ATOMIC ENERGY

TUESDAY, OCTOBER 9, 1945

HOUSE OF REPRESENTATIVES,
COMMITTEE ON MILITARY AFFAIRS,
Washington, D. C.

The committee met at 10 a. m., Hon. Andrew J. May (chairman) presiding.

The CHAIRMAN. Gentlemen of the committee, we have met this morning for consideration of H. R. 4280, a bill for the development and control of atomic energy.

A few days ago, the President of the United States sent to the Congress a message recommending the enactment of this legislation. The development of atomic energy was done by the War Department. The President's recommendations are very definite and, at this point, will be incorporated in the record.

(The matter above referred is as follows:)

[H. Doc. No. 301, 79th Cong., 1st sess.]

MESSAGE FROM THE PRESIDENT OF THE UNITED STATES TRANSMITTING REQUEST FOR THE ENACTMENT OF LEGISLATION TO FIX A POLICY COVERING THE USE AND DEVELOPMENT OF THE ATOMIC BOMB

To the Congress of the United States:

Almost 2 months have passed since the atomic bomb was used against Japan. That bomb did not win the war, but it certainly shortened the war. We know that it saved the lives of untold thousands of American and Allied soldiers who would otherwise have been killed in battle.

The discovery of the means of releasing atomic energy began a new era in the history of civilization. The scientific and industrial knowledge on which this discovery rests does not relate merely to another weapon. It may some day prove to be more revolutionary in the development of human society than the invention of the wheel, the use of metals, or the steam or internal combustion engine.

Never in history has society been confronted with a power so full of potential danger and at the same time so full of promise for the future of man and for the peace of the world. I think I express the faith of the American people when I say that we can use the knowledge we have won, not for the devastation of war, but for the future welfare of humanity.

To accomplish that objective we must proceed along two fronts—the domestic and the international.

The first and most urgent step is the determination of our domestic policy for the control, use, and development of atomic energy within the United States.

We cannot postpone decisions in this field. The enormous investment which we made to produce the bomb has given us the two vast industrial plants in Washington and Tennessee, and the many associated works throughout the country. It has brought together a vast organization of scientists, executives, industrial engineers, and skilled workers—a national asset of inestimable value.

The powers which the Congress wisely gave to the Government to wage war were adequate to permit the creation and development of this enterprise as a war project. Now that our enemies have surrendered, we should take immediate action to provide for the future use of this huge investment in brains and plant. I am informed that many of the people on whom depend the continued successful operation of the plants and the further development of atomic knowledge are getting ready to return to their normal pursuits. In many cases these people are considering leaving the project largely because of uncertainty concerning future national policy in this field. Prompt action to establish national policy will go a long way toward keeping a strong organization intact.

It is equally necessary to direct future research and to establish control of the basic raw materials essential to the development of this power whether it is to be used for purposes of peace or war. Atomic force in ignorant or evil hands could inflict untold disaster upon the Nation and the world. Society cannot hope even to protect itself—much less to realize the benefits of the discovery—unless prompt action is taken to guard against the hazards of misuse.

I therefore urge, as a first measure in a program of utilizing our knowledge for the benefit of society, that the Congress enact legislation to fix a policy with respect to our existing plants, and to control all sources of atomic energy and all activities connected with its development and use in the United States.

The legislation should give jurisdiction for these purposes to an Atomic Energy Commission with members appointed by the President, with the advice and consent of the Senate.

The Congress should lay down the basic principles for all the activities of the Commission, the objectives of which should be the promotion of the national welfare, securing the national defense, safeguarding world peace, and the acquisition of further knowledge concerning atomic energy.

The people of the United States know that the overwhelming power we have developed in this war is due in large measure to American science and American industry, consisting of management and labor. We believe that our science and industry owe their strength to the spirit of free inquiry and the spirit of free enterprise that characterize our country. The Commission, therefore, in carrying out its functions should interfere as little as possible with private research and private enterprise, and should use as much as possible existing institutions and agencies. The observance of this policy is our best guaranty of maintaining the preeminence in science and industry upon which our national well-being depends.

All land and mineral deposits owned by the United States which constitute sources of atomic energy, and all stock piles of materials from which such energy may be derived, and all plants or other property of the United States connected with its development and use should be transferred to the supervision and control of the Commission.

The Commission should be authorized to acquire at a fair price, by purchase or by condemnation, any minerals or other materials from which the sources of atomic energy can be derived, and also any land containing such minerals or materials, which are not already owned by the United States.

The power to purchase should include real and personal property outside the limits of the United States.

The Commission should also be authorized to conduct all necessary research, experimentation, and operations for the further development and use of atomic energy for military, industrial, scientific, or medical purposes. In these activities it should, of course, use existing private and public institutions and agencies to the fullest practicable extent.

Under appropriate safeguards the Commission should also be permitted to license any property available to the Commission for research, development, and exploitation in the field of atomic energy. Among other things such licensing should be conditioned, of course, upon a policy of widespread distribution of peacetime products on equitable terms which will prevent monopoly.

In order to establish effective control and security, it should be declared unlawful to produce or use the substances comprising the sources of atomic energy or to import or export them except under conditions prescribed by the Commission.

Finally, the Commission should be authorized to establish security regulations governing the handling of all information, material, and equipment under its jurisdiction. Suitable penalties should be prescribed for violating the security regulations of the Commission or any of the other terms of the act.

The measures which I have suggested may seem drastic and far-reaching but the discovery with which we are dealing involves forces of nature too dangerous to fit into any of our usual concepts.

The other phase of the problem is the question of the international control and development of this newly discovered energy.

In international relations, as in domestic affairs, the release of atomic energy constitutes a new force too revolutionary to consider in the framework of old ideas. We can no longer rely on the slow progress of time to develop a program of control among nations. Civilization demands that we shall reach at the earliest possible date a satisfactory arrangement for the control of this discovery in order that it may become a powerful and forceful influence toward the maintenance of world peace instead of an instrument of destruction.

Scientific opinion appears to be practically unanimous that the essential theoretical knowledge upon which the discovery is based is already widely known. There is also substantial agreement that foreign research can come abreast of our present theoretical knowledge in time.

The hope of civilization lies in international arrangements looking, if possible, to the renunciation of the use and development of the atomic bomb, and directing and encouraging the use of atomic energy and all future scientific information toward peaceful and humanitarian ends. The difficulties in working out such arrangements are great. The alternative to overcoming these difficulties, however may be a desperate armament race which might well end in disaster. Discussion of the international problem cannot be safely delayed until the United Nations Organization is functioning and in a position adequately to deal with it.

I, therefore, propose to initiate discussions first with our associates in this discovery, Great Britain and Canada, and then with other nations, in an effort to effect agreement on the conditions under which cooperation might replace rivalry in the field of atomic power.

I desire to emphasize that these discussions will not be concerned with disclosures relating to the manufacturing processes leading to the production of the atomic bomb itself. They will constitute an effort to work out arrangements covering the terms under which international collaboration and exchange of scientific information might safely proceed.

The outcome of the discussions will be reported to the Congress as soon as possible, and any resulting agreements requiring congressional action will be submitted to the Congress.

But regardless of the course of discussions in the international field, I believe it is essential that legislation along the lines I have indicated be adopted as promptly as possible to insure the necessary research in, and development and control of, the production and use of atomic energy.

HARRY S. TRUMAN.

THE WHITE HOUSE, October 3, 1945.

THE CHAIRMAN. We have here as witnesses this morning a number of very busy men who, like the committee, have to be at work all the time. Mr. Secretary Patterson is present and we will ask you, Judge, to open the hearing with a statement or in any way you care to proceed.

STATEMENT OF THE HONORABLE ROBERT P. PATTERSON, SECRETARY OF WAR

Secretary PATTERSON. Mr. Chairman, I appear in support of H. R. 4280. This bill is in line with the President's message last week relative to the development of atomic energy. As you have just pointed out, this project at the present time is a war project developed by the War Department. The time has come, as we see it, when the project should be put on a broader basis and where not only its war-time aspects but its peacetime aspects for the longer range future should be dealt with and covered by legislation of a basic character, declaring the national policy and providing for the further intensive development of the production of nuclear fission and the release of atomic energy.

I have a short statement. If the committee sees fit, I will read it; then I will have some remarks of a more general character.

THE CHAIRMAN. You may proceed in your own way, Judge.

Secretary PATTERSON. The atomic bombs that dropped on Hiroshima and Nagasaki did more than destroy the Japanese will to fight. They delivered into the custody of the people of this country the responsibility for developing and administering a force of such incalculable potentialities that we are even now only dimly aware of their ultimate extent.

It is the desire of every American that this mighty power be used to make secure and lasting the peace for which a quarter of a million

of our young men gave their lives, and also that the horizons of our knowledge be pushed outward so that atomic energy may become as effective an element in the enrichment of our daily lives as it proved itself in the ending of the war against Japan.

In the years when the existence of our Nation was threatneed and the speed of our victory depended on the speed with which we unlocked the energy that lies within the atom, the responsibility for directing research, constructing facilities, and producing weapons in this field was entrusted to the War Department.

General Groves, who is here with me today, was placed in charge of the project and given unlimited authority to carry this urgent war task to a successful conclusion. He reported directly to the Chief of Staff and the Secretary of War. Time was the only scarce commodity, so far as his assignment was concerned. Everything else was made available as fully and as fast as it was needed. Over all our work hung the ever-present possibility that Germany or Japan might discover the secret first and that the United States might have to bear the crushing impact of the first atomic bomb.

We succeeded in our mission and thereby cut months from the probable length of the war. We would have won without the bomb, but thousands of American soldiers who are alive today would have died before final victory was achieved.

The story of our success is a story of teamwork. The combined efforts of science, management, labor, and the armed forces produced the atomic bomb. Now it is up to us to turn this discovery into a bulwark of the peace it helped to win.

No single department of Government should be charged with a responsibility that affects the whole future of mankind so directly and so immediately. Even the winning of a war seems a minor matter by comparison with the importance of applying fully and controlling wisely the power of the atom.

If we misapply the knowledge we now have or fail to carry forward our research with the utmost vigor, we may be passing a sentence of death on the future of our own country and the entire world.

The bill that is before your committee today reflects the views of the men who were most responsible for the wartime development of atomic energy as to the most effective method of controlling and carrying forward development in this field within the United States. It embodies all the points on domestic policy recommended by the President in his message to the Congress last week.

The manner in which this legislation was prepared will be of interest to you. In May of this year, 2 months before the test in New Mexico showed conclusively that the atomic bomb would work, Secretary Stimson, with the approval of the President, appointed an interim committee to recommend legislation that would insure that this discovery would be controlled and developed in the best interests of the people of this country.

The Secretary served as chairman of the committee, with George L. Harrison, former chairman of the Federal Reserve Bank of New York and present president of the New York Life Insurance Co., as his alternate. Mr. Harrison is here today. The other members of the committee were Secretary James F. Byrnes, then a private citizen; Ralph A. Bard, Under Secretary of the Navy; William L. Clayton, Assistant Secretary of State; Dr. Vannevar Bush, director of the

Office of Scientific Research and Development and president of the Carnegie Institution of Washington; Dr. James B. Conant, chairman of the National Defense Research Committee and president of Harvard University; and Dr. Karl T. Compton, president of the Massachusetts Institute of Technology, and Chief of the Office of Field Service in the Office of Scientific Research and Development.

General Groves was present in an advisory capacity at all meetings of the committee. The members were also aided by the advice and experience of eminent scientists who had rendered invaluable service in the atomic bomb project—Dr. J. R. Oppenheimer, Dr. E. O. Lawrence, Dr. Enrico Fermi, and Dr. Arthur H. Compton. Representative industrialists who had taken a prominent part in the project also assisted the committee in its work.

The drafting of the bill, in line with the principles and policies established by the committee, was done by Brig. Gen. Kenneth C. Royall and Mr. William L. Marbury, both of whom have frequently appeared before your committee and who are present this morning to answer any questions you may have as to the details of the bill.

When the interim committee had reached unanimous agreement on the scope and language of the proposed legislation, it was submitted to interested Government agencies, including the Department of State, the Department of the Interior, and the Department of Justice. With one or two minor exceptions, the revisions suggested by these departments were incorporated into the bill.

In the opinion of the interim committee, the legislation you now have is the soundest and most comprehensive that could be drawn to cover all those phases of domestic control of atomic energy that require action in the interest of national security, world peace, and the promotion of human welfare. The final draft was reviewed by the President before its transmittal to Congress.

There has been distributed to the members of your committee a summary of this bill. You will note that the essential provisions are these:

The first section declares that all activities connected with the release of atomic energy shall be conducted in the interest of the Nation and world peace, so as to promote the national defense, protect the safety of our inhabitants, safeguard world peace, and further the acquisition of knowledge in this field.

Under the bill, jurisdiction is in an Atomic Energy Commission of nine members appointed by the President, with the advice and consent of the Senate, to serve for 9 years. Members of the Commission are not expected to devote their full time to the work of the Commission, but the Commission will exercise general supervision over all atomic-energy activities. For the actual day-to-day administration of the act, there is provided a full-time Administrator and Deputy Administrator. To aid these officials, the President is empowered to establish and appoint the advisory boards that he deems proper. The bill grants to the Commission the full general powers necessary to the performance of its functions, such as the right to adopt regulations, to acquire property by purchase or eminent domain, to make contracts, and to create corporations. With certain exceptions, similar general powers are conferred upon the Administrator.

All items of Government-owned property relating to the production of atomic energy, including the plants and other property of the Manhattan Engineer District, are transferred to the Commission. The Manhattan Engineer District, of course, is the branch or organization of the War Department organized to carry on activities of the atomic energy project under the title of "Manhattan Engineer District." All rights in substances found in Government-owned lands which are directly connected with the release of atomic power are forever vested in the United States, and such lands or deposits are to be turned over to the Commission at its request. The Commission is also authorized to require private persons to declare any property now or hereafter determined to be directly connected with atomic energy, and to acquire such property, at a fair price, by purchase or eminent domain.

With the property thus coming into its custody, the Commission is empowered, through its own employees or through contractors, to conduct all necessary research and experimentation in this field, to develop processes for the release of atomic energy and for its use for military, industrial, scientific, or medical purposes. To this end, the Administrator may license or dispose of the Commission's property to other Government agencies or private persons, upon appropriate terms and conditions.

As a necessary corollary to the power of supervision which comes to the Commission, the bill also grants to the Commission full control over the use, processing, export, and import by private persons, of all substances determined to be sources of or directly connected with atomic energy.

In the licensing of its property and the control of private activities the bill expressly imposes upon the Commission the policy of minimum interference with and the encouragement of private research and of maximum employment of other Government agencies, educational institutions, and private enterprise. The Commission is also enjoined to encourage the widespread distribution, so far as feasible, of permission to engage in activities subject to its jurisdiction, and to discourage the growth of monopoly in trades and industries affected by these activities.

This proposed legislation also authorizes the Commission to adopt and administer the necessary security regulations, and provides suitably strict penalties for their violation. Penalties for violation of the other provisions of the act and the regulations of the Commission are also established.

The question of international control or interchange of information concerning atomic energy is not determined by this legislation. In his message the President drew a clear line between the domestic phase and the international phase of this problem. This bill concerns itself with the domestic phase. Under section 11 (a), the Atomic Energy Commission would be specifically prohibited from granting any information or rights to foreign nations without the express approval of the President. In all its activities the Commission would function under the basic principles laid down by Congress in this bill.

Logic demands, it seems to me, that we set our domestic house in order, so far as the development of atomic energy is concerned, before we enter into discussions or reach decisions as to what should

be done in the international field. What we need now is a body under legislative authority to take possession of the resources we have, to acquire other resources, and to administer them in such a way that the United States will leave nothing undone in furtherance of knowledge and application in this field.

By establishing a Commission of nine members to be selected by the President with the advice and consent of the Senate, you will take the first step toward the determination of a sound permanent policy for the research and manufacturing organization that was built up under the stress of war.

It is the thought of those who participated in the drafting of this legislation that the citizens designated by the President to serve on the Commission, as well as the Administrator and his Deputy, would be representative of all that is best in our national life—men of demonstrated wisdom and judgment who would accept appointment not because of any emoluments that might attend their membership but rather because of a profound recognition of the significance of atomic power to the future of civilization.

There are many important decisions that must be made in the immediate future, notably those involving the further operation of the Manhattan District Project. We now have three enormous manufacturing plants in operation, as well as many smaller ones, and we have built up a well-integrated and irreplaceable organization of scientists, executives, engineers, and skilled workers. To allow this organization to disintegrate because of uncertainty concerning future national policy would be nothing less than a national disaster. Some of our most valuable people have already left and more will go unless prompt action is taken to clarify the situation that affects their future.

No one, not even the scientists most familiar with what has already been achieved, can foresee the ultimate fields into which atomic research will lead. At present, however, there are three great fields that call for our utmost in the way of research and reduction to practice: (1) The development of atomic energy as a controlled source of power, to make available heat and power in supplement to existing sources and also as a means to brand-new developments; (2) the application of atomic energy to weapons, subject to international arrangements that may be later made; (3) the application of activities characteristic of this field of growth of the sciences and practical arts, particularly of medicine, chemistry, and physics.

None of these developments will come overnight or without the most intensive research. The prompt passage of this bill is bound to accelerate our progress along these lines and so to promote the national welfare and safety.

The War Department has taken the initiative in proposing that it be divested of the great authority that goes with the control of atomic energy, because it recognizes that the problems we now face go far beyond the purely military sphere.

The atomic bomb is the most devastating weapon we know, but the means of releasing atomic energy which it employs may prove to be the greatest boon to mankind in the world's history. The wisest minds in our Nation will be required to administer this discovery for the benefit of all of us.

My statement, Mr. Chairman, covers the development of the energy in simple fashion; makes mention of the vast importance of the project, the vast importance not only to the winning of the war, but, as we see it and as we are advised by those most expert in the field, also the vast importance to all phases of our national life.

You all know the history of this enterprise that was conducted by the War Department under the title of the Manhattan Engineer District. It cost the people of this country over \$2,000,000,000 expended upon that project, but the results of that expenditure made the cost thus far seem cheap, because the work that was done has unlocked possibilities of a vaster extent than we can conceive of today.

As we see it, we have this need for legislation along the lines of H. R. 4280: As I have pointed out, the uncertainty as to the future of this project has led to some of the valuable personnel leaving on account of the vagueness in which the matter now rests as a matter of the national will.

We also have, as one of the urgent needs, pressing forward along the lines of research and development—further research as to the possibilities along the line of nuclear fission and release of atomic energy—and we have the need of putting the knowledge we acquire into practical application at the earliest possible date. I think the need of legislation of a more permanent character at this time is evident to all. But what kind of legislation? This discovery, contributed to by scientists, industrialists, executives, engineers, and military personnel, represents national property, a national asset, developed solely at the cost of the United States. Therefore, the legislation that is before you carries out that idea—that it is national property.

Of course, another thing that makes it necessarily of national concern is that the tremendous power that is locked up in this enterprise, the tremendous power that is locked up that will be unlocked—power to be used for further development of our national safety and national welfare, but at the same time power that could be most dangerous, indeed, to us if not controlled—is a national asset.

This bill is far reaching and the powers of the Commission are most extensive; but it is submitted that nothing less than this will answer the need. Therefore, there are very few restrictions, indeed, upon the power of the commission of nine, the Atomic Energy Commission, that is proposed to be set up by this bill, that will control the problem.

I would close my statement by again pressing, as I have already, the need for prompt consideration and prompt passage of legislation. Once in awhile I will admit there are advantages to be gained by slow deliberation, but not generally. Generally it has been my experience that prompt consideration, prompt disposition of cases, has advantages vastly outweighing the slower processes.

The matter is presented now for your consideration and I press the urgency of the problem. That is nothing new, because the President's message presses the same point.

The CHAIRMAN. Mr. Secretary, the Chair is advised that General Groves is here as a witness and has some kind of an early engagement that makes it necessary for him to get away.

Secretary PATTERSON. I will be in attendance and I will respond later to questions.

The CHAIRMAN. That is what I was going to suggest.

Secretary PATTERSON. We have General Groves, Dr. Bush, and Dr. Conant here to testify at the committee's pleasure.

The CHAIRMAN. We will call General Groves now and will call the Secretary back later for questions.

General Groves, do you have a statement you wish to make?

General GROVES. Yes, sir.

STATEMENT OF MAJ. GEN. LESLIE R. GROVES

General GROVES. In coming before your committee today we are appealing for an opportunity to give you our existing powers. In the interest of the war effort, there was delivered into our care the responsibility for directing all activities relating to the release and use of atomic energy.

We have discharged that responsibility to the best of our ability. Thanks to the brilliant and selfless efforts of the thousands of scientists, engineers, industrialists, workers and Army and Navy officers associated with the project, and to the wise counsel of Secretary Stimson and his advisers and the members of the Military Policy Committee, our work achieved its purpose. It helped to shorten the war and to save the lives of American and Allied fighting men.

But the individual responsibility that was desirable in wartime should not be continued today. The hopes and fears of all mankind are so inextricably bound up with the future development of atomic energy, and the problems requiring immediate solution are so fundamental that control should be vested in the most representative and able body our democratic society is capable of organizing.

The bill you are considering today is intended to create such a body.

It would establish a commission of nine distinguished citizens, with a revolving membership to guard against political domination or the development within the commission of frozen attitudes that would act as a brake on experimentation and new ideas.

