renewal. In the NRC staff issued SER for the license renewal (ADAMS Accession No. ML16124A887), Section 13.1, "Maximum Hypothetical Accident—Failed Fueled Experiment," the NRC staff documented those assumptions and/or calculations that were determined to be inconsistent or non-conservative.*

- 7.1. LAR, Attachment 1, Section 10.1.1, "Description of Maximum Hypothetical Accident Scenario," identifies the MHA as an accident involving the release of radioactive material from one target rod due to assumed target rod cladding failure or end cap weld failure. The NRC staff review of the MHA observes that the postulated release is limited to the failure of only one (1) target rod as the credible accident. Based on the information provided in the application, it is not clear why the postulated accident does not involve more than a single target rod failure for the TEF MHA. Provide a justification for limiting the MHA postulated target rod failure to a single target rod, including supporting information as to what controls would be effective to prevent damage to multiple target rods in a postulated target rod assembly handling malfunction or common mode failures, or justify why no additional information is needed.

Design of the Target Experimental Facility (TEF) is such that no normal or accident condition leads to target rod cladding failure or consequences except inadvertent physical damage to the TEF, cladding defects born from manufacturing, or inappropriate target handling. Safety measures and strictly controlled quality and administrative procedures in the design, fabrication and operation of the facility give high confidence to the improbable nature of cladding failures of an SGE target rod. Furthermore, as shown in Figure 9 of LAR Part 1 Attachment 1, the Zircaloy-4 tubing (cladding) of the target rod is welded to the solid end caps, and not a "butt-welded" where two parts are connected which are nearly parallel and don't overlap.

The target rods are manufactured under the auspice of General Atomics' ASME NQA-1 2008/-1a-2009 Quality Program [Quality Assurance Program Document – Phase II, Reactor-Based Molybdenum 99 Supply System, General Atomics Document QAPD-30441-II (January, 2017) and as revised. *General Atomics Proprietary Information*], which provides extensive controls over the quality during the manufacture and fabrication of the target rods. The gap gas source term for the

worst-case target rod included several conservative assumptions: maximum total target assembly power and an upper bound of all uncertainties (statistical, impurity, fabrication density, enrichment and rod position); therefore, the MHA (i) occurs on the highest-powered target rod in an assembly, and (ii) occurs at the worst possible time at the end of the maximum irradiation period. The MHA initiating event, a postulated breach of the target rod cladding during full power operation from a defect in the cladding or a defect in either of the welds that attach the upper and lower end fittings, is a failure mode independent of the other target rods. The chance of this occurring for multiple target rods at the exact same time was considered an incredible event.

However, it is recognized from review of IAEA Nuclear Energy Series No. NF-T-2.1: Review of Fuel Failures in Water Cooled Reactors, that cladding failures do occur. The average worldwide cladding failure rate between 1994 and 2006 in Pressurized Water Reactors was calculated to be  $10^{-5}$  in the commercial nuclear power industry. The below provides a distribution of failure rate mechanisms presented in the aforementioned report.

• Grid to Rod Fretting:	54.8%
• Unknown:	25.1%
• Debris Related:	11.0%
• Fabrication Related:	5.0%
• Crud/Corrosion Related:	3.6%
• Handling Related:	0.4%
• Pellet Cladding Interaction-Stress Corrosion Cracking:	0.1%

It should be noted that the coolant pressures, temperatures, and the duration of use under which light water cooled commercial nuclear power reactors operate are considerably more extreme than those that are germane to operation of the TEF. In addition, TEF design and operation preclude Grid to Rod Fretting and Crud/Corrosion related failures, which account for approximately 58.4% of all cladding failures given above. Therefore, a fuel cladding failure rate of  $10^{-5}$  for the TEF is considered a conservative and bounding value based on the IAEA report.

The most susceptible cladding failure mechanisms for the TEF are fabrication-related and handling-related failures. External damage to the target rod by handling should be even less likely than handling current MURR fuel elements in that Zircaloy-4 is a more robust cladding material than the aluminum used in the current MURR fuel element design. A fabrication-related or handling-related failure could result in target rod cladding failures; however, these failures would either become evident immediately upon reaching steady-state operation, via indication from radiation monitoring systems, or one (1) hour after the end of irradiation, the minimum decay time prior to handling, when the target rods are being removed from the TEF.

7.2. *LAR, Attachment 1, Section 10.1.4, "Radionuclide Concentration in Reactor Pool Water," states that the failed target rod releases its fission product gases over a 5 minute time period, from a postulated pressure of approximately 80 pounds per square inch. Based on the*

*information provided in the application, it is not clear to the NRC staff why it would take the fission gas 5 minutes to release to the pool water? Provide a justification for the 5 minute fission gas release time under the assumed accident conditions, or justify why no additional information is needed.*

The accident analysis does not assume the fission gasses are released to the pool over a five (5) minute period. The analysis assumes all iodine activities available for release are instantaneously released and mixed into the reactor pool volume. Additionally, the noble gases krypton and xenon are assumed to pass directly from the target rod through the pool and directly into the reactor containment building atmosphere. This is illustrated by the values provided in Table 40 of Section 10.1.4 of the LAR Part 1, Attachment 1. Table 40 provides the initiating activity concentrations of the pool water, which are calculated by taking the total fission gas inventory available for release from Table 39 and dividing each nuclide by the reactor pool volume. The resulting calculated activity pool water concentrations are then used to calculate the initial activity released into the containment building volume when calculating the containment air concentrations, which then is used for calculating the resulting doses to workers and the general public.

Likewise, the kryptons and xenons are released from the target rod, pass through the pool water and disperse instantaneously into the reactor containment building air. This is a conservative assumption but provides bounding activity concentrations in the containment air from which to calculate doses to both occupational workers and offsite members of the public.

7.3. *LAR, Attachment 1, Section 10.1.4, states that the target rod failure results in fission gas inventory mixed instantly and uniformly with the entire reactor pool water volume (20,000 gallons). The NRC staff is not clear if this assumption is conservative (i.e., over-predicts the dose calculations) since it dilutes the fission gas concentration to a minimum concentration. Provide a justification for instant mixing of the gas inventory with the entire pool water inventory that demonstrates its conservative nature, or justify why no additional information is needed.*

As noted in the response to RAI No. 7.2, only the iodine is instantaneously mixed with the pool water prior being released into the reactor containment building atmosphere. This is due to its reactive nature as an element. The fission gases krypton and xenon are assumed to instantaneously travel through the pool water and are emitted at the pool water surface for direct incorporation into the containment building air. No credit is taken for mixing in the pool coolant system and subsequent decay when traveling through the pool decay hold-up tank or pool clean-up system. Additionally, no credit is taken for the solubility of krypton or xenon of which there are published values, which would minimize the release of these gasses into the containment building air. Thus, we believe that our analysis is conservative in nature due to the omission of the above noted delay and decay mechanisms.

7.4. *LAR, Attachment 1, Section 10.1.5, "Radionuclide Concentration in Containment," provides calculations of radionuclides released from the reactor pool to the containment air, which assume that 0.1 percent (based on 20 gallons out of the 20,000 gallon reactor pool*

*evaporating) of the iodines released to the pool are subsequently released to containment. However, the LAR, Attachment 1, Section 10.1.1, states that it is only the fission gas in the void volume of the target rod that is released to the target cooling water which is then discharged to the reactor pool water. Given that the iodines released to the pool are entirely in gaseous form (rather than solid form), the NRC staff note that a scenario in which the iodines become completely dissolved in the pool, and then are slowly released due to pool water evaporation, may not be realistic. Because the iodines released to the pool are entirely gaseous, greater than 0.1 percent of the iodines released from the target rod to the pool could potentially be released to the containment air via bubbles that rise to the pool surface. Justify the assumption that no iodine is released to the containment air by this mechanism; provide a revised calculation that considers additional iodine that could be released to containment by this mechanism; or, justify why no additional information is needed.*

Iodine was discovered in 1811 and has been long studied. While not particularly soluble in water, iodine exhibits increasing solubility in water as temperature increases, as is true with many compounds. Based on the fact that MURR pool water is approximately 100 °F (37.8 °C) during operation, the MURR reactor pool has a huge capacity for total elemental iodine and even higher capacity if the iodine is compounded. Depending on the reference material used and water temperature assumed for solubility, this capacity ranges from 35,000 to 72,000 total grams of iodine. At the temperature range that MURR's pool operates, we assume the lower value, 35,000 grams total capacity of iodine. This value exceeds by orders of magnitude the total amount of iodine available in the gap gas of the hottest target rod and even in all 11 target rods, of 0.276 milligrams and 3.03 milligrams (11 times the hottest target rod), respectively. Thus, we believe our assumption based on the evaporation of pool water containing iodine over a given time period is conservative with regards to the calculation of doses to workers or members of the public.

7.5. *LAR, Attachment 1, Section 10.1.7, "Dose Consequences to Members of the Public," provides example calculations of Iodine-131 and Krypton-85 in containment which appear to assume that radionuclides released to the confinement air are mixed within a containment volume of 229,800 cubic feet. Current MURR TS 5.5.a, states, "The reactor and fuel storage facilities shall be enclosed in a containment building with a free volume of at least 225,000 cubic feet." The NRC staff notes that the assumption of a 229,800 cubic foot containment volume does not appear to be consistent with the TS 5.5.a value. Provide an explanation for the use of a containment volume that is greater (less conservative) than the TS value for the calculations in the LAR, Section 10.1.7; provide revised public dose calculations that utilize the TS value; or, justify why no additional information is needed.*

The 225,000 ft<sup>3</sup> value is based on standard temperature and pressure as a representation of the free volume of the containment building under those conditions. The 229,500 ft<sup>3</sup> volume is based on an overpressure condition of 0.33 psig that is assumed to occur during the accident (barometric pressure change that occurred in conjunction with the onset of the MHA). This slight overpressure condition provides some of the driving force that moves containment volume air out into the laboratory building and into the ventilation exhaust stack where it takes approximately 16.5 hours to equalize the overpressure condition within the containment building (the other being the slightly negative pressure

differential between the containment and the laboratory buildings from the continually operating facility ventilation exhaust fan moving air out of the laboratory building and through any containment leakage points). If radionuclide releases occurred during the overpressure condition, the dilution would be into the additional volume thus slightly diluting the concentration of nuclides in air. However, this dilution would only result in an approximately 2.1% dilution of the nuclide concentration in air were the free volume used and thus is not deemed to be significant from a health physics (public dose) perspective. However, the new dose values stated in the response to RAI No. 7.8 were calculated using the more conservative reactor containment building Technical Specification volume of 225,000 ft<sup>3</sup>.

7.6. *LAR, Attachment 1, Section 10.1.7, discusses the method used to calculate the mixing and release of the radionuclides from the reactor laboratory building. The NRC staff review finds that the free air volume of the reactor laboratory building is not provided, and no discussion whether or not the reactor building ventilation system would provide mixing with the entire free air volume of the reactor laboratory building or only a portion of the free air volume. The NRC staff also needs clarification if the reactor laboratory building ventilation system would intake an air flow rate from outside the building, at the exhaust air flow rate of 30,500 cubic feet per minute (which would result in a "double" constant dilution of the laboratory building radionuclide concentration due to inflow of uncontaminated air and outflow of contaminated air). Provide the free volume of the reactor laboratory building used in the analysis, and a description of the mixing and release concentrations, or justify why this information is not needed.*

As discussed in the response to RAI No. 7.5, the 225,000 ft<sup>3</sup> value is the free air volume of the containment building and is based on standard temperature and pressure as a representation of the free volume of the containment building under those conditions. The 229,500 ft<sup>3</sup> volume that was used in the release calculations are based on an overpressure condition of 0.33 psig that is assumed to occur during the accident (barometric pressure change that occurred in conjunction with the onset of the MHA). This slight overpressure condition provides some of the driving force that moves containment volume air out into the laboratory building and into the ventilation exhaust stack where it takes approximately 16.5 hours to equalize the overpressure condition within the containment building (the other being the slightly negative pressure differential between the containment and the laboratory buildings from the continually operating facility ventilation exhaust fan moving air out of the laboratory building and through any containment leakage points). While the relatively clean air of the laboratory building would dilute air leaving the containment building through the laboratory building, it would still leave the facility via the main ventilation exhaust stack, which is constantly monitored by the MURR stack radiation monitoring system. There would be no "double dilution," only a mixing of containment air with laboratory building air resulting in air released via the facility exhaust stack, which as noted is continuously monitored. Additionally, as stated in the response to RAI No. 7.8, the new dose values were calculated using the more conservative reactor containment building Technical Specification volume of 225,000 ft<sup>3</sup>.

7.7. *LAR, Attachment 1, Section 10.1.7, states that most leakage pathways from containment discharge into the reactor laboratory building, which surrounds the containment structure. The*

*NRC staff review questions if ignoring any direct leakage of radionuclides from the reactor containment building to the environment is a conservative assumption. Furthermore, the NRC staff finds that these direct leakage paths would result in essentially a ground level release to the environment without benefit of diluted dispersion through the laboratory building exhaust stack. Provide justification for ignoring possible direct leakage paths from the containment building to the environment, or justify why no additional information is needed.*

All penetrations, or potential leakage paths, through the reactor containment building are listed in Section 6.2.3 of the MURR Safety Analysis Report. All of these penetrations are within the laboratory building – none are external to the laboratory building structure. The containment building walls are 12-inch thick reinforced concrete walls internally coated with DECADEX, a waterborne, synthetic rubber polymer, which cures to form an elastomeric membrane. All horizontal and vertical seams created in the pouring of the building are sealed with polyvinylchloride (PVC) plastic waterstop of the dumbbell type. A leakage rate test on the containment structure is performed annually as required by MURR Technical Specification (TS) 4.4.a. The test meets the requirements of TS 5.5.c, where the building is pressurized to 1.0 psig and make-up air is measured to ensure that the leakage rate does not exceed 16.3 ft<sup>3</sup> at STP. During these annual tests, the only leakage points that are identified, using a soap bubble solution, are the pedestrian entry (airlock) and heavy equipment entry (Door 101) doors through the inflatable gaskets – both within the laboratory building. No leaks have been identified on the walls of the containment building external to the laboratory building.

Therefore, since 1) there are no penetrations through the containment building outside of the laboratory building structure, 2) no leakage points have been identified on the walls of the containment building during the annual leakage rate tests, and 3) the laboratory building is at a negative pressure in relationship to the outside environment, a ground level release is not credible since there are no possible direct leakage paths from the containment building straight to the environment.

- 7.8. *LAR, Attachment 1, Section 10.1.7, states the assumed leakage rate out of containment results in a radiological release to the environment for 16.5 hours (elapsed time for the containment building pressure to reach equilibrium with the laboratory building pressure, effectively ending the radiological release to the environment). The NRC staff review notes that the licensee's calculation of post accident reactor building radionuclide concentrations is based on the evaporation from the reactor pool water that occurs in the first 5 minutes and ignores any additional pool evaporation that could occur during the post accident time period from 5 minutes to 16.5 hours. Provide justification for ignoring any additional radionuclide addition to the reactor building atmosphere due to pool water evaporation during the time period from 5 minutes to 16.5 hours.*

MURR agrees with the NRC's comment and has adjusted its calculation to reflect the continued release over the entire 16.5-hour period. MURR has refined its calculation to reflect that the evaporation rate previously postulated occurs over both the 5-minute time period for the restricted area dose and the 16.5-hour time period for the unrestricted area dose to allow the iodine to be released into

the reactor containment building atmosphere. Additionally, MURR corrected its calculation to reflect that public exposure to a noble gas through the submersion pathway results in a dose of 100 mrem/year at the effluent concentration limit. Normally, the evaporation rate from the reactor pool into the containment building is approximately 80 gallons of water per day. For the purposes of this calculation, MURR conservatively doubled this evaporation rate to 160 gallons per day. Based on this assumption we are now using an evaporation rate of 0.1 gal/min for our radioiodine nuclide release rate. We assume this rate to continue during the 5-minute evacuation period and the 16.5-hour release to the public. We no longer take into account the 17-second bubble rise time previously used in our analysis and we continue not to use any radionuclide decay, which adds to the conservatism of the calculations. The source terms are assumed to remain the same as in the original submittal.

Doses to the worker and public are summarized in Tables 7-1 and 7-2 below based on 5-minute (restricted area) and 16.5-hour (unrestricted area) exposures, respectively. Additionally, as was performed in past calculations, MURR used the NRC-accepted value of a 50% reduction of radioiodines from plate-out and deposition in the containment building structure prior to release to the environment (Regulatory Guide 1.3, "Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Boiling Water Reactors").

Table 7-1

5-Minute Dose from Radioiodines and Noble Gases in the Containment Building (mrem)

Iodine – Committed Dose Equivalent	15.25
Iodine – Committed Effective Dose Equivalent ( $CDE \times 0.03$ )	0.46
Krypton – Committed Effective Dose Equivalent	297.72
Xenon – Committed Effective Dose Equivalent	130.20
Total Effective Dose Equivalent	428.38

Table 7-2

Dose from Radioiodines and Noble Gases in the Unrestricted Area (mrem)

Iodine – Committed Effective Dose Equivalent	0.36
Krypton – Committed Effective Dose Equivalent	1.55
Xenon – Committed Effective Dose Equivalent	0.59
Total Effective Dose Equivalent	2.50

- 7.9. *LAR, Attachment 1, Section 10.1.8, "Dose Assessment in Unrestricted Area," provides public dose calculations that appear to be based on the assumption that the airborne effluent concentrations (AECs) for noble gases in Appendix B, Table 2, of 10 CFR Part 20, are based on a total effective dose equivalent (TEDE) of 50 millirem per year (mrem/yr). The NRC staff notes that the AECs for noble gases in Appendix B, Table 2, of 10 CFR Part 20, are based on a TEDE of 100 mrem/yr, and therefore dose calculations based on the assumption that the AECs*

*for noble gases in Appendix B, Table 2, of 10 CFR Part 20, are based on a TEDE of 50 mrem/yr may not be conservative. Provide an explanation for the assumption, used in the calculations in the LAR, Section 10.1.8, that the AECs for noble gases in Appendix B, Table 2, of 10 CFR Part 20, are based on a TEDE of 50 mrem/yr; provide revised public dose calculations that use the 100 mrem/yr; or, justify why no additional information is needed.*

MURR agrees with the NRC's comments. MURR mistakenly used the 50 mrem/yr dose conversion factor for effluent releases instead of the 100 mrem/yr as needed for submersion isotopes. As noted in the response to RAI No. 7.8, this has been corrected and the calculations modified to reflect this change.

*7.10. LAR, Attachment 1, Section 10.1.8, provides public dose calculations that are based on an effluent dilution factor of 292, which assumes that the maximum public dose would occur for an individual 760 meters north of MURR (the location of the nearest residence to MURR) during Class F stability conditions. However, the basis for the use of this dilution factor is not clear to the NRC staff. The NRC staff notes that higher accident doses could potentially occur at locations other than the nearest residence, even if those locations are not continually occupied. Additionally, it is not clear to the NRC staff whether this dilution factor is based on worst-case meteorological conditions. Justify the use of an effluent dilution factor of 292 for determining the dose to the maximally-exposed member of the public during worst-case meteorological conditions, and provide a revised calculation using an alternate dilution factor that considers the worst-case level of dilution that could occur for any location and reasonable meteorological condition (include consideration of fumigation conditions and/or conditions that could result in plume downwash due to building wake, if appropriate).*

A dilution factor of 292 was chosen as it represents the absolute worst-case dilution factor that results when using the Pasquill-Gifford atmospheric dispersion model to calculate X values for concentrations of nuclides north (at all distances) of the MURR facility, which is the location of the nearest resident. In our particular case, the highest nuclide concentrations occur during stability Class 'F' at this location. This is due to the change in elevation between the stack release point and the receptor site at that distance, which is generally uphill from the MURR facility and the fact that at this distance, stability Class 'F' provides the worst-case dilution. The worst-case dilution factor for the 400 meters north of the site is 590, a factor of two (2) less conservative as the 292 noted above. While the possibility exists for a higher dose potential at the 400 m north location, as noted in earlier correspondence, this event occurs on University of Missouri controlled property and as such, actions can be taken to remove individuals or mitigate exposure of anyone located in this area.

Additionally, the University has less control over removal of persons who are located on private property at the 760-meter location north of MURR, thus we believe that the factor of 292 is entirely appropriate. It should be noted that the 292 factor is in good general agreement with our Technical Specification 3.7(b) multiplication factor of 350, which has been in use for several decades and has been shown to provide an adequate safety margin for the protection of members of the general public from airborne effluents.

8. LAR, Attachment 1, Section 10.5, "Pipe Break Locations Out of the Reactor Pool," provides an analysis of a pipe break in the air region of the TA flow loop with opening of the decay heat removal valves. The NRC staff review of the analysis find that there appears to be no heatup of the target rods because there is a forward and reverse "chugging" flow between the pool and the TA. The NRC staff is not clear on details associated with the "chugging analysis."

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.6, "Thermal-Hydraulic Design," provides guidance that the LAR should include all necessary information on the primary coolant hydraulics and thermal conditions of the fuel, including design parameters and correlations, test results, for all modes of normal operation and accident scenarios.*

- 8.1. *Provide an explanation of why the positive flow in the broken loop persists for more than 10 seconds and then reverses for tens of seconds (as counter current flow limitation could prevent coolant water from entering the exit flow restriction of the TA), or justify why no additional information is needed.*

For the pipe break in air without the Target Decay Heat Removal Valves (TDHRVs) opening, Figure 84 in LAR, Attachment 1 needs additional explanation. During the break opening time, the TCS pump trip and early coastdown have a declining contribution to the overall flow through the Target Assembly (TA). After the break is completely open, water in the broken pipe above the reactor pool level slowly drains into and through TA 2. As the water head in the broken pipe decreases, the flow rate also decreases. After 10 seconds, TA 2 inlet and outlet flow rates go through an oscillation as the water level in the broken pipe achieves pressure equilibrium with the reactor pool. Void-induced chugging does not occur until 40 seconds, as indicated by the transition from oscillatory flow to more erratic spikes in TA 2 inlet and outlet flow rates during the early phase of the transient as shown in Figure 8-1 below. It should also be noted that the flow meters are not indicative of the flow rate through the TAs since they are located above the reactor pool and upstream of the break location. No counter current flow limitation (CCFL) was applied to this analysis. The application of CCFL is discussed in the response to RAI No. 8.2 below.

- 8.2. *Provide a model of the counter current flow limitation at the exit of the test assembly in the RELAP5 model of the test loop, if one was done, or justify why no additional information is needed.*

A counter current flow limitation (CCFL) was not used in the RELAP5 analyses in the LAR. The analysis discussed in RAI No. 8.1 above was repeated with a CCFL applied at the upper and lower target rod cartridges. The parameters in the RELAP5 model are as follows:  $b = 0$ ,  $m = 1$ , and  $c = 0.725$  for sharp edges, which will be the case for the TA. The CCFL had minor effects on the analysis. When high void fractions occurred after 40 seconds, TA 2 inlet and outlet flow rates, outlet temperature, and cladding temperature agreed within 10% with the case reported in LAR, Attachment 1, Section 10.5.

Figure 8-1  
Mass Flow Rate Details for LAR Attachment 1, Figure 84

9. LAR, Attachment 1, Section 10.5, states that, the operator is assumed to trip the TCS pump on the high flow alarm. The NRC staff is not clear the effect on the accident scenario that would result if the operator would fail to trip the TCS pump.

*The regulations in 10 CFR 50.90 require that the applicant submit an application fully describing the changes desired, and following as far as applicable, the form prescribed for original applications. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 13, indicates that the LAR should also describe how equipment will work when needed in accident situations.*

*Describe or reference the result of an analysis, which provides the results on the scenario should the operator action not occur as assumed, or justify why no additional information is needed.*

Should the operator fail to secure the Target Cooling System (TCS) pump at 110% of nominal flow (high flow alarm), the pump will automatically secure at 115% of nominal flow. There is a valve/pump interlock associated with the Target Decay Heat Removal Valves (TDHRVs) and the TCS pumps.

Section 4.2, "Target Cooling System Control System Description," of LAR Part 1 Attachment 1 states (Sentence underlined for emphasis):

"The TCS Control System is designed to control TCS pump operation and the position of the Target Decay Heat Removal Valves (TDHRVs). From the TCS Control System, the operator can start, stop, and change speed of the TCS pumps. In addition, the TCS Control System contains an interlock between the TCS pumps and the TDHRV position that secures the TCS pumps when any one of the TDHRVs open. The interlock is actuated from a position indication switch located on each TDHRV actuator which opens a contact de-energizing both of the TCS pump control circuits."

As stated in Section 4.2, the TCS pump will secure when any one of the TDHRVs open. Section 4.3.1, "Target Cooling System Low and High Flow Rate Protection," of LAR Part 1 Attachment 1 states:

"In addition to a low flow condition, the TCS Protection System will provide protection on TCS high flow rate. In this case, the chart recorder will initiate a "TCS Hi Flow" alarm when TCS branch flow to either target increases to 110% of its normal value. If TCS branch flow increases to 115% normal flow, then the following actions are initiated by the system:

1. Reactor scram;
2. Opening of the two (2) TDHRVs in the associated branch; and
3. Actuation of the "TCS Flow Scram" annunciator alarm."

Therefore, because of the TDHRV/TCS pump interlock, the TCS pump will automatically secure at 115% of nominal flow should the operator not secure the pump at 110% of nominal flow. This valve/pump interlock is also discussed in detail in the response to RAI No. 4.

10. LAR, Attachment 1, Section 10.8, " Mishandling of Target Cartridge or Target Rods," provides a description of the mishandling of a target cartridge or target rods and states that based on additional decay prior to handling, the consequences of mishandling the target cartridge or target rods are bounded by the TEF MHA. However, the NRC staff review finds that a quantitative analysis of the potential doses from target mishandling accidents was not provided. Furthermore, LAR Section 10.8, states, in part, that "Multiple barriers separate the fission products in the target material from potential release locations within the TA." The NRC staff can not identify the multiple barriers.

*The regulations in 10 CFR Part 20 require that radiation doses to workers and members of the public be limited. Furthermore, the guidance in NUREG-1537, Part 2, Chapter 13, indicates that the LAR should also describe the dose consequences of accidents.*

- 10.1. *Provide a quantitative analysis to show that a target mishandling accident is bounded by the TEF MHA, or justify why no additional information is needed.*

The first opportunity to potentially damage a target rod after shut down would occur no earlier than one (1) hour after the end of irradiation, as explained in the response to RAI No. 7.1 above and in Section 7.2.2 of LAR Part 1 Attachment 1 – maintaining forced cooling to the Target Assembly for a minimum of one (1) after shut down is an administrative requirement. This is when handling of the target cartridge and subsequently the target rods will be allowed in order to prepare them for eventual transfer via a transfer cask from the reactor pool to the processing hot cells at  $t = \text{EOI} + 6$  hours. The most credible scenario, although highly unlikely, would be dropping a target rod while removing it from the target cartridge and breaching the Zircaloy-4 cladding or damaging either weld at the target rod end caps. As shown in Figure 74 of LAR Part 1 Attachment 1, the Target Rod Remote Handling Tool is of a robust design with a spring-loaded positive lock mechanism. This accident condition, that could potentially release the entire gap gas source term, was calculated for  $t = \text{EOI} + 1$  hour post irradiation and found to be less than the worst-case of a release of the gap gas of the hottest target rod after the maximum irradiation period at  $t = 0$  (End of Irradiation, or immediately after reactor shutdown). The same methodology was used to determine the doses in the restricted and unrestricted areas during a target rod handling accident as explained in the response to RAI No. 7.

Doses to the worker and public are summarized in Tables 10-1 and 10-2 below based on 5-minute (restricted area) and 16.5-hour (unrestricted area) exposures, respectively, from a target rod handling accident. Additionally, as was performed in past calculations, MURR used the NRC-accepted value of a 50% reduction of radioiodines from plate-out and deposition in the containment building structure prior to release to the environment (Regulatory Guide 1.3, "Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Boiling Water Reactors").

Table 10-1  
5-Minute Dose from Radioiodines and Noble Gases in the Containment Building (mrem)

Iodine – Committed Dose Equivalent	14.94
Iodine – Committed Effective Dose Equivalent (CDE $\times$ 0.03)	0.45
Krypton – Committed Effective Dose Equivalent	186.86
Xenon – Committed Effective Dose Equivalent	49.53
Total Effective Dose Equivalent	236.84

For comparison the total occupational dose at  $t = 0$  is 428.38 mrem for the target rod MHA, as explained in the response to RAI 7.8.

Table 10-2  
Dose from Radioiodines and Noble Gases in the Unrestricted Area (mrem)

Iodine – Committed Effective Dose Equivalent	0.17
Krypton – Committed Effective Dose Equivalent	0.97
Xenon – Committed Effective Dose Equivalent	0.20
Total Effective Dose Equivalent	1.34

*10.2. Provide the multiple barriers to potential release locations with the TA, or justify why no additional information is needed.*

The two (2) primary barriers for a release of fission products from a target rod to the environment are the target rods themselves (Zircaloy-4 cladding) and the reactor containment building structure. The target rods are located within the reactor pool during irradiation and are manufactured under a Quality Assurance Program, as explained in the response to RAI No. 7.1 and LAR Part 1 Attachment 3, as QAL I components that helps assure that the potential for leakage is minimized due to their design and manufacture under a program with adherence to high quality standards.

The second primary barrier to the environment is the containment building structure itself. It is designed to be essentially leak proof and its integrity is tested on an annual basis to ensure that it meets the leakage rate requirements of Technical Specification 5.5.c.

Additionally, the pool provides some protection of accidental release to the outside environment as many of the fission products, if released, will be bound up in the reactor pool coolant system, usually due their solubility in the 100 °F pool water. Additionally, any particulate matter released into the pool system would be filtered out by the pool clean-up system, which uses both mechanical filtration and ion exchange resins to remove solid and ionic-based contaminants from the pool coolant system.

Finally, although not an actual release barrier, but a physical barrier, the target rod cartridge provides protection of the target rods during transfer from the Target Housing to the Loading/Unloading Station for eventual loading into the transfer cask.

11. LAR, Attachment 1, Section 12.1.2, "Critical Heat Flux Tests," states, in part, that "[T]he NRC-accepted correlations show that the CHF for the system will continue to provide sufficient margin". The NRC staff notes that thermal limit calculations were performed with a variety of critical heat flux (CHF) correlations. However, the NRC staff is not aware of an NRC-accepted CHF correlation for the unique application provided by the LAR design.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.6, provides guidance that the LAR should include all necessary information on the primary coolant hydraulics and thermal conditions of the fuel, including design parameters and correlations, and test results, for all modes of normal operation and accident scenarios.*

*Provide a description of the CHF correlation that was used, and provide the supporting information used to determine its acceptability for this application, or justify why no additional information is needed.*

A unique critical heat flux (CHF) correlation was not developed for the design presented in LAR Part 1, as it was not deemed necessary. CHF correlations that are NRC-approved were used with this design, as both RELAP5/MOD3 [Ref. 11-1] and TRACE [Ref. 11-2] are NRC-approved codes containing the CHF lookup tables compiled by Groeneveld et al. [Refs. 11-3 to 11-5]. In the code manuals, this lookup table is sometimes referred to as the AECL-UO or AECL-IPPE table, as it was developed as a collaboration between Atomic Energy of Canada, Limited (AECL), the University of Ottawa (UO), and Russia's Institute of Physics and Power Engineering. RELAP5/MOD3 uses the lookup table published by Groeneveld in 1986 [Ref. 11-3].

The RELAP manual [Ref. 11-1] states:

*"The RELAP5/MOD2 computer program had been criticized for using the Biasi correlation [4.2-50] for predicting the CHF in rod bundles when the correlation is based on tube data [4.2-51]. The Royal Institute of Technology in Sweden [42-51] tested MOD2 against their tube data and found it to generally overpredict the value of CHF, particularly in the mid-mass flux range (1500-3000 kg/s\*m<sup>2</sup>). MOD3 uses the 1986 AECL-UO Critical Heat Flux Lookup Table [4.2-52] method by Groeneveld and co-workers. The table is made from tube data normalized to a tube inside diameter of 0.008 m but has factors that are applied to allow its use in other sized tubes or in rod bundles. In addition, it considers both forward and reverse flow, axial power shape, and the effect of boundary layer changes at both the bundle inlet and behind grid spacers."*

TRACE, a newer code, utilized an improved version of the CHF lookup tables published by Groeneveld in 1995 [Ref. 11-4]. The TRACE manual [Ref. 11-2] states:

*"Therefore, for the default CHF model in TRACE the 1995 AECL-IPPE CHF look-up table (Ref. 6-36) was selected. It is based on an extensive database of CHF values obtained in*

*tubes with a vertical upflow of a steam-water mixture and provides the value of the critical heat flux as a function of the local conditions. As described below, a correction factor is included to improve the accuracy of this table when applied to rod bundles. This look-up table allows for a reasonably accurate prediction of CHF based on the local flow conditions for a much wider range of conditions than would be possible with either empirical correlations or phenomena based models."*

The GA analysis calculated CHF using three (3) separate correlations: Bernath, Macbeth, and Groeneveld's 2006 lookup table [Ref. 11-5]. While all three (3) correlations yield similar results [Ref. 11-6], Groeneveld's values are considered the most reliable, and the University of Wisconsin CHF testing [Ref. 11-7] was benchmarked against its predictions. Groeneveld's 2006 lookup table improved upon the 1986 and 1995 iterations with additional data sets and more advanced screening to remove non-applicable data.

The 2006 Groeneveld lookup table is applicable to the design of the target assembly, as it meets all of the criteria outlined in Reference 11-5 and presented below in Table 11-1. This was verified by the results of the University of Wisconsin test, where the observed critical heat fluxes matched the lookup table predictions to within 10%, with an average absolute error of 3.4% (two tests were unable to reach CHF due to power limitations, and these exceeded the predicted CHF values).

Table 11-1  
Comparison of GA System to Groeneveld 2006 Lookup Table Applicability

Parameter	Groeneveld 2006 Applicable Range [5]	GA RB-MSS Target Cartridge
Tube diameter, mm	3 – 25	6.1
Coolant mass flux, kg/(s*m <sup>2</sup> )	0 – 8,000	4,200 – 5,100
System pressure, kPa	100 – 21,000	180 – 230
Tube aspect ratio L/D	>50	100

In summary, the use of the 2006 Groeneveld lookup tables to predict CHF values for the target assembly is appropriate for the following reasons:

- The parameters of the system fall within the range of data that the Groeneveld tables support;
- Empirical data gathered from experiments specifically designed to imitate the LAR design confirmed the accuracy of the lookup tables in predicting CHF for the given operating conditions; and
- The NRC has approved nuclear design and analysis codes that use earlier, less-refined versions of the Groeneveld lookup tables.

12. LAR, Attachment 1, Section 12.1.3, "System Integration and Cooling Flow Tests," Table 57, indicates that the system integration and cooling flow test report would be completed by June 23, 2017. The NRC staff notes that, as of the issuance of this RAI, the test report has not been provided. Additionally, the NRC staff did not find any RELAP5 modeling results against data from the System Integration and Cooling Flow Tests section of the LAR.

*The regulations in 10 CFR 50.90 require that the applicant submit an application fully describing the changes desired, and following as far as applicable, the form prescribed for original applications. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 5, "Reactor Coolant Systems," provides guidance that the LAR should include a functional analysis of the cooling system, including test results, for all modes of normal operation and accident scenarios.*

- 12.1. *Provide the system integration and cooling flow test report described in LAR Section 12.1.3, Table 57, or justify why the report is not needed.*

General Atomics' Design Report No. 30441R00045, "Target Cooling System Flow Test Report," was submitted to the NRC on October 17, 2017, as Attachment 11 to LAR Part 1 [Ref. 12-1]. With the exception of the "target handling procedure confirmatory testing" section of the report, Design Report No. 30441R00045 provides all of the "system integration and cooling flow tests." The "target handling procedure confirmatory testing" section of the report will be submitted to the NRC as soon as it has been completed.

- 12.2. *Provide assessment of the RELAP5 modeling against data from the System Integration and Cooling Flow Tests described in Section 12.1.3, or justify why no additional information is needed.*

The "Target Cooling System Flow Test Report" [Ref. 12-1] presents results for the pressure drop through the target assembly (TA) and flow results during pump coastdown. The RELAP5 calculations were compared to the results obtained from those two (2) tests.

#### Pressure Drop:

The pressure drop through the TA was measured as a function of flowrate. At a mass flow rate of 6.93 kg/s the measured pressure drop of the TA was 14.3 psi (obtained from an average of the measured data presented in Appendix C of Ref. 12-1). The RELAP5 calculated pressure drop of 12.41 psi through the TA was calculated at a mass flow rate of 6.73 kg/s. Since the pressure drop through the TA is dependent upon the water properties and the mass flow rate, the RELAP5 results were extrapolated to match the conditions of the test results using the method described in Appendix D of Reference 12-1. The calculations for extrapolating the RELAP5 results are shown below.