Within the limits of general policy, as defined by Congress, and of appropriations, as authorized by Congress, the commission would have broad power to conduct or supervise all research and manufacturing activities relating to the use of atomic energy for military or civilian purposes; to control the raw materials from which atomic energy may be derived and to provide for the security of information and property connected with the release of atomic energy. It is also the aim of this legislation that the commission capitalize on the initiative and ingenuity of American science and America industry by giving as much freedom and encouragement to private research and private enterprise in this field as it is possible to give consistent with the requirement of American security.

The success of the Manhattan District Project would have been impossible without the support it received from colleges and universities, from large and small industrial corporations, and from the skill of American labor.

Our progress in the future atomic development will depend equally on the utilization of the fullest support that can be drawn from all of these sources. At the root of this legislation lies a recognition of the importance of maintaining continued leadership by the United States

in scientific progress, utilizing existing private and public facilities to the broadest extent.

The bill specifically provides for the most widespread practical distribution of licenses for atomic research and development within the United States and enjoins the Commission to discourage the growth of monopoly in trades and industries affected by these activities.

In order that the membership of the Commission may include outstanding leaders in American life, its members are not expected to devote their full time to the work of the Commission but are left free to engage in other activities.

The day-by-day work under the law would be carried out under the direction of an administrator and a deputy administrator, who will, of course, devote their entire time to their duties. These, too, should be men of the highest caliber who are willing to make the financial sacrifice necessary to accept such posts in the face of industry's ability to make more tempting salary offers.

The scientific and other personnel to be employed by the Commission would be chosen without regard for civil-service regulations. My experience in operating the Manhattan District Project leads me to the conclusion that such a provision is essential if atomic development is to proceed with efficiency and effectiveness.

It is hoped that this work will attract young and highly talented scientists who will stay with the commission 5 or 6 years, after which they would leave to take better-paying jobs outside. I will say quite frankly that they should not be men who look forward to lifetime jobs on the project. The key staff of the project, both scientific and administrative, should be a rotating one so that the commission will not degenerate into a static organization with an inflexible approach to the problems involved in this vast and complicated field.

I should like before I close to emphasize what Secretary Patterson has already said about the desirability of speedy action on this measure. The decisions we now have to make will affect the welfare of the United States and of the world for many years to come. They should not be made by one man. I am convinced that the prompt adoption of this bill will be a powerful and necessary stimulus to continued advances in our development and control of atomic energy.

Here, more than ever before in our history, it is a case in which man is the keeper of his own destiny. In irresponsible hands, the power of the atom might destroy the world. Properly developed and properly administered, this same force can help light the way to a future of lasting peace and prosperity for all the people of the world. This bill is an important step in that direction.

The CHAIRMAN. Does that conclude your statement, General?

General GROVES. Yes, sir.

The CHAIRMAN. I think I want to ask you one question. You invited my interest when you referred to the fact that this ought not to be a static organization, that it ought to be able to utilize the talents of young scientists who would serve for 5 or 6 years, and then go to better jobs. Is there anything in your understanding of this legislation that would enable the compulsory use of a man for research in this organization if he decided that he wanted to quit and go out, when we needed him as an essential man?

General GROVES. No, sir; there is no way that he could be compelled to serve.

The CHAIRMAN. It is your idea that the business will be inviting enough and men will be patriotic enough so that they will render this service?

General GROVES. Yes; and also the fact that they are young men. What we should offer them is an opportunity to come into this field, work with us for 5 or 6 years and develop and become capable then of seeking better employment outside.

It would be a serious mistake to build up a permanent scientific organization where once they were there they would stay for a lifetime.

The CHAIRMAN. What you have actually done in the laboratories of this Manhattan Project is to develop a force that is loose and has to be harnessed by the Government and controlled in the interest of the public and of the country and of our national defense?

General GROVES. Yes, sir.

The CHAIRMAN. It is a vitally important thing.

General GROVES. There is no question of that, and I think the best answer is where the world would be if Hitler had developed this bomb and then started his attack on the other countries of the world. The war would have been over in a few days and the world capital would have been Berlin.

Mr. THOMASON. I think, General Groves, we are all agreed on the importance of this marvelous discovery, and also that there ought to be very speedy legislation on the subject. My quick reaction to the bill, from its explanation by both Secretary Patterson and yourself, is quite favorable.

What I am interested in, though, is that I want to know if we are going to give this secret to any other country or let it leak out to them, and if this will do the trick. If they can discover it themselves, it is all right with me. Perhaps that is not quite the feeling of the Army, but I do think in view of legislation coming up, and in view of the President's statement this morning, which was quoted in the press, that it behooves this committee, if we are going to pass legislation, to write it so that we know that this valuable secret is going to be retained by this country and not leak out to other countries.

Mr. SHORT. I wish the general would tell us, though, just how much of a secret it is.

Mr. THOMASON. Yes, I was just coming to that. I do not know what the General wants to say about it, or whether he wants somebody else to answer that, but I think this committee is going to be expected to determine, as the gentleman from Missouri says, how much of a secret it is, and since it is such a powerful thing, both in the interest of war and peace, and inasmuch as we, through our efforts and our money and our fine minds, have discovered it, if we are going to keep it. My own feeling is that if some other country has some scientists who are able to discover it themselves, that that comes under the head of their business, but I am not for giving this secret, or letting it leak out to anybody.

With that comment, General Groves, I would like to know how you feel about it.

General GROVES. In reply to your question, the bill provides certain security regulations in section 17 with sections 18 and 19; which are largely a part of 17, and gives us a better control of the

security than exists, I believe, on any other item which should be kept as national property.

Mr. THOMASON. Is there any permissive authority for this commission that you propose to set up to give it to another country under any conditions?

General GROVES. There is a provision in there which the Secretary referred to about that being done under whatever directions are received from the President.

Mr. THOMASON. Then, under the terms of the bill, in the last analysis, it would be left to the discretion of the President?

General GROVES. Yes, sir.

Mr. THOMASON. Would it not if he wanted to give it to somebody else?

General GROVES. That is correct.

Mr. THOMASON. Congress would have nothing to do with it. The commission would make its recommendations to the President, and then if the President, in the exercise of his discretion, wanted to give it to somebody else, why, he would have authority to do it, is that what the bill means?

General GROVES. I believe, unless Congress otherwise decides.

Mr. THOMASON. That is the very thing I am coming to. Does the bill say that?

General GROVES. I do not believe so, sir.

Mr. THOMASON. I, for one, think it ought to.

General GROVES. That, of course, is a matter of international relationships, and that is wholly out of my field.

Mr. THOMASON. Yes; I see. Everybody has agreed this is a marvelous discovery and it is of national and international importance. In it is almost the determination of the future of civilization, but I think Congress and the people ought to know who is going to control this great secret. If somebody else can find out, as they probably will, that is just a repetition of history.

General GROVES. I believe that to understand that problem satisfactorily it is necessary to consider what Mr. Short brought out, which is essentially how much of a secret it is.

The CHAIRMAN. That is what we want to know.

General GROVES. The big secret was really something that we could not keep quiet, and that was the fact that the thing went off. That told more to the world and to the physicists and the scientists of the world than any other thing that could be told to them. It was something that we did not know until we had spent almost \$2,000,000,000 and had worked about 3 years. We did not know whether it would go off or not, and that is the thing that really told them more than anything else that could be told.

The secrets, as they are loosely termed in the public discussion, are divided properly, I think, into about three classes. One class of these secrets consists of established scientific facts which were not secret at all. They were well known to the best scientists of the world before this work ever started. They had been published. They had been published in odd places, but were easily collectible. Anyone who wanted to could find those secrets. Coupled with those were certain others which had been theories before the explosion confirmed them, and the deductions were what would naturally be made by competent scientists. When we speak of competent scientists in this field we

mean scientists that are top-notch, not just first-class men. Those secrets could be deduced by those men knowing that the bomb had actually gone off. The extent of that information which, in fact, was public knowledge to the scientists of the world, is the limit of the Smyth report which you have heard so much about. In other words, nothing in that report discloses any secrets to the world.

The second classification of secrets is the scientific developments which went beyond this, and most of those developments were not basic. They were made up of hundreds and hundreds of problems that had to be solved before this work could be done.

They involved things such as the purification of metals and the purification of other products and the handling of certain products that are not easy to handle safely. They involved all the research work, principally that which was done in many laboratories by thousands of scientists. There are other ways to do this. We hit one way. Probably there are several ways in which you can do those various items, but they require a tremendous amount of work.

This could undoubtedly be achieved by other nations if they spend the money, the labor, and the time and have the scientific organization with which to do it. In time they can, of course, do it. It is merely a case of relative speed.

Another class of secrets falls in the industrial sphere. This contains many industrial applications which, in the course of time, will be made known in this country.

A man who has worked on this project and who is confronted with a similar problem in industrial life cannot forget the solution that was used on this project, and he is going to use that information no matter how honorable he is, and he cannot be prevented from doing it. It is just like a child who is given an arithmetic problem to solve and knows the answer in advance. He cannot help but take advantage of knowing that answer.

The other class of secret, which is the biggest field, is the ingenuity and the skill of the American worker and the American management, both the top management and the junior management, and that is a secret that I do not think any other nation has, and I do not think anyone is going to have it in a hurry.

The net effect is that we are ahead at the present time. It will take the other countries a number of years to catch up, and opinion as to that number of years will depend entirely on to whom you are talking, how optimistic he is, and how easily he forgets some of the problems that we had.

I have talked recently to engineers who told me how fast they can do certain things. Well, they never did it while the job was going despite all of the pressure that we put upon them. I am sure they cannot do it when they do not have that pressure upon them, and I do not think that foreign nations that do not work as hard as we do, both as to hours and as to industry and effort can catch up with us for some time.

That is really the secret. In other words, we are ahead. They can catch us, but it is going to take them time; it is going to take them effort, and it is going to cost them money. How fast other countries can do it I do not know. I have never been in most of them. I spent the war in Washington.

Mr. THOMASON. Are you willing to say, General, the progress that other nations are making in the discovery of this atomic energy, and what the present status of that progress is?

General GROVES. I think we can state this: That we do not know what other nations are doing, but we have pretty good ideas. Our intelligence of Germany and Japan was perfect, insofar as to how far they were along. We did not know whether we were right. That is, of course, always a danger in military intelligence, but we were not taking any chance that maybe we were wrong. It turned out, as we expected, that they were not in our class in the solution of this problem, and they learned more by knowing that this bomb went off than they had learned since the world was closed to communications with them.

Mr. THOMASON. But you do know that Germany and Japan were both working on this thing?

General GROVES. They were interested in it. Germany was working on it. How much Japan was working on it we do not know, but it was not anything of a serious effort. It was too big a job for Japan, and they knew it.

Mr. ANDREWS. We are all quite interested in this great subject which is now before the committee, General. Would you explain your association during the last 3 or 4 years with the Office of Scientific Research and Development?

General GROVES. Do you mean Dr. Bush's office?

Mr. ANDREWS. Yes.

General GROVES. We had the very closest relations with them, Dr. Bush and Dr. Conant were members of the Military Policy Committee, and Dr. Conant assisted me personally with advice, and also Dr. Tolman. Dr. Bush helped me all the time throughout our work. I will say, as far as I am concerned, that there was the closest of relations. They did everything that could be done to make the thing go in the way of giving me the very best advice, which was, in some cases, all-controlling.

Mr. ANDREWS. With that reply, General, my question may be reserved for Judge Patterson, Dr. Conant, and Dr. Bush.

We have been very much interested in this committee in the post-war period in the operation of the Office of Scientific Research and Development, and the establishment of a permanent National Agency of Sciences. My understanding is that this bill has not yet really been acted upon in the Senate. Assuming that that bill became law and the National Academy of Sciences were established and then a commission were set up, what would be the relationship between the two bodies, General?

General GROVES. I believe the proposed commission would be a body by itself working on one problem. That is essential because it is such a complex problem. Its relations with the other body would be, I hope, similar to our own past relations with other agencies, in which there was the freest cooperation by all concerned in this work. If we developed a product in our process that was of value to them, we would give it to them. An example of that was a special lubricant which was developed. That information was passed over to them. I hope that there would be liaison there which would enable each to take advantage of the knowledge and advice of the others, and that there would not be any interference between them. There

are certain benefits to each as far as they are concerned in this project, I believe enough to help in both directions.

Mr. ANDREWS. I understand you definitely favor the permanent establishment of a National Academy of Sciences?

General GROVES. I think that is stretching my answer a little. My answer really would be that with the establishment of this Commission it should work with the other body if that were decided upon.

Mr. ANDREWS. Do you favor that too?

General GROVES. I am not familiar enough with that to testify on that. It certainly would not be objectionable to this bill.

Mr. ANDREWS. The relationship to be finally established as a matter of fact is a matter of policy to be decided upon by this new board or set-up?

General GROVES. Yes, sir; and the head of the other agency, and if they worked along in that fashion it would be fine.

Mr. BROOKS. General, the term "nuclear fission" occurs throughout the bill. Would you explain just what that is?

General GROVES. That is quite a job, I think, to explain it in simple language, and I hesitate to do it when I have all of these distinguished scientists here behind me. It is really what is known as the splitting of the atom, which occurs when a neutron hits the atom and releases one or more neutrons, which then go on.

Mr. BROOKS. In other words, that is the heart of the whole bill, is it not?

General GROVES. Nuclear fission and the modifying words that follow really describe what is the heart of atomic energy, and it is believed to be inclusive of everything that might be applicable to atomic energy.

The CHAIRMAN. Do not go into the details of that.

Mr. BROOKS. No; I am not going to expose any figures here.

The CHAIRMAN. I know you are not.

Mr. BROOKS. I want to ask you this from the standpoint of national defense. You know the processes required to develop this atomic energy. Would you say in time of peace that another great nation could develop this process without our knowing about it?

General GROVES. Yes, sir; if they took time enough.

Mr. BROOKS. They could conceal it and handle it in such a way that it would be impossible for us to know about it?

General GROVES. Yes, sir.

Mr. BROOKS. Is there anything in this bill that would help us to gain information of that character in the event some other nation decided to go into that field?

General GROVES. No; there is nothing that would enable us to enter into any international negotiations or anything of that kind.

Mr. BROOKS. Is there anything you have in mind that we could put into the bill that would assist in that respect?

General GROVES. No. Of course, an effort has been made to make this a domestic bill without getting into international phases.

Mr. BROOKS. That is all.

Mr. SHORT. General Groves, is it not factual to say that many minds and a great many countries for a long time have contributed to the discovery of the atomic bomb?

General GROVES. Yes, sir.

Mr. SHORT. And that science, by its very nature, is international and universal?

General GROVES. That is correct.

Mr. SHORT. And no nation and no people have a monopoly on the discovery of truth, and that while, perhaps, the secret is widely known, the elements that control the atomic bomb, the mechanics for its development and production, are more or less a secret principle?

General GROVES. Yes, sir.

Mr. SHORT. So that we can at least keep the methods of its manufacture, or the assembling of it and the mechanics and machine tools and the knowledge from the different laboratories, we can keep all that data more or less a secret?

General GROVES. We cannot keep it secret for any great number of years because other nations will find out how it is done. There will be other applications, and engineering is progressing, particularly scientific engineering, so it is merely a question of time.

It could be well compared to a football team which develops the T-formation. When the originators no longer have a monopoly on it, and if the opposition has the best team, why, they can beat the originator.

Mr. SHORT. Of course, Germany was pretty far advanced in the development and had gotten a long way toward the development of this bomb in Norway. If it had not been for the Norwegian underground and the British Intelligence, Hitler might have beaten us to the draw?

General GROVES. No, sir; I think that is an exaggerated statement because he could not have beaten us. He just did not have the industrial capacity and the capacity to get teamwork that we had here. There was a great deal of friction within Germany. It was subrosa friction, not on the surface, but he did not have the capacity to do it because he had not organized it well and it could not have succeeded.

Mr. SHORT. Of course, the destruction of the plant in Norway by the Norwegian underground certainly disrupted it.

General GROVES. There was undoubtedly something to that, but it was not a controlling factor. Even if that had not been destroyed, he would not have gotten there first. It was undoubtedly annoying to them, but it was not a controlling factor.

Mr. SHORT. They are not as far advanced as some newspaper and magazine articles would lead us to believe.

General GROVES. That is a correct statement.

Mr. SHORT. I am glad to have you make that statement.

General GROVES. In other words, we were way ahead from the time we really got into this business, and then we kept going at a real speed, while they were going relatively at a snail's pace.

Mr. SPARKMAN. As I understand it, this proposed legislation is for the purpose of controlling within our own Nation for the present, the bomb, and the President's message related primarily to that, but also touched on international control. That is not referred to in this legislation, and it is not thought that in this legislation we should touch on the international aspect of it at all.

General GROVES. No, sir; we would like very much to avoid that in its entirety, for it has no bearing on it.

Mr. ARENDS. General, I am very happy that this matter is up for early consideration, because you may or may not remember I intro-

duced a bill on this general subject on September 24, 1945, and I am very much interested in it, as well as people all over the Nation.

The bill I introduced, H. R. 4152, provides for the establishment of a commission of national defense to study the revision of our national defense necessitated by atomic and other weapons, and because of the question raised by the gentleman from Texas, Mr. Thomason, I would like to read this particular bill for the benefit of some of the members of the committee who have not had an opportunity to look it over. It touches on this very point. The bill reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there is hereby established a commission to be known as the Commission to Study the Technological Revision of Our National Defense Necessitated by Atomic and Other Weapons.

SEC. 2. The Commission shall be civilian in character, composed of fifteen members to be appointed by the President of the United States and shall include representatives of scientific and industrial research and other leading citizens who are conversant with the problems of the nations defense. The scope of the Commission shall be limited to the study of technological data pertaining to national defense.

SEC. 3. It is the intent of Congress that the President shall require technical advisers from the military services and other branches of the Government to serve in an advisory capacity. The military services and other branches of the Government shall give the Commission full access to the facts relating to technological revolution in warfare, so far as it shall not endanger national security.

SEC. 4. The Commission shall make interim quarterly reports to Congress for its information in the formulation of an adequate national defense program. The Commission shall be terminated not earlier than January 1, 1948.

SEC. 5. There is hereby authorized to be appropriated, out of any money in the Treasury not otherwise appropriated, the sum of \$500,000, or so much thereof as may be necessary, to carry out the provisions of this act.

Mr. ARENDS. In other words, in this bill we leave any decision or final determination in the hands of Congress, whereas the bill under consideration leaves everything in the hands of the Commission, or one man, to do as he sees fit.

Mr. CLASON. I wonder if the General can give us any idea of the value of the property which would be turned over to this Commission as a result of this legislation, if it is passed.

General GROVES. I could give you the value of about what it cost us.

Mr. CLASON. I believe you said that was over \$2,000,000,000.

General GROVES. The project to date has cost in the neighborhood of \$2,000,000,000 and more, and that is really the value of what we are turning over; and if we consider it as a going concern and the cost of the development as properly chargeable to what we have developed.

If you are thinking of the physical property we are not turning over that much property, because a great deal of this expense was in operational cost, research, and development; but if you refer to the physical property only, I cannot give you that figure as a firm figure, but it would be on the order of probably a billion and a half first cost. If you apply some of these new theories on prevalent investment, I do not know just how much that would be worth. But if you put it on a reproduction cost, it would be about a billion and a half. But that is purely a guess; I would like you to understand that.

Mr. CLASON. As I read the bill, it rather indicates that all of the items that will go into the bomb can be secured within the confines of the United States; is that a fact?

General GROVES. As far as the Commission is concerned, it has to do only with operations in the United States, but the Commission is subject to the President as to what goes on elsewhere.

Mr. CLASON. It seems to me it is broad enough so that if a scientist from Russia, let us say, or anyone else, is developing an atomic bomb, based on some other ore than uranium, the Commission would have the right to seize, within the United States, all of the lands that carry that ore, even though it proved to be coal or some other mineral or ore; is not that true?

General GROVES. Yes; that would be true with the wording of the bill, but I think that is getting into a field that we certainly do not foresee, and I do not believe anyone else does. It is possible that in the dim future that would occur.

Mr. CLASON. Would you expect that any scientific explorations that might be made in other countries at this time would be along the same line of employing the same ores that we would?

General GROVES. I am certain of that.

Mr. CLASON. As I read the statement of Dr. Langmuir yesterday before the Senate committee, it appears that in his mind that within from 5 to 10 years Russia will have the process and the information in regard to the atomic bomb, and that there will be probably 10 years in which we might, perhaps, keep ahead of Russia.

What would you think about that statement?

General GROVES. I read what he said in the Washington Post this morning, and to me he seemed to be talking about how fast Russia would go and how slow we would go.

Mr. CLASON. How long would it take Russia, if it goes after the development of this bomb, to develop it?

General GROVES. I think that depends. It can vary, and it varies according to how much of an all-out effort they make, and how much they are willing to sacrifice in the way of security. It varies most of all with how much is done in secret. You can take your choice, but it will take time and a lot of money before they can catch up with us, but they can do it. In that I speak only for myself and not for any of my officers or any people that we have consulted with. That is a personal opinion which is primarily on the industrial basis rather than the scientific. I believe that for another country to do this work, if it had the power of the greatest countries left in the world, but had no particular ideas, that it would take them from 5 to 20 years, and the difference in time would depend entirely on how "all-out" they made their efforts and how much they threw security to the winds.

If they do make the same equipment we have made, that could only be made in the United States, and possibly in Switzerland, and when they place foreign orders they are disclosing their hand. It would all depend on how far they disclosed their hand.

In other words, if people are going to starve in their countries to do this project, or if they want to do it in some forest where nobody goes, it varies from 5 to 20 years. Just where that is I do not know.

Mr. SHORT. Because of the tremendous, enormous cost, it is not likely that atomic energy will be used in the immediate future for commercial purposes, is it?