Table 12-1 presents the results for the water density and viscosity through the TA for the test and RELAP5 analyses at a pressure of two (2) atmospheres.

Table 12-1  
Water Properties for the Pressure Drop Test and RELAP in the Target Assembly<sup>(1)</sup>

	Test Conditions	RELAP5 Conditions	Test / RELAP5
$\rho \text{ (kg/m}^3\text{)}_{\text{avg}}$	998.2536	990.6722	1.0077
$\rho \text{ (kg/m}^3\text{)}_{\text{inlet}}$	998.2536	992.6396	1.0057
$\rho \text{ (kg/m}^3\text{)}_{\text{outlet}}$	998.2536	988.5283	1.0098
$\mu \text{ (kg/m-sec)}_{\text{avg}}$	0.001002	0.000607	1.6507

<sup>(1)</sup> The test conditions are at 20 °C while the temperatures for the RELAP5 results are presented at an average temperature of 44 °C (with the inlet at 39 °C and the outlet at 49 °C).

The difference in pressure drop over the TA for the test and RELAP5 calculations due to *friction* can be approximated by:

$$\frac{(\Delta P_{\text{friction}})_{\text{test}}}{(\Delta P_{\text{friction}})_{\text{relap}}} \approx \left( \frac{\rho_{\text{test}}}{\rho_{\text{relap}}} \right)^{-1/4} * \rho_{\text{test}} / \rho_{\text{relap}}$$

The difference in pressure drop between the test and RELAP5 due to *momentum changes* at the inlet and outlet can be approximated by:

$$\frac{(\Delta P_{\text{momentum}})_{\text{test}}}{(\Delta P_{\text{momentum}})_{\text{relap}}} \approx \frac{\rho_{\text{test}}}{\rho_{\text{relap}}}$$

As calculated in LAR Part 1, Attachment 9 [Ref. 12-2], the pressure drop through the TA can be attributed to the following sources: 26.2% of the total pressure to inlet momentum drop, 20.4% as frictional pressure drop, and 53.4% outlet momentum drop leads to the following factor to extrapolate RELAP5 conditions to those of the test based upon water properties:

$$\frac{(\Delta P)_{\text{test}}}{(\Delta P)_{\text{relap}}} \cong 0.262 * 1.0057 + 0.204 * \left( \frac{1.0077}{1.6507} \right)^{\frac{1}{4}} + 0.534 * 1.0098 = 1.0335$$

Furthermore, in order to adjust for differences in the mass flow rate between the test and RELAP5, the following relation is used:

$$\frac{(\Delta P)_{\text{test}}}{(\Delta P)_{\text{relap}}} = \left( \frac{\dot{m}_{\text{test}}}{\dot{m}_{\text{relap}}} \right)^2$$

Evaluating this equation leads to the following mass flow rate adjustment factor:

$$\frac{(\Delta P)_{test}}{(\Delta P)_{relap}} = \left( \frac{6.93}{6.73} \right)^2 = 1.0603$$

Combining these factors leads to a total correction on the pressure drop of 1.0958. Modifying the RELAP5 pressure drop by this factor leads to an extrapolated RELAP5 TA pressure drop of 13.6 psi at the test conditions. This extrapolated value is 4.9% lower than the measured value of 14.3 psi. The results of the pressure drop test compared to the RELAP5 calculations are show in Table 12-2.

Table 12-2  
Target Assembly Pressure Drop Results

<b>ΔP Source</b>	<b>ΔP (psi)</b>
RELAP5 Result at 44 °C, 6.73 kg/s	12.4
Extrapolated RELAP5 Result at 20 °C, 6.93 kg/s	13.6
Test Result at 20 °C, 6.93 kg/s	14.3

Therefore, we conclude that the RELAP5 model accurately models the pressure drop through the assembly while erring on the conservative side by having a smaller pressure drop through the TA. A larger pressure drop through the TA would lead to greater margins to the onset of boiling. Since the exit pressure of the TA is set (the flow exits into the pool at a known depth), a larger TA pressure drop will result in higher inlet water pressure and higher water pressure outside the SGE target rods. The pressure outside the target rods determines the temperature at which the water will boil. The higher the pressure, the higher the boiling temperature and critical heat flux.

#### Pump Coastdown:

For the pump coastdown testing, flow rate versus time measurements were obtained for cases with different flow rates and pressure drops. RELAP5 pump coastdown results for the nominal flow (6.73 kg/s) case were compared to the test results with flow rates of 6.19, 7.08, and 8.19 kg/s and 25% margin on ΔP. As described in Reference 12-1, valves and the pump were tuned to obtain specific flow rates and pressure drops calculated through analysis. The flow results presented include a 25% increase in the calculated system ΔP to add conservatism. Table 12-3 shows the pressure drops for the cases investigated.

Table 12-3  
System Pressure Drops for RELAP and Test Cases

Case	System $\Delta P$ (psi)
RELAP (6.73 kg/s)	30.41
Test (6.19 kg/s with 25% margin on $\Delta P$ )	27.92
Test (7.08 kg/s with 25% margin on $\Delta P$ )	38.09
Test (8.19 kg/s with 25% margin on $\Delta P$ )	49.71

For these cases, the Target Decay Heat Removal Valves do not open. Results for the flow rate versus time after loss of pump power for the tests as well as for RELAP5 are shown in Figure 12-1. As shown in the figure, the flow rate for the RELAP5 calculation reduces more quickly during a pump coastdown than what was observed in the tests, even for the test case with increased margin on the pressure drop. The RELAP5 modeling of the pump is therefore determined to be conservative, as the reduced flow shortly after pump shutdown causes a faster reduction in heat transfer, leading to higher temperatures.

Figure 12-1  
RELAP5 and Experimental Results for Pump Coastdown

The target system flow tests documented in Reference 12-1 show that the RELAP5 model presented in the LAR is conservative with respect to the pressure drop in the TA, as well as for the pump coastdown model.

## **LAR Attachment 2**

13. LAR, Attachment 2, requested changes to the current MURR TSs. The NRC staff review finds that the proposed changes generally were not accompanied by a justification, basis or reference to the SAR.

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, "Technical Specifications," provides guidance that the TSs should include a justification, basis and/or reference to the SAR.*

*Provide a justification, basis, and/or SAR reference to each proposed TS, or justify why no additional information is needed.*

MURR is referencing sections of the attachments to LAR Part 1, specifically Attachment 1, which is the primary safety bases of the LAR, and the General Atomics' Design Reports since there is no standalone "Safety Analysis Report." This is consistent with the way Amendment No. 37 (Amendment to produce radioactive iodine-131) is referenced in the current MURR Technical Specifications (TSs). The proposed TSs have been revised to reference a section of the Amendment, where applicable, or another document. The revised, proposed TSs are Enclosure 1 to this submittal. For the purposes of this submittal, MURR will assume that this Amendment will be numbered No. 38, the next license amendment number for MURR.

*14. Proposed TSs, Section 1.0, "Definitions," provided additional definitions to support the operation of the TEF. However, during its review, the NRC staff noted that the following items were not clearly understood:*

*14.1 The numbering for the proposed TS Definitions, was not completely sequential, as definitions for 1.36 through 1.41 are repeated for different items.*

As discussed with the NRC staff, the Technical Specifications (TSs) have been revised where the Specifications specific to this Amendment will now have its own section in Appendix A of the MURR TSs and will follow the format of ANSI/ANS-15.1-2007. This has been corrected in the revised, proposed TSs.

*14.2 The TS definition for item 1.36, "Secured Experiment," was provided twice (i.e., repeated) within the definitions.*

This has been corrected in the revised, proposed TSs.

*14.3 The TS page numbers were not provided, as such, the NRC staff is not clear as to the completeness of the proposed TSs.*

This has been corrected in the revised, proposed TSs; page numbers have been added.

*14.4 The TS definition 1.39, "Selective Gas Extraction (SGE) Target Experimental Facility (TEF)" does not provide a description of the major components or systems which constitute the TEF.*

Proposed TS 5.7.a (now TS 5.1B.a) lists the major components of the SGE TEF. However, Definition 1.3B has been revised to also include the major components of the SGE TEF.

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance for definitions, and that the TSs should follow the format in ANSI/ANS-15.1-2007.*

*Provide TSs with complete and accurate format and definitions; or justify why no changes are needed.*

Attached to this submittal is the revised, proposed SGE TEF Technical Specifications with complete and accurate format and definitions following the guidance of ANSI/ANS-15.1-2007.

15. *Proposed TS 3.2, Specification g, added items 22 through 26 to the Reactor Safety System Instrument Channel table, which provided low flow, high flow, and high temperature setpoints of 95 gallons per minute (gpm), 129 gpm, and 105 degrees Fahrenheit (°F), respectively.*

15.1 *The NRC staff noted that the setpoints were provided in the LAR, Attachment 1, Section 10.4. However, the NRC staff could not find a description or justification, relative to the safety analysis, for the determination of the setpoints (+ 15 percent) for the proposed TS 3.2, Specification g, items 22 through 26.*

*Provide a justification for the setpoints in proposed TS 3.2, Specification g, items 22 through 26, or justify why no changes are needed.*

The set points provided in LAR Part 1, Attachment 1, Section 10.4, and Technical Specification 3.2 Specifications 22 through 26 are based on the following:

- The SGE Target Assembly Coolant Low Flow scram set point of 85% of nominal value was chosen based on the thermal-hydraulic analyses which showed a minimum critical heat flux ratio (CHFR) of 2.07 for worst-case operations [85% flow, 115% of nominal reactor power level and irradiation with three (3) target rods] (Ref. Amendment No. 38, Attachment 4, Table 9).
- The SGE Target Assembly Coolant High Flow scram set point of 115% of the nominal value allows the target assembly pressure to stay well within the design limit of 21.5 psi (Ref. Amendment No. 38, Attachment 8).
- The SGE Heat Exchanger Outlet Water Temperature scram set point of 105 °F is based on the thermal-hydraulic analysis with three (3) rod target operations (worst-case). For these operations to occur, the reactor pool temperature cannot exceed 108 °F, as exceeding this limit would allow the CHFR to fall below 2.0. The scram set point for the SGE Heat Exchanger Outlet Water Temperature was based on this reactor pool temperature condition (Ref. Amendment No. 38, Section 6.1.4 of Attachment 1 and Section 4 of Attachment 4).

These justifications have been added to the "Bases" of the Specification. This Specification is now TS 3.2B.

15.2 *The NRC staff noted that footnote (9) states the SGE Heat Exchanger Outlet Water Temperature limit is not needed if the SGE TEF is "secured." Secured is not defined in the TSs, and the NRC staff does not understand the criteria needed to establish the secured condition of the TEF.*

*Provide a definition or description to indicate the criteria associated with the term "secured" in TS 3.2, footnote (9), or justify why no change is needed.*

A description of what "secured" is has been added to the footnote.

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide additional description or justification needed to assess the acceptability of the proposed TS 3.2, Specification g, items 22 through 26, and the footnote (9) for TEF "secured," or justify why no changes are needed.*

Attached to this submittal is the revised, proposed SGE TEF Technical Specifications with the additional description/justification needed to assess the acceptability of proposed TS 3.2, Specification g, items 22 through 26, and the footnote (9) for TEF "secured." This Specification is now TS 3.2B, Specification a, items 1 through 5, and footnote (4).

16. *Proposed TS 3.8, Specification n, describes "Amendment No. X." It is not clear to the NRC staff what "Amendment No. X" refers to in the application.*

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should describe facility-specific terms needed to clarify terms used in the TSs.*

*Remove, revise or describe "Amendment No. X."*

The phrase "Amendment No. X" was merely a placeholder for the actual amendment number that will be issued for this LAR. As explained in the response to RAI No. 13, for the purposes of this submittal, MURR will assume that this Amendment will be numbered No. 38, the next license amendment number for MURR.

17. *Proposed TS 3.11, includes the Safety Limits and Limiting Safety System Settings, and other specifications. However, it is not clear to the NRC staff which specifications are specifically considered LCOs.*

*The regulations in 10 CFR 50.36(c) provide requirements to include safety limits, limiting safety system settings, LCOs, SRs, design features, and administrative requirements. NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should include LCOs.*

*Provide some indication to differentiate the LCOs and identify the corresponding SR in the TS for these LCOs, or justify why no change is needed.*

As previously discussed with the NRC, MURR has reformatted the proposed Technical Specifications such that the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) has its own section and follows the format and content of 10 CFR 50.36(c) and ANSI/ANS-15.1-2007. The Definitions, Safety Limits, Limiting Safety System Settings, Limiting Conditions for Operations, Surveillance Requirements, and Design Features are clearly differentiated.

18. *Proposed TS 3.11, Specification b, Mode 1 Operation, SGE Heat Exchanger Outlet Water Temperature, provides a limit of 105 °F (Maximum). The NRC staff is unable to find the corresponding analysis which provides the basis for the temperature limit of 105 °F, which is needed to determine the adequacy of the basis for this safety limit.*

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should be supported by their respective safety analysis.*

*Provide an analysis for the proposed TS 3.11, Specification b, temperature limit of 105 °F, or justify why no additional information is needed.*

As discussed in the response to RAI 15.1, the SGE Heat Exchanger Outlet Water Temperature Limit of 105 °F is based on the thermal-hydraulic analysis with three (3) rod target operations (worst-case). For these operations to occur, the reactor pool temperature cannot exceed 108 °F, as exceeding this limit would allow the CHF to fall below 2.0. The scram limit for the SGE Heat Exchanger was based on this reactor pool temperature condition. This has been added to the basis of Specification 3.2B.a.

19. *Proposed TS 3.11, Specification d, provides a limit for the target irradiation of 480 hours at 10 megawatts (MWs). The NRC staff is not clear if this limit could be interpreted as an integrated neutron fluence, i.e., 4,800 MW-hours, or simply 480 hours at full power operation. This information is needed to determine the adequacy of the basis for this safety limit.*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff, and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide a clarification for the proposed TS 3.11, Specification b., limit of 480 hours at 10 MWs.*

Yes, TS 3.11, Specification d, is based on integrated neutron fluence. MURR will revise this specification so that it reads, "Each SGE target rod shall not be irradiated for greater than 480 hours at full power operation." This Specification is now TS 3.1B.b

The basis for this Specification will also be revised to read, "Thermal steady-state and transient analyses are based on an SGE target rod being irradiated for no greater than 480 hours at full power operation (Ref. Amendment No. 38, Attachment 1)."

Additionally, TS 4.11, Specification b, will be revised so that it reads, "The operating history of each SGE target rod shall be verified prior to placing it into an SGE target cartridge to ensure that the SGE target rod will not be irradiated for greater than 480 hours at full power operation." This Specification is now TS 4.1B.b.

The basis for this Specification will also be revised to read, "Specification 4.1B.b assures that the SGE target rods are not irradiated for greater than 480 hours at full power operation as assumed in the thermal-hydraulic and transient analyses (Ref. Amendment No. 38, Attachment 1)."

20. *Proposed TS 3.11, Specification g, provides the required instrument channels for operation of the TEF. However, the SGE Heat Exchanger Outlet Water Temperature, provided as an LCO in proposed TS 3.11, Specification b, is not listed as a required instrument channel in proposed TS 3.11, Specification g. Clarification is needed for the NRC staff to determine the adequacy of proposed LCOs for required instrument channels.*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide a TS requirement and associated SR for operability of the SGE Heat Exchanger Outlet Water Temperature instrument channel, or justify why no change is needed.*

SGE Heat Exchanger Outlet Water Temperature instrument channel listed in TS 3.11.b (Now TS 3.4B.a.3) is indeed listed as an instrument channel in TS 3.2.g.26 (Now TS 3.2B.a.5) – SGE Heat Exchanger Outlet Water Temperature scram. This instrument channel provides both an input to the reactor safety system as well as display in the control. All of the instrument channels listed in Section 3.2 of the current MURR Technical Specifications are not duplicated in Section 3.5 since this would be redundant and they all have the same surveillance requirements. Nonetheless, since there is only one instrument, it has been added to TS 3.4B.a to remove any confusion.

21. *Proposed TS 4.11, Applicability, states "Select" versus "Selective," which is used throughout the LAR. The inconsistent use of terminology, creates uncertainty of the use of facility-specific terms used in the TSs and LAR.*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Revise TS 4.11, Applicability, to use "Selective" consistent with the LAR, or justify why no change is needed.*

The word "Select" is a typographical error, MURR will ensure that the correct word – "Selective" – is used throughout the Technical Specifications.

22. *Proposed TS 4.11, Specification c, states “tested for operability” which does not match the surveillance definitions in ANSI/ANS-15.1-2007 which include “channel check,” “channel test,” and “channel calibration.” The inconsistent use of terminology, creates uncertainty of the use of facility-specific terms used in the TSs and referenced guidance.*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide a description or definition to ensure consistent understanding of the term “tested for operability,” or revise to match the definitions in ANSI/ANS-15.1-2007, or justify why no change is needed.*

Specification 4.11.c (now TS 4.3B.a) has been revised to use “channel check.”

23. *Proposed TS 4.11; Specification e, states "checked for operability" which does not match the surveillance definitions in ANSI/ANS-15.1-2007 which include "channel check," "channel test," and "channel calibration."*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide a description or definition to ensure consistent understanding of the term "checked for operability," or revise to match the definitions in ANSI/ANS-15.1-2007, or justify why no change is needed.*

Specification 4.11.e (now TS 4.5B.b) has been revised to use "channel check."

24. *Proposed TS 4.11, Specification f, provides a channel calibration for the instruments listed in TS 3.11, Specification g. However, it is not clear if an operability, or channel test, is required prior to startup. This information is needed to ensure the safe operation of the facility.*

*The regulations in 10 CFR 50.36 require each applicant to propose TSs. Furthermore, ANSI/ANS-15.1-2007 provides guidance acceptable to the NRC staff, and, unless acceptable alternatives are justified by the licensee, should be utilized whenever appropriate. Furthermore, NUREG-1537, Part 2, Chapter 14, provides guidance that the TSs should state the limits, operating conditions, and other requirements imposed on facility operation to protect the environment and the health and safety of the facility staff and the public in accordance with 10 CFR 50.36, and each of the TSs should be supported by the SAR.*

*Provide a TS which requires a verification of channel operability or a channel test, prior to startup of the TEF, or justify why no change is needed.*

New Specification 4.4.B.a has been added where instrumentation as required by Specification 3.4B.a is now channel-checked prior to startup of the SGE TEF.

### LAR Attachment 3

25. LAR, Attachment 3, "Codes and Standards," states that the TEF was designed and fabricated in accordance with applicable codes and standards. However, the NRC staff review was unable to find the specific codes and standards to which the I&C system was designed and fabricated (only American Society of Mechanical Engineers standards are listed). This information is needed to determine the adequacy of the design basis for the I&C system.

*The regulations in 10 CFR 50.34 require information related to design bases and the principal design criteria of the I&C systems. NUREG-1537, Part 1, Chapter 7, Section 7.2.1, provides guidance that the applicant should discuss the criteria for developing the design bases for the I&C systems. The basis for evaluating the reliability and performance of the I&C systems should be included. All systems and components of the I&C systems should be designed, constructed, and tested to quality standards commensurate with the safety importance of the functions to be performed. Where generally recognized applicable codes and standards are used, they should be named and evaluated for applicability, adequacy, and sufficiency. The draft ISG augmenting Chapter 7 of NUREG-1537, Part 1 & Part 2, provides revised guidance for preparing and reviewing applications for I&C systems for non-power production or utilization facilities.*

*Furthermore, the draft ISG guidance states that design criteria should be specified for each structure, system, or component that is assumed in the safety analysis to perform an operational or safety function, and design criteria should include references to applicable up-to-date standards, guides, and codes. Specific references to the draft ISG are provided in [brackets].*

*Provide the following information on design criteria for the TEF I&C systems [draft ISG 7.2.1], or justify why no additional information is needed:*

- 25.1. Design for the complete range of operating conditions for both system and facility (environmental) parameters to cope with anticipated transients and potential accidents,*

The sensors and transmitters used in the Target Cooling System (TCS) control system were selected to have measurement ranges that cover normal operating and transient conditions. Table 25-1 provides details on the process parameters, sensor types, process parameter selected ranges, sensor ranges, and accuracy of the sensors. The maximum value for the process parameters in the table is the value for the accident situation and the normal operation value is the nominal value for the operating process parameter during normal conditions. This table confirms that the measurement devices, including those for safety, cover the anticipated ranges for the operating conditions and possible accident conditions.

Table 25-1  
TEF Process Parameters and Corresponding Sensors and Transmitters  
for the Anticipated Range of Operating Conditions

Process Parameters	Qty	Process Values			Sensor Range		Accuracy	Sensor Type
		Min	Normal Operation	Max	Min	Max	Sensor	
<sup>1</sup> Target coolant flow, gpm	x 2	96	113	350	50	500	±0.5%	V-Cone
Temperature of pool (TCSM inlet), °F	x 1	35	102	212	-58	500	Class A Accuracy (standard)	RTD
Target cooling supply pressure, psia	x 2	10	59	70	0	150	±0.075%	Piezoresistive sensor and welded metallic membrane
Target cooling supply temperature, °F	x 2	35	83	212	-58	500	Class A Accuracy (standard)	RTD
Target cooling inlet temperature, °F	x 4	35	83	212	-58	500	Class A Accuracy (standard)	RTD
Target cooling outlet temperature, °F	x 4	35	108	300	-58	500	Class A Accuracy (standard)	RTD
Differential pressure across TCSM, psid	x 1	0	17	48	0	232	±0.075%	Piezoresistive sensor and welded metallic membrane
<sup>1</sup> HX outlet temperature from TCSM, °F	x 4	35	83	212	0	500	Class A Accuracy (standard)	RTD
N-16 used to monitor reactor power, %	x 2	0	100	125	10 <sup>-1</sup> (mR/h)	10 <sup>7</sup> (mR/h)	±10% (with Field Test Source)	Ion Chamber
<sup>2</sup> I-132 used to monitor pool coolant, %	x 1	1	< 10	100	1	100	±20%	Sodium Iodide Scintillation Detector

<sup>1</sup> Sensors provide inputs to the MURR reactor safety system (reactor scram).

<sup>2</sup> Pool Coolant Monitor is used for detection of a leaking target rod; it is not used to quantify the release.

The bases for the maximum ranges are as follows:

- The maximum flow rate is 350 gpm total, which is the maximum value that the TCS pump can deliver according to the pump curve.
- The maximum temperature for the TA outlet is ~300 °F, which is approximately the boiling point of water at 54 psig. The 54 psig is the pump deadhead pressure according to the pump curve. Note that the pool is open to atmosphere but this shows the worst case.
- The maximum temperature range for the TA inlet, HX outlet and TA supply is 212 °F, which is the boiling point of pool water at atmospheric pressure.
- The maximum target coolant supply pressure of 57 psia is the difference between the pump deadhead pressure (54 psig) and HX pressure drop (12 psig), converted to psia.
- The maximum pressure drop across the Target Cooling System Module (TCSM) of 42 psid is also the difference between the pump deadhead pressure (54 psig) and HX pressure drop (12 psid)
- The maximum core reactor power is 125%, which is greater than the anticipated value at possible accident conditions.
- The maximum pool coolant monitor is 100%, which is the anticipated value if major target rod leakage occurs.

*25.2. Design redundancy to protect against unsafe conditions in case of single failures of the TEF or reactor protective and safety systems,*

The process instrumentation and electrical components used in the Target Cooling System (TCS) control system that interface with the TCS protection system are redundant pairs to prevent single point failures of the Target Experimental Facility (TEF) or reactor protective and safety systems. The coolant flow measurement on TCS branch A for Target A accomplishes this redundancy with two (2) TCS flow transmitters (TCFT), TCFT-1A and TCFT-2A. Similarly, the coolant flow measurement on TCS branch B for Target B also accomplishes this redundancy with two (2) flow transmitters, TCFT-1B, and TCFT-2B. These flow signals are fed to the chart recorders (one for Target A and one for Target B) to log and display the flow data. The high or low flow signals are processed by analog alarm units that initiate a reactor scram, open the Target Decay Heat Removal Valves (TDHRVs), and secure the TCS pumps.

The temperature measurements on the TCS are also equipped with a redundant pair of temperature sensors and signal conditioners. The temperature sensors are 4-wire, platinum resistance temperature detectors (RTDs). The signal conditioner converts the RTD signal into a 4 to 20 mA output signal to be used in the chart recorders, where the temperature data are logged and displayed. Temperature measurement at the exit of the TCS heat exchangers is a redundant pair of two (2) TCS temperature transmitters (TCTE), TCTE-2 and TCTE-3. The high temperature signal for TCTE-2 and TCTE-3 at the exit of TCSM is processed by analog alarm units that initiate a reactor scram. Different from abnormal flow, the high temperature signals will not open the TDHRVs and will not secure the TCS pumps.

Redundant pairs of solenoid-operated valves in the control circuit are used to control air to open or close each TDHRV with compressed air from the Valve Operation Air System. Each TDHRV has a pneumatic actuator with a spring return. The solenoid-operated valves are electromechanically-actuated valves that control the compressed air flow to the pneumatic actuator, which controls the opening and closing of the TDHRV. During normal operation, the solenoid-operated valves are energized open, allowing compressed air to flow to the valve actuator. The compressed air applies pressure against the spring of the actuator, keeping the TDHRV in a closed position. During a reactor scram or loss of electrical power, the solenoid-operated valve is de-energized, the compressed air is vented off, and the actuator spring returns back to its uncompressed state, which opens the TDHRV.

The TCS control system has a redundant pair of 24VDC power supplies that provide power to the instrumentation and electrical components, such as the signal conditioners and transmitters. If one power supply fails, then the other power supply will automatically switch online to provide power to the instrumentation and electrical components. Each power supply has a fault indication light on the TCS control panel. The reactor's non-redundant power supply provides power to the alarm annunciation, trip, or scram function. If power is lost to the reactor's non-redundant power supply, then the loss of power will place the alarms, trips, or scram functions into a fail-safe condition.

The TCS protection system design has two redundant relay circuits, "Yellow Safety Leg" and "Green Safety Leg," that provide inputs to the MURR reactor safety system (see Figure 32, LAR Part 1 Attachment 1). The safety legs contain a series of dry relay contacts from the analog alarm units that are configured for abnormal TCS conditions of flow and temperature. Any opening of these dry contacts due to critical operation conditions or electrical power failure will immediately initiate scram signals to the MURR reactor safety system. The TCS protection system design also has redundant bypass keys to bypass the TCS control system. The function of the bypass is to allow for operation of the reactor when one or both Target Assemblies are not in use. The bypass keys must be in the correct positions to use the bypass functions.

The AC power source for the TEF I&C Systems is an uninterruptible power supply (UPS) and the MURR Emergency Electrical Power System. After loss of normal electrical power, the UPS is used to provide power to the TEF I&C until the emergency power generator starts. After the emergency diesel generator starts, the emergency power generator is the main source of AC power for the control systems.

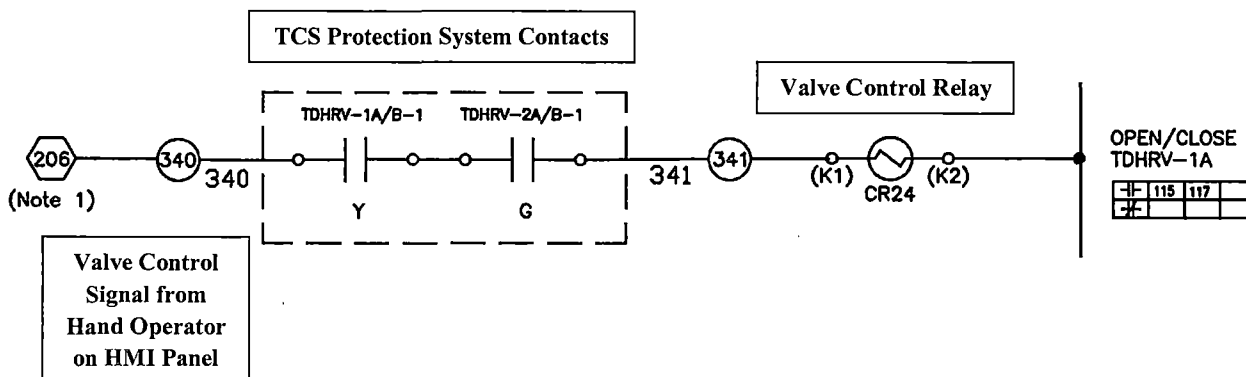

*25.3. Design independence to protect against TEF system failures or malfunctions preventing the reactor protective system from performing its safety function or preventing safe reactor shutdown,*

The TCS protection system is designed to initiate a reactor scram via the MURR reactor safety system, which is independent of all other systems governing TEF operation. The TCS protection system interfaces with TCS control system sensors and relay logic in safety circuits called the "Yellow Safety Leg" and "Green Safety Leg." TCS protection system has dedicated instrumentation solely for its use.

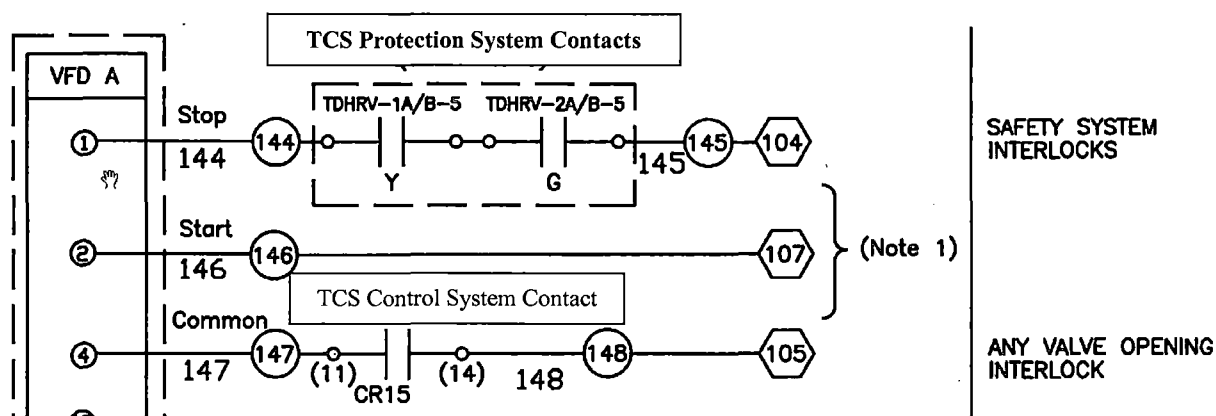

The scram signal for the TCS protection system is based on low TCS flow rate ( $\leq 85\%$  nominal flow), high TCS flow rate ( $\geq 115\%$  nominal flow), or high TCS heat exchanger outlet temperature ( $> 105^\circ\text{F}$ ). Regardless of the operational status of the TCS control system, the hardwired, fail-safe, and redundant “Yellow” and “Green” safety legs (Figure 32, LAR Part 1 Attachment 1) will initiate a reactor scram for both high and low flow, and high temperature signals. This independent control is enabled by:

- 1) Inserting redundant, fail-safe relay contacts in the TCS protection system in series with valve control circuits in the TCS control system.

- 2) Inserting redundant, fail-safe relay contacts in the TCS protection system in series with each TCS pump drive control circuit in the TCS control system.

25.4. Design fail-safe when required by the safety analysis, to assume a safe state on loss of electrical power or has a reliable source of emergency power sufficient to sustain the operation of those specific devices credited in safety analysis,

The hardwired control logic for the TCS uses a fail-safe circuit design to mitigate hazards. During a loss of normal electrical power, the TCS fails into a safe condition. Therefore, emergency electrical power backup and UPS are not required. Fail-safe conditions include initiating a reactor scram, opening the TDHRVs, and securing the TCS pump.

During normal operation, the control circuit is energized and the relay contacts are closed. When normal electrical power is lost for this fail-safe design, the relay contacts will open. Opening of the relay contacts will allow compressed air to be vented from the actuator, allowing the mechanical spring to open the TDHRVs and secure the TCS pump.

Field wiring breaks related to the TDHRV limit switches will trip the fail-safe circuits, preventing the use of non-operational instrumentation during operation. Similarly, open control enclosure wiring and faulty control relay coils belonging to the fail-safe circuits will be detected at the time of the failure, reducing the likelihood of control system failure in the event of an actual incident.

*25.5. Design to facilitate inspection, testing, and maintenance (e.g., readily testable and capable of being accurately calibrated), including justification for test intervals for the surveillance testing proposed as part of the facility TSs,*

Safety-related instrumentation (i.e., coolant flow and temperature sensors) are installed to allow for easy reach and accessibility for inspection, testing and maintenance. The individual analog loop wiring for the TCS has fuses, which help troubleshoot the system when needed. Indicators for the control panel components (fuse holders and control relays) are provided for ease of inspection as well. Technical Specification surveillance testing intervals are consistent with the guidance of ANSI/ANS-15.1-2007, "The Development of Technical Specifications for Research Reactors," and what is currently in the MURR Technical Specifications for reactor instrumentation.

*25.6. Design surveillance test and self-test features for a digital computer-based protection systems, where applicable, to address failure detection, self-test features (e.g., monitoring memory and memory reference integrity, using watchdog timers or processors, monitoring communication channels, monitoring central processing unit status, and checking data integrity), and TEF system actions taken upon failure detection,*

The TCS control system and protection system are analog hardwire-based designs. They are not a digital computer-based design. Therefore, more information does not need to be provided for these two (2) sub-systems.

*25.7. Design to limit the likelihood and consequences of fires, explosions, and other potential manmade conditions. (This can include mitigating features of other facility or system design features),*

Design features in the TCS control system and protection system include redundancy, diversity, and fail-safe operation, with multiple interlocks to mitigate potential hazards to the TEF. The fail-safe design limits the likelihood and consequences of fires, explosions, and other potential man-made conditions.

Redundancy is provided for the following systems:

- TCS flow transmitters.
- TDHRVs, each with dual solenoid-operated air supply valves

- Temperature monitoring sensors/transmitters for the Target Assemblies, cooling water supply, and secondary cooling water
- Redundant “Yellow” and “Green” safety legs in the TCS protection system
- Redundant bypass keys in the TCS protection system

Signal diversity is used in the TCS protection system to initiate a reactor scram signal for abnormal functioning of the TCS. Either out-of-range high/low coolant flow rates or a high coolant temperature will trip the control circuit in the TCS protection system, which produces the protective action of causing a reactor scram. The high/low flow signal also produces protective action of opening the TDHRVs and securing the TC pump.

Fail-safe design of the hard-wired control interlocks transitions the system into a safe state upon loss of electrical power or damage to the individual components and field wiring. The energized state of these interlock circuits during normal operations contributes to reducing the chance of faults going undetected, thereby limiting unsafe TEF conditions.

Any failure of one of the redundant pair of flow sensors, temperature sensors, control solenoid-operated valves, and transmitters will initiate reactor scram. Also, any wrong position of one of the bypass keys by the operator will not put the intended Target Assembly in bypass mode; therefore, any abnormal operation conditions of flows and temperature would still initiate a reactor scram.

#### *25.8. Design quality standards commensurate with the safety function and potential risks, and*

The analysis, design, and fabrication of the required structures, systems, and components will be under an established system of Quality Assurance (QA) requirements, specifications and inspections, based on safety significance. QA levels for the components are determined in accordance with a graded approach to quality requirements, and safety-related components are defined in the General Atomics’ QA Manual. Project-specific requirements for the TEF, including a list of QAL I components, are defined in the project-specific QA Program Document (LAR Part 1 Attachment 3 and Ref. 25-1). All vendors and suppliers of equipment are approved via QA audits to ensure they have required QA processes and procedures in place to meet required quality standards. These structures, systems, and components will also meet the applicable IEEE standards.

#### *25.9. Analysis of function, reliability, and maintainability of systems and components.*

The safety-related sensors (flow and temperature sensors) used in the TCS control system provide signals to the TCS protection system. These sensors have been selected to be off-the-shelf, robust in design, and have a low probability of failure. The flow sensors are V-Cone and have no moving parts, which minimizes the pressure drop across the sensors ( $< 2$  psid), and provides high accuracy ( $\pm 0.5\%$ ) measurement. Temperature sensors are 4-wired Platinum RTDs, with Class A accuracy.

## LAR Attachment 6

26. LAR, Attachment 6, Section 2.3.1.2, "Driver fuel element loading pattern," the NRC staff notes that a reference is made to the "extreme burnup core" having the "worst power peaking in both the driver and target assemblies" (page 10). The elemental and core average burnups for all four Xenon/burnup configurations is presented Table 2-1. The peaking factors for the extreme burnup and maximum burnup cores are presented in Tables A-1 through A-16 for all eight fuel elements. The NRC staff is not clear if peaking factors were calculated for the other two burnup/Xenon combinations demonstrated in Table 2-1 (e.g., the Minimum and Average burnup cores), and if so, what were the calculated peaking factors for these other two combinations. Also, nuclide compositions for all eight-fuel elements for the xenon/burnup configurations referenced in Table 2-1 were not provided.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, "Nuclear Design," provides guidance that applications should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

- 26.1. *Provide the peaking factors for the Minimum and Average burnup cores, if calculated, provide which peaking factors were used, or justify why no additional information is needed.*

During the nuclear design calculations, peaking factors were calculated for all four (4) core configurations/states (viz., minimum burnup, average burnup, maximum burnup and extreme burnup). Since the nuclear peaking factors were found to be more challenging in the maximum and extreme burnup cases, as compared to the remaining two (2) core states, only those values were provided in the LAR. The peaking for the other two (2) core states, minimum and average burnup, are provided in Supplements 26.1.a and 26.1.b, respectively.