General GROVES. I think that is correct, if you define the immediate future as being within the next 10 years. But you must give due consideration to the fact that there will be development in atomic

energy, with possible side developments that might lead toward commercial use as a result of governmental research.

Mr. SHORT. Until such time and some other country develops this atomic bomb, so far as any one nation now is concerned, no other country could wage war successfully against the United States, is that true?

General GROVES. I think they would have to think of what would happen to them.

Mr. SHORT. And so long as the United States can retain sole knowledge and possession of the atomic bomb, it is in a position of being able to wage war successfully against any other nation.

General GROVES. Yes; with two qualifications. First that nobody finds out a means for stopping us from delivering on the target. That is the reason that makes it very important not to place our sole reliance upon this weapon and say that with it we cannot be defeated. It is a very strong weapon, but it is not a substitute for our Army and Navy, and it would be a terrible mistake to consider it so. It is very strong but it is not overwhelming because somebody may stop it.

Also, we must not forget that this is a secret that cannot be held; it is just a question of time. The worst thing that could be done would be to rely only on this weapon and say that with it we cannot be defeated. It is not a substitute for an army and navy. It is a very strong weapon, but someone may discover something to stop it.

Mr. CLASON. Up to the present time, we do not know of any Nation that has found any defense for it?

General GROVES. No; I do not know of any; but I do not know much about the rest of the world.

Mr. CLASON. If that be true, I would like to know whether or not, in the development of this bomb the Government has used any foreign personnel who are not American citizens?

General GROVES. Yes; they have been used.

Mr. CLASON. If they return to their home countries, are they not in position to aid in the swifter development of the atomic bomb in the foreign countries from which they come?

General GROVES. Yes, sir.

Mr. CLASON. Some of them are very capable scientists?

General GROVES. Yes, sir.

Mr. CLASON. But as I read this bill, this bill does not prevent the Commission from employing foreigners hereafter.

General GROVES. No, I do not believe it does.

Mr. CLASON. Is it the purpose of the Commission to retain in its employ the scientists from other nations who are now employed there?

General GROVES. No; of course, I do not know what the Commission will decide to do, but I would not imagine that they would frequently do that.

Mr. CLASON. Why is the bill drawn so they can do that, to permit nationals from all other countries to be employed by and with their salaries paid by the United States Government?

As to secrecy, in connection with this bill—

General GROVES. I believe the only reason I can give for that is the fact that we were so determined to avoid any of the international problems involved that we did not set it up in this bill. So far as our employment of foreigners, I cannot tell you the exact figures, but they are extremely limited. They were necessary if we were to accomplish the purpose. I cannot even recall now just who they are.

Mr. CLASON. In employing these persons, as I read the bill on page 18, they do not have to comply with any civil-service law or any other statute, and apparently they can put foreigners in positions where they may get a considerable amount of, if not full, knowledge of what is going on in the Commission.

Is not that a rather dangerous proposition, in view of the fact that so far as your criminal processes are concerned, you can even send a man to jail for violating simple regulations?

It seems to me, from the criminal standpoint, you are making it a serious proposition all the way through and opening that up pretty wide.

General GROVES. I do not believe the Commission would, in fact, employ any foreign citizens normally. If I were in a position of responsibility with the Commission I certainly would not employ any foreign citizens unless the rewards to be gained for the project were sufficient compensation for the risk to security.

I would like to say that the only thing that would preserve security would be to lock everybody up, and when they decided to leave to shoot them and be done with it. That is the only way you could have perfect security.

Mr. CLASON. How much do you expect this Commission would need in the way of funds?

General GROVES. That is extremely difficult to answer, because it depends a great deal upon what the Commission decides upon. We do not know about certain essential things. We do not know what the situation will be abroad; we do not know how many bombs we should have in storage, and we do not know what future developments may bring forth.

Mr. CLASON. The bill also provides for the setting up of a corporation, as the Commission sees fit, for various things. What is the need of a corporation? Why cannot the United States Government go ahead without the formation of a corporation?

General GROVES. It is sometimes quite essential for security reasons to have a corporation established, and there are certain other places where it is desirable. In this project to date, there has been no widespread use of any specially set-up corporation. There have been some things done entirely for security reasons to enable us to do the job in a better way. As soon as it is known the United States Government is doing something, everybody knows we are doing it.

Mr. CLASON. Why should not this Commission save money? In its transactions it will be involved probably in many millions of dollars, but without being subject to the General Accounting Office to the same extent that most agencies of the Government are.

General GROVES. In order to insure that our procedure on accounts was correct the Comptroller General has arranged with us to have field auditors practically associated with us throughout, in passing on the bills promptly, so in case of doubt the bills could be straightened out promptly. As you know, accounts that run for 2 or 3 years are very hard to adjust. We have had many unusual projects in connection with these properties, and while those provisions are difficult to write, we have done so to the satisfaction of the Comptroller General. However, there are possibilities where there would be disputes, and I think the committee will appreciate the fact that in carrying on this extremely complex program, it has to be free of that possibility.

Mr. CLASON. I have read the bill, and while I appreciate the purposes for which it was drawn, how can any large corporation proceed with the development of research on the use of atomic principles, based upon the same ores used in the bomb under this bill?

General GROVES. They will proceed under a license given by the Commission. That is provided for in section 13, I think, on page 21 of the bill.

Also, in section 13 it provides that—

it shall be unlawful for any person without the consent of the Administrator and upon such conditions as he, with the approval of the Commission, may prescribe to do certain things that may be done with such consent.

Mr. CLASON. It also provides, on page 22, subsection (d), line 20—

it shall be unlawful for any person to conduct research involving the release of atomic energy in amounts deemed and to be prescribed by the Commission as constituting a national hazard or being of military or industrial value—

And so forth.

General GROVES. Yes, sir.

Mr. CLASON. Do you not think that is going to be a pretty severe restriction combined with section II, so you cannot bring anything into the United States in quantities enough to accomplish anything under this bill? There is nothing you can bring in here in large quantities.

General GROVES. It has set up the most rigid limitations, and it is put in the hands of this authority for the reason that has been set forth, that this is a situation so complex and so complicated that it makes it impossible to write laws in advance as to how each particular operation shall be conducted. It also is something that cannot wait. If a mistake is made in this instance it may easily be a fatal mistake. If a mistake is made in this field it may be irreparable.

This whole thing is so complicated and of such magnitude that no mistake can be allowed; it is like a man on skis going down hill who cannot stop, and it would mean that it could get out of control.

Irreparable damage might result to the United States if a mistake were made now in connection with the control of atomic energy.

We are flirting with national suicide if this thing gets out of control. If one mistake is made we may face national disaster.

Mr. CLASON. You think it would not be financially wise for a big corporation to conduct any of this research work, like the fellow who provides an engine or a motor vehicle, or for any other purpose, in view of the fact that without that he could go no further.

General GROVES. It would be unwise from that standpoint, and also it would be unwise because there is not enough fundamental knowledge at this time, and they would not do it because they would not see any returns.

Corporations interested in doing research work with no returns are interested in doing more basic research, with financial support from the Government, in which case a patent of that character would go to the Government.

Mr. CLASON. If I get the picture, the public is not likely to get much benefit out of this development, if any, in the near future.

General GROVES. I think that is correct, from the power standpoint. From the medical standpoint, perhaps there will be some benefits.

Mr. CLASON. Why is it that you are interested in allowing colleges and universities to carry on in a small way in connection with research and do not want big corporations to do it?

General GROVES. I think we also have control over the colleges in the same way as the corporations.

Mr. CLASON. But you did furnish them with funds and train the men to do everything to help them out. It means a big thing, a big research program? Is not that true?

General GROVES. Many of the basic discoveries are made in the college laboratories, and by people proceeding on shoestrings, and it would be most unwise to say to them and have them feel that nobody in the United States can do that unless he has a license.

The CHAIRMAN. Does not that follow, that these private workers do work in harmony with industry, oftentimes, and that it is not unusual?

Mr. CLASON. It is not unusual, in many cases, but from the standpoint of financial investment it is certainly out of this picture under this bill.

General GROVES. No, sir; because at the present time there are big corporations interested in conducting research along these lines in cooperation with the United States. I think that would be one of the first things taken up by the new commission, that is the handling of that type of commitments in which the corporation would be doing this work for the United States without profit. Their profit is in the training of certain people for this particular field.

Mr. CLASON. Are they under the pay of the United States Government or the corporation?

General GROVES. In the normal instance, the corporation would naturally do research, and the United States would reimburse them for their expenses.

Mr. CLASON. As I get the picture, the United States Government would control everything from start to finish, and no private corporation or individual can go ahead under that method.

General GROVES. That is correct; he has to have a license from the Commission.

Mr. CLASON. The word "license" means that the Commission can still increase these wages, and the word "license" on page 28 of the bill includes "license, lease, loan, sell, furnish, make available, dispose, grant, any right or interest"?

General GROVES. Yes, sir.

Mr. SHORT. It is imperative that you keep it tight and rigid and make the control of this thing as absolute as possible?

General GROVES. Yes, sir.

Mr. SHORT. And that is the reason the Commission is granted practically unlimited power, as it should be?

General GROVES. Yes.

Mr. CLASON. After this bill is passed, Congress is out of the picture. I just want the facts for the record. I think we all agree that something has got to be done. But as I see the picture, after this legislation is passed, if it is passed in the form of this bill, Congress will have nothing further to do with any control over it excepting to pay the bill, as has been suggested, out of appropriations from the Appropriations Committee, and to receive expurgated reports, the President receiving the full report and the Congress getting something less. Is that right?

General GROVES. I think there is one thing that you have left out, and that is that the Congress at any time can change the act.

Mr. CLASON. Yes; but that has not been very easy to do in the past. Other than that, if the bill is passed, as long as it stays on the statute books Congress is out of the picture except as regards appropriations?

General GROVES. Yes.

Mr. DURHAM. Under this bill would a college be prevented from doing experimental work without securing a license from the Commission?

General GROVES. They would have to have a license.

A VOICE. No.

General GROVES. It depends on the quantity and on the type of experimental work it is. Subsection (d) on page 22 is the one that really applies to that. It provides as follows [reading]:

It shall be unlawful for any person to conduct research or experimentation involving the release of atomic energy in amounts deemed and to be prescribed by the Commission as constituting a national hazard or being of military or industrial value, * * *

You cannot have a thing of industrial value without its being of military value also.

Mr. DURHAM. I am interested in research work by the colleges in this country.

General GROVES. I believe that the effect of the bill will be to greatly increase the power of the colleges to do research, and will not diminish them in any instance.

Mr. MARTIN. General, with reference to the power to acquire property, it seems to be a rather broad power to acquire almost any property that the Commission deems essential or important in the development of this project for atomic development. After it gets the property, the Commission has the power to license the use of it to private firms or individuals; is that correct?

General GROVES. Yes, sir.

Mr. MARTIN. I wonder if there is any limitation needed on the power to acquire property and how far afield they can go in getting and then taking over property and licensing it just because it has a possible bearing on this field of development. I foresee some possible abuse of that power. I have seen mentioned in the papers recently the possibility of its extending out to the point of power institutions similar to TVA. We have one in the Middle West in which some of us are interested—the Missouri Valley Authority—and I wonder just how far the Commission can go in building up such an empire as that in the name of atomic energy development.

General GROVES. I believe that is measured by the statement on page 15, line 14—

which, in the judgment of the Commission, are peculiarly related to the transmutation of atomic species, the production of nuclear fission, or the release of atomic energy.

Mr. MARTIN. The Missouri Valley Authority could be very peculiarly related to it, could it not?

General GROVES. I do not think so.

The CHAIRMAN. There is no Missouri Valley Authority yet.

Mr. MARTIN. I am not talking about things that are; I am talking about things that might be; and that is what we are called on to

consider. There was not any Tennessee Valley Authority when the bill was first enacted.

There is no limitation, as I see it, in this bill as to how far the Commission can go if, in its judgment, the development might have a sufficient bearing on the development of atomic energy.

General GROVES. I think that is correct. In other words, you are turning over to the Commission this subject, and you are turning it all over with the understanding that it is too complex to be handled by detailed advance legislation.

Mr. MARTIN. My interest in asking that question was just to call the attention of the committee at this time to the fact that this might be used as a cloak for future expansion of Government control of industry, and we want to go into this with our eyes open.

I will drop that matter at this point, and we will discuss it later in committee.

Another point is the matter of control of the individual. You answered Mr. Clason with reference to men who are not American citizens, but I think the question in mind was men who are American citizens. We know, in watching the activities of some industrialists in America, that they do expand into foreign countries, and we know of some firms of engineers who go into foreign countries to do developmental work there. As I understand it, you believe that the penalty section, section 19, and the security section, section 17, would be adequate for the checking of American citizens who have been employed by the Commission, leaving this country and selling their professional services to foreign countries where they might use the information gained in their experience here?

General GROVES. I believe it does not provide, and I do not believe it should, that an American who works on this is from then on restricted to the United States. He can go abroad; he can engage in business abroad. The purpose is to prohibit him from disclosing any information which is gained as the result of his employment with the Commission. It is awfully hard to cut out knowledge from a man's brain.

Mr. MARTIN. That is the reason I am asking the question. You made the remark a while ago when you were justifying the fields of secrecy, that in the industrial field it is well-nigh impossible to keep a man who has been closely associated with this development from using his knowledge.

General GROVES. That is correct. And it is the same in the scientific field. If, as the result of his experimental work, he sees a machine or an instrument used to make a certain measurement, and he is faced in his own laboratory later, 2 or 3 years later, with that same problem in front of him, he is going to use that knowledge, and you cannot strike it out of his brain.

Mr. MARTIN. The only place where he goes counter to this bill is in the security section and the penalty section, in the general statement with reference to using it with intent to jeopardize the interests of the United States. That is on page 27 of the bill, line 11.

General GROVES. It starts earlier than that, I believe.

Mr. MARTIN. That is the key, though, that determines whether or not he is violating the provisions of the bill.

General GROVES. Sections (a), (b), and (c) of paragraph 19 are all pertinent. They define different degrees of violation of security.

Mr. MARTIN. The intent to harm the United States is the principal test.

General GROVES. That is only section (c). As to the other sections, you do not have to show such intent.

Mr. MARTIN. To the extent that the penalty and security provisions are in here, we are dealing definitely with the matter of international effect of further research and development?

General GROVES. I think that is correct. If there were no international effect, there would not be the same need for security.

Mr. MARTIN. There is one general question I would like to ask you. You have been discussing here at some length the matter of other nations keeping up with us. I would like to ask you whether, in your opinion, we will be marking time during the 10 years that it takes them to catch up to the point where we now stand?

General GROVES. I do not believe we will, if we proceed wisely.

Mr. SHERIDAN. Is it permissible under this bill for the Commission or the Administrator to take property even before a hearing is held under petition?

General GROVES. I think that is correct.

Mr. SHERIDAN. It is so provided, is it not, on page 16, line 12?

General GROVES. Yes, sir.

Mr. SHERIDAN. Is not that violative of the very principles of our Constitution?

General GROVES. I cannot answer that. I am not a lawyer. I think that is really a legal question.

General ROYALL. There is plenty of custom for that.

Mr. SHERIDAN. As a matter of fact, once the Administrator or the Commission is established, there is no further provision except by limitation of authority?

The CHAIRMAN. That is a law question that we have got to settle; and this gentleman is not a lawyer. We have statutes authorizing the seizure of property now, upon the payment of 50 percent of the value.

Mr. SPARKMAN. It is in line with the Second War Powers Act.

Mr. SHERIDAN. But the status of this Commission will be a peacetime status.

The CHAIRMAN. That is correct.

Mr. ELSTON. General, I do not think anybody can quarrel with you about the objectives of this legislation. I want to talk to you about some of the provisions of this bill. In the first place, did you have any thing to do with the drafting of this bill?

General GROVES. I sat with the interim committee, as the Secretary said, throughout its preparation of the bill, which was to lay down the principles. The drafting of the bill was under the charge of General Royall. I am in favor of the provisions of the bill. I have gone over it very carefully during that time. It incorporates everything I would want to see in it and it has nothing that I would not want.

Mr. ELSTON. In the first place, you set up a commission that has more power than has ever been given to any other commission in the history of this Nation, and yet you do not provide that the members of the Commission be even confirmed by the Senate.

General GROVES. Yes, sir; that is in here.

Mr. ELSTON. I am looking at the summary, and the summary does not mention it.

General GROVES. I am sorry, sir. It is on page 2, lines 23 and 24 [reading]:

which shall be composed of nine members, who shall be appointed by the President, by and with the advice and consent of the Senate.

Mr. ELSTON. I am glad to know that it is in there. General authority is given to the Commission, however, to have plenary supervision and control, within the United States, of all matters connected with atomic energy. It gives the Commission complete and absolute and unqualified control over atomic energy. Is that correct?

General GROVES. Yes, sir.

Mr. ELSTON. And that, of course, includes everything. It would preclude any company from proceeding with any research work at all with a view to developing atomic energy for industrial uses, without a license from this Commission?

General GROVES. That is generally correct. In other words, the Commission has the control there.

Mr. ELSTON. Of course in time atomic energy may take the place of all other types of energy, such as electricity, energy developed from coal, natural gas, and everything else. That is conceivable?

General GROVES. Many years in the future.

Mr. ELSTON. Well, it is conceivable; and yet it is all in the hands of this one Commission. That is correct, is it not?

General GROVES. Yes, sir.

Mr. ELSTON. I notice that the bill gives the Commission the right to make contracts without regard to provisions of law?

General GROVES. Yes, sir.

Mr. ELSTON. Do you conceive of any reason why they should make contracts without regard to existing law?

General GROVES. Yes, sir; a great many. For example, in normal times contracts must be given to the lowest bidder. This is not a case of selecting the lowest bidder. This is just as if you were securing a surgeon to do an operation. You are not interested in taking bids on that. That is because of the type of work. Things must be decided on reputation and what you think of the ability of the person.

Mr. ELSTON. Do you not think it would be better in cases of that kind to have the Congress specifically indicate in what respects existing law should be changed, rather than to give the Commission carte blanche authority just to go ahead and ignore the law in regard to any contract at all?

General GROVES. I do not believe so, because I do not believe that it is possible at this time—and I speak from my experience in the last 3 years—to determine just what problems this Commission is going to be faced with. It is faced with problems that have got to be decided promptly. If they are not, it is going to cost the Government tremendous sums of money. I feel that, with the national security so vitally concerned, mistakes, as I said before, may not be retrievable, and those mistakes may be of tremendous cost.

Mr. ELSTON. Congress is always in session.

General GROVES. That does not mean that we can necessarily have prompt action.

Mr. ELSTON. Just give us one illustration of where you would have to act without waiting for Congress to pass a law.

General GROVES. You mean, as to what might happen?

Mr. ELSTON. Yes. Just give us one case where you might have to act so fast that Congress could not consider it.

General GROVES. The Commission might have to, in the procurement of raw materials, proceed without any delay. If you are hunting for raw materials and someone else is only a step ahead of you or following where you are, you have got to move and you have got to move fast and you cannot wait, judging from the decisions that have had to be made in the last 3 years; practically instantaneous decisions. I mean decisions involving large sums and involving very important policies that had to be made in a few hours' time, whereas in normal times and under normal procedure we would get together and sit and argue for maybe weeks. That has not been possible, and I do not believe it will be possible in the future.

Mr. ELSTON. Congress can give you the power to make contracts for the purchase of materials without giving you absolute power to do anything you want to by contract and completely disregard the existing provisions of law.

You also ask in this bill that Congress give you the power to adopt regulations which shall be published in the Federal Register, and then for violation of whatever regulations the Commission may decide to make, people may go to jail for as much as 30 years.

Mr. SHERIDAN. Also they are not even subject to the General Accounting Office for audit.

Mr. ELSTON. I understand. But you are given by this bill power to make regulations which are hidden away somewhere in the Federal Register; and it is impossible for anybody to know everything that is in the Federal Register, and yet for the willful violation of one of those regulations it is possible to impose a penalty of \$300,000 and 30 years in the penitentiary.

General GROVES. I believe that the courts would consider carefully any excessive penalties; but I would like to point out that our practice in the past, and I believe it would be the Commission's practice, has been to require anyone who is employed by us or by any of our contractors to sign certain agreements of secrecy. He is put definitely on notice and he knows what he is doing if he violates it. I think that will be the main purpose of these regulations.

Mr. ELSTON. Congress can pass a law making it an offense to reveal secrets. You do not have to do it by regulation.

General GROVES. If we could anticipate all the things that might come up on this. The reason that we cannot is that this whole subject is approximately 2 years old, as far as getting into the complexities of today are concerned. You cannot sit and discuss the thing or explain it to people who have not had the background. You cannot explain it just because they have the education or training to understand it, because the whole thing is so staggering in its implications that you have got to have the background that comes with time.

Mr. ELSTON. I grant you all that; but I do not think that justifies giving legislative power to the Commission, power to make laws and hide them away in the Federal Register and send somebody to the penitentiary for 30 years for their violation.

The CHAIRMAN. Will the gentleman yield to the gentlewoman from Connecticut who has got to take a plane directly?

Mr. ELSTON. Surely.

Mrs. LUCE. General, I welcome this opportunity to ask you a question with reference to the past history of the atomic bomb. I think your answer to it will be conclusive.

When, in your opinion, was the atomic bomb as a weapon first ready for target release; on what date?

General GROVES. You mean, when it could have been released?

Mrs. LUCE. When could that bomb have been released, in your opinion; on what date?

General GROVES. I think that bomb could first have been released on the day that it was released.