- 26.2. *Provide the nuclide compositions of all eight fuel elements for the xenon/burnup configurations referenced in Table 2-1, or justify why no additional information is needed.*

In the detailed model of the MURR core used for nuclear design calculations, the twenty-four (24) fuel plates of each fuel element that comprise the MURR core are divided into twelve (12) axial material zones. The fuel compositions used in those 288 material zones (24 plates x 12 axial divisions) of each fuel element for all four (4) analyzed core configurations are provided in the following Supplements:

1. Supplement 26.2.a – Driver Fuel Composition for Average Burnup Core
2. Supplement 26.2.b – Driver Fuel Composition for Extreme Burnup Core
3. Supplement 26.2.c – Driver Fuel Composition for Minimum Burnup Core
4. Supplement 26.2.d – Driver Fuel Composition for Maximum Burnup Core

27. LAR, Attachment 6, Section 5.1, "Validation for Computational Methods and Calculations at MURR," provides reference to a library of beryllium reflectors at various stages of depletion that were created with MONTEBURNS (page 73). The NRC staff is not clear as to the burnup methodology for the beryllium structure (i.e., are these libraries distinguished from each other solely by changes in composition or density?). Additionally, reference is made to the central flux trap composition, but no other details are provided (i.e., what are the compositions of these targets at the most limiting core configuration?).

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

*27.1. Provide the burnup methodology and the burnup libraries, or justify why no additional information is needed.*

Two aspects of the reactor core that affects the steady-state control blade height and axial flux shape are the core residence time (or megawatt-days) on the beryllium reflector and the weekly loading of the removable experiment sample canister in the center test hole of the flux trap. The loss of beryllium atoms is caused mainly by the fast neutron  ${}^9\text{Be}$  ( $n, x$ ) capture reaction, where  $x$  can be  $2n$ ,  $\alpha$  or  $\gamma$ . The fast neutron flux (i.e.,  $> 0.1$  MeV) within the beryllium peaks at  $\sim 3.0 \times 10^{14}$  n/cm<sup>2</sup>s. In the case of the ( $n, \alpha$ ) reaction channel, the loss of the Be atom is accompanied by neutron poisoning due to the production of Lithium-6 ( ${}^6\text{Li}$ ) and Helium-3 ( ${}^3\text{He}$ ). The loss of Be atoms, the production of neutron poisons, and the production of gases are the major causes of degradation in the reflector's reflective efficacy as megawatt-days increase. For a beryllium reflector at the end-of-life at MURR, it was found that the core excess reactivity decreases by  $\sim 0.050 \Delta k/k$  [Ref. 27-1]. There is a potential for the beryllium to develop cracks due to the thermal stresses that are created within the beryllium during reactor operation as well as the gas build-up. Based on operational experience and calculations, the beryllium reflector is replaced at MURR approximately every eight (8) years.

To track these changes in the beryllium reflector as a function of time, the program MONTEBURNS [Ref. 27-2] was utilized. The reflector was discretized into three (3) radial and five (5) axial burn zones to capture the depletion profiles correctly [Ref. 27-1]. The general movement of data within MONTEBURNS is a cyclic, stepwise process where each depletion or burnup step completes an MCNP5 [Ref. 27-3] coupled ORIGEN2 calculation, and every decay step employs an ORIGEN2 [Ref. 27-4] calculation. MONTEBURNS collapses all ENDF continuous-energy neutron data [Refs. 27-5 and 27-6] into one-group (i.e., spectrum averaged) data that are used by ORIGEN2. ORIGEN2 then calculates and returns new isotopic concentrations that are used to update and modify the MCNP5 material data cards for the next cycle of MCNP calculations. The depletions describe the beryllium burnup states from fresh to 26,000 MWd (i.e., 0 to  $\sim 8$ -year runtime) in increments of 1,638 MWd (6 months). Libraries of the beryllium atom density and depletion status, for each of 15 zones, as a function of runtime in years can be conveniently selected for any core configuration (beryllium

reflector libraries for the limiting core cases are given in Supplement 27.1).

*27.2. Provide the compositions of the targets at the most limiting core configuration, or justify why no additional information is needed.*

The central flux trap region is where the peak thermal neutron flux exists within the MURR core. Therefore, the MURR utilizes the flux trap region extensively for irradiating various positive and negative reactivity worth samples for research and development, and commercial applications. The flux trap irradiation positions are located at the center of the core region and consist of three (3) large tubes and a set of three (3) smaller tubes (removable experiment sample canister) packed tightly together. Each of the larger diameter sample tubes has the capacity to hold 30 vertical inches of various sample materials centered about the core axial centerline. The target materials loaded into the flux trap region for the limiting core case is described in Supplement 27.2.

The combined total reactivity worth of all six (6) flux trap tubes and contained samples has a limit of 0.011  $\Delta k/k$  (Reactivity worth of the removable experiment sample canister plus administrative limit of the sample materials). Samples loaded weekly into the removable experiment sample canister can have a maximum reactivity worth of  $\pm 0.006 \Delta k/k$ . The mixtures of samples irradiated in the flux trap region vary slightly from week-to-week. Therefore, for the flux trap configuration, a typical sample loading was modeled to give the weekly average of the reactivity worth.

28. LAR, Attachment 6, Section 5.2, "Validation of MURR Control Blade Depletion Model," Figures 5-6 and 5-7, list the Boron-10 (neutron, alpha) reaction rate profiles for the control blades, and Table 5-4 provides a demonstration model that the control blade burnup has a significant effect on the deviation of the  $k$ -effective (page 84). However, the NRC staff notes that the control blade composition at the most limiting core configuration is not provided.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

*Provide the control blade composition at the most limiting core configuration, or justify why no additional information is needed.*

Since MURR employs Boron-10 ( $^{10}\text{B}$ ) as the neutron absorber/poison in the control blades (Shim Blades – A, B, C and D), there is a high depletion rate of the  $^{10}\text{B}$  due to the 3840 barns  $^{10}\text{B}(\text{n},\alpha)\text{Li}^6$  capture cross-section. Consequently, the  $^{10}\text{B}$  depletion causes a decrease in the overall effective length of the control blade as its core residence time or megawatt-days (MWd) increases. The range of MWd for an operational control blade is from 0 MWd (fresh) up to 33,000 MWd, after which it is removed from service. The effective length of a control blade at 33,000 MWd is about 4 inches (10.16 cm); much shorter than a fresh or un-irradiated control blade. This level of burnup is achieved in roughly 2-year (approximately 6,552 MWd) increments to allow for the required inspection and decay of each control blade in use. Due to radiation dose considerations, no preference is given to a particular control blade's prior runtime or its in-core position during replacement. Therefore, a MURR core configuration at any given time could have some control blades with very high MWd burnup (approaching 33,000 MWd) and some with very low burnup (new or close to 0 MWd). This mixed-burnup control blade use will affect the equilibrium-xenon control blade position and consequently the axial flux profile shape.

To improve the MURR core MCNP model, the exact depletion state of each in-core control blade had to be accurately defined. The models of individual control blades were obtained by selecting the correct runtime of a given blade burnup provided by Reference 28-1. For the control blade depletion simulations in Reference 28-1, each blade was discretized into 292 depletion zones. The first 144 depletion zones were focused on the first four (4) bottom inches (10.16 cm) of the blade. The bottom inch of the control blade was discretized into four (4) axial, nine (9) radial and four (4) azimuthal sections (see Figure 28-1 in Supplement 28). A combination of the nuclear simulation program MCNP and a depletion methodology described in Reference 28-1 was used to deplete the control blades by cycling them in and out of the core in 2-year increments to obtain the control blade boron concentrations for various burnup states.

For the limiting core case, the control blade runtime used for the blade in positions A, B, C and D are 0.0, 8.0, 8.0 and 0.0 years, respectively. The list of compositions for each depletion zones are provided in Supplement 28.

## LAR Attachment 7

29. LAR, Attachment 7, Section 4.2, "FRAPCON Generic Code Assumptions," provides assumptions for use of the FRAPCON computer code. However, the NRC staff review noted that the use of FRAPCON's thermal model with the stated Linear Heat Generation Rate (LHGR) of 54.2 kilowatts per meter (kW/m) (Attachment 6, page 59), specifically with respect to fuel centerline measurements at these temperatures, is higher than any of the documented thermal integral assessment cases in the FRAPCON-4.0: Integral Assessment (PNNL-19418, Vol.2 Rev.2). Additionally, the NRC staff noted that FRAPCON's radial power distribution model (tubrnnp) used an enrichment of 19.75 percent uranium (U)-235; however, FRAPCON is validated for light water reactor fuel with a maximum enrichment of 5 percent U-235. The NRC staff needs additional clarification on the use of FRAPCON given these values used.

The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.

29.1. Provide data to support the use of FRAPCON's thermal model with the stated LHGR of 54.2 kW/m, specifically with respect to fuel centerline measurements at these temperatures, or justify why no additional information is needed.

General Atomics' (GA) recognizes that the FRAPCON fuel rod performance data covers Linear Heat Generation Rates (LHGR) up to 43.7 kW/m and maximum measured centerline temperatures up to approximately 1850 °C (3362 °F) [Ref. 29-1, Figure 3.1]. The performance of the SGE target rods exceeds these validation bases in the following three (3) respects:

1. More than half (58%) of all target rod pellets over two (2) full target assemblies (22 target rods) exceed an LHGR of 43.7 kW/m for the case with the peak linear power rod. For a typical Pressurized Water Reactor (PWR) fuel pellet, 43.7 kW/m corresponds to a volumetric heat generation of 829.5 MW/m<sup>3</sup>. If the smaller diameter target pellet had this PWR power density, it would correspond to a LHGR of 16.3 kW/m. However, all of the 2200 target pellets exceed this LHGR; the minimum, average and maximum values are 17.5 kW/m, 42.2 kW/m and 56.5 kW/m, respectively.
2. A small fraction (5%) of the UO<sub>2</sub> exceeds 1850 °C (3362 °F).
3. The UO<sub>2</sub> enrichment of 19.75% exceeds the FRAPCON validated limit of 5% enrichment.

There is no publicly available Zircaloy/UO<sub>2</sub> fuel rod performance code that has been validated for the full range of the proposed SGE target rod operation. Therefore, GA opted to use FRAPCON on the basis that any error due to extending the application of the code to the above deviations would be small. Further, results from ongoing post-irradiation examination (PIE) of the pellets that have been irradiated to representative conditions in test target pellet capsules using the National Research

Universal (NRU) reactor at the Canadian Nuclear Laboratories (CNL) will be used to verify this basis by modeling NRU target pellet capsule irradiation conditions in FRAPCON. The PIE on the pellets includes (a) cladding profilometry, (b) fission gas characterization, and (c) metallographic examination for changes to the macro-dimensions, structural cracking, smaller microstructural changes, evidence of  $\text{UO}_2$  melting, and pellet deformation. The final test report is expected to be available in mid-January 2018.

Second, we note some important ameliorating effects that contrast the target assembly with a large PWR core:

- Lower coolant temperature [38-50 °C (100-120 °F) vs. 320 °C (608 °F)]
- Smaller pellet diameter (5.0 mm vs. 8.2 mm)
- 32% greater cladding thickness to diameter ratio (cladding stress equals pressure times radius divided by cladding thickness; therefore, a greater cladding thickness to diameter ratio reduces cladding stress)
- Shorter irradiation time (several weeks vs. approximately 230 weeks)
- Lower maximum burnups (6 GWd/MTU vs. 60 GWd/MTU)

The impact of these differences on the validity of FRAPCON for the target assembly is discussed below.

The important parameters that affect the SGE target rod performance analysis with FRAPCON are (1)  $\text{UO}_2$  temperatures, and (2) Zircaloy-4 cladding strain. The critical heat flux ratio (CHFR) is also important but is not analyzed in FRAPCON. The safety limit on  $\text{UO}_2$  temperature is the melting point, 2840 °C (5144 °F) [Ref. 29-2]. The limit on cladding strain is 1%, as determined from ASME Section III-Division 1-NH, T-1310, page 102.

#### $\text{UO}_2$ Temperatures:

The cladding surface temperature of the target rod is a fixed boundary condition provided by RELAP. Therefore, the temperature buildup to the  $\text{UO}_2$  centerline consists of three (3)  $\Delta T$  segments for cladding, gap and pellet radius, as shown in Figure 29-1. Of these, the Zircaloy-4 cladding temperatures are well within the validated range of FRAPCON.

The pellet radial  $\Delta T$  is accurately predicted by FRAPCON, given an accurate power generating profile, because the  $\text{UO}_2$  thermal-physical property database [Ref. 29-3, Page 1.2] extends to the  $\text{UO}_2$  melting point of 2840 °C (5144 °F). An issue arises from the fact that the target pellet is at 19.75% enrichment, whereas FRAPCON is validated to only 5% enrichment. The enrichment affects the self-shielding effect on the power profile. In this regard, it was found that the FRAPCON model over-predicts the pellet centerline power at 19.75% enrichment compared to a neutronics analysis of the target rod by the MCNP\* code, as shown in Figure 29-2. This effect is further discussed in the response to RAI No. 29.2 below.

\* During the conference call with NRC staff on October 16<sup>th</sup>, GA discussed using the WIMS lattice code to determine power profiles. WIMS was initially used to obtain a reasonable answer very quickly. Since all physics calculations for this project have utilized MCNP, all power profiles in this response were consistently performed with MCNP.

Figure 29-1  
SGE Target Rod Temperature Segments

The effect of the different radial power profiles on pellet temperature can be seen in Figure 29-3. The results are from a SINDA thermal analysis of the SGE target rod at nominal conditions, with the only difference being that the power profiles are obtained from the MCNP and FRAPCON 19.75% power profiles in Figure 29-2. The centerline temperature using the MCNP power profile was 1940 °C (3524 °F), compared to 2070 °C (3758 °F) for the case with the FRAPCON power profile. Experimental data for performance of 19.75% enriched pellets are not available, but the following case gives some indication of FRAPCON performance with higher-than-LWR enrichments. For UO<sub>2</sub> fuel enriched to 10% in U-235, experimental measurements performed by Oak Ridge showed that FRAPCON over-predicted the centerline temperature [Ref. 29-4, page 9].

Figure 29-2  
SGE Target Radial Power Profiles for FRAPCON and MCNP Cases

Figure 29-3  
Temperature Profile through the SGE Target Rod Pellet as Calculated by SINDA  
using Power Profiles Calculated by MCNP and FRAPCON for 19.75% Enriched Fuel

The gap  $\Delta T$  is subject to two (2) uncertainties; the composition of the gap gas, and the relocation of the pellet relative to the cladding. The thermal conductivity vs. temperature database for helium, krypton and xenon in FRAPCON encompasses the gap temperatures in the target rods. An uncertainty arises from the composition of the gap gas, which is dependent on the temperature of the  $\text{UO}_2$  pellet. As stated above, about 5% of the  $\text{UO}_2$  in the SGE target rods is above the validation temperature of 1850 °C (3362° °F). Since FRAPCON predicts the higher-temperature pellets to close the pellet-clad gap to around 5  $\mu\text{m}$  after about a week of irradiation, effect of the gas thermal conductivity on gap  $\Delta T$  is minimized.

The second uncertainty affecting  $\text{UO}_2$  temperature is pellet relocation relative to the cladding. The relocation is due to pellet thermal expansion relative to the cladding and irradiation-induced swelling. Because the pellets are irradiated for only several weeks, the irradiation-induced swelling is very small. For burnups under 6 GWd/MTU, the FRAPCON model predicts no pellet growth due to fission product accumulation [Ref. 29-3]. Thermal expansion is a thermal-physical property that is accurate in FRAPCON up to the melting point.

These conclusions would be confirmed by results from irradiation and PIE of target pellet capsules currently in progress (final report on these experiments is due in mid-January 2018).

#### Cladding Strain:

Cladding strain can be impacted by the gas pressure in the target rod and by mechanical interaction of the pellet against the cladding. Of these, the effect of cladding pressure can be dismissed because it is only initially filled to 14.7 psia with helium. Even if all krypton and xenon generated after the maximum irradiation period is released from the pellet, the primary stress on the cladding is estimated to be about 20 MPa, compared to a primary stress limit of 430 MPa.

The second effect that influences cladding strain is mechanical interaction between the pellet and cladding. This can be from irradiation-induced swelling and thermal expansion (previously discussed), or it can be caused by pellet fragment ratcheting against the cladding. Pellet ratcheting is due to the fact that high thermal gradients in the pellet can cause cracking and fragmentation of the pellet. Successive thermal cycles, such as startup and shut down of irradiation, can push a fragment against the cladding, causing strain. Since the target pellets have higher thermal gradients than PWR pellets, a greater degree of cracking would be expected. The higher thermal gradient in the SGE  $\text{UO}_2$  target pellets compared to a typical PWR will likely cause predominantly radial cracking. Circumferential cracking tends to decrease radial heat transfer, but the net effect of radial and circumferential cracking is a lower  $\text{UO}_2$  temperature due to closure of the pellet/clad gap.

As noted in Reference 29-3, pages 2.53 to 2.43, fuel pellet centerline temperatures measured at beginning-of-life (BOL) in instrumented test rods have repeatedly been found to be lower than values predicted by computer codes in which the fuel-cladding gap is calculated based only on fuel and cladding thermal expansion. It has long been concluded, based on microscopic examination of fuel cross sections, the fuel pellet cracking promotes an outward relocation that causes additional gap closure. Fuel pellet cracking is predominantly radial. However, some circumferential components to

these crack patterns exist, and could alter the fuel thermal conductivity. The FRAPCON relocation model implicitly includes any crack effects on heat transfer because the model is based on fuel centerline temperature data.

An SGE target rod that is irradiated for the maximum irradiation period could in principle have up to six (6) cycles if successive MURR mid-week shutdowns occur. For this reason, the GA modeling assumed six (6) startup/shutdown transients to maximize, and determine the effect of, any thermal expansion that may occur.