Mrs. LUCE. When was the actual bomb itself ready to be released?

General GROVES. I cannot remember the exact date, but I believe it was about 3 days before it was released. It was ready to be assembled. It was not necessarily ready to go. We waited until the last minute to make certain final assemblies. But, as to the real intent of your question, it was ready 2 or 3 days before.

Mr. JOHNSON. You mean, before it was released?

General GROVES. I can recall now that it was ready on the 1st of August.

Mrs. LUCE. I bring this up because there was an astounding remark made—you may have seen it—in the newspaper columns.

General GROVES. I have seen a lot of astounding remarks. I think I know the one you mean.

Mrs. LUCE. That remark said that the bomb has been ready for release and the War Department had been so notified on January 15, 1945, and it was not released until 6 months later for political reasons or reasons of state.

General GROVES. It is very easy to answer that with a definite "No."

Mrs. LUCE. I know it does not make good sense, but as I get many inquiries about it I wanted to ask you that question.

General GROVES. The answer is "No," unqualifiedly.

Mr. ELSTON. Relating to the question that the gentleman from Pennsylvania asked about, and that is the power to requisition, I grant that in the past power has been given to requisition property, but it was purely a wartime act. There is no government that I know of that has the power in peacetime to requisition property without giving the owner his day in court. Under this bill this Commission could requisition any property, real or personal, anywhere in the United States, that it saw fit to take, without going into court first. There would be compensation afterward, but it could just take the property and decide afterward what it would pay for it. That power is in this bill?

General GROVES. Yes.

Mr. ELSTON. The Commission may take over an entire industry if it wants to, and nothing could be said about it?

General GROVES. There certainly could be plenty said about it.

Mr. ELSTON. But nothing could be done about it?

General GROVES. That is correct.

Mr. ELSTON. Do you think that is necessary?

General GROVES. I think it is. I think it is one of the many provisions that are in this bill that are necessary, because we do not know what the future of this thing holds for us, and we may have to move very quickly. It has happened in the past, in the course of our developments, where certain things suddenly became of importance to us

and it was of the utmost necessity that they be obtained promptly and without any fooling around of any kind; and those items were not items which were necessarily due to the speed with which we had to work.

Mr. ELSTON. In the development of atomic energy so far have you requisitioned any property?

General GROVES. You mean, taken possession before a court order?

Mr. ELSTON. Yes.

General GROVES. I cannot state definitely. I cannot recall any offhand.

Mr. ELSTON. Then, if you have not had to do it so far, what makes you think you will have to have all this power to do it in the future?

General GROVES. I think the answer to that is that we just do not know what the future holds for us in this problem; but we do know that it moves fast and that a mistake in this can be national suicide, as I explained before. I feel that if the Commission is selected as we hope it will be, the Commission will not take advantage of those powers.

Mr. ELSTON. Well, it is a dangerous thing to just give them the power and hope that they will not take advantage of it.

The CHAIRMAN. Is that all, Mr. Elston?

Mr. ELSTON. No; I have another question.

The CHAIRMAN. Go ahead. I want to be able to excuse this witness finally, very soon.

Mr. ELSTON. I want to call your attention now to another section which authorizes the Administrator to license the Commission's property, including its funds, for research and experimentation, development, exploitation, and use of processes or methods for the release of atomic energy, and any use of such property where it is deemed advisable for the purposes of this act to retain control or supervision in the Commission over the property, its utilization, or disposition; and incidental and related purposes. Then you provide that no license for purposes (1), (2), or (3) shall be given by the Administrator to a foreign government or any person who is not under and within the jurisdiction of the United States, without the approval of the President.

You have asked for all these vast powers for the control of atomic energy, and yet you make it possible in the bill to give them all away to some foreign government by the act of one man, namely, the President of the United States.

General GROVES. Also the act of nine other people who have to recommend that, if they do.

Mr. ELSTON. I am assuming that the Commission recommends that. Then you give the President alone power to give it all away, and in that you include the atomic bomb and everything else. Do you think that is a wise provision?

General GROVES. All I can say is that that is getting into the international field, and that is really out of my sphere.

Mr. ELSTON. Well, it is in this bill.

The CHAIRMAN. I wonder if I can get an agreement from my colleagues and the other members of the committee that Judge Patterson and General Royall are both good lawyers and that we can discuss the legal aspects of the bill with them.

Mr. ELSTON. All right. Maybe I do not have any more to ask this witness.

The CHAIRMAN. I do not want to be disagreeable about it.

Mr. ELSTON. No, you are not. I do want answers to my questions, and I would rather get them from the ones most capable of answering them.

The CHAIRMAN. The witness is a mechanic and not a lawyer.

Mr. ELSTON. The Secretary, I know, is a very able lawyer.

I am through with this witness for the time being.

The CHAIRMAN. Mr. Sikes?

Mr. SIKES. No questions.

The CHAIRMAN. Mr. Harness?

Mr. HARNESS. I have a couple of questions.

General, would you care to tell us what research has been made and what progress has been made in developing a defense to this bomb?

General GROVES. I do not think that should be disclosed even to this committee. All I can say is that I think you know that we naturally would be interested in it and that we are not sleeping on it.

Mr. HARNESS. Would that be one of the functions of this Commission, to continue to study and develop a defense?

General GROVES. Everything pertaining to it. I would certainly feel that the Commission was decidedly negligent if it did not think of the defense as well as the offense.

Mr. HARNESS. There is nothing in the bill that directs them to do that, is there?

General GROVES. No, sir, but I feel that it is within their power. I also believe that the major defense for this will be the same type of defense as against anything else. There are two types, passive and active, and the best one is always the active.

The CHAIRMAN. Have you any questions, Mr. Pinero?

Mr. PINERO. No questions, Mr. Chairman. I only want to state that I think the United States should lead the world in the development of this atomic energy. I would rather stand on the past record of these scientists who have developed this weapon.

The CHAIRMAN. Thank you very much.

Mr. JOHNSON. In your opinion, General, does the Administrator have the same power as the Commission?

General GROVES. No, sir. He has some of the powers of the Commission, but there are certain ones that are reserved to the Commission.

Mr. JOHNSON. I see you use the words "Commission or Administrator."

General GROVES. In some instances; but the power of the Administrator is set forth in one portion of the bill.

Mr. JOHNSON. As I get your testimony, this has so many implications and is so dangerous that you cannot let it out at large; and that is why you want this type of procedure, where you can maintain secrecy and conduct experimentation?

General GROVES. And where we can make decisions quickly.

Mr. JOHNSON. If the control should get away from us you said it would result in national suicide. What do you mean by that?

General GROVES. For example, if this weapon had been developed by Germany it would certainly have been national suicide for us. The same thing might apply later. We do not know what the weapon may develop into. Until the international situation has changed, we certainly would be remiss if we did not provide for our national strength in this particular weapon.

Mr. JOHNSON. You mean that just our conduct might result in some other nation destroying us?

General GROVES. Yes, sir.

Mr. JOHNSON. It does not have any implications of danger in itself?

General GROVES. No, sir. We cannot destroy ourselves with it—that is, that we know of.

Mr. JOHNSON. This question has been asked several times, I know, but I want to see if I can get at it in another way. Last Sunday I read Mr. Byrnes' report, and you perhaps read it too. He gave the impression that these international conferences were largely at a place where they might bargain and trade. Under this bill would it be possible for the President to go to a conference in the next few months, and if he felt that he could get something that was worth while, for instance, some kind of an assurance that he thought would maintain peace perpetually or for a long time, he could trade off this secret?

General GROVES. As I said before, I cannot go into the international phases. I can only speak from the national side of it.

Mr. JOHNSON. But you sat in when they drew this bill, and you said that it contains everything you want and also that it does not contain anything you do not want. That is part of the problem that we have to pass on in passing on this bill. He can give away the secret?

General GROVES. He can.

Mr. JOHNSON. Through his representatives, and he can make up his mind to give it away for what we got back?

General GROVES. That is correct.

Mr. JOHNSON. Another thing: As I read the appointing power provided for, the members of the Commission must be confirmed by the Senate, but afterward even the President cannot remove them?

General GROVES. Yes, sir. There is a provision for that—inability to act, neglect of duty, malfeasance in office, conflict of interest, or because the continuance of the member in office would be inimical to our national interest.

Mr. JOHNSON. In other words, you think the President has the arbitrary power, if he thinks their continuance in office is bad for the public interest, to remove them?

General GROVES. I believe so. Of course, I am not a lawyer, as the chairman emphasized.

Mr. JOHNSON. Out in the University of California they conducted experiments on the breaking up of atoms. Would that type of activity by them in the future require a license?

General GROVES. Yes, sir. They are required to have a license.

Mr. JOHNSON. So that any extended experimentation by universities would require permission from the Commission? Is that a fact?

General GROVES. When you speak of the University of California, they had a tremendous project there. There was a large number of people, and they fall into the classification of what would be of military value.

Mr. JOHNSON. There are other colleges or universities carrying on a similar program today; are there not?

General GROVES. There are others that are carrying it on.

Mr. JOHNSON. And they would have to have licenses?

General GROVES. Yes, sir.

Mr. JOHNSON. Why do you think they would have to have a license?

General GROVES. If we are to maintain security we have to require that.

Mr. JOHNSON. Does it not boil down to this, that whatever the activity may be, if this Commission or the Administrator thinks that what they are doing might jeopardize the national security, they must procure a license?

General GROVES. Yes, sir.

Mr. JOHNSON. You mentioned the fact that we have to do this right now or in the next few days or weeks. From what you have said regarding the progress in other countries it may be years until they catch up with us. Why is it so imperative that we have to do this this week or month?

General GROVES. It is imperative because the project now is in the uncertain stage. It has been under very close control and responsibility. The people on the project want to know what the future is going to be so that they can decide whether they wish to remain with it. Also, from the security standpoint, we cannot get back information that is once disclosed. Any information we disclose now is disclosed forever. But the main thing is, as I stated in the introduction, that we have had very broad powers and we want to give up those powers. We would like to have a commission appointed. We would like to get the thing settled and made a going concern that is going to be a concern in the future, and not have people wondering what is going to happen. The people want to know where they can get assurance of what is going to happen. They want to know whether this thing is going to go on and who is going to run it and how it is going to be operated. We have laboratories that are being operated by universities because it was the only way we could handle it in time of war. Those universities do not want to continue operating. They have to be Government laboratories; and the people that we want to work in those laboratories want to know what the situation is going to be. At the present time I cannot give them any assurance as to position or salary beyond just the immediate future.

Mr. JOHNSON. Is it possible to divide this up and segregate those parts of it that might be useful for other purposes? For instance, the laboratory at the University of California was conducting experiments along medical lines.

General GROVES. It was; but it also cannot be separated from this. I think that is covered in the first line on page 23 [reading]:

In administering this provision, the Commission and the Administrator shall interfere to the least possible extent with small-scale experimentation in research laboratories of nonprofit institutions.

Mr. JOHNSON. All that resolves itself into the determination of one man, who is Administrator?

General GROVES. He has got the Commission there.

Mr. HARNESS. Will the gentleman yield there a moment?

Mr. JOHNSON. Yes.

Mr. HARNESS. General, you say that licenses are necessary for colleges and other people who want to delve into the realm of this science. Do you mean to say that that is to preserve the secrets that

our scientists have already discovered, or is it to protect the people of the country against some disaster that might occur as the result of further development?

General GROVES. It is to preserve the past secrets and the future secrets; and certainly if it were poorly handled it could endanger others.

Mr. JOHNSON. As I see your purpose, it is to get complete domination of this thing in the hands of the Commission and under the Federal Government?

General GROVES. Yes, sir.

Mr. JOHNSON. And that is for perpetuity, too?

General GROVES. Yes, sir.

Mr. JOHNSON. That is all.

Mr. MARTIN. General, are the penalties in section 19 broad enough to be applicable to those heretofore employed in this project?

General GROVES. Yes; they are believed to be. They are designed for that purpose.

Mr. MARTIN. That is all.

The CHAIRMAN. The committee is going to be in recess until 2 o'clock. I am sure you want to hear these famous scientists, Dr. Bush and Dr. Conant. Please be here promptly at 2 o'clock.

(Thereupon, at 12:10 p. m., a recess was taken until 2 p. m. of the same day.)

AFTERNOON SESSION

The hearing was resumed at 2 p. m., upon the expiration of the recess, Hon. Andrew J. May, chairman, presiding.

The CHAIRMAN. The committee will please be in order.

Gentlemen, Secretary Patterson will be available most any time we want to use him. We have some other gentlemen here from out of town who are busy men, and I have decided to call them next and let the Judge wait a little while and be available if we need him. Our first witness this afternoon is Dr. Vannevar Bush, Director of the Office of Scientific Research and Development. Doctor, will you come around, please, sir, and give us your statement?

STATEMENT OF DR. VANNEVAR BUSH, DIRECTOR, OFFICE OF SCIENTIFIC RESEARCH AND DEVELOPMENT

Dr. BUSH. Mr. Chairman and gentlemen, the releases made by the President and the Secretary of War on the subject of atomic energy have been so complete that I do not need to elaborate upon the history of this project or its importance for the future.

Very briefly, the work was carried on initially under the auspices of the Office of Scientific Research and Development, of which I am Director, for a considerable period, after which it was transferred to the War Department and carried on under the Manhattan district. I continued to be associated with the matter, first as Chairman of the Military Policy Committee, set up under orders from the President, which passed on the policies governing the work of the Manhattan district and before which General Groves placed his plans and program before reporting on them to the Chief of Staff. I also served as a member of the Interim Committee under the chairmanship of the Secretary of War, which advised the Secretary and the President in

regard to various aspects of this subject, such as releases to the public and the preparation of legislation.

The release of atomic energy holds enormous possibilities for the future, both for good and for evil. It appeared, fortunately, in time to bring an abrupt end to the Japanese war and thus to save a very large number of lives which otherwise might have been lost in further struggle. It was a very expensive undertaking, because of its magnitude and difficulty, but its cost has already been saved many times over, and its importance for the future renders the question of cost a matter that can now be approached with equanimity. During the war full attention was paid to the development of an atomic bomb. This was done under enormous pressure, for there was a race on with Germany, and for a long time we did not know just where we were in that race, the outcome of which might be determining in regard to the entire future history of the world. That race was fortunately won by a wide margin. However, there was no time in such circumstances to consider possible future industrial applications of atomic energy. Now that peace has returned we need to think deeply of these things.

The application of the science of atomic energy is in its infancy. No man can tell what may emerge from this vast new field during the next generation. At the time that Faraday performed his notable experiments on electricity no one could have envisaged the great power systems and communication systems of the present day. No one can tell what lies ahead in this present field, but we can be sure that the opening up of this area gives new possibilities for the human mind and that the ultimate results may indeed be very great.

On the other hand, there are no immediate great commercial applications just around the corner. It is evident that there can ultimately be applications to the production of power within the reasonably near future, but the matter has not as yet been studied sufficiently to indicate just how economical these may be in comparison with other sources of power. Study by many minds and a great deal of experimentation will be required before the possibilities of industrial application even become clear. The situation in which we are placed at the present time, therefore, is one of great potential importance, but one in which practical results will certainly not come immediately.

Nevertheless it is essential that legislation be enacted at once or with reasonable promptness for the Federal control of all phases of atomic energy. This is an art which it is very dangerous indeed to practice. Merely for the safety of the people it is essential that it be carried on only under such strict regulation as will insure that proper safeguards are always taken. This can be done effectively only if the Federal Government establishes new means for the purpose.

It is also essential that the future of atomic energy in this country be controlled in a manner having due regard to the problem of national security. We all hope that means will ultimately be found for preserving the peace of the world, but it is equally clear that at the present time this country must pay close attention to its own military strength from every angle, and the angle of atomic energy is certainly an important one. The subject of atomic energy, therefore, has both military and civilian aspects and I believe that it is wise to provide for its control by a civilian commission as is provided in the bill before you.

I have been questioned by my associates in regard to many phases of this bill, but particularly concerning the phases bearing on research and on the proper preservation of security over aspects of the subject requiring secrecy. I believe that the bill as drawn provides for both of these matters in an appropriate fashion.

In regard to research on atomic energy, I believe that the bill is particularly wise. It provides for the full control by the commission of all research wherever carried out if it is of such magnitude that the public safety or the public security might be endangered. On the other hand, it provides for regulation by the commission which will enable universities and scientific institutions generally in this country to proceed with experimentation without interference by the commission whenever the amount of energy which they release in the experimentation is so small that licensing and control are not necessary to provide for the public safety. The bill also emphasizes strongly that one object is to increase the knowledge of atomic fission in this country, and it also emphasizes that the commission should encourage experimentation for this purpose in universities to the maximum extent consistent with the controls that it is necessary it should exercise. I believe this is a wise manner in which to handle this particular matter.

Last June, pursuant to a request made of me by President Roosevelt, I submitted to President Truman a report entitled "Science—The Endless Frontier." This embodied a plan for the promotion of scientific research in this country by the formation of a National Research Foundation. I have also recommended that the Research Board for National Security, concerning which this House passed the May bill, be continued until the final form of Federal organization for research is determined by legislation. Bills incorporating the primary recommendations of my report have been introduced in the Senate by Senator Magnuson and in the House by Representative Mills. Hearings on these bills and also on a bill by Senator Kilgore having somewhat parallel objectives are now being carried on by a joint committee in the Senate from the Military Affairs Committee and the Committee on Commerce. I have been asked whether there is any conflict between this proposal for a National Research Foundation and the present bill to establish a Commission for the Control of Atomic Energy. I believe that there is no such conflict. In fact, I believe that the proposals are supplementary, and that both steps are necessary. The commission here proposed is primarily a regulatory and controlling body. While it is enabled to do research to the extent that it deems necessary, it is instructed in the bill to further as far as possible the research done by other governmental agencies and by private organizations. If a National Research Foundation is formed it will undoubtedly wish to support research in physics and in chemistry on matters related to atomic fission. In so doing, and as far as the regulations require, it will obtain the approval of the Atomic Energy Commission. I believe, however, that the National Research Foundation as provided for in the bill introduced by Representative Mills furnishes a body which will be able to further scientific research in this and other fields to great advantage, and I believe that the Commission will agree with this point of view and will support the foundation strongly in its endeavors.

Another point which has been raised is the question of security of information. This is a matter which it is very difficult to judge. It is certainly true that some parts of our information in regard to atomic fission must at the present time be kept secret, and that every possible step should be taken to insure that this secrecy is not broken. On the other hand, we all know that research and scientific advance generally prosper best in an atmosphere of freedom and complete interchange among scientists. It is necessary to provide in a wise manner for both these aspects of the subject. I believe that the bill accomplishes this. It places in the hands of the Commission the duty of determining the rules which shall apply. It places under their control for security purposes quite completely the results attained by their own efforts, or by their contractors, or by those that they may license to operate in the atomic-energy field. On the other hand, it makes it quite clear that science will still be free in universities and research institutions to carry on experimentation of such nature that the Commission does not feel that the national safety or the national security require licensing. Judgment as to how far the clamp on information, internally in this country, should continue has to be exercised at some point, and I believe that the bill wisely provides for this judgment to be exercised by a Commission, guided by the language which is incorporated in the bill.

This bill has to do entirely with the control of atomic energy within this country. There are two parts to the problem of atomic energy: (1) Internal controls and (2) international relations. The bill deals entirely with the former. We are not concerned at this hearing, therefore, with the international aspects of the subject, which the President has indicated in his message to Congress he proposes to treat as a separate matter. However, I believe that the bill is properly formulated to exercise the internal controls in such manner that they will be appropriate whatever foreign policy is finally pursued on this entire subject after due consideration.

I find the bill adequate for its purpose, and it seems to me wise in its general provisions. I hence recommend that it be reported favorably and enacted.

The CHAIRMAN. Are there any questions?

Mr. THOMASON. I suppose, Doctor, that oil would be a very necessary commodity in the manufacture of the atomic bomb, would it not, or in connection with atomic energy?

Dr. BUSH. I think it would be used, but I do not think that it could be considered a material which was essential or especially concerned with atomic fission.

Mr. THOMASON. You would almost have to have it, though, would you not, in order to carry out the manufacturing end of it?

Dr. BUSH. Yes, sir. I think you would also have to have it to carry out the manufacture of narcotics, but I do not think it would be a material that would be considered subject to the regulations of this Commission.

Mr. THOMASON. The same would be true, as suggested by my colleague, as to electricity?

Dr. BUSH. Yes.

Mr. THOMASON. The first sentence of section 3 reads as follows (reading):

The Commission shall have plenary supervision and control, so far as the jurisdiction of the United States extends, over all sources of atomic energy and over

all matters connected with research on the transmutation of atomic species, the production of nuclear fission, and the release of atomic energy.

Would oil be included in that?

Dr. BUSH. No, sir; not in my opinion.

Mr. THOMASON. That is all.

Mr. DURHAM. Dr. Bush, I understood from your statement that of course there would be a continuation of research in colleges throughout the country, and it would be on an internal basis and not on an international scale. Suppose they carry on this experimentation in colleges and a college were requested by one of our good neighbors to enter 10 or 15 students for the study of atomic energy: how are we going to do that under this bill?

Dr. BUSH. I would have no fear, sir, that the universities in this country would not keep secret any subject that they should keep secret in the national interest, whether or not they had foreign visitors or foreign students. I depend on this experience for that answer. During this war we carried on throughout this country in a very large number of universities and colleges projects of great secrecy in regard to the development of weapons. I have yet to hear of one instance where there was any serious leak of information from such a laboratory. I believe that the record of the universities in that regard has been very fine indeed, and I believe that, given proper guidance as to what should be maintained secret and what should be disclosed, you can depend upon the universities and colleges of this country to do a very good job indeed in hewing to the line in that regard.