The relocation model in FRAPCON was used to predict the SGE target rod strain. Although the SGE target pellet thermal gradients are larger, the SGE pellet is smaller than a PWR pellet, and the SGE cladding thickness-to-diameter is about 32% greater than the ratio of PWR cladding thickness-to-diameter. Currently, FRAPCON predicts about 0.6% radial strain and 0.3% axial strain for the worst operating condition of a 3-week irradiation with six thermal cycles. This is within the limit of 1% strain.

The tests currently in progress at CNL are expected to confirm the FRAPCON prediction. In these irradiation/PIE tests, four (4) target pellet capsules with 20 pellets each were irradiated in the NRU reactor for various irradiation times and thermal cycles to correspond to MURR's weekly and twice weekly shutdown cycles. The irradiations have been completed and PIE is currently in progress. As part of the ongoing PIE, profilometry examinations have been completed on all target pellet capsules after irradiation and none had any measurable permanent tensile strain. This would suggest that FRAPCON conservatively predicts the target rod cladding strain from pellet-clad interaction. As discussed in LAR Part 1, Attachment 1, a separate test report will be submitted to the NRC on the CNL irradiation/PIE conduct and results.

#### Critical Heat Flux:

While not calculated in FRAPCON, critical heat flux (CHF) is an important safety parameter. It has been calculated independently and verified experimentally. The results show that the CHF values agreed with the Groeneveld predicted values (which are even less conservative than Bernath correlation), on an average to well within 10% [Ref. 29-5]. The Groeneveld predicted CHF values are at least 200% of the design heat fluxes.

Due to the location of the SGE target rods relative to the MURR reactor, one side of the target pellets will experience higher heating than the other side, leading to non-axisymmetric heating. The hotter and cooler sides will be the front-side and backside, respectively, relative to their position with the driver fuel. This heating offset is  $\pm 8\%$  of the average target pellet heating. The front-side experiences 8% higher heating compared to average while the backside experiences 8% lower heating compared to average. To quantify this effect on CHF, the heat flux was increased by 8% for the peak linear heating rod and the maximum heating rod while varying the following parameters: gap radius (nominal and minimum); reactor power (10.0 MW and 11.5 MW); target coolant flow (100% and 85%) and the number of target rods (11 and 3). All cases using a normal operating condition (either 10.0 MW, 100% flow or 11 target rods) result in a CHF ratio above 2.0 for all correlations. This

calculation is conservative because it does not account for circumferential conduction, which would reduce the maximum heat flux.

In conclusion, the above reasoning supports GA's use of FRAPCON for the target rod performance prediction. The use of the code as GA has done will be validated by the CNL tests.

*29.2. Provide an explanation for using FRAPCON's radial power distribution model (tubrnnp) with an enrichment of 19.75 percent U-235, or justify why no additional information is needed.*

The FRAPCON radial power distribution module (TUBRNP) calculates the radial power distribution within fuel as a function of burnup. The distribution changes due to the increased fraction of plutonium as the fuel is burned. Because the TUBRNP radial power distribution is validated for U-235 enrichments up to ~5%, we agree that the actual radial power distribution for 19.75% enrichment in the SGE target rods may not be accurately calculated by TUBRNP.

To quantify the effect of higher enrichment, a separate analysis was performed using MCNP to generate a radial power profile representative of the SGE target rod (19.75% enriched), as well as a profile with a typical PWR enrichment (3% enriched). Figure 29-2 compares the power profiles for these calculations; the FRAPCON curves are calculated for the maximum target pellet temperature case, while the MCNP curves are calculated for SGE and PWR enrichments, respectively. Comparison of the FRAPCON PWR and MCNP PWR power profile curves show that MCNP calculates similar power profiles to that of FRAPCON. The MCNP SGE curve shows, however, the effect on the radial power profile of using higher enrichment, namely, increased power generation toward the edge of the pellet and decreased power generation at the pellet centerline, both due to increased self-shielding. Compared to the FRAPCON PWR calculations, the shift in power towards the surface of the pellet for the MCNP SGE case will result in lower centerline temperatures. Because GA imposed a fixed cladding surface temperature boundary condition in the FRAPCON runs, a smaller thermal gradient will exist across the pellet. We can conclude that the radial power profile used in LAR Part 1 analysis (FRAPCON/TUBRNP) is more conservative than using a SGE power distribution as calculated with MCNP.

Second, to quantify the effect of burnup on radial power distribution, the power profiles from FRAPCON were compared at the beginning and end of the maximum irradiation period. As seen in Figure 29-4, there is very little burnup effect on the radial power distribution due to the small SGE target rod burnup (both curves in Figure 29-4 overlap). The SGE target pellet maximum burnup is only 6 GWd/MTU, which is well within the FRAPCON validated rod-average burnup limit of 62 GWd/MTU. Since there is only a minor change in the power profile, the radial power profile is still determined to be conservative with burnup.

Figure 29-4  
FRAPCON Radial Power Factors at 0.05 Days (0 GWd/MTU)  
and 20.33 Days (6 GWd/MTU) for the SGE Target Rod

30. LAR, Attachment 7, Section 4.3, "FRAPTRAN Generic Code Assumptions," provides assumptions for use of the FRAPTRAN computer code. However, the NRC staff noted that the use of a temperature limit of 2,860 degrees Celsius (°C) (Attachment 1, page 14) for transients for uranium dioxide (UO<sub>2</sub>) appears to exceed the melting temperature for fresh fuel in FRAPTRAN.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

*Provide data to support the temperature limit of 2,860 °C for transients for UO<sub>2</sub>, or justify why no additional information is needed.*

The temperature limit of 2,860 °C (5180 °F) (Attachment 1, Table 1, Page 14) is consistent with the melting temperature for UO<sub>2</sub> in literature. Reference 30-1 provides UO<sub>2</sub> melting temperatures of  $2847 \pm 30$  °C ( $5156.6 \pm 54$  °F); therefore, both the FRAPTRAN limit for fresh fuel of 2840 °C (5144 °F), and Table 1 cited transient limit of 2860 °C (5180 °F), fall in this range. Further, the value of 2860 °C (5180 °F) is not inconsistent with melting temperatures of  $2865 \pm 15$  °C ( $5189 \pm 27$  °F) cited elsewhere [Ref. 30-2], so both the LAR transient temperature limit and the FRAPTRAN melting temperature are within uncertainties found in literature.

Notwithstanding the above, MURR will use the lower temperature limit of 2840 °C (5144 °F), as a safety limit consistent with FRAPTRAN in determining margins of safety.

31. LAR, Attachment 7, Section 5.1, Table 2, provides a value of 0.055 centimeters (cm) for the dish shoulder. The NRC staff noted that Attachment 6, Section 3.1.1, Table 3-1 provides a value of 0.031 cm.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core.*

*Provide a clarification as to the dish shoulder value, or justify why no additional information is needed.*

The value of 0.55-mm (0.055 cm) listed in LAR, Attachment 7, Section 5.1, Table 2 is the dimension from pellet dish shoulder to the pellet end, which includes the following two (2) dimensions:

- a. Dish shoulder width = 0.31mm (0.031 cm);
- b. Chamfer width = 0.24 mm (0.024 cm); and
- c. Pellet end-dish shoulder width = a + b = 0.55 mm (0.055 cm).

LAR Attachment 6, Section 3.1.1, Table 3-1 shows dimensions (a) and (b) above separately, whereas Attachment 7, Section 5.1, Table 2 shows the sum of the two (2) dimensions, or the value shown as (c) above.

32. LAR, Attachment 7, Section 6.3, "Loss of Target Coolant," provides analyses, including the break location and size, for two loss-of-coolant accident (LOCA) scenarios: 1) in-pool; and 2) out-of-pool. The NRC staff needs a more comprehensive understanding of the LOCA analyses, including if other break/size locations were considered, rupture times, or break sizes less than a full double ended break at the limiting in-pool location.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.6, provides guidance that the LAR should include all necessary information on the primary coolant hydraulics and thermal conditions of the fuel, including design parameters and correlations, and test results, for all modes of normal operation and accident scenarios.*

- 32.1. *Indicate if other LOCA analyses were performed (i.e., other break/size locations were considered, rupture times, or break sizes less than a full double ended break at the limiting in-pool location) and if so, provide the results of for these analyses, or justify why no additional information is needed.*

Other break locations were considered during the earlier designs of the Target Cooling System (TCS) which showed that limiting results occur when the break is as close to the Target Assembly (TA) as physically possible. As the break location is moved further away from the TA, there is more cooling water in the cooling pipe downstream of the break, which reduces the consequences. This additional cooling water drains through the TA prior to the onset of natural circulation flow.

For the final design of the TCS, one additional break location was analyzed which was not reported in either LAR, Attachment 1 or Attachment 7. This break location is before the wye where the TCS splits in two and provides cooling to two (2) TAs. The water in the broken pipe provides an additional 10 seconds of target water flow compared to the break in one line close to the reactor pool as shown in Figure 32-1. Cladding temperatures during the boiling and chugging flow remain essentially the same since they are determined by water saturation temperature as shown in Figure 32-2. No other break sizes or break opening times were analyzed for the LAR. Additional analyses were performed in response to RAI No. 32.2 and No. 32.3 below.

Figure 32-1  
Mass Flow Rates during a Loss of Coolant Accident  
before the Wye without Target Decay Heat Removal Valves

Figure 32-2  
Maximum Cladding ID Temperatures during a Loss of Coolant Accident  
before the Wye without Target Decay Heat Removal Valves

32.2. *The limiting LOCA scenario provided is a full double ended break at the inlet to the target fuel assembly. The calculation assumes a rupture time of 0.5 seconds. The NRC staff needs additional information to evaluate the system response. Provide sensitivity calculations showing the system response with assumed rupture times of 0.25, 0.1, and 0.01 seconds, or justify why no additional information is needed.*

Additional RELAP5 runs were performed for the full double-ended break at the inlet to the Target Assemblies (TA) with break opening times of 0.25, 0.1, and 0.05 seconds. For the 0.25-second break opening time, the decrease in flow through TA 2 (also referred to as TA 'B' in the LAR) is quicker and chugging begins just after 0.3 seconds. Peak cladding temperature increases from 688 °C (1270.5 °F) in the LAR case to 787 °C (1448.6 °F) as presented in Table 32-1. Chugging in TA 2 still quits after 3 seconds when natural circulation flow has been established.

For the 0.1-second break opening time, the decrease in flow through TA 2 causes chugging to begin at about the same time as the 0.25-second break opening time. Chugging in Target 2 does not quit until after 4 seconds, when natural circulation flow has been established. Peak cladding temperature occurs sooner than either the 0.5- or 0.25-second breaks and remains elevated for an additional second. The peak cladding temperature is slightly lower than the peak temperature in the 0.5-second break by a few degrees as shown in the table below.

For the 0.05-second break opening time, chugging once again begins at about the same time as the 0.25- and 0.1-second breaks. In this case, chugging stops after about 3.5 seconds. Peak cladding temperature reaches 772 °C (1421.6 °F) and then quickly drops when natural circulation flow is established.

Table 32-1  
Peak Cladding Temperatures as a result of Pipe Break Times

Break Opening Time (s)	Peak Cladding Temperature
0.5	688 °C (1270.5 °F)
0.25	787 °C (1448.6 °F)
0.1	684 °C (1263.2 °F)
0.05	772 °C (1421.6 °F)

Fluid momentum within the TA, along with boiling and chugging when the flow approaches zero, are able to keep peak cladding temperatures below 900 °C (1652 °F) until natural circulation flow through the break can be established, as shown in Figure 32-3 below.

Figure 32-3  
Cladding Temperatures vs. Pipe Break Times

32.3. *Provide a description or analysis of any review of potential break sizes less than a full double ended break to establish the bounding break condition, or justify why no additional information is needed.*

For the limiting LOCA in the reactor pool just above the TA, three (3) additional analyses were performed to assess the consequences of potential break sizes less than a full double-ended break. Using a 0.1-second break opening time, break sizes of 75%, 50%, and 25% were analyzed. Peak cladding temperatures in the hottest target rod are presented in Table 32-2. For the 25% open break, there is sufficient flow through the broken pipe to the TA during the pump coastdown to prevent any peak cladding temperatures higher than normal operation. The bounding break size remains the full double-ended break.

Table 32-2  
Peak Cladding Temperatures as a result of Pipe Break Sizes

Break Size (%)	Peak Cladding Temperature
100	745 °C (1373.0 °F)
75	738 °C (1360.4 °F)
50	736 °C (1356.8 °F)
25	280 °C (536.0 °F)

33. LAR, Attachment 7, Section 6.4, "Loss of Target Flow," provides a description of the loss of target flow analysis, which includes consideration for a loss of pump flow from a loss of electrical power to a pump. The NRC staff notes the possibility that a more severe reduction in coolant flow could occur from debris blocking the suction inlet screen of a locked pump rotor, and did not find any description or discussion of this possibility.

The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.6, provides guidance that the LAR should include all necessary information on the primary coolant hydraulics and thermal conditions of the fuel, including design parameters and correlations, and test results, for all modes of normal operation and accident scenarios.

Provide sensitivity analyses of rapid reduction in flows that occur on a timescale significantly shorter than what was analyzed (e.g., debris blocking the suction inlet screen of a locked pump rotor), or justify why no additional information is needed.

The pump model in RELAP5 gradually reduces in speed within 3.5 seconds. Additional RELAP5 analyses were performed to examine more rapid reduction in flow in which the pump speed was reduced to zero within 1.0, 0.5, and 0.1 seconds. The results for the 0.1-second pump stoppage are presented since they are the most limiting. Figure 33-1 below compares the RELAP5 pump coastdown profile with the 0.1-second pump seizure.

Figure 33-1  
Pump Rotational Speed vs. Time – 0.1-Second Pump Seizure

The mass flow rate for the 0.1-second case exiting Target Assembly 2 (also referred to as TA 'B' in the LAR) decreases by a factor of two (2) at 1 second, compared to the 3.5-second case, and shows some flow instability after that time. This flow instability is due to boiling and void generation, which is calculated to be less than 3%. Fluid momentum and natural circulation through the stopped pump provide sufficient flow to keep the target rods cooled as shown in Figures 33-2 and 33-3. Peak cladding temperature during the transient remains essentially unchanged.

Figure 33-2  
Target Assembly 2 Flow Rate vs. Time – Pump Coastdown and Seizure

Figure 33-3

Target Rod Peak Cladding Temperature vs. Time – Pump Coastdown and Seizure

An additional RELAP5 case was analyzed which combined a 90% flow blockage of the suction line filter with a 0.5-second pump stoppage. At 0.6 seconds, shortly after pump stoppage and 90% flow blockage is achieved, the mass flow rate out of the Target Assemblies (TAs) initially shows flow spikes due to boiling and void formation of around 40%. Near 2 seconds, as shown in Figure 33-4 below, flow spikes at the TA exits become more extreme as void fractions experience spikes of 90 to 100%. After 10 seconds, the decay heat level has fallen sufficiently such that the small amount of flow (near 0.1 kg/s) making it through the blocked filter and stopped pump due to thermal density differences is able to remove enough heat to prevent boiling.

Peak cladding temperature reaches 860 °C (1580 °F) after 4.4 seconds, but starts rapidly falling after 6 seconds and is below normal operating temperature before 8 seconds has elapsed, as shown in Figure 33-5. Fluid momentum within the TA, along with boiling and chugging when the flow approaches zero, are able to keep peak cladding temperatures below 900 °C (1652 °F).

Figure 33-4  
Target Assembly Flow Rate vs. Time – Flow Blockage

Figure 33-5  
Target Rod Cladding Temperature vs. Time – Flow Blockage

34. LAR, Attachment 7, provides assumptions for the use of the FRAPCON and FRAPTRAP computer codes. The NRC staff reviewed the assumptions and identified the following items needing additional information: gas composition (see Attachment 1, Section 2.2.3); uncertainties used in the analyses; and power curve data. This information is needed for the NRC staff to complete its independent modeling and verification.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

*Provide the following information, or justify why no additional information is needed:*

- 34.1. Gas composition (Attachment 1, Section 2.2.3, page 30, states, in part, that "[T]he target rod is filled with > 95% Helium (He), at  $\approx 1$  atmosphere"). If it is not 100 percent, please state the remainder of the gas composition assumed in the analysis.

The target rod fill gas is conservatively assumed to be as low as 95% He, with remainder of the gas composition being air.

The helium gas intended for use in the target rods is 99.999% pure. The remainder of the gas composition will depend on individual procured batches, but is typically made up of trace amounts of O<sub>2</sub>, H<sub>2</sub>O, CO, CO<sub>2</sub>, N<sub>2</sub>, Ar, and hydrocarbons. The trace gas impurities in the procured gases are less than the following: 1 ppm O<sub>2</sub>, 1 ppm H<sub>2</sub>O, 1 pm CO, 1 ppm CO<sub>2</sub>, 5 ppm N<sub>2</sub>, and 0.5 ppm hydrocarbons.

The target rod weld procedure is summarized as follows:

- The pellets are loaded into the Zircaloy-4 cladding tube, and the loaded tubes are placed in the welding antechamber.
- The antechamber is evacuated a minimum of three (3) times, each time refilling with 99.999% helium gas.
- The antechamber helium content is verified to be  $\geq 99\%$ .
- The lower end caps are welded onto the cladding (Helium weld gas is drawn from same source as for antechamber atmosphere).
- The lower end cap welds are inspected.
- The antechamber helium content is again verified to be  $\geq 99\%$ .
- The upper end caps are welded on (Helium weld gas is drawn from same source as for antechamber atmosphere).
- The upper end cap welds are inspected.

LAR Part 1 analyses using the FRAPCON and FRAPTRAN codes used a gap gas concentration of 100% He for both normal and transient analyses. For the purposes of analyzing pellet conditions as a function of varying gap gas composition, we have assumed that while the weld antechamber must be filled to  $\geq 99\%$  before welding, that the fill gas within the target rod itself could be lower. A sensitivity analysis was then performed for various gas gap compositions for normal operation using FRAPCON, for compositions ranging from 100% He - 0% Air, to 95% He - 5% Air. Both beginning-of-life (BOL) and end-of-life (EOL) conditions were analyzed for the nominal, minimum and maximum fuel-clad gaps. Table 34-1 provides the results of this sensitivity analysis, which show that the largest difference in pellet centerline temperature due to He content being reduced from 100% occurs for the BOL maximum gap case, with a  $\Delta T$  of  $+14.2\text{ }^{\circ}\text{C}$  ( $25.6\text{ }^{\circ}\text{F}$ ) if the He gas contains 5% air.