Mr. DURHAM. Certainly we would have a different student body in peacetime from what we had in wartimes, but we might have visitors from other parts of the world, depending on how far you were getting with this experimentation in colleges.

Dr. BUSH. I hope we will go very far indeed with experimentation in colleges. In fact, that is one reason why I urge that prompt action on this bill, consistent with proper deliberation, is very essential. Many of the universities and colleges of this country are anxious to proceed at the present time with research on this subject. They do not know whether they will be allowed to proceed or, if so, in what circumstances, or whether they can gain access to materials for that purpose. We hence have a pause at the present time which will continue until this Commission is formed to give the answers; but I think that in the interest of progress in the science of atomic energy the pause should be as short as we can make it.

Mr. DURHAM. Certainly we do not want to stymie it, because some other scientist might bring out a way of developing and manufacturing which would be cheaper than what you are doing at the present time. That is a possibility, is it not?

Dr. BUSH. That certainly is. At the present time if some scientist working in this country should find out, on his own initiative and working along the usual lines, some information that was very crucial, very important, there is no law that in any way controls his maintaining that secret in the public interest; and I believe that it is essential that we should have such a law as soon as we can.

Mr. DURHAM. You do not think that this proposed legislation would have any effect whatever to stymie it?

Dr. BUSH. This bill has been drawn very carefully in the attempt to secure a proper balance between the controls essential to provide

for the safety of the people, and the freedom of inquiry which we know is the best for progress in science. This bill enables the colleges and the universities and research institutions to proceed with a minimum of control and a minimum of interference, consistent with safety.

Mr. SHERIDAN. You just stated that the universities would proceed without interference from the Commission, is that true?

Dr. BUSH. Yes, sir. The bill instructs the Commission to interfere with the research work of the universities as little as is consistent with the maintenance of proper security.

Mr. SHERIDAN. But you propose to repose in the universities a certain degree of latitude in this realm of secrecy in the progress of science, is that true?

Dr. BUSH. I believe the Commission has the entire power to determine what is the region, the area, which shall be maintained secret, but after it is thus defined, the colleges are quite free to operate outside that area.

Mr. SHERIDAN. This bill would give them that authority, would it not?

Dr. BUSH. It would give the Commission that authority, that is right.

Mr. SHERIDAN. They only have to give what information they feel is necessary to the Congress, under this bill, is that true?

Dr. BUSH. I do not understand you, sir.

Mr. SHERIDAN. This bill provides that the only report made by the Commission is to the President, and the only other information will be given—

Dr. BUSH. I do not remember the exact language.

Mr. SHERIDAN. You have stated that universities have conducted research during the war. There has been no violation of secrecy, has there?

Dr. BUSH. They have followed the rules very well indeed.

Mr. SHERIDAN. For which they are to be complimented.

Dr. BUSH. Yes.

Mr. SHERIDAN. But still you do not want to repose such confidence in the Congress of the United States?

Dr. BUSH. I think you are drawing a parallel that is not quite exact, because what I said was this, that I believed that the Commission would leave the universities free to instruct and tell the entire world in regard to the results of their experimentation whenever, in the Commission's opinion, they would not in that way jeopardize the national security. On the other hand, the question of how much information of a secret nature the Commission divulges seems to me to be an entirely different question.

Mr. SHERIDAN. But you ask that this bill be passed favorably upon by this committee, and it provides that so far as the Congress of the United States is concerned, only such information as in the opinion of the Commission should be given, will be given to that body.

Dr. BUSH. I suppose that is still true today in regard to the War Department in its relations to Congress, and I judge that the Commission, in handling, for example information that they might have about the embodiment of atomic-energy products in new weapons, would have the same relation to the Congress as the War Department would on the same subject. In other words, it would not put such information into public reports. It would confer with the appro-

priate committees of Congress with regard to information, in executive session, and the matter would be handled in an entirely parallel fashion.

Mr. SHERIDAN. But that is a supposition without foundation. The War Department has no such authority as disclosed by this bill. This goes far beyond any authority ever delegated by the Congress.

Dr. BUSH. Yes, sir; I think it does, so far as my experience is concerned.

Mr. SHERIDAN. Even the powers we gave under the Second War Powers Act to the President during the war could not exceed the authority given by this bill in peacetime.

Dr. BUSH. On the other hand, Mr. Sheridan, this country has never faced a situation like this before, or such a necessity for rigid controls. That has never been so insistent as it is here. I certainly, as a citizen living in this country after the war, want to see rigid Federal control of what is done in this area. I certainly do not wish to think that some group of experimenters might set up a laboratory half a mile from my house and family and experiment on atomic energy carelessly, poison the neighborhood, or possibly blow it up. We have never before had a thing of this sort to control. Whether it needs exactly these powers, whether some go too far and some not far enough, I would not attempt to say. But, in general, I say we are faced with a very difficult thing to control. It must be controlled for the public safety, and I would create a very strong commission to do it.

Mr. SHERIDAN. You are aware of the fact that there were never such powers in this country as it is proposed to give to this Commission?

Dr. BUSH. But if Congress can set up such a Commission, it can also terminate it. If it can give these powers, it can also take them away.

Mr. MARTIN. Is this bill broad enough to cover related fields of development in this line? Suppose your further experiments develop some related product that might not be technically classified within the definition of atomic energy as described in this bill: Is this bill so drawn as to reach out and include those, or would they call for new legislation?

Dr. BUSH. That would call for new legislation. This bill, so far as its definitions are concerned, is very carefully limited to the fission of the nucleus and the release of energy by atomic fission, and nothing else. Perhaps new ways of doing it may be discovered in the future.

Mr. MARTIN. Will this bill cover all those methods?

Dr. BUSH. If it is a method of releasing large quantities of energy by nuclear fission, by a new method not now understood, yes; it would cover it.

Mr. MARTIN. If they got over into some family of cousins of this project, you would need new definitions?

Dr. BUSH. Yes; but I am well assured in my own mind that that will not occur for some time to come.

Mr. MARTIN. I was interested in Mr. Thomason's questions about oil; and as I read section 7 on the power to acquire property, you have a very broad grant of power there; and the last clause of section (a) relates to contracts, agreements, leases, and rights which, in the judgment of the Commission, are peculiarly related to the transmutation of atomic species, the production of nuclear fission, or the release of atomic energy.

I believe that is the limitation placed on the grant of power for taking over property?

Dr. BUSH. That is right.

Mr. MARTIN. That leads me to ask this question, in view of my question this morning. Is the production of electric energy so classified that the bill would authorize it to be taken?

Dr. BUSH. I cannot see how it could possibly be, under the language that you have just cited.

Mr. MARTIN. I am interested as to your idea of how far this limitation clause limits the authority that the Commission would have to take over.

Dr. BUSH. Suppose I take your own example, electric power. That is certainly not peculiarly related to the transmutation of atomic species. It is related to many other things in addition. Certainly, therefore, the Commission has by this language no authority over electric power plants generally.

Mr. MARTIN. That is what I had in mind.

Dr. BUSH. I think that is clear.

Mr. STEWART. Dr. Bush, do you not think that the average Congressman is as trustworthy with regard to keeping secrets as our foreign professors who participated in these experiments?

Dr. BUSH. My experience with both has been rather pleasant. During the war I think our preservation of secrecy was extraordinary.

Mr. SHORT. More miraculous than the bomb itself?

Dr. BUSH. I think it was extraordinary. There were no leaks in spite of the fact that very many people had to know a good deal about it, including foreign scientists who worked with us and including Members of Congress.

Mr. JOHNSON. Dr. Bush, how long have they been experimenting with atomic energy in this country?

Dr. BUSH. It depends, Mr. Johnson, on how you define it. If you define it broadly, it is 50 years. If you define it narrowly, then only since 1939.

Mr. JOHNSON. They broke up the atom before the war; did they not?

Dr. BUSH. Yes; but there was a certain thing that happened that has to be remembered. The atom had been broken before that, but not with the release of substantial amounts of energy. It was only in 1939 that we got the key which showed how, by the breaking of the atom in the chain reaction, large amounts of energy could be released. And it is for that reason that all of this came to a head about that time.

Mr. JOHNSON. When was your group organized that you were the secretary of during the war?

Dr. BUSH. Shortly after those important discoveries in 1939 President Roosevelt set up a committee to study the question of whether the Federal Government should become active in this field or not. That was under the chairmanship of Dr. Briggs of the Bureau of Standards. In June of 1940 the National Defense Research Committee was formed, and that committee was transferred to its jurisdiction. Experimentation was continuous from the time that Dr. Briggs' committee was formed, on a very small scale at first, on an enlarged scale when the National Defense Research Committee was formed, and on an increased scale until 3 years ago when the matter was entirely turned

over to the War Department, except that the Office of Scientific Research and Development continued to do some auxiliary development in aid of the War Department's main effort.

Mr. JOHNSON. When you say "research," do you mean just on this atomic problem, or research generally?

Dr. BUSH. No; I am talking about this problem.

Mr. JOHNSON. At that time they conceived the idea that they could harness this energy, put it into a capsule and use it as a bomb?

Dr. BUSH. That really occurred in May of 1939. At that time information was brought to this country of experiments which showed that the atomic nucleus could be split with the release of large amounts of energy. Before that time no physicists knew how to make a bomb. After that time any competent physicist in the field of atomistics knew, theoretically at least, how to go to work to make a bomb.

Mr. JOHNSON. When was the Manhattan project set up?

Dr. BUSH. Three years ago, approximately.

Mr. JOHNSON. In 1942?

Dr. BUSH. Yes, sir.

Mr. JOHNSON. At that time you had thoroughly in mind that you were trying to harness that energy to use it in the war?

Dr. BUSH. At that time we had gone a long distance down that path. We had gone so far that the matter had come to the point where full-scale construction was needed, and it was at that point that the matter was turned over to the War Department.

Mr. JOHNSON. Was the nucleus of your idea really developed by civilians outside of the Government service?

Dr. BUSH. The basic ideas behind this were developed all over the world and over a considerable period of years. The work from 1940 to 1942 was in the Office of Scientific Research and Development, which is a civilian agency, and the work was carried on in various universities. After the project was turned over to the Manhattan district the same civilian scientists continued their work under the auspices of the Manhattan district, and, of course, their work was combined with that of engineers and industrialists, and so on.

Mr. JOHNSON. You mentioned a moment ago that there came to this country this idea. Where did it come from?

Dr. BUSH. It happened that crucial experiments on this were performed in Europe. In the science of atomistics there are a number of important milestones, most of which have been developed on the other side of the water. This country has contributed something, but I think in that field most of our physicists would testify that prior to this war we leaned heavily on Europe for our basic scientific research and development in this field—In France, Germany, England.

Mr. JOHNSON. Is the ore mixed with other metals, or is it found free?

The CHAIRMAN. I wonder if that is not going a little bit too much into detail?

Mr. JOHNSON. This is a very important bill, Mr. Chairman. It is just a preliminary question to something else.

Dr. BUSH. I do not think there is anything secret about that, Mr. Chairman.

Mr. JOHNSON. Any question that I ask you, if you think it is improper to answer it, just frankly tell me so.

Dr. BUSH. Shall I go ahead?

The CHAIRMAN. Yes. Use your own judgment.

Dr. BUSH. It is found as ore, as many other metals are.

Mr. JOHNSON. Is it found with coal, silver, or iron?

Dr. BUSH. It is found principally in pitchblende, which has been for many years the principal source of radium and is mined for that purpose. Uranium and thorium have been known for many years.

Mr. JOHNSON. I ask that question to find out if it exists in the strata of the mountains out in my country, where we have all kinds of ores.

Dr. BUSH. I think there is probably some in your country, but I suspect it is there in somewhat diluted form.

Mr. JOHNSON. I just wanted to see how far the Government might go in taking over things. What do you think of the future prospects of this? Does it have more of a future in its utility for civilian use or for military use?

Dr. BUSH. The immediate use is a military use. As I said in my opening statement, there will be, in my opinion, ultimately very important results in this matter of a commercial nature. But I put that a generation ahead, with some possibilities of some results in 10 years. The great, and the most important, application is the military application. The first application was to a bomb which ended the war. You will note that this bill is drawn with that strongly in mind. In the preamble, for example, one of the objects is to secure the national defense. There is a provision here that—

The primary objectives of all action taken under or pursuant to this act shall be the promotion of the national defense, * * *

Some of the members of the Commission may, under the bill, be officers in the armed services. I have no doubt that the Commission will and should pay a great deal of attention indeed to the military aspects of this subject in the years ahead of us.

Mr. JOHNSON. Is it your view, then, that it is so dangerous to our security and our national life at the present time that we cannot afford to let it get out of control; that some power, either military or otherwise, must control it absolutely?

Dr. BUSH. I think it should be controlled absolutely. I would rather see narcotics sold without limit and without control.

Mr. JOHNSON. Is it your view that you should trust to a university to experiment with something that may get out of control and may injure people?

Dr. BUSH. I fear that if there were no control of experimentation, some well-meaning but careless or ignorant people might perform experimentations that might be very dangerous indeed to the national safety.

Mr. JOHNSON. Do you mean that the experimentation itself will be dangerous, or that it will get into the hands of some hostile persons?

Dr. BUSH. The experimentation itself can be very dangerous indeed, if a substantial amount of atomic energy is released.

Mr. JOHNSON. During the development of this problem was there any loss of life?

Dr. BUSH. I believe there was no man lost by any accident inherent in the nature of the work. There were some men lost on construction, but they were construction accidents. I do not remember any instance of any man being killed by reason of the fact that he was

working on atomic energy as contrasted with working on something else.

Mr. JOHNSON. One other question. When you were up here talking about the National Academy of Sciences, in connection with the bill that we had here, did you have some of these things in mind then?

Dr. BUSH. I have not had anything more prominently in my mind in 5 years.

Mr. JOHNSON. Will the other bill be strong enough and broad enough to handle this?

Dr. BUSH. We have, sir, at least four bills on that subject at the present time.

Mr. JOHNSON. I am talking about the one we had before our committee.

Dr. BUSH. You had before your committee the May bill. It was set up to perpetuate the Research Board for National Security. That Board is in existence. It is at the present time being asked by the Secretaries of War and Navy to make a very comprehensive study of the problem of research on military weapons; and I believe that it can perform no greater service than to make that study at the present time. However, we have all understood that that organization was set up as a temporary organization to fill a gap; and that ultimately we should have, by some form of legislation, a permanent agency for research in this country; not as a continuation of the Office of Scientific Research and Development but to perform in peacetime those necessary functions in research in which the Federal Government should directly participate. There are several bills for that purpose. I recently made a report on the subject. My particular recommendations have been embodied in bills introduced by Senator Magnuson and Representative Mills. I hope those bills will be enacted, because I think we need that type of organization in this country. But I do not believe that there is any conflict between the foundation we would have then established and this Commission, for the reasons that I have stated.

To go into that for just a moment, this Commission is primarily a controlling and regulatory body, which will be created to handle these plants, to do the development that is needed in those plants, to control, license, and so forth. It is enabled to do such research as in its opinion it should carry on. But I believe that if a Federal research agency is set up for the explicit purpose of furthering scientific research in this country, the Commission will be very glad to lean upon that organization to carry on those parts of the research that are fundamental.

Mr. SHORT. But the chief functions of the Commission are administrative rather than experimental?

Dr. BUSH. Yes, sir. In my opinion, the chief objects of the Commission are to regulate and to control.

Mr. JOHNSON. While this bill is for internal security, you realize that you could have a situation where the President could give away the secrets if he wanted to?

Dr. BUSH. You have that situation now, so far as I know. I do not see that this bill will affect that one way or another. This bill says specifically that the Commission shall do nothing of that sort. That is limiting on the Commission. It says nothing else about the subject.

Mr. ELSTON. Doctor, it seems to me that our greatest concern is not so much the developing of atomic energy in this country as the developing of it in other countries. This bill does not regulate that at all. Why do you feel, for example, that American industry cannot be trusted with the development of atomic energy as the colleges and universities?

Dr. BUSH. I did not say so, sir.

Mr. ELSTON. You said you had all faith and confidence that the colleges would go ahead and develop this, under proper licenses, and that you had no fear that the personnel of the colleges, either the student body or professors, would reveal any secrets or do anything that would be detrimental to this country? Why cannot the same thing be done in private industry?

Dr. BUSH. It can. You are the first one that asked me about that. Now that you have brought it up, I would say also that American industry has a very fine record in this war in having kept its secrets well. It has certainly demonstrated during the war that it can be trusted with secrets.

Mr. ELSTON. Do I understand that the greatest fear is that if this is developed without all this grant of power people might be injured by dangerous experiments? Or just what is your fear?

Dr. BUSH. Well, there is plenty to fear. One fear that I have is that someone, thinking that he had a new idea on this subject, might start experiments in an attic with the idea that he would develop a new commercial process, and the result might be that he developed so much radioactive energy from this fission process that he would sterilize, perhaps, all of the passers-by. That is entirely possible. I think that sort of thing needs to be regulated by the Federal Government.

Mr. ELSTON. We now have bodies which regulate communications and everything of that kind, but we do not have to resort to any extreme grant of power as we do in this bill in order to have the kind of control you just mentioned.

Dr. BUSH. Communications, Mr. Elston, have their danger; but it is danger of a different order and nature from the dangers involved here.

Mr. ELSTON. Persons may experiment with electricity and with other things that accomplish the result you speak of?

Dr. BUSH. In experimenting with electricity they might possibly electrocute themselves. I can conceive that they might kill one or two people, but I see no possibility that anyone experimenting with electricity could blow up a section of the town or poison a whole neighborhood, and I do see those possibilities here.

Mr. ELSTON. You say it is impossible to regulate it except with these extreme and unprecedented grants of power?

Dr. BUSH. I say that I believe that in the regulation of a thing that is as important and dangerous as this, we need to be sure that the commission charged with the job of regulating has ample powers with which to do the job; and if we are going to err on either side I would err on the side of giving them too much power rather than too little.

Mr. ELSTON. You realize, of course, that this bill completely nationalizes the use of atomic energy?

Dr. BUSH. Yes, sir. That is the intention.

Mr. ELSTON. For commercial purposes as well as for purposes of national security?

Dr. BUSH. It places all commercial operations under Government license in this field; yes, sir.

Mr. ELSTON. Completely and absolutely?

Dr. BUSH. Under Government license; yes, sir.

Mr. ELSTON. Was there ever a time when it was necessary to place any other type of energy under the same rigid controls?

Dr. BUSH. Well, I do not think anyone can manufacture military explosives in this country without controls; but a military explosive is a very gentle thing compared with this explosive.

Mr. ELSTON. The question is whether you have to completely nationalize its control in order to have proper control.

Dr. BUSH. I think you have to.

Mr. ELSTON. Take oil, for example. You could not conduct the war without oil; yet we never attempted to completely nationalize the control of oil, and we got along all right, did we not?

Dr. BUSH. Yes; but you have long controlled narcotics by Federal control which is very rigid; and there are other things that affect the public safety which the Federal Government controls.

Mr. ELSTON. We do not control narcotics by any different method than you would control any other crime; that is, by enacting a statute which makes the use of narcotics an offense.

Dr. BUSH. Without a license. That is right.

Mr. ELSTON. You did not have to completely nationalize anything in order to accomplish that.

Dr. BUSH. I think the conditions are fairly parallel. Under this bill an industry can develop, when the time comes, atomic energy for commercial purposes. It can do that in a commercial manner, provided it is licensed to do so and, under the license, inspected in order to be sure that it is not endangering the public safety.

Mr. ELSTON. Under this bill could you grant to one company, say, General Motors, a license to experiment in the development of atomic energy, but deny a license to Chrysler?

Dr. BUSH. That is right; you could.

Mr. ELSTON. Do you think any board should have that power?

Dr. BUSH. Well, I think the board is bound to have that power. Someone is bound to choose which companies can be relied upon to do this well, which companies that wish to do it. I would depend upon having a Commission of such standing that they would use no discrimination that would be unfair; but they certainly must be enabled to use such discrimination as is necessary to promote public safety.

Mr. ELSTON. Suppose a company that claimed it was being discriminated against wanted to appeal from a decision of the Commission; is there any appeal under this bill?

Dr. BUSH. I do not see any specific provision for it.

Mr. ELSTON. You think that is a good idea?

Dr. BUSH. I see no harm in it.

Mr. ELSTON. There is no opportunity for appeal to the court on the ground that the Commission has exceeded its authority or abused its discretion?

Dr. BUSH. There is always a right of resort to a court if there is an abuse of authority or acts not contemplated by law. In this case

there is no need for special provision for this reason: What injury is being done to a company if it is not allowed to appear in this field? This entire field was developed with Government money and at Government expense. As it stands at the present time it was wholly put in its present situation by reason of experimentation carried on with Government funds to the extent of a very large amount of money indeed. If some company is now denied the right to appear, if some group wishes to utilize this knowledge but is denied the right to do so, nothing is being taken from it.

Mr. ELSTON. Yes, something is being taken from them, and that is their opportunity to develop an energy which would be of incalculable value to industry and to the Nation. That is a lot taken from them.

During the war private industry experimented with all types of weapons, with all types of explosives, and there was no control, was there?

Dr. BUSH. There was very rigid control, of course.

Mr. ELSTON. So far as development was concerned?

Dr. BUSH. Yes, sir.

Mr. ELSTON. What controls were placed on them?