Table 34-1  
Sensitivity Analysis Summary of Peak Pellet Temperatures (K)  
as a Function of Gap Helium Concentration

	<b>BOL</b>		<b>EOL</b>	
<b>Gap</b>	<b>100% He</b>	<b>95% He</b>	<b>100% He</b>	<b>95% He</b>
Minimum	2278.7	2282.2	2439.1	2445.3
$\Delta 100\%$	N/A	3.5	N/A	6.2
Nominal	2395.7	2406.4	2434.9	2443.0
$\Delta 100\%$	N/A	10.7	N/A	8.1
Maximum	2578.2	<b>2592.4</b>	2558.1	2568.5
$\Delta 100\%$	N/A	<b>14.2</b>	N/A	10.4

*34.2. Please provide a description of the model uncertainties used in the analysis.*

The maximum target rod power distributions from page 20 of LAR Part 1, Attachment 7 (30441R00032):

*The total target rod powers are presented in Table 5 and conservatively include 2-sigma uncertainties from statistical error, density, enrichment, and target rod position. Target rods 5 and 17 have uncertainties of 4.26%. Target rods 6 and 22 have uncertainties of 3.52%. All of the remaining rods represent have an uncertainty of 2.27% based on the total target power.*

Sensitivity analyses have been performed using built-in features of FRAPCON and FRAPTRAN. For this purpose, uncertainty formulations for fuel thermal conductivity and thermal expansion in the FRAPCON code had to be modified in the uncertainty formulations in order to allow for negative factors on the standard deviation. FRAPCON was also modified to use the end-of-life (EOL) radial

power distribution across the target pellet from MCNP that is separately discussed in the response to RAI No. 29.

These code modifications were as follows:

In FRAPCON subroutine burnup.f90, the power profile determined by MCNP was hard-coded into the tubrnp routine before the radial power normalization step. The following code was inserted at line 648:

```
formf(lschni,1)=0.810096
formf(lschni,2)=0.821480
formf(lschni,3)=0.851408
formf(lschni,4)=0.894081
formf(lschni,5)=0.947818
formf(lschni,6)=1.005193
formf(lschni,7)=1.064441
formf(lschni,8)=1.126134
formf(lschni,9)=1.187865
formf(lschni,10)=1.244220
formf(lschni,11)=1.289363
formf(lschni,12)=1.320197
formf(lschni,13)=1.337152
formf(lschni,14)=1.343592
formf(lschni,15)=1.344507
```

In UraniumDioxide.f90, the fuel conductivity and fuel thermal expansion uncertainty calculations were modified to allow for negative uncertainties.

Line 154 in subroutine fthcon was modified from:

```
con = con × [1.0_r8k + ABS(sigftc × 0.088_r8k)]
```

to:

```
con = con × [1.0_r8k + (sigftc × 0.088_r8k)]
```

This line modifies the thermal conductivity (con) by an uncertainty factor (sigftc × 0.088\_r8k). Previously, the absolute value in the formulation did not allow thermal conductivity to be reduced by a negative uncertainty factor.

Line 155 in subroutine fthexp was modified from:

```
fthexp = fthexp × [1.0_r8k + ABS(sigftex × 0.103_r8k)]
```

to:

$$f_{thexp} = f_{thexp} \times [1.0\_r8k + (sigftex \times 0.103\_r8k)]$$

This line modifies the fuel thermal expansion ( $f_{thexp}$ ) by an uncertainty factor ( $sigftex \times 0.103\_r8k$ ). Previously, the absolute value in the formulation did not allow fuel thermal expansion to be reduced by a negative uncertainty factor.

The FRAPCON results summarized in Table 34-1 below apply to nominal pellet dimensions and the nominal pellet-clad gap. Each uncertainty was applied individually to assess its effect on the FRAPCON results. The largest effect is from thermal conductivity due to the large thermal gradients in the  $UO_2$  pellet. The larger effect at EOL conditions is partially offset by the lower nominal centerline temperature of the hottest target rod at EOL due to gap closure.

Table 34-1  
FRAPCON Hottest Rod (17) Centerline Temperatures

Nominal (no uncertainties)	BOL 1995 °C (3623 °F)	EOL 1893 °C (3439.4 °F)
+2σ $UO_2$ thermal conductivity	1811 °C (3291.8 °F)	1586 °C (2886.8 °F)
-2σ $UO_2$ thermal conductivity	2231 °C (4047.8 °F)	2238 °C (4064.4 °F)
+2σ fission gas release	1995 °C (3623.0 °F)	1935 °C (3515.0 °F)
-2σ fission gas release	1995 °C (3623.0 °F)	1863 °C (3385.4 °F)
+2σ $UO_2$ thermal expansion	1881 °C (3417.8 °F)	1796 °C (3264.8 °F)
-2σ $UO_2$ thermal expansion	2118 °C (3844.4 °F)	1911 °C (3471.8 °F)

The FRAPTRAN sensitivity results are for the 600 pcm positive reactivity insertion transient, which starts from 115% of nominal power, are shown in Table 34-2 below. The FRAPTRAN uncertainty factors are the same values as the  $\pm 2\sigma$  used in the FRAPCON sensitivity analyses with the exception of heat capacity, which is not a variable in the steady-state FRAPCON analysis. The standard error for  $UO_2$  heat capacity is approximately 1% up to approximately 2300 K (3680 °F) but increases to around 10% near the  $UO_2$  melting point (NUREG/CR-7024, page 2.6). The FRAPTRAN peak temperature results summarized in the table below apply to nominal pellet dimensions and nominal pellet-clad gap. The FRAPTRAN calculations use the same radial power distribution as in the nominal FRAPCON calculations. A single property was changed for each run to determine effect of change of individual parameters. The largest effect due to a  $2\sigma$  reduction in thermal conductivity results in a centerline temperature 215 °C (387 °F) under the  $UO_2$  melting temperature of 2840 °C (5144 °F) for beginning-of-life (BOL) conditions and 140 °C (252 °F) under the melting temperature for EOL conditions after the maximum irradiation period, all for the hottest target rod. Per NUREG/CR-7024, page 2.14 [Ref. 34-1], the thermal conductivity correlation under-predicts unirradiated  $UO_2$  data by -2.4%, which has not been taken into account.

Table 34-2  
FRAPTRAN Hottest Rod (17) Centerline Temperatures  
during 600 pcm Positive Reactivity Insertion Transient

Nominal (no uncertainties)	BOL 2425 °C (4397.0 °F)	EOL 2358°C (4276.4 °F)
1.176 UO <sub>2</sub> thermal conductivity	2266 °C (4110.8 °F)	2176 °C (3948.8 °F)
0.824 UO <sub>2</sub> thermal conductivity	2625 °C (4757.0 °F)	2700 °C (4892.0 °F)
1.20 UO <sub>2</sub> heat capacity	2389 °C (4332.2 °F)	2311 °C (4191.8 °F)
0.80 UO <sub>2</sub> heat capacity	2478 °C (4492.4 °F)	2415 °C (4379.0 °F)
1.20 UO <sub>2</sub> thermal expansion	2317 °C (4202.6 °F)	2336 °C (4236.8 °F)
0.80 UO <sub>2</sub> thermal expansion	2541 °C (4605.8 °F)	2466 °C (4470.8 °F)

The power transient during the 600 pcm positive reactivity insertion transient reaches a peak in under 0.05 seconds, whereas the temperature transient peaks in about 0.5 seconds. In finite element analysis, the thermal time constant of individual elements in the model depends on the heat capacity of the material in the elements and the conductances connected to them. The pellet thermal model accounts for variation of density, thermal conductivity, and heat capacity due to the thermal gradient in the target pellets. In the FRAPTRAN model, the pellet is discretized into 15 equal-volume elements consisting of concentric cylinders. Thermal time constants were calculated for each element, and the smallest time constant ( $1.8 \times 10^{-3}$  seconds) is for the outermost element. The initial time step in the FRAPTRAN model is  $1 \times 10^{-6}$  seconds for 0.4 seconds, and then increases to  $1 \times 10^{-5}$  seconds thereafter. These time steps are much smaller than the minimum thermal time constant in the pellet model.

Fuel swelling due to fission gas is not calculated by FRAPTRAN, particularly during a reactivity-initiated accident due to the short time scales involved. Swelling would be provided to FRAPTRAN from FRAPCON; however, due to the low burnup, there is no fission gas swelling predicted by FRAPCON even after the maximum irradiation period at the peak flux location. At the EOL, FRAPCON predicts cumulative fission gas release of 13 to 17% at 115% of nominal power. Due to the low burnup, this fission gas release is about 2/3 of the gas moles in the target rod. The remainder of the gas is from the one (1) atmosphere of helium originally added to the target rods.

34.3. Please provide the following FRAPTRAN power curves in tabular form (LHGR vs. time):

34.3.1. The 600 percent mille step reactivity insertion (Attachment 1, Section 10.2.1, page 156).

Table 34-3 provides axial peaking factors for the maximum linear power target rod analyzed with FRAPTRAN. Local linear powers are obtained by multiplying these factors by the linear heat generation rate of the peak target rod. These factors, along with the responses to RAI No.

34.3.1 and 34.3.2, are used to determine the power profile in FRAPTRAN for the 600 percent mille (pcm) positive reactivity insertion and control blade withdrawal cases, respectively.

Table 34-3  
Axial Peaking Factors for the Maximum Linear Power Target Rod

Elevation (m)	Axial Peaking Factor
0.00	0.952

0.60	0.418

Table 34-4 provides the pin linear heat generation rate for the peak target rod with respect to time for the 600 pcm step reactivity insertion. The table reaches 100% power after 30 seconds and then goes to 115% power at 40 seconds. The reactivity transient starts at 61 seconds from 115% of nominal power. This table, when used with the axial peaking factors provided in the response to RAI No. 34.3.1, defines the axial linear heat generation rate for the target rod.

References:

34-1 NUREG/CR-7024, Rev. 1, "Material Property Correlations: Comparisons between FRAPCON-3.5, FRAPTRAN-1.5, and MATPRO," US NRC, October 2014.

35. LAR, Attachment 7, provides the results of various accident scenarios. The NRC staff is not clear as to why some of the safety analyses assumed 115 percent power on the first and last day, with 100 percent power on the remaining days (such as the step reactivity insertion) while others assumed 100 percent power on all days analyzed.

*The regulations in 10 CFR 50.9 require that information provided to the Commission by a licensee shall be complete and accurate in all material respects. Furthermore, the guidance in NUREG-1537, Part 1, Chapter 4, Section 4.5, provides guidance that the LAR should include all necessary information on the nuclear parameters and characteristics of the reactor core and should analyze the kinetic behavior of the reactor for steady-state and transient operation throughout its life cycle of allowed cores and burnup, as discussed in the safety analysis.*

*Provide an explanation why the safety analyses assumed 115 percent power on the first and last day, with 100 percent power on the remaining days, versus other analyses which assumed 100 percent power on all days analyzed, or justify why no additional information is needed.*

The power levels at the beginning of each analyzed transient are consistent with the power levels that were used for the reactor transients that were analyzed for the recent relicensing of MURR.

For the positive reactivity insertion accident, on Page 13-9 of NUREG-1537, Part 2, *Standard Review Plan and Acceptance Criteria*, for the Insertion of Excess Reactivity accident, “*The accident scenario assumes that the reactor has a maximum load of fuel (consistent with the technical specifications), the reactor is operating at full licensed power, and the control system...*” The accident was analyzed at a much more conservative starting power level (11.5 MW or 115%) than required by NUREG-1537. 11.5 MW was chosen, instead of the Limiting Safety System Setting (LSSS) set point of 12.5 MW, since the rod run-in system will initiate a rod run-in at 11.5 MW (Technical Specification 3.2.f.1) and shutdown the reactor prior to reaching the LSSS scram set point of 125%.

For the loss of flow/coolant accidents, as stated on page 13-7 of NUREG-1537, Part 1, *Format and Content*, item 13.2(1), “*State the initial conditions of the reactor and equipment. Discuss relevant conditions depending on fuel burnup, experiments installed, core configurations, or other variables. Use the most limiting conditions in the analyses.*” On Pages 13-9 and 13-10 of NUREG-1537, Part 2, *Standard Review Plan and Acceptance Criteria*, for both the LOCA and LOFA, “*The scenario assumes that the reactor is operating at full licensed power and has been operating long enough for the fuel to contain fission products at equilibrium concentrations.*” Therefore, a steady-state power level of 10 MW was used to establish the required decay heat for the LOCA and LOFA for the target assemblies.

### Physical Security Plan Considerations

36. *The NRC staff review finds that the current PSP does not discuss the type of SNM, nor the additional amount of SNM, that will be stored and used as a result of this amendment. The amendment seems to indicate that the category of SNM will be low strategic significance (10 CFR 73.2 Category III). Therefore additional information is needed for the NRC staff to determine whether MURR's PSP properly accounts for the amount of SNM stored and used in connection with this amendment request.*

*The regulations in 10 CFR 73.2 define SNM of low strategic significance as less than 10,000 grams but more than 1,000 grams of U-235 (contained in uranium enriched to 10 percent or more but less than 20 percent in the U-235 isotope).*

*Revise this PSP to describe the added SNM, its type, and the amount, or justify why no change is needed.*

As explained in the response to RAI No. 5, MURR is not requesting a change to Section 2.B.2.b of MURR Renewed Facility Operating License No. R-103 as part of LAR Part 1 submission. Therefore, no changes are required to the current MURR Physical Security Plan (PSP). However, an increase in the possession limit and the quantity of SNM that will be handled in the hot cells during an SGE process will be included in LAR Part 2 submission. The PSP will be revised to support an increase in the amount of contained uranium-235 of an enrichment less than 20 percent in the isotope uranium-235, for use in experiments that MURR is allowed to receive, possess and use and will be included as part of LAR Part 2 submission.

37. *The NRC staff review finds that the current PSP does not discuss the location of use or storage of the SNM used for the target assemblies described in the LAR.*

*The regulations in 10 CFR 73.2 define SNM of low strategic significance as less than 10,000 grams but more than 1,000 grams of uranium-235 (contained in uranium enriched to 10 percent or more but less than 20 percent in the U-235 isotope). The regulations in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," requires licensees to store or use SNM within a controlled access area (CAA).*

*Verify the added SNM is Category III, and clarify its use and storage location. If there will be a new CAA revise the plan to include a description of the location of the SNM while in storage and in use (add locations to the maps as well). Describe the added physical barriers, if any, the means and criteria for controlling access, and the access control points of the CAA, or justify why no additional information is needed.*

As explained in the response to RAI No. 5, MURR is not requesting a change to Section 2.B.2.b of MURR Renewed Facility Operating License No. R-103 as part of LAR Part 1 submission. Therefore, no changes are required to the current MURR Physical Security Plan (PSP). However, an increase in the possession limit and the quantity of SNM that will be handled in the hot cells during an SGE process will be included in LAR Part 2 submission. The PSP will be revised to support an increase in the amount of contained uranium-235 of an enrichment less than 20 percent in the isotope uranium-235, for use in experiments that MURR is allowed to receive, possess and use and will be included as part of LAR Part 2 submission.

38. *The NRC staff review is not clear if any licensed material will be stored within a new CAA not already described in the PSP. If so, discuss the means for the monitoring the CAA and responding to indications of intrusion into the CAA.*

*The regulations in 10 CFR 73.67 require the CAA to be monitored by an intrusion alarm, device, or procedures to detect unauthorized access.*

*Revise the PSP to include a description of the means to monitor for unauthorized access, and procedures for responding to an alarm, or justify why no additional information is needed.*

As explained in the response to RAI No. 5, MURR is not requesting a change to Section 2.B.2.b of MURR Renewed Facility Operating License No. R-103 as part of LAR Part 1 submission. Therefore, no changes are required to the current MURR Physical Security Plan (PSP). However, an increase in the possession limit and the quantity of SNM that will be handled in the hot cells during an SGE process will be included in LAR Part 2 submission. The PSP will be revised to support an increase in the amount of contained uranium-235 of an enrichment less than 20 percent in the isotope uranium-235, for use in experiments that MURR is allowed to receive, possess and use and will be included as part of LAR Part 2 submission.

**1B DEFINITIONS – Selective Gas Extraction Target Experimental Facility**

Note: Definitions previously defined in the Technical Specifications are not repeated in this Section.

**1.1B Selective Gas Extraction (SGE) Target Assembly** - The Selective Gas Extraction (SGE) Target Assembly consists of (1) a water inlet section, (2) a target housing, (3) a lower plenum, (4) a target cartridge, (5) an outlet diffuser, and (6) a target cartridge locking mechanism.

**1.2B Selective Gas Extraction (SGE) Target Cartridge** - The Selective Gas Extraction (SGE) Target Cartridge is designed to (1) position and support the SGE target rods, (2) provide a cooling passage for the SGE target rods, (3) reduce neutron flux peaking at the axial center by the use of a neutron absorber, and (4) mix and guide the cooling water outlet flow.

**1.3B Selective Gas Extraction (SGE) Target Experimental Facility (TEF)** - The Selective Gas Extraction (SGE) Target Experimental Facility (TEF) is designed to (1) provide forced cooling to the target rods during normal operation, (2) provide natural circulation cooling during shutdown periods, (3) transfer and reject heat to the secondary coolant system, (4) maintain sufficient cooling flow and temperature conditions to ensure a Critical Heat Flux Ratio of greater than 2.0, and (5) provide instrumentation to assure cooling flow rates, temperatures, and pressures are within specified conditions for operation.

The SGE TEF consists of the following major components: two (2) coolant pumps, two (2) coolant heat exchangers, (2) target assemblies plus all associated instrumentation, piping and valves. One (1) coolant pump and one (1) coolant heat exchanger shall be designed to provide the necessary cooling for either one (1) or two (2) operating target assemblies; the other coolant pump and heat exchanger are installed spares.

**1.4B Selective Gas Extraction (SGE) Target Housing** - The Selective Gas Extraction (SGE) Target Housing is designed to (1) direct the flow of cooling water, (2) provide structural support, and (3) position the target cartridge within the graphite reflector region.

**1.5B Selective Gas Extraction (SGE) Target Rod** - The Selective Gas Extraction (SGE) Target Rods consist of upper and lower Zircaloy-4 end caps, Zircaloy-4 cladding, a stainless steel spring, and low-enriched uranium dioxide pellets nominally enriched to 19.75% in the isotope uranium-235 with a nominal active length of 600 millimeters.

**2B SAFETY LIMITS AND LIMITING SAFETY SYSTEM SETTINGS – Selective Gas Extraction Target Experimental Facility**

**2.1B Safety Limits**

Applicability:

This specification applies to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) target rods.

Objective:

The objective of this specification is to define the maximum SGE target rod pellet and cladding temperature that can be permitted to ensure that the integrity of the target rod is maintained to guard against an uncontrolled release of radioactivity.