Dr. BUSH. The controls exercised by my office were as complete as this: Any contract which we entered into was entirely under the supervision of the scientific officer named by me for that purpose. The contractor performed his work at all times subject to the full knowledge and approval of that officer, and there was always provision in the contract for termination on 30-days notice of any contract.

Mr. ELSTON. That is an entirely different thing. That is where there is a contractual relationship between the Government and the party where the Government was paying the bill.

Dr. BUSH. That is the way all research on weapons was conducted during the war, which I thought was your question.

Mr. ELSTON. Any company that was not under contract had a right to conduct any experiments it saw fit?

Dr. BUSH. I do not know of any companies that were working on the development of weapons during this war except under Government auspices.

Mr. ELSTON. That was because we needed them all; but this would deny them that right.

Dr. BUSH. Except under license, which I judge the Commission would exercise with due discretion and due fairness.

Mr. ELSTON. You do not know that it would be due discretion or that it would be fair.

Dr. BUSH. There is no guaranty of fairness, sir, except to get a commission of the highest possible caliber.

Mr. ELSTON. We provide for appeals to our courts of appeal, not because of unfairness but because they might be wrong.

The CHAIRMAN. Let us not argue with the witness. Ask him questions.

Mr. ELSTON. He is getting along all right. We will not have any trouble. It is very interesting to get his viewpoint about these things.

Now, Doctor, Mr. Johnson asked you about control over the sources of atomic energy. Those sources are very vast, are they not?

Dr. BUSH. You mean the extent of ores and materials?

Mr. ELSTON. The sources of atomic energy.

Dr. BUSH. The ultimate source is the material.

Mr. ELSTON. Those materials are what?

Dr. BUSH. There are only two named here, uranium and thorium.

Mr. ELSTON. But it extends to ores?

Dr. BUSH. The ores of those materials.

Mr. ELSTON. Does it extend, for example, to coal?

Dr. BUSH. No, sir.

Mr. ELSTON. As to any other ores or anything else that it did extend to, this Commission would have control over it, would it not?

Dr. BUSH. Yes, sir.

Mr. ELSTON. Complete control?

Dr. BUSH. Yes.

Mr. ELSTON. Although those same ores might be used for countless other purposes?

Dr. BUSH. No, sir. I know of no other use for uranium ore, except this, for which we see any commercial importance or significance.

Mr. ELSTON. Are they not experimenting to see whether or not this atomic energy may be gathered from other things?

Dr. BUSH. Oh, yes.

Mr. ELSTON. So it might be found in coal or in oil or other things?

Dr. BUSH. I think it is exceedingly improbable, sir.

Mr. ELSTON. But if you do not experiment, you are not going to find out, are you?

Dr. BUSH. That is right.

Mr. ELSTON. If it did develop in something else, this Commission would technically have control over those materials?

Dr. BUSH. Yes, sir; if you found other materials that were a source of power by the process of atomic fission, this Commission would have control. In my opinion, it is exceedingly improbable that other materials than uranium and thorium will be found to have those properties.

Mr. ELSTON. Do you know of any reason why the War Department and the Navy Department cannot proceed to conduct experiments just the same as they did during the war in the development of the atomic bomb? Why is it necessary to take it away from those services and put it into the hands of a civilian body?

Dr. BUSH. The War Department itself has recommended transfer to a civilian body. I think that is a very wise move on its part, and I think that really it is fortunate in having had a Secretary of War, and having him replaced by another Secretary of War; both of whom took such a broad-minded view as they did toward this subject. The War Department itself wishes this transferred to a civilian commission, because it believes, and I agree, that that is the proper way to control it in peacetimes. I thoroughly agree that it should be a civilian commission. I hope and trust that that Commission will not neglect the military aspects of this subject. I am sure they will not.

Mr. ELSTON. The War Department is subservient to this Commission. As a matter of fact, this Commission could refuse the War Department and the Navy Department the right to go ahead with experiments in the development of this, could it not?

Dr. BUSH. I believe it could, as far as this particular type of weapon is concerned.

General ROYALL. Except in time of war, or with the approval of the President.

Mr. ELSTON. You do not wait until the war starts to develop your weapons. You develop them in time of peace.

Dr. BUSH. I should have no fear, sir, that this Commission would prevent the War Department from experimenting.

Mr. ELSTON. But the War Department and the Navy Department would have to get permission from this Commission in order to proceed to develop any weapons, growing out of atomic power and energy?

Dr. BUSH. That is right.

Mr. ELSTON. Do you think that is a wise provision?

Dr. BUSH. I do not think it is necessary to put in the bill that the Commission must extend that permission. I cannot conceive that the Commission would deny permission to the War Department or the Navy Department to continue research on important atomic weapons.

Mr. ELSTON. The War Department has to come to the Commission to get the permission?

Dr. BUSH. I think that is very wise, in order that the Commission may have in its hands the entire information, the entire knowledge of what is going on, in order that it may properly correlate experimentation in military fields with experimentation aimed at ultimate commercial ends.

Mr. ELSTON. Do you subscribe to every part of this bill?

Dr. BUSH. Yes, sir.

Mr. ELSTON. Even this part that gives the President the right to give away atomic bomb secrets?

Dr. BUSH. I do not find that in the bill, sir.

Mr. ELSTON. Let me find it here. It says he may give it to other nations.

Dr. BUSH. I did not find that in the bill.

Mr. ELSTON. It is here.

Dr. BUSH. I find in the bill a statement that the Commission shall not divulge this information. I find nothing in the bill that says anything about the President.

Mr. ELSTON. There is a provision in the bill, but I cannot find it at the moment. But, if it is in here, do you think that is a good provision?

Dr. BUSH. I would call that a hypothetical question.

Mr. ELSTON. It is here all right.

Mr. ARENDS. The President could divulge it now if he wanted to.

Mr. ELSTON. This is the provision: "The Administrator is authorized"—I am reading from the summary, now.

Dr. BUSH. Where are you; on what page of the bill, please?

Mr. ELSTON. It is page 19. It is section 11:

(a) The Administrator is authorized to license any or all of the property available to the Commission, without regard to the provisions of the Surplus Property Act of 1944 or of any other statute, to any person or Government agency for (1) research and experimentation in nuclear fission or the transmutation of atomic species; (2) the development, exploitation, and use of processes or methods for the release of atomic energy; (3) any use of such property where it is deemed advisable for the purpose of this Act to retain control or supervision in the Commission over the property, its utilization, or disposition; or (4) any other purpose incidental or related to the purposes of this Act. No such license for purposes (1), (2), or (3) shall be given by the Administrator to a foreign government or any person who is not under and within the jurisdiction of the United States, without the approval of the President of the United States.

Dr. BUSH. Yes, sir; and I say that that is limiting upon the Commission, and in no way creates powers of the President of the United States.

Mr. ELSTON. But if the President of the United States and this Commission decide they want to give the secrets of the atomic bomb to any foreign country, it may be done.

Dr. BUSH. That is right, and the President can do it now without the Commission.

Mr. ELSTON. Do you not think it would be better if it were with the permission of Congress?

Dr. BUSH. I do not think that subject is before us, sir.

Mr. ELSTON. You said you approved of every paragraph of the bill.

Dr. BUSH. The bill has to do with internal control, sir, not with foreign relations.

Mr. ELSTON. This part deals with foreign relations, the part I just read. The question is whether you do not think that it is a wise provision that that be vested in Congress.

Dr. BUSH. I think it would be very unwise, sir, to deal in this bill with all of these difficult questions of foreign relations. The President has said that he is going to send a separate message on that subject. That is a very important matter indeed, which will require a great deal of discussion and thought in this country. I believe that this bill ought to be concerned with internal controls, that we ought to get it into operation for the internal controls, for which we need it very, very much indeed, and then we should approach the whole problem of foreign relations deliberately and properly, but I think it would be a great mistake to confuse this bill with that subject and thus to hold it up for a long time.

Mr. ELSTON. Aside from making appropriations and passing this bill, Congress has nothing to do with the whole matter of atomic energy, has it?

Dr. BUSH. No; but that is a very large exception, sir, as I know very well.

Mr. ELSTON. All right, that is all.

The CHAIRMAN. Mr. Holifield, have you any questions?

Mr. HOLIFIELD. I would like to ask Dr. Bush a question.

This question of national control has been discussed, Dr. Bush. In your opinion, if national control were vested in the Federal Government, would it not tend to prevent a monopoly of the use of it by any private patentee of any particular process? In other words, if research were done by any individual industrial company, that research would be made known to this Federal body, and any corporation in the United States that could come with clean hands before that Commission would have a right to use that knowledge where, if the secrets of the atomic power and energy were developed by an individual corporation without governmental control, they could so control it through the patent laws that it would automatically become a monopoly and therefore work a discrimination on any other corporations that wanted to use it.

Dr. BUSH. You will notice that this bill provides very definitely that the Commission can take over any patent in this field. I think that that is a wise provision. It would be very unfortunate, I think,

if we had a race among industrial organizations in this country on a patent basis for control of a process of this magnitude and importance.

Mr. HOLIFIELD. I agree with you perfectly, and it seems to me that so far as widespread commercial use is concerned of any of the benefits of this energy, it is more liable to accrue under a Government licensing system than under a private patent system, because through private patents monopoly is created, and discrimination against wide diffusion is also created.

Dr. BUSH. Of course, I am a great believer in the patent system, and I think it has been of enormous benefit to this country in times past, but I do not believe that it ought to operate in this field.

Mr. HOLIFIELD. In dealing with this we are not dealing with oil or coal or something that does not have within itself an inherent danger to civilization.

Dr. BUSH. No; and again, we are not depending here upon the initiative of industrial concerns to break new ground and open up new areas to anywhere near the extent that we are ordinarily in a new field, because Government has already broken the way.

Mr. HOLIFIELD. And is it not true that under Government supervision and financing we will get further in research and development of this thing, because Government, after all, is the only one that is financially able to go into this field and do it, and, therefore, that will be the quickest way to bring the benefits of this to the domestic scene?

Dr. BUSH. I think so, although let me repeat again that I think the time is still quite far distant when there will be any substantial influence of the use of atomic energy upon your daily life or mine. I think the potential importance is great, but the time before that comes into effect is long.

Mr. HOLIFIELD. I want to refer to one of the first clauses here in the bill, in which it says "insure the national safety." Can you conceive of us securing the national safety without cooperation between this Commission and the War and Navy Departments?

Dr. BUSH. No; I cannot.

Mr. HOLIFIELD. The question was brought up that you had a right to withhold this, but if you followed out the purpose of this bill, to insure the national safety, you would automatically cooperate with the Army and Navy and other defense agencies.

Dr. BUSH. The language runs all the way through the bill that indicates that it was expected that this Commission will further the military development of this weapon.

Mr. HOLIFIELD. We are dealing with a subject that is so big, and of such pioneer impact, that the ordinary laws relating to commerce, patents, and so forth, must be conceived in their relative insignificance with the subject under discussion.

Dr. BUSH. We are entering a new world. We are entering a new world that is very different from the one from which we emerged.

The CHAIRMAN. Any further questions, Mr. Price?

Mr. PRICE. No.

The CHAIRMAN. Dr. Bush, I want to make a statement here for the record, to the effect that this committee on two occasions passed legislation completely nationalizing one industry and taking it over. That is the helium industry; and in addition to that, it passed an act

before we even got into war prescribing a license system for scrap iron and steel shipments to foreign countries, neither of which was anything in comparison with this.

Thank you very much, Dr. Bush.

Now, gentlemen, we are favored with the presence of Dr. James B. Conant, the president of Harvard University. Dr. Conant, we will be very happy to have you discuss this subject with us, and appreciate having you here.

**STATEMENT OF DR. JAMES BRYANT CONANT, PRESIDENT OF
HARVARD UNIVERSITY**

Dr. CONANT. Thank you, Mr. Chairman.

Mr. Chairman and members of the committee, I shall try and make my remarks as brief as possible.

Together with Dr. Bush and as his deputy, I was associated with the early days of the development of the atomic bomb, when this work was done as part of the Office of Scientific Research and Development. Later I had the privilege of assisting General Groves in connection with certain phases of that vast undertaking, which he so successfully brought to a dramatic conclusion. I was also a member of the interim committee which prepared in the first instance the legislation which is before you.

I should like to associate myself with Dr. Bush in the statement which he has made to you. The need for this legislation, as has already been said, is obvious. The bill has been drawn with great care, taking into account the point of view of the type of people who will be affected by it: scientists, engineers, business executives, administrative heads of universities, and nonprofit scientific institutions. I think all that I could add to the discussion in these few remarks of mine is to try and emphasize two points brought out by Dr. Bush; first, the need for the extraordinary powers which are to be given to this Commission, and they are very extraordinary and unusual, as has been brought out in the questions from this committee; and second, the need for prompt action.

Speaking to the first subject first, I should like to call the attention of the committee to the first section of this bill, because it seems to me that has not been emphasized enough, perhaps, in the discussion, Findings and Declaration of Policy, section 1. The second sentence says—

The proper development and utilization of such energy will advance the national welfare, secure the national defense, insure the national safety, and promote world peace, to an extent and by means which cannot now be measured. The misuse of such energy, by design or through ignorance, may inflict incalculable disaster upon the Nation, destroy the general welfare, imperil the national safety, and endanger world peace. In the highest national interest, and to protect the national existence, it is essential that all further development and exploitation of this newly tapped source of energy be centrally directed and controlled for the benefit of the entire Nation.

It is very difficult, gentlemen, to one who has been so closely associated with this project so long, to try to convey to you my feeling as to the importance of those few sentences which I have read. As Dr. Bush has said, we are entering into a new world. Nothing like this has happened in the course of science or invention, unless it

be the invention of fire itself in prehistoric times. This is an extraordinary bill, drawn for extraordinary circumstances. It is not just another commission.

Perhaps you could realize the potential dangers to the Nation—the potential good, also—for civilization that may be involved in this tremendous energy, only if you had been, as I was, at the test of the bomb at the Alamogordo Air Base on that morning in July, and seen the effect, that tremendous illumination that burst all over the sky, which so surprised even those who had been anticipating the explosion and knew all about it in advance.

We are dealing here with something that is so new, so extraordinary and so powerful, gentlemen, that I, for one, feel that we are justified in setting up a commission with equally extraordinary powers.

Second, as to the need for prompt action, I hope this bill will be passed by both the House and Senate and made law as soon as possible, for I know from personal observation with the scientists with whom I have been associated in connection with my assisting General Groves, the present state of unrest and uneasiness which exists throughout the project, and which is losing us time and monumental effort. It is costing the country, from the point of view of getting ahead in further development of this weapon, and from the point of view of cutting down the time, whether 10 years or how long, the time when this energy can be used for peaceful purposes. There is also the possible loss of security. Present regulations under which the Manhattan district project is operating are based on war powers and do not give so much security on information as I think we should have, and I feel sure that this bill would provide it if it were passed. There is more of a chance of the secret's leaking away to some other country than if this legislation were now law.

And then there is the possibility—I do not know how great—that as long as the situation is in its present fluid and uncertain state, with the knowledge that this can be done, and published, of course, as a result of the two bombs, someone can initiate private research along these lines and step into a situation through patents or control of a certain know-how without the Government's knowing it, and perhaps jeopardize security, perhaps secure an unfair advantage.

Finally, there is the whole situation in regard to the basic research, the scientific knowledge in our universities. As Dr. Bush pointed out, this whole bomb was possible because of certain fundamental discoveries in basic physics which were made by men all over the world, in the laboratories of physics and chemistry, and it is that basic knowledge which must be extended in this country if we are going to progress in the use of atomic energy for peacetime purposes.

At present every university laboratory which is concerned with this subject, and they would all like to be, is in a position of stalemate. They cannot move; they do not know what the Government policy is going to be. They are not sure that the Government is going to allow any experimentation. I can illustrate it by a personal story, if I may.

One of the brilliant young men in this project who would like to devote his life to this subject, and who might make great advances if permitted to continue, said the other day that he was not at all sure he was going into university work. He thought he would go into

industry in another field, because he said the Government has not declared that it is going to do this work and, he said, "What is the use in my working on a subject if the Government will not let you do anything about it?" That reflects the point of view of a certain number of people.

So I sum up, gentlemen, by saying that I feel that the extraordinary powers granted to the Commission are justified by the extraordinary nature of the situation, and urge you to take as prompt action as you can.

That is my statement, Mr. Chairman.

The CHAIRMAN. Thank you very much, Dr. Conant.

I would like to say for myself, and speaking I think for this committee, that they are awfully proud of our country, with its scientists that have been able to accomplish so much in advance of our enemy. I can remember when I was a small boy, the first weapon I ever bought was a bowie knife. That was a two-bladed knife with a horn handle, and it was made in Germany. Ever since that day I have been led to believe that the greatest scientists of the world were in Germany, and they were ahead of all the rest of the world. I think now we have outclassed them through the leadership of yourself, Dr. Bush, and the War Department.

Dr. CONANT. Thank you.

The CHAIRMAN. Are there any questions?

Mr. CLASON. What type of commission organization will you have in the event that this becomes law?

Dr. CONANT. I really could not tell you. Do you mean the details of how the Commission would operate?

Mr. CLASON. No; how large an organization would be necessary to carry out the purposes of this bill?

Dr. CONANT. You really could not answer that until you learned how the Commission is going to decide a number of fundamental problems. It would have to take evidence from the scientists on the job. You will understand that my connection is such that I have been in touch with the scientists who know this sort of thing. If I were sitting on the Commission, for example, I should want first of all to find out what the various scientists in charge of the different compartments of the work to be done said should be done next, see what their budget was, the size of the plant, what is their next problem. I do not have the evidence on which to base an answer. I doubt if there is evidence available.

Mr. CLASON. How many persons have been employed in the development of this atomic bomb?

Dr. CONANT. I am afraid I do not know that. General Groves would know it. I do not. It is a very large number. It has been published. There is a break-down into scientists, technical men, assistants, operators, and so on. It is many thousands, I suppose.

Mr. CLASON. Would you assume that the properties which are now used in connection with the development of the atomic bomb would remain in Commission in the development of the atomic bomb further, and other uses for atomic energy?

Dr. CONANT. That I think you would have to tell by weighing the efficiency of the different plants and methods. It has already been stated in a public release that there are several ways. One would

have to make a study of that, and I could not answer your question in advance of making such a study.

Mr. CLASON. As I understand it, the important elements are two, both ores; is that right?

Dr. CONANT. Those two ores are very important at the present status of the work. That is correct.

Mr. CLASON. As I get the power of condemnation on page 15, they can condemn minerals, metals, ores, and other substances, and materials, real property, and everything. They could take over the entire field of petroleum, on the theory that this oil is necessary to run the machinery to run the plants that run the atomic energy.

Dr. CONANT. Not if I read the bill correctly. It is line 10 on page 15, is it not, that determines the powers of the Commission in that regard? They can do the things you mention which, in the judgment of the Commission, are peculiarly related to the transmutation of atomic species, the production of nuclear fission, or the release of atomic energy.

Mr. CLASON. In other words, the Commission is the sole judge. There is no court that can pass upon it whatsoever; there is nothing that you can say that you can take to a higher tribunal. They can decide in their best judgment that they ought to take over helium or something else. They probably would not start with oil, because that would be obviously a very large and important segment of our domestic economy. But they might very well commence with going into other fields, on the theory that there might be atomic energy involved, and there would be no check on this Commission at all.

Dr. CONANT. I wish you would ask a lawyer that question. I am told by those who studied this that there would be a check, that you could come into court if you felt the Commission were trying to take over something that was not peculiarly concerned with the transmutation of atomic energy, and you would have a hearing, and thereafter it would be for the court to determine whether the judgment of the Commission had been reasonably carried out.

The words "peculiarly related to the transmutation of atomic species", if interpreted correctly, would enormously limit the field and would rule coal and oil and all those things out completely.

Mr. CLASON. You do not think there would be any possibility of oil or coal being included?

Dr. CONANT. None. I think there is a very important, and I believe sufficiently binding limitation, but of course on the law I bow to the opinion of lawyers.

Mr. CLASON. In this bill, will you tell me what the relationship would be between the Government and institutions like colleges? I do not mean research laboratories of private individuals, but, on the other hand, those of colleges. Do I understand that they would expect to receive some money to interest students and sort of develop the scientific branch of that particular university?

Dr. CONANT. No; I do not see anything about students in the bill at all. I should suppose that the Commission here, under the authority, which I cannot turn to for the moment, would have to license those universities. That was brought out this morning, I think, in the testimony of General Groves. Those universities where there is experimentation on transmutation of atomic species, the

production of nuclear fission, or the release of atomic energy would be included. That is a general phrase that covers this whole field, so far as anybody can see.

It is page 22, subsection (d), to which I should like to call your attention:

It shall be unlawful for any person to conduct research or experimentation involving the release of atomic energy in amounts deemed and to be prescribed by the Commission as constituting a national hazard or being of military or industrial value, without the consent * * *

And so on. So if an experiment were going on in physics which obviously did not involve a national hazard, was not of military or industrial value, or did not release any large amount of atomic energy, the Commission would presumably not pay any attention to the physics department. It would do so only if they were doing it on a large scale.

It has been suggested to me that you were referring to another section. I am sorry. .

Mr. CLASON. I had in mind page 17.

Dr. CONANT. May I turn to that?

I think the advantage of having that in, just as with the provision I read, is to allay any thought on the part of the people in either universities or industrial concerns that this Commission was not going to try to do all that it could to encourage research under license, so that people would go ahead and make these discoveries in the best way possible.

Mr. CLASON. I was wondering, there. It says, "to utilize, encourage, and aid colleges * * *," and it occurred to me that that kind of language represented a little gift or grant from the Federal Government, but I understand from your testimony that you would expect the colleges to pay their own way on this research, experimentation, and teaching of the student body.