Specification:

- a. The temperature of a SGE target rod low-enriched uranium dioxide pellet shall not exceed 5144 °F (2840 °C) for any operating condition.
- b. The temperature of a SGE target rod Zircaloy-4 cladding shall not exceed 1652 °F (900 °C) for any operating condition.

Bases:

- a. The maximum normal operating temperature limit for the SGE target rods is established such that even at their hottest conditions of a maximum power level and a minimum flow rate loss of forced coolant accident, the maximum pellet temperature will still be below the uranium dioxide melting temperature of 5144 °F (2840 °C) (Ref. Amendment No. 38, Attachment 1, Section 1.4).
- b. The design limit on Zircaloy-4 cladding is the predicted temperature for the onset of rapid oxidation of 1652 °F (900 °C). The cladding temperature predicted by transient analysis for the most severe loss of forced coolant accident is 1448.6 °F (787 °C), well below the onset of rapid oxidation temperature. Further, the same analysis shows that during this time, retraction of the contained uranium dioxide pellet eliminates any compromise of the cladding mechanical strength (Ref. Amendment No. 38, Attachment 1, Section 1.4).

UNIVERSITY OF MISSOURI RESEARCH REACTOR  
TECHNICAL SPECIFICATIONS  
Docket No. 50-186, License No. R-103

**2.2B Limiting Safety System Settings**

Applicability:

This specification applies to the set points for the reactor safety system channels monitoring the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) target assembly coolant flow rate and heat exchanger outlet water temperature.

Objective:

The objective of this specification is to assure that automatic protective action is initiated to prevent a safety limit associated with the SGE TEF from being exceeded.

Specification:

a. **Mode I Operation**

SGE Target Assembly Coolant Low Flow Rate	95 gpm (Minimum) <sup>(1)</sup>
SGE Target Assembly Coolant High Flow Rate	129 gpm (Maximum) <sup>(1)</sup>
SGE Heat Exchanger Outlet Water Temperature	105 °F (Maximum)

<sup>(1)</sup> Each SGE target assembly.

Bases:

- a. The limiting safety system settings (LSSS) for the SGE TEF are set points which, if exceeded, will cause the reactor safety system to initiate a reactor scram to prevent a safety limit for the SGE target rods from being exceeded. The LSSS help ensure that coolant flow rate and temperature will remain within the operating limits for the SGE TEF under the most severe anticipated transients (Ref. Amendment No. 38, Section 10 of Attachment 1, and Attachment 7).

**3B LIMITING CONDITIONS FOR OPERATIONS – Selective Gas Extraction Target Experimental Facility**

**3.1B Target Rod Parameters**

Applicability:

This specification applies to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) target rods.

Objective:

The objective of this specification is to assure that the SGE target rods are operated within acceptable design considerations thus ensuring target rod integrity is maintained.

Specification:

- a. Each SGE target cartridge shall contain eleven (11) SGE target rods.
- b. Each SGE target rod shall not be irradiated for greater than 480 hours at full power operation.

Bases:

- a. Thermal steady-state and transient analyses are based on the SGE target cartridge being fully loaded with eleven (11) SGE target rods (Ref. Amendment No. 38, Attachment 1).
- b. Thermal steady-state and transient analyses are based on an SGE target rod being irradiated for no greater than 480 hours at full power operation (Ref. Amendment No. 38, Attachment 1).

Docket No. 50-186, License No. R-103

### 3.2B Reactor Safety System

Applicability:

This specification applies to the reactor safety system as it relates to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF).

Objective:

The objective of this specification is to specify the minimum number of reactor safety system instrument channels that must be operable for safe SGE TEF operation.

Specification:

- a. The reactor safety system and the number (N) of associated instrument channels necessary to provide the following scrams shall be operable whenever the reactor is in operation. Each of the safety system functions shall have 1/N logic where N is the number of instrument channels required for the corresponding mode of operation.

	<u>Reactor Safety System Instrument Channel</u>	<u>Number Required (N)</u>			<u>Trip Set Point</u>
		<u>Mode I</u>	<u>Mode II</u>	<u>Mode III</u>	
1.	SGE Target Assembly 'A' Coolant Low Flow	2 <sup>(1)</sup>	0 <sup>(3)</sup>	0 <sup>(3)</sup>	95 gpm (Min)
2.	SGE Target Assembly 'A' Coolant High Flow	2 <sup>(1)</sup>	0 <sup>(3)</sup>	0 <sup>(3)</sup>	129 gpm (Max)
3.	SGE Target Assembly 'B' Coolant Low Flow	2 <sup>(2)</sup>	0 <sup>(3)</sup>	0 <sup>(3)</sup>	95 gpm (Min)
4.	SGE Target Assembly 'B' Coolant High Flow	2 <sup>(2)</sup>	0 <sup>(3)</sup>	0 <sup>(3)</sup>	129 gpm (Max)
5.	SGE Heat Exchanger Outlet Water Temperature	2 <sup>(4)</sup>	0 <sup>(3)</sup>	0 <sup>(3)</sup>	105 °F (Max)

- (1) Not required if SGE target assembly 'A' is not in operation. This safety function shall only be bypassed with specific authorization from the Reactor Manager.
- (2) Not required if SGE target assembly 'B' is not in operation. This safety function shall only be bypassed with specific authorization from the Reactor Manager.
- (3) The SGE TEF shall only be operated during Mode I operation; therefore, not required for Mode II and III operation. This safety function shall only be bypassed with specific authorization from the Reactor Manager.

**3.2B Reactor Safety System - Continued**

- (4) Not required if the SGE TEF is secured: both SGE TEF coolant pumps are off and no target rods are installed in the target assemblies. This safety function shall only be bypassed with specific authorization from the Reactor Manager.

Bases:

- a. The SGE target assembly coolant high and low flow scrams provides assurance that the reactor will be shut down on a loss of target coolant or forced cooling flow.

The SGE target assembly coolant low flow scram set point of 85% of nominal flow was chosen based on the thermal-hydraulic analyses which showed a minimum critical heat flux ratio (CHFR) of 2.07 for worst-case operations [85% flow, 115% of nominal reactor power level and irradiation with three (3) target rods] (Ref. Amendment No. 38, Attachment 4, Table 9).

The SGE target assembly coolant high flow scram set point of 115% of nominal flow allows the target assembly pressure to stay well within the design limit of 21.5 psi (Ref. Amendment No. 38, Attachment 8).

The SGE heat exchanger high outlet water temperature scram provides assurance that the reactor will be shut down on a loss of secondary cooling flow to the SGE Target Experimental Facility.

The SGE heat exchanger outlet water temperature scram set point of 105 °F is based on the thermal-hydraulic analysis with three (3) rod target operations (worst-case). For these operations to occur, the reactor pool temperature cannot exceed 108 °F, as exceeding this limit would allow the CHFR to fall below 2.0. The scram set point for the SGE Heat Exchanger Outlet Water Temperature was based on this reactor pool temperature condition (Ref. Amendment No. 38, Section 6.1.4 of Attachment 1, and Section 4 of Attachment 4).

**3.3B Selective Gas Extraction Target Experimental Facility Coolant System**

Applicability:

This specification applies to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) coolant system.

Objective:

The objective of this specification is to protect the integrity of the SGE target rods and to prevent the release of fission product radioisotopes.

Specification:

- a. The SGE TEF shall not be operated unless the following components or systems are operable:
  - (1) One (1) SGE TEF coolant pump and one (1) SGE TEF coolant heat exchanger; and
  - (2) SGE TEF Decay Heat Removal System.

Bases:

- a. Specification 3.3B.a assures that the SGE TEF can operate safely during steady-state and transient conditions (Ref. Amendment No. 38, Attachment 1).

**3.4B Selective Gas Extraction Target Experimental Facility Instrumentation**

Applicability:

This specification applies to the instruments that provide information, which must be available to the operator during Selective Gas Extraction (SGE) Target Experimental Facility (TEF) operation.

Objective:

The objective of this specification is to ensure that sufficient reliable information is presented to the operator to assure safe operation of the SGE TEF.

Specification:

- a. The SGE TEF shall not be operated unless the following instrument channels are operable:

	<u>Instrument Channel</u>	<u>Number</u>
1.	SGE Target Assembly Inlet Water Temperature	1
2.	SGE Target Assembly Outlet Water Temperature	1
3.	SGE Heat Exchanger Outlet Water Temperature	2

Bases:

- a. Specification 3.4B.a assures that sufficient instrumentation is available to safely operate the SGE TEF (Ref. Amendment No. 38, Attachment 1).

Docket No. 50-186, License No. R-103

**3.5B Selective Gas Extraction Target Experimental Facility Radiation Monitoring System**

Applicability:

This specification applies to radiation monitoring information, which must be available to the reactor operator during Selective Gas Extraction (SGE) Target Experimental Facility (TEF) operation.

Objective:

The objective of this specification is to assure that sufficient radiation monitoring information is available to the reactor operator during SGE TEF operation.

Specification:

- a. The SGE TEF shall not be operated unless the following instrument channels are operable:

	<u><b>Radiation Monitoring Channel</b></u>	<u><b>Number</b></u>
1.	Pool Coolant Radiation Monitor	1 <sup>(1)</sup>

- (1) Exception: The pool coolant system shall be sampled and analyzed at least once every four (4) hours for evidence of SGE target rod failure if the pool coolant radiation monitor is inoperable.

Bases:

- a. Specification 3.5B.a provides for the early detection of a leaking SGE target rod so that corrective actions can be taken to minimize the release of fission products (Ref. Amendment No. 38, Attachment 1, Section 10.1).

4B **SURVEILLANCE REQUIREMENTS – Selective Gas Extraction Target  
Experimental Facility**

4.1B **Target Rod Parameters**

Applicability:

This specification applies to the surveillance requirements of the Select Gas Extraction (SGE) Target Experimental Facility (TEF) target rod parameters.

Objective:

The objective of this specification is to reasonably assure proper operation of the SGE TEF.

Specification:

- a. Each SGE target cartridge shall be verified to consist of eleven (11) SGE target rods prior to inserting the SGE target cartridge into the SGE target assembly.
- b. The operating history of each SGE target rod shall be verified prior to placing it into an SGE target cartridge to ensure that the SGE target rod will not be irradiated for greater than 480 hours at full power operation.

Bases:

- a. Specification 4.1B.a assures that the SGE target cartridges have the correct number of SGE target rods as assumed in the thermal-hydraulic and transient analyses (Ref. Amendment No. 38, Attachment 1).
- b. Specification 4.1B.b assures that the SGE target rods are not irradiated for greater than 480 hours at full power operation as assumed in the thermal-hydraulic and transient analyses (Ref. Amendment No. 38, Attachment 1).

#### 4.2B Reactor Safety System

Applicability:

This specification applies to the surveillance requirements on the reactor safety system as it relates to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF).

Objective:

The objective of this specification is to reasonably assure proper operation of the reactor safety system instrument channels associated with the SGE TEF.

Specification:

- a. The reactor safety system instrument channels listed in Specification 3.2B.a shall be channel calibrated on a semiannual basis.

Bases:

- a. Experience has shown that the identified frequencies will ensure performance and operability for each of these systems or components (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).

Enclosure 1

**4.3B Selective Gas Extraction Target Experimental Facility Coolant System**

Applicability:

This specification applies to the surveillance requirements on the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) coolant system.

Objective:

The objective of this specification is to reasonably assure proper operation of the SGE TEF coolant system.

Specification:

- a. The following components or systems shall be channel-checked for operability at monthly intervals except during extended shutdown periods when the components or systems shall be channel-checked prior to SGE TEF operation:
  - (1) One (1) SGE TEF coolant pump and one (1) SGE TEF coolant heat exchanger; and
  - (2) SGE TEF decay heat removal system.

Bases:

- a. Monthly testing of the SGE TEF coolant pumps, coolant heat exchangers, and decay heat removal system is adequate to provide assurance of continued operability (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).

**4.4B Selective Gas Extraction Target Experimental Facility Instrumentation**

Applicability:

This specification applies to the surveillance requirements of the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) instrumentation.

Objective:

The objective of this specification is to reasonably assure proper operation of the SGE TEF instrumentation.

Specification:

- a. The instrumentation required to monitor the parameters required by Specification 3.4B.a shall be channel-checked prior to startup of the SGE TEF.
- b. The instrumentation required to monitor the parameters required by Specification 3.4B.a shall be channel calibrated on a semiannual basis.
- c. A thermal power verification of SGE TEF power, using coolant flows and differential temperatures, shall be performed weekly when the reactor is operating at 10 MW.

Bases:

- a. Channel checking of the instrument channels prior to startup of the SGE TEF will ensure proper operation (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).
- b. Semiannual channel calibration of the instrument channels will assure that long-term drift of the channels will be corrected (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).
- c. Thermal power verification of the SGE TEF helps ensure that the reactor steady-state thermal power limit is not being exceeded (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).

Enclosure 1  
UNIVERSITY OF MISSOURI RESEARCH REACTOR  
TECHNICAL SPECIFICATIONS

**4.5B Selective Gas Extraction Target Experimental Facility Radiation Monitoring System**

Applicability:

This specification applies to the surveillance requirements of the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) radiation monitoring instrumentation.

Objective:

The objective of this specification is to reasonably assure proper operation of the radiation monitoring instrumentation.

Specification:

- a. The radiation monitor as required by Specification 3.5B.a shall be channel calibrated on a semiannual basis.
- b. Radiation monitoring instrumentation required by Specification 3.5B.a shall be channel-checked with a radiation source at monthly intervals.

Bases:

- d. Semiannual channel calibration of the radiation monitoring instrumentation will assure that long-term drift of the channels will be corrected (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).
- b. Monthly verification of operability of the radiation monitoring instrumentation is adequate assurance of proper operation over a long time period (Ref. NUREG-1537 and ANSI/ANS-15.1-2007).

**5B DESIGN FEATURES – Selective Gas Extraction Target Experimental Facility**

**5.1B Selective Gas Extraction Target Experimental Facility Coolant System**

Applicability:

This specification applies to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) coolant system.

Objective:

The objective of this specification is to assure proper coolant for safe operation.

Specification:

- a. The SGE TEF shall consist of not less than two (2) coolant pumps, two (2) coolant heat exchangers, plus all associated piping and valves. One (1) coolant pump and one (1) coolant heat exchanger shall be designed to provide the necessary cooling for either one (1) or two (2) operating target assemblies; the other coolant pump and heat exchanger are installed spares.
- b. The secondary coolant system shall be capable of continuous discharge of heat generated by the SGE TEF.
- c. The coolant pumps and heat exchangers of the SGE TEF shall constitute two (2) parallel systems separately instrumented to permit safe operation at 10 MW, on either system operating, for either one (1) or two (2) operating target assemblies.
- d. The SGE TEF shall have a decay heat removal system.
- e. All major components of the SGE TEF in contact with pool water shall be constructed principally of aluminum alloys, stainless steel or Zircaloy-4.

Bases:

- a. - e. The SGE TEF is described and analyzed in Amendment No. 38. The SGE TEF and SGE target rods can be safely operated at a reactor power level of 10 MW as described in the Amendment.

## 5.2B Target Rod Parameters

### Applicability:

This specification applies to the Selective Gas Extraction (SGE) Target Experimental Facility (TEF) target rods.

### Objective:

The objective of this specification is to assure that the SGE target rods are of a type designed for use in the SGE TEF.

### Specification:

The following design features apply to the SGE target rods:

- a. Each SGE target rod shall contain nominally 100 low-enriched uranium dioxide pellets with a nominal active length of 23.6 inches (600 mm) and a target rod nominal total length of 26.5 inches (673 mm).
- b. The SGE target rod low-enriched uranium dioxide pellets shall have a nominal height of 0.236 inches (6 mm) and a nominal outside diameter of 0.197 inches (5 mm).
- c. The SGE target rod low-enriched uranium dioxide pellets shall be nominally enriched to 19.75% in the isotope uranium-235.
- d. Each SGE target rod shall have a maximum uranium-235 loading of 21.6 grams.
- e. The SGE target rod cladding material shall be Zircaloy-4.
- f. The SGE target rod cladding shall have a nominal inside diameter of 0.201 inches (5.1 mm) and a nominal outside diameter of 0.240 inches (6.1 mm).

### Bases:

- a. – f. Specifications 5.2B.a, 5.2B.b, 5.2B.c, 5.2B.d, 5.2B.e and 5.2B.f require uranium content, materials, and dimensions of the SGE target rods to be in accordance with the design and fabrication specifications (Ref. Amendment No. 38, Attachment 1).

### 5.3B Target Rod Storage

Applicability:

This specification applies to the storage of Selective Gas Extraction (SGE) Target Experimental Facility (TEF) target rods.

Objective:

The objective of this specification is to assure that the SGE target rods, which are stored, shall not become critical and will not reach an unsafe temperature.

Specification:

The following design features apply to the SGE target rod storage:

- a. All SGE target rods shall be stored in a geometrical array where the value of  $K_{eff}$  is less than 0.9 under all conditions of moderation and reflection.
- b. Irradiated SGE target rods shall be stored in an array, which will permit sufficient natural convection cooling such that the temperature of the target rods will not exceed design values.

Bases:

- a. - b. The limits imposed by Specifications 5.3B.a and 5.3B.b are conservative and assure safe SGE target rod storage.

## MURR fuel element peaking factor for the minimum burnup core (CB=30 cm)

Supplement 26.2.a - Driver Fuel Composition for Average Burnup Core

c  
c Driver fuel composition for the average burnup core  
c  
c material number: m1IJKL  
c I = driver fuel element number (1 to 8)  
c JKL = fuel material number (1 to 288)  
c 1 = top layer, inner-most, 24 = top layer, outer-most  
c 25 = 2nd from the top inner-most, 48 = 2nd from the top outer-most  
c Note: There are 24 radial and 12 axial material zones.  
c One axial material zone is divided into two numerical zones  
c  
=====

c Fuel definition for MURR 2015 Reflector Model  
c 2016 average burnup core: Equilibrium xenon, 600 MWD

# Supplement 26.2.b - Driver Fuel Composition for Extreme Burnup Core

c

c Driver fuel composition for the extreme burnup core

c

c material number: m1IJKL

c I = driver fuel element number (1 to 8)

c JKL = fuel material number (1 to 288)

c 1 = top layer, inner-most, 24 = top layer, outer-most

c 25 = 2nd from the top inner-most, 48 = 2nd from the top outer-most

c Note: There are 24 radial and 12 axial material zones.

c One axial material zone is divided into two numerical zones

c

c

c Fuel definition from ANL Fitted UALx HEU data November 2016

c 2016 extreme burnup core: Clean, 652 MWD

c