Dr. CONANT. On the last part. I would like to separate them, if I may. On the teaching of the student body, certainly; and on ordinary research. But if they were going in in a large way, into research that involved a lot of people and a lot of equipment, I think they might very well need Federal aid, which might flow this way or, as Dr. Bush has pointed out, through the other bills he spoke of, and which are now before Congress. I think if this thing were to be done in a big way in some universities it might need some Federal money.

Mr. CLASON. Then would you not think it would be only fair that all scientific schools and all colleges that are equipped to teach physics ought to receive a license or a permit to carry on the studies?

Dr. CONANT. Oh, I assume they would. It never occurred to me that they would not.

Mr. CLASON. There would be no limitation there?

Dr. CONANT. No; except for control; and any well-established place should carry on such studies. They would have to check in, however, to show that they were not going to run something that would blow up the college town or poison the inhabitants.

Mr. CLASON. I get the impression you take an awfully little piece of atomic energy and have a pretty big explosion. Do I understand you can work with it in such small quantities that if it goes off a whole lot does not go off with it?

Dr. CONANT. Yes. For me as a chemist it is as unbelievable as for anybody else, because this is the work of physicists. They can actually come pretty close to handling individual atoms. Some of their transmutations which took place and showed the possibility of getting atomic energy from a transformation of one kind of atom to another were actually done with only a few atoms, and the results were recorded by instruments and photographic plates, so that if you construed any act governing atomic energy very closely, you could say that even those experiments involved the release of atomic energy and, of course, they were perfectly harmless and they were done for years. The results were recorded by instruments and on photographic plates. It is only when you come into the realm of the material which the chemist deals with that you begin to get into hazards, and it is with that intent in mind that all this material was put in here.

Mr. CLASON. It is possible to have enough of the elements in the possession of the Government to turn them over to these colleges so that there will be enough to go around?

Dr. CONANT. Oh, yes; I think so. That, of course, is one of the things that the Commission would do. It would allocate materials, and that is one of the reasons the universities and industrial concerns are anxious to get some legislation established, and some authority, so that the green light can be given, licenses can be issued, and we can get ahead with this development.

Mr. CLASON. Then I understood from what you stated that you felt that 10 years might pass before any peaceful or useful purpose could be developed from atomic energy.

Dr. CONANT. Those 10 years were first mentioned by General Groves and spoken of by Dr. Bush. I do not know. It certainly is not going to happen tomorrow. I should be surprised if within 10 years there has not been some industrial use of this whole subject of atomic energy, but it will be a gradual thing. I think the impression that we do not want to leave is that within a couple of years everybody is going to be running automobiles with it, or anything like that. It is going to be a slow, gradual development, and no one can foresee the future, least of all in science and in technology.

Mr. CLASON. Will you tell us whether or not out of atomic energy at the present time any useful peaceful development has come?

Dr. CONANT. Certainly there has been none.

Mr. CLASON. The only known use for it at the present time is as a military weapon in a bomb?

Dr. CONANT. That is the only use of it that has been made. There might be a byproduct, but in that case it would be a byproduct in the sense that the radioactive materials—and I am not revealing any military secrets—have probably valuable uses for medical purposes, and to that extent you could say that the immediate future might hold some promise there, but that is not, strictly speaking, the use of atomic energy, but some materials made incidental to the release of atomic energy.

Mr. CLASON. Do I understand that from the expenditure of two and a quarter billion dollars up to the present time the only direct, tangible result has been the bombs which have been used in connection with the war, and there have been byproducts which have a value in medicine?

Dr. CONANT. I should say they would be negligible compared with the value which accrued to the nation by the dropping of the two bombs and the ending of the war.

Mr. CLASON. You would say at the present time the Government has developed nothing which it could turn over to industry to be used in any way for peacetime economy?

Dr. CONANT. As it now stands. They have the potentialities and beginnings of a great deal.

Mr. CLASON. They have the potentialities, but nothing has been developed far enough to be actually put into use?

Dr. CONANT. That would be my belief.

Mr. CLASON. Do I understand that you feel that this can be used ultimately or developed ultimately as a substitute for the types of engines which are used today, in case we run out of oil or coal or something?

Dr. CONANT. No; I would not want to predict as far ahead as that. I should think there would be some special supplementary uses for it as a source of energy, in special circumstances which I cannot foresee now. That is the way it would start. After all, all energies come in that way—special uses. Electrical energy first was used for very special things, where it would be better than steam. It will be a slow process.

Mr. CLASON. So far as you know, the Commission, if one is appointed, is not by virtue of this bill immediately taking possession of some valuable knowledge that is not generally known throughout the country, with the exception of its relation to war?

Dr. CONANT. That is correct, if you interpret the word "valuable" as being immediately valuable and rule out the value which is inherent in basic knowledge, from which something can be developed.

Mr. CLASON. Do you feel that the Government has now, with the expenditure of one and a half billion dollars in existing properties, expended all the money that is going to be necessary to continue its experiments and its work?

Dr. CONANT. Oh, no. Appropriations will be needed, of course, to implement this act.

Mr. CLASON. Can you give us any idea of how much of an appropriation you will expect the Commission to ask for in the first year after the passage of this act?

Dr. CONANT. I am afraid I cannot, for the reasons I gave. I am just not in a position to make those estimates.

Mr. CLASON. It would be a very large sum of money, would it not?

Dr. CONANT. I am not sure of that. After all, the word "large" has been changed around during the war as applied to sums of money.

Mr. CLASON. If you expended two and a quarter billion dollars in 3 years, as I understand it—

Dr. CONANT. That was for construction, of course, a large amount of it, as the general explained this morning.

Mr. CLASON. Would you expect any more construction to be necessary?

Dr. CONANT. Not on that scale.

The CHAIRMAN. Thank you very much.

Mr. MARTIN. Dr. Conant, I am interested in your comments about the young men who have been associated in this work, the Manhattan project. Has your force been demobilized pretty much by now?

Dr. CONANT. No. I have to speak here pretty much second-hand. You understand that these remarks would have to be addressed to General Groves, who has been in charge of it, of course. My information is from what I have heard from him, but it is my understanding that it has not been demobilized. Far from it.

Mr. MARTIN. This will enable the Commission to hold it intact and to build on from here?

Dr. CONANT. That is correct.

Mr. MARTIN. That is one of the urgent features of it?

Dr. CONANT. That is one of the arguments I am presenting for prompt action.

Mr. MARTIN. I have had some letters from young men working on this project, personal friends, who are wondering about the future of it and what they have to look forward to. They are naturally in a state of wondering what is ahead, for their own future occupation in this direction. That raised the other question I had in mind, and that is more nearly in your field, that of the universities and getting back to the rehabilitation of our research work in the universities of the country.

I gather from your testimony that you are particularly interested in seeing the Commission follow a rather liberal course in encouraging study in this field.

Dr. CONANT. Research in this field by all research institutes and the research staffs of industry as well.

Mr. MARTIN. The granting of these licenses to the educational institutions is more that of regulation in the interest of the national safety than it is to curtail or cut down the work in the experimental field by the universities?

Dr. CONANT. Quite.

Mr. MARTIN. With regard to this paragraph that Mr. Clason mentioned here, about aid to the universities, it is not your idea that this bill will be the vehicle for granting financial aid to the schools for that work, is it?

Dr. CONANT. I think it would be permissive, if I may use the word, as I read it. The Commission might decide they wanted to or not. They might do it directly or they might do it through the mechanism Dr. Bush spoke of when he was addressing you earlier.

Mr. MARTIN. The present situation, due to the war, is that of great need for encouragement of young men to go back into work of this kind. This undoubtedly would come in, or through individual work of the students through the GI bill, indirectly. Your idea is that the encouragement was more that of making the projects available, or in reach of the educational institutions, rather than individual help to the students.

Dr. CONANT. Yes. I had not thought of individual help to the students, or anything in regard to teaching, but if a research project were going on under a license, it might need Federal support.

Mr. THOMASON. What is the present supply of uranium, and where are the principal deposits?

Dr. CONANT. I am sorry I do not have that information.

Mr. HARNESS. I would like to ask one question. It has not been made clear by any of the witnesses—maybe it is not proper for you to say—but could you give us a few more details on the effect of the

release of this energy, from your experiments in New Mexico and what you have learned from the two bombs that were dropped on Japan?

Dr. CONANT. Well, if I understand your question correctly, you are speaking of my statement that need of this legislation is very great because of the national hazard.

Mr. HARNES. That is right.

Dr. CONANT. Therefore, let me distinguish between two kinds of hazard. One is the hazard incident to an explosion of the type which is brought about on purpose when you have an atomic bomb. I do not have to speak to that; the pictures have. It is an enormous explosion.

The other is the hazard which would be incident to an experiment that went wrong in industry or in a university laboratory, because, as it says here, of "ignorance or design." In that case the explosion would be of a different order of magnitude so far as its demolition on buildings and so on is concerned, an entirely different order of magnitude, but the health hazard would come from the materials produced, the rays and the radioactive materials which might be disseminated through the atmosphere. Dr. Bush spoke of the fact that a passer-by might be affected.

Mr. HARNES. What would it do besides kill or destroy?

Dr. CONANT. That is all. It kills you. I do not know what more you want. I call that a major hazard to health.

Mr. JOHNSON. Do you think this development is more revolutionary than the discovery of gunpowder?

Dr. CONANT. I do. I would think so, because if you rolled together the discovery of gunpowder right up through dynamite and TNT into a couple of years, you would have had the same dramatic effect. You see, the development of the use of chemical energy was distributed over many centuries. If man had discovered gunpowder and woke up 2 or 3 years later and had all modern explosives, you would have a comparable situation. That is what has happened here—in a short time the enormous use of this energy in large amounts.

The CHAIRMAN. Thank you very much. We certainly appreciate your statement.

Secretary PATTERSON, will you come around, please, sir, for further examination? Mr. Thomason, have you any questions?

Mr. THOMASON. No questions.

Mr. CLASON. What I would like to know, if it is possible to secure it, Mr. Secretary, is how much money would be necessary in the way of appropriations during the first year after this bill is passed.

TESTIMONY OF THE HONORABLE ROBERT P. PATTERSON, SECRETARY OF WAR

Secretary PATTERSON. I have no idea, Mr. Clason. I can say this, that over the 3 years we have spent \$2,000,000,000. The bulk of that has been on construction, building and equipping two enormous plants and then a plant of somewhat smaller size in New Mexico. In fact, this high rate of employment that we have had on the project has been mostly on construction work. I think the high point was around 125,000 persons. It is way below that now.

Some question was asked here a few moments ago about the number of employees there. I am not certain of my figures, but the last ones I heard were about 60,000 now. Some of those are still on construction, but I recently went down there to the east Tennessee plant, called Oak Ridge. We call it the Clinton Engineer Works. I went down there 10 days ago. There was still some building going on there of an industrial character, but I should say that 90 percent of the building was done. That was what the great expenditure of funds was for.

Mr. CLASON. From your knowledge of the whole project, would you say that it would be in the interest of the Government to maintain in operation the various plants which the Government has been operating in connection with the development of the atomic bomb?

Secretary PATTERSON. I can only answer that this way, and with no particularly expert knowledge, that all of the scientists and engineers connected with the project are sure that some short cuts can be found, and that they will not have to pursue the same route, exactly, again, and that a great amount of economy and savings could be introduced if the thing were to be repeated with the experience of what they have done behind them.

Mr. CLASON. Do you feel that the Commission would have an employment list of perhaps 50,000 persons as they went ahead in the future?

Secretary PATTERSON. I just cannot say. My best estimate would be that it would be below that, but I would not know.

Of course, one of the great activities of the Commission, I am certain, will be to farm out portions of the research and development and practical application. There was some question addressed here a moment ago as to the part universities and colleges would play. I think, as Dr. Conant pointed out, that there are two sorts of activities. One would be the contracting by the Commission with certain universities for the carrying on in behalf of the Commission of developments in atomic energy, and then the other would be a license or permission, and the furnishing of materials, for others to go along and experiment and research on their own initiative.

Mr. CLASON. I think most Americans have the impression that it is only at these Government plants that there is the proper equipment and proper apparatus for continuing experiments with this peculiar atomic energy.

Secretary PATTERSON. A vast amount of work in this was done at certain colleges under direct supervision of the Manhattan Engineer District. The University of Chicago was one of them; Columbia, Princeton, California Tech, and California. A great deal of work was done there.

Mr. CLASON. I got the impression from reading the magazine articles that you still had to bring whatever they developed in these universities' laboratories into the central plant in order to get anywhere.

Secretary PATTERSON. That is true. The industrial development was in eastern Tennessee and in the State of Washington. That is true. The work in science was done at the universities, but that had to be translated into industrial use, and that was done at these large plants that I mentioned.

Mr. CLASON. Would it require the purchase of much real estate, do you believe, referring to this part on the right of condemnation all over the country. Do you have any idea that there is going to be any great amount of condemnation?

Secretary PATTERSON. No, sir; I would say not. If there are discoveries of the ores that are necessary, there would have to be some action on that line in order to control the substance that produces atomic energy, but so far as need of condemning real estate, taking it by eminent domain for industrial purposes, I would think that there was not much need of that. These plants that we have now involve very large tracts of land in Tennessee and Washington and New Mexico.

Mr. CLASON. It would be just a question of some uranium ore, or something other than uranium, being discovered, and then, to protect yourself, you have to buy it.

Secretary PATTERSON. I think so.

Mr. CLASON. Then I would like to know why, in this bill, it is felt that the expenditures of this Commission should not go through the General Accounting Office. We have had so many fights over that in Congress in recent years that it seems to me that—

Secretary PATTERSON. They go through the Accounting Office, all right. The only particular provision is that there shall not be disallowance of credit or withholding of funds. That comes back, Mr. Clason, to several other provisions of the bill that take this Commission out of the category of, oh, commissions like the National Battle Monuments Commission, and things like that, due to a feeling on the part of the interim committee responsible for the drafting of it, and the Secretary of War, and I believe of everyone connected with the project, that it is a matter of urgency, a matter of high national policy on safety and future welfare, that some leeway be given this Commission.

Mr. CLASON. Do you think yourself it is necessary to the extent that is involved in a provision of this type?

Secretary PATTERSON. Yes; I do; and I have no fears of any real abuse, no fear at all that they would try to take over the coal mines or the oil industry or any of those things. I do not think they would have any legal basis for it, and I am sure their common sense would tell them they should not do it.

The CHAIRMAN. John Lewis would not let them take over the coal mines.

Mr. KILDAY. Judge, I am interested in these eminent-domain provisions of the bill, because they are so broad and far-reaching. The only control placed on any of them is in the discretion of the Commission. Of course, we are dealing with a matter that is secret in all of its processes, so that we are creating by legislation a power of eminent domain controlled only by the Commission which we here create.

Secretary PATTERSON. The United States Government today, through the Post Office Department, can take over real estate for a post office in any location.

Mr. KILDAY. But it cannot take over all the real estate.

Secretary PATTERSON. They can take over and move in before the value is settled.

Mr. KILDAY. This says it can take all ores and minerals that in the opinion of the Commission are necessary. On the other one you have the question of public purpose, and that sort of thing. I do think that in executive session we ought to be able to get something from some of your legal staff to see if something might be done about that.

Secretary PATTERSON. They must be peculiarly connected.

Mr. KILDAY. In the opinion of the Commission.

Secretary PATTERSON. Yes. I think Dr. Conant pointed out that right now it is only thorium and uranium that are directly concerned.

Mr. KILDAY. And this Commission we create will, in the final analysis, be in complete control of it. Now, is it proper legislative policy for us to create a commission here to the extent that it becomes all powerful and supersedes the courts?

The CHAIRMAN. Let me ask this question, directed both to the witness and Mr. Kilday. Any condemnation under the power of eminent domain must be in accord with statute. This Commission could not go out and do it. They have recourse to the courts and there would be a judicial determination.

Mr. KILDAY. Here the public purpose passes out.

The CHAIRMAN. They have to find it for a public necessity before they can condemn it.

Mr. KILDAY. I think it is something we do have to consider.

Secretary PATTERSON. Some mention was made of the power of requisitioning this morning, and I said I did not recall in the Manhattan Engineer District a single case of requisition. In the War Department we had very few cases of actual requisition of personal property for war materials. Nevertheless the presence of that Requisition Act on the books had a wonderful effect when you had some fellow that was holding out for an outrageously high price. I mean by that that you were able to acquire the property at a fair price, where you would have had an awful gouging if you had not had that act on the books.

Mr. KILDAY. We have a new department here. We are going into the preservation of ores and minerals, and also the restriction of them from other people. We have an entirely new phase here.

The CHAIRMAN. Is there anything further, Mr. Durham?

Mr. DURHAM. What is the ratio between the civilian personnel and military personnel? What division was there?

Secretary PATTERSON. It was initially developed, of course, by scientists and taken over by Dr. Bush's Office of Scientific Research and Development, and when they were convinced that the theories of the scientists could be put to practical application in the production of atomic energy for a bomb or for a weapon of war, they recommended that it be turned over to the War Department, and at that point it was turned over to the War Department, I believe in 1942, and it has since been in charge of the War Department. But, of course, we have had a very large number of civilians working on the project—far more civilians than officers.

Mr. DURHAM. As to why I ask the question, I have quite a number of young doctors with doctors' degrees who have been farmed out there as privates, and they are still there. Of course, naturally, at this time they are wanting to get out and want to get some action somewhere, or something from this scientific branch to remunerate them so they can make a living.

Secretary PATTERSON. I will be glad to have their names turned over to General Groves. He may be able to use them.

Mr. MARTIN. Judge Patterson, with regard to the matter of appropriations here, I am not clear in my mind whether or not this bill, if enacted into law, provides that the appropriations under it would be charged up to the War Department.

Secretary PATTERSON. I hope not. One of the troubles we have now in getting appropriations is the large amount we have to take in for the Manhattan Engineer District, and if this bill passes, the appropriations for this project will go to the Atomic Energy Commission and disappear from our budget.

Mr. MARTIN. I am a little worried about that, too.

The other point is that this bill is following a pattern that is rather new in our experience. That is, it has no ceiling to it. When I first got on this committee, our general practice was to put some sort of a limitation on the over-all appropriations authorized. We had quite a battle on that early in the war because, being a war measure, we started taking the lid off. Immediately this committee lost all further control in the matter. In fact, it was then left entirely to the Appropriations Committee from there on, and this bill has that carry-over aspect on our wartime experience.

I just wonder if this is going to be a general practice of leaving the lid off wherever possible on authorizations.

Secretary PATTERSON. Our money does not come down to this committee. It would be all right with me if it did, but it does not.

Mr. MARTIN. The other question I had in mind was with regard to the penalties. I wanted to ask you about those penalties.

In your opinion, are they broad enough to cover all people, whether or not they have had any direct connection with the project or not?

Secretary PATTERSON. I believe so.

Mr. MARTIN. I wanted to be sure that they do have broad enough coverage in there to reach all individuals, whether they were over within the jurisdiction of the Commission directly or not.

Secretary PATTERSON. I believe they are broad enough.

Mr. MARTIN. That is all I have.

Mr. SHERIDAN. In your opening statement this morning you stated that many now attached to the Manhattan District project had left because of the vagueness of their future. How many are in that category?

Secretary PATTERSON. I do not know.

Mr. SHERIDAN. Have you any appraisal?

Secretary PATTERSON. No, sir. That was reported to me by General Groves.

Mr. SHERIDAN. Does General Groves have the figure?

Secretary PATTERSON. He will give it to you.

Mr. SHERIDAN. You also stated that much of the future experimentation will have to be farmed out to universities.

Secretary PATTERSON. I think it would be wise for the Commission to do it.

Mr. SHERIDAN. You said that is what it was proposed to do.

Secretary PATTERSON. They are directed by this bill to make use of existing institutions, and so on, insofar as feasible, and I am sure

that under that direction they would in fact contract out a great deal of work that they wanted to see pursued.

Mr. SHERIDAN. Would that not result in a most natural mathematical calculation that the project as it is now constituted would be reduced?

Secretary PATTERSON. That is quite possible.

Mr. SHERIDAN. So that those who leave now to private enterprise or go back to colleges would still be available?

Secretary PATTERSON. They are scattered all over. I think what General Groves is worried about is his organization, his team, with members, as he says, leaving, not pursuing the work as part of the team.

Mr. SHERIDAN. You do not have any knowledge of who have already left?

Secretary PATTERSON. No; I do not.

Mr. SHERIDAN. I am just trying to reconcile some of the statements that have been made here.

Have you any idea of approximately what the future appropriation may be with respect to this? Has there been any discussion as to the approximate amount?

Secretary PATTERSON. I have no idea as to what the appropriation would be. I have only pointed out that the bulk of the moneys that we have had appropriated to the War Department for this project went to construction, rather than to operation.

Mr. SHERIDAN. Approximately \$2,000,000,000 have already been expended; is that not true?

Secretary PATTERSON. \$2,000,000,000 is right.

Mr. SHERIDAN. How much remains that would be transferred over to the Commission? I see this bill provides for such transfer.

Secretary PATTERSON. I can find that out for you readily enough in the appropriation we have for the fiscal year ending June 30, 1946. There would be an item there under Corps of Engineers allotted for this.

Mr. SHERIDAN. What is that item? Do you know?

Secretary PATTERSON. No. I will have to find that out.

Mr. SHERIDAN. Does anybody here of your staff know?

Secretary PATTERSON. No. I can supply that. Of course, some of that has been spent already.

Mr. SHERIDAN. I figure that if we deduct that we will know how much remains that will be available for transfer.

Secretary PATTERSON. I can find that out for you.

Mr. ELSTON. Judge Patterson, I notice in this bill no provision is made for the War and Navy Departments to be represented on the Commission.

Secretary PATTERSON. Not directly; no. There is no requirement that they be represented.

Mr. ELSTON. Do you not think it would be a good idea that it be made mandatory that they be represented on the Commission?

Secretary PATTERSON. It was thought that if qualifications as to who could serve on the Commission were made it would ramify out and then there would be so many from industry, so many from labor, so many from the War Department, so many from the Navy Department, and so on, and that there would be no real play left there.

You will notice, Mr. Elston, that provision is made for the event of officers of the armed services serving on the Commission, because it provides as to what shall happen as to their still being eligible for pay, and there is mention made in several places in the bill of the military features of it. The very first section, containing the findings and declaration of policy, shows, in the final sentence of it, that the primary objectives of all action taken pursuant to this act shall be the promotion of the national defense, protection or the safety of the inhabitants of the United States, the safeguarding of world peace, and the furtherance of the acquisition of knowledge concerning atomic energy, and then the Commission is charged, over here, with safeguarding the national defense, and so is the Administrator, so that the phases of this work that relate to any military weapons are not lost sight of in this bill at all.

Mr. ELSTON. I appreciate that, but still that does not require the appointment of the Army or Navy personnel on this Commission.

Secretary PATTERSON. That is true.

Mr. ELSTON. Are you entirely in accord with the setting up of a Commission which might not have representatives of the War Department on it, to which Commission the War Department would have to go for authority to experiment in the development of weapons?

Secretary PATTERSON. Yes; I would abide by the wisdom and prudence of the Commission in that respect, particularly with these directions right in the law from Congress that they must promote the national defense.

Mr. ELSTON. That is a mere statement of policy, but there is nothing mandatory about it. You agree with me, do you not, that this bill, if passed, leaves out the War Department and the Navy Department entirely? They can only go ahead and develop weapons which are created through atomic power so far as this Commission gives them the authority to do it.

Secretary PATTERSON. There is an exception made here for time of war and national emergency, over here somewhere.

Mr. ELSTON. That may be, but most of your weapons are developed in peacetime and not in time of war.

Secretary PATTERSON. That is true.

Mr. ELSTON. You do not wait until a war is on before you develop them.

Secretary PATTERSON. I am entirely in agreement with you there, but I would have full confidence that the Commission would carry out the directives of Congress with regard to furthering national defense. It is not only in this preamble, section 1, to which I called attention a moment ago, but it is over in the provisions having to do with the powers of the Commission and also with the authority of the Administrator. I think it is section 10 on the Administrator, which mentions the exploitation and use thereof for military, industrial, scientific; or medical purposes, so that I am sure the military aspects of this measure have not been lost sight of. I quite agree with you that they are very important for the War Department and the Navy Department.

Mr. ELSTON. I am wondering if it would not be better for the bill to be drafted along the lines of our recent bill giving the Scientific Research Board and the Academy of Sciences power to receive appro-

priations from Congress to go ahead and make experiments and indulge in research work, but at the same time we took nothing from the Army and the Navy. They can go ahead and continue to have done the very fine work that they have been carrying on for many years. The other work is simply a supplement to it.

Would it not be better if this were set up as a supplement to the power and authority of the War and Navy Departments now existing to go ahead and continue research into the use of the atomic bomb or other atomic weapons in the national security?

Secretary PATTERSON. I would not have them do it independently of the Commission. I have no fear that the armed forces will not have the chance to assist in the development of weapons that use atomic energy under this bill and under the jurisdiction of the Commission.

Mr. ELSTON. But you are surrendering a lot of authority.

Secretary PATTERSON. We are surrendering the whole project thus far, because it has been the War Department's for the last 3 years.

Mr. ELSTON. Judge, did you participate in the drafting of this legislation?

Secretary PATTERSON. No, sir.

Mr. ELSTON. There is one provision that you perhaps heard me refer to before, and that is the provision that makes it possible for the Commission and the President to reveal the secrets of the atomic bomb to other nations.

Secretary PATTERSON. I recall the provision. Of course, the President has that power right today. The provision here is that the Commission shall not do it unless the President says so.

Mr. ELSTON. That means that if the President says so and six of the Commission concur, it can be delivered to some other country. Congress is left out of it entirely. Congress declares war and does a lot of other things in connection with the war, but it is deprived of the power and authority of passing on this very important question of whether or not this should be turned over to some other nation. It seems to me that that is more important than anything else, that these secrets do not get into the hands of other nations, yet that is not taken care of in this bill.

Secretary PATTERSON. I think that on all of these things on foreign relations we must bear in mind that the President indicated in his message that he would have more to say on the international aspects of this. This bill relates almost entirely to domestic control. I can conceive of conditions where it would be to our advantage to reveal certain matters, and the President has already said that he would not reveal the atomic bomb itself at all, but I can conceive of conditions where it might be to our advantage to reveal certain matters.

I think there was some discussion earlier about the employment of a foreigner by the Commission. I can conceive of cases where it would be to our own vital interest to employ a foreigner. I have no doubt that the Commission and the Administrator, too, would weigh the pros and cons of that very carefully, but we are indebted, heavily indebted, now, to foreigners for what we have done in the way of the production of the atomic bomb already. I would not want to see a square prohibition in this act against the employment of any person of foreign citizenship. I think we can safely trust the Commission, the people who administer the act, to employ them under proper condi-

tions, where they have a real contribution to make that perhaps our own citizens would not have. This knowledge is not confined to citizens of the United States by any means.

Mr. ELSTON. I am not referring so much to the employment of someone from another country, but this bill would make it possible, if six members of the Commission concurred and the President was agreeable, that the whole secret could be turned over to a foreign country.

Secretary PATTERSON. Mr. Marbury points out that it only says "licensed property."

Mr. ELSTON. If you give them a license you give them the secret. I do not think it makes much difference whether you give it to them one way or another, so long as they get it.

Mr. SHERIDAN. Will the gentleman yield?

Mr. ELSTON. Just a minute and I will be glad to yield.

The bill does make it possible to grant a license to a foreign country if the President approves of it. Now, in a matter of as great importance as this, do you not think it would be better that Congress approve of that, rather than the President?

Secretary PATTERSON. No; I do not. I think the provision as it stands is a wise provision. I think the power that the President has under our system in all kinds of ways, power involving the safety and welfare of the Nation, of his own determination, is proper.

Mr. ELSTON. You are familiar, of course, with the law that this Congress passed during the war saying that the President could not give ships belonging to the Navy to any foreign country. Congress did put some prohibition against the President in that respect. This is certainly of much greater importance than giving away some ships that belonged to the Navy.

Mr. KILDAY. Will the gentleman yield before he leaves that point?

Secretary PATTERSON. I do not think there is any real risk.

Mr. ELSTON. It might be better from the standpoint of the President. The President meets with representatives of foreign governments, and particularly right now they are asking for certain things, and some of them are granted and some of them are not. But they are rather insistent on certain things, and if we can believe some of the things that we have heard, I think it has even appeared in the press that some of these countries would like to have the atomic bomb secret. The President can say in those conferences, "I do not have the authority; that is up to the Congress." It would certainly relieve him of a tremendous amount of responsibility, and I think it would make the American people feel a little bit more secure.

Mr. KILDAY. Will the gentleman yield?

Mr. ELSTON. Yes.

Mr. KILDAY. This bill is supposed to take care of its control within the United States, and we are told there is going to be a request for other legislation with reference to foreign control. We set up here legislation with but one prohibition, that they shall not grant it to any other nation. It conserves it for the United States, and if it is to be used in international affairs, that is to be controlled by other legislation.

Mr. ELSTON. What I do not understand is, what is the objection to letting Congress approve of it, rather than letting the President have the sole authority?

Secretary PATTERSON. I suppose it is an Executive matter of management. As Mr. Kilday has said, the restriction on licenses is that they shall not be given abroad unless the President approves. It would seem to me that you might have licenses on collateral lines not relating to the atomic bomb itself directly at all, that the President would approve of. Dr. Conant pointed out that there are by-products and that there are other phases of the general subject that would be under the control of the Commission, and it is possible—I do not know; it is possible—that it might be advantageous for the President to direct or consent to a certain license given to a certain foreign government for limited purposes. I do not think there is any peril in it.

Mr. ELSTON. While it is true that the unimportant things are there, the serious things are there too. They can give the whole bomb away, the whole secret of it, under the provisions of this bill.

Mr. SHERIDAN. In line with your line of questioning, Mr. Elston, if you refer to page 1, Judge Patterson, I do not think you can reconcile your answer with line 9. The very purpose of the passage of the bill is to promote and safeguard world peace. Why could not the Commission, under the interpretation of the preamble, give it to a foreign government?

Secretary PATTERSON. They cannot do it under the specific language here in section 11, except by the consent of the President.

Mr. SHERIDAN. How would you interpret section 1, which you referred to in your opening statement, line 9, to promote world peace?

Secretary PATTERSON. So far as it would relate to any license given to a foreigner to promote world peace, it would be governed by the specific provisions of section 11, and the approval of the President required. There is no doubt of that.

Mr. ELSTON. I just yielded for a question, Mr. Chairman.

Judge Patterson, I notice in this bill that the Commission is given the authority to pass regulations, and those regulations have the force of law. Of course we know as a proposition of law that if Congress gives them the authority to pass the regulations, they do have the force of law.

Secretary PATTERSON. I never heard of a commission that did not have the power to pass regulations.

Mr. ELSTON. But Congress has not necessarily given them the power to pass regulations that have attached to them a penalty by fine or imprisonment such as we have here.

Secretary PATTERSON. It is very common.

Mr. ELSTON. It has been done, but it does not necessarily follow that the practice should be continued forever. The way this bill is written, the Commission can pass any amount of regulations they want; so long as they put them in the Federal Register it is sufficient notice to the world.

Let me call your attention particularly to page 26, section 19 (b), to the effect that any violation of the regulations promulgated by the Commission pursuant to section 17 of this act, shall, regardless of intent, be punishable by a fine of not more than \$500, or by imprisonment of not more than 30 days, or both; or, if willful or through gross negligence, shall be punishable by a fine of not more than \$100,000 or imprisonment for a term not exceeding 10 years, or both.

Now, would not failure to read the regulations in the Federal Register be construed to be gross negligence?

Secretary PATTERSON. Any regulations under section 17—

Dr. BUSH. Those are the security regulations.

The CHAIRMAN. The first one applies to the licensing of somebody like the Standard Oil Co.

Secretary PATTERSON. I do not see anything unreasonable in that. If it is unintentional, it is a small fine or a short penalty by confinement, and if it is willful or grossly negligent, by a much heavier penalty. There are certainly many, many precedents in the statutes passed by Congress within the last 20 years of power to pass regulations given to an executive body and making the violation of them penal.

Mr. ELSTON. And I do not know of a worse practice than that.

Secretary PATTERSON. It is done every day.

Mr. ELSTON. If you confine it to the last dozen years or so, they have piled regulations upon regulations until even a lawyer cannot today tell his client when he is violating the law, because they are hidden away somewhere in the Federal Register.

Secretary PATTERSON. I would not differ with you on some things that are of no very great moment, where some rather obscure commission may have the right to pass regulations and make the violation of them criminal; but I submit that on a matter of such high urgency as this, the power given to the Commission is a necessary one, and I think the making of the violation of a regulation penal is quite proper.

Mr. SHERIDAN. Even without intent?

Secretary PATTERSON. Yes, sir.

Mr. ELSTON. I should say we should not deprive the Commission of the right to make regulations, not for a moment. They have to do that. But would it not be far better, when you come to the penal provisions of the act, for the Congress to indicate in plain and unmistakable terms just what shall constitute a violation of the law?

Secretary PATTERSON. I do not think you can, except by reference to the regulations that may be passed.

Mr. ELSTON. We have been able to do it with respect to every other crime on the statute books.

Secretary PATTERSON. This differentiates between an unwitting violation and a knowing violation by the severity of what a man may be subjected to. I think that is entirely reasonable.

The CHAIRMAN. All right.

Mr. JOHNSON. I want to get your view on this, Judge. It provides for the appointment of nine Commissioners by the President, and the concurrence by the Senate. As I understand it, that means that once a man is appointed for at least 6 or 9 years he can retain that office so long as his term lasts.

Secretary PATTERSON. Subject to that removal power; yes, sir.

Mr. JOHNSON. Generally speaking, he can hold office to the end of the term. Would it not be wiser in a thing like this to give the President power to remove him? Suppose he became sick.

The CHAIRMAN. He has it in the bill.

Mr. JOHNSON. He must commit a crime or be guilty of misfeasance.

Secretary PATTERSON. Inability to act includes the case when he is ill. I think that is enough.

Mr. JOHNSON. Do you think that is broad enough?

Secretary PATTERSON. Yes, sir. I think that will require activity on the part of all nine men, activity in the affairs of the Commission.

Mr. JOHNSON. Suppose a man travels abroad for a year. You could remove him, or he could, for that reason?

Secretary PATTERSON. He could.

Mr. JOHNSON. I would like to give the President the power to remove him.

The CHAIRMAN. The President of the United States removed Dr. Morgan on his own will.

Mr. JOHNSON. Yes, and he removed Humphries; and we had to pay his back salary for 6 or 7 years.

The CHAIRMAN. Thank you, Judge. Thank you very much. Do you have any other witnesses?

Secretary PATTERSON. No, we have no others, Mr. Chairman. We will produce any witnesses this committee would like.

The CHAIRMAN. The purpose of this committee is to consider this promptly in the full significance of its importance and of the urgency of it, and with that in view the committee will meet in executive session tomorrow morning at 10 o'clock to start reading the bill for amendment, for consideration and final disposition.

The committee will go into executive session.

(Whereupon, at 4:20 p. m., the committee went into executive session.)

ATOMIC ENERGY

THURSDAY, OCTOBER 18, 1945

HOUSE OF REPRESENTATIVES,
COMMITTEE ON MILITARY AFFAIRS,
Washington, D. C.

The committee met at 10 a. m., Hon. Andrew J. May (chairman) presiding.

The CHAIRMAN. The committee will be in order.

We have met this morning for further hearings and consideration of H. R. 4280, a bill to provide for development and control of atomic energy. These hearings have been continued for the purpose of permitting a group of interested people, known as scientists, to present their views on the questions involved in this proposed legislation. We have five witnesses, and they have been selected at the request of the committee so as to give the viewpoints of four different groups of those interested in the subject.

I would like to add to my statement that there has been some criticism of the action of the committee in closing the hearings when they were closed, and that has been carried in the press and editorially commented upon. There was apparently an effort to make it appear that this committee was trying to rush things and unnecessarily doing so. I can say that up to this moment nobody has requested of me, as chairman of this committee, a hearing on behalf of the scientists except what came to me through the War Department by General Royall, who, while he did not request it, simply did not object, but rather encouraged further hearings on the matter. It is the purpose of the committee now to give patient consideration and hearing to those representing scientific work in the United States.

We have as our first witness Dr. Leo Szilard. Will you come around, please, Doctor? Let me say to you what I have already stated, that we are considering the bill H. R. 4280 which has for its purpose the development and control of atomic energy.

Please give us your name and your experience and tell us about your qualifications to appear here as a witness, and then you may make any statement that you wish to make with respect to this proposed legislation.

STATEMENT OF DR. LEO SZILARD, UNIVERSITY OF CHICAGO

Dr. SZILARD. My name is Leo Szilard. I was born in Hungary and am a naturalized citizen of this country. I was naturalized in 1943. I worked for a time, from 1925 to 1931, on the teaching staff of the University of Berlin. In 1931, when the German Reichstag began to pass legislation giving the German Government sweeping powers, I came as an immigrant to this country.

In subsequent years I worked at the University of Oxford, England, and in March 1939 I began to work on the development of atomic energy at Columbia University. I have been working in that field ever since. From Columbia I was later transferred to the University of Chicago. I am at the present time working in this field at the University of Chicago.

The CHAIRMAN. You have read this bill, I take it?

Dr. SZILARD. I have read the bill and, with your permission, I would like to make a statement.

The CHAIRMAN. All right, sir. You may proceed.

Dr. SZILARD. I am exceedingly grateful to this committee for the opportunity to make a statement. I am not qualified to discuss the merits of the bill. It is written in legal language, and many others are more qualified to discuss the bill than I am.

I have to apologize for the very hastily prepared statement which I am going to submit. When I came down to Washington I understood that the committee had closed its hearings. Day before yesterday, late in the afternoon, I was notified that I was to appear as a witness. Subsequently I dictated my statement to a stenographer while she was operating a switchboard. In these circumstances, I hope to have your indulgence if the statement is not as clear as it might otherwise have been.

In the last few days I have discussed the Johnson bill with some of my colleagues who happened to be in Washington. This bill proposes to set up machinery presumably for the purpose of fulfilling certain functions which are not very clearly defined in the bill. My colleagues and I found it quite easy to reach an agreement on the following question:

What are the problems which face us in connection with atomic energy, and what are the functions for which we have to set up some Government-controlled machinery by legislative action?

We found that, after we had reached an agreement on this question of the functions for which we need machinery, we were in a position to discuss intelligently what kind of machinery we need in order to fulfill these functions.

There may be, of course, differences of opinion as to what kind of machinery may be best to perform any given sort of function, but at least if we all have the same function in mind we can avoid confusion in our discussion. It does not seem possible, to me, to have an intelligent discussion about the machinery which is needed if some of those who take part in the discussion believe that the function of this machinery is to construct and operate atomic power plants in order to supply electricity in remote regions of the United States, while some others who participate in the discussion believe that the main function of the machinery is to provide us with atomic bombs so that we can blast the hell out of Russia before Russia blasts the hell out of us.

I would, therefore, with your permission, like to outline the functions which, in my opinion, the machinery which you may set up by legislative action will have to perform.

One of the functions of such machinery will undoubtedly be the manufacture of two substances: Uranium 235 and plutonium. These two substances are at present manufactured in factories operated by large companies. These factories were constructed at the expense of the Government at an expenditure of \$2,000,000,000.

What are these two substances: Uranium 235 and plutonium? Uranium 235 is a heavy metal. It is a substance which is contained in natural uranium. It is contained in natural uranium in a very small quantity. Natural uranium contains less than 1 percent of this "light" uranium. When we say it is manufactured we are not quite correct. It is not so much manufactured as it is separated at great cost from the bulk of natural uranium.

How much of this substance can we hope to produce? If I am not mistaken, the United States imported in peacetime a few hundred tons of uranium. If all the light uranium should be extracted from, say, 400 tons, about the amount which was imported in one of the years preceding the war, we could have extracted from these 400 tons of uranium less than one-third of a ton of light uranium. We would have obtained this amount if we had extracted all the light uranium which was contained in 400 tons of natural uranium. If we used the methods which are applied in our factories at present a much smaller quantity could have been obtained only because these methods are not very efficient. But however efficient we may make our methods we can never extract more light uranium from natural uranium than there is in it, and this is a small quantity. From this you see that the future development along this line for purposes of power production will be necessarily limited by the scarcity of light uranium in natural uranium.

The other substance which we are manufacturing at present is called plutonium. This is also a heavy metal. It is derived not from the light component of uranium, but from the heavy component of uranium; and 99 percent of natural uranium consists of this heavy component. You can see, therefore, that we might ultimately obtain, roughly, a hundred times as much plutonium from uranium as we can obtain of light uranium.

What are those two substances good for? They can be used for either of two purposes, and they can be used for either of the two purposes in the near future. They can be used either for producing atomic power to supply electricity in remote regions of the United States which have no coal or oil easily available, or they can be used for manufacturing bombs.

We do not have to decide at this stage of the discussion for which of these two purposes we want to use the plutonium which we are manufacturing in our factories and which we shall manufacture in other factories to be built in the future. But let me not mention this subject without expressing my hope, which is at this time, I believe, the hope of all physicists, that a situation will be created with respect to our relations with other nations, that will permit us to use plutonium for the production of electric power rather than for the manufacture of bombs.

Here we have, then, the first function which the machinery which you propose to create by legislative action has to fulfill—and if I may have the use of the blackboard, I would like to make a diagram.

The first function of the machinery which is to be set up by legislative action would be to take care of a large manufacturing program operating factories which have cost \$2,000,000,000. I will put on the blackboard a possible scheme as to how this could be done. Many other schemes could be proposed, but I would like to concentrate on one scheme.

This function could be performed by a Government-owned corporation, the managing director of which would be directly appointed by the President. Advisory to the director would be two members appointed by the President, serving full time, at a high salary of, say, \$25,000. This [indicating] would be one piece of machinery that, in my opinion, might be needed and useful.

We must ask by what methods shall we manufacture plutonium and light uranium after this war. Is it necessary to develop new methods? New methods would be not only less costly but could produce a far greater quantity of plutonium per pound of uranium than our old methods. They would be both less costly and more efficient from the point of view of utilizing the available uranium. Moreover, we could produce really large quantities of plutonium which would become a factor in our national economy if used for the purpose of power production.

The answer to this question is, I believe, as follows: Some of the methods which we have developed and which are used at present might carry over into the postwar period, but not all of them. But even those methods which can carry over will represent only the first stage of this development. Behind this first stage we see already the outlines of the second stage represented by methods which are very different from our present-day methods. In order to find these methods we will have to engage in research and development. Therefore we will need another piece of machinery that can take care of research and development and that can carry the development into the pilot-plant stage. I do not believe that research and development should be separated. I do not believe that research, development, and the building of pilot plants should be separated.

You see, therefore, the need for another Government-owned corporation. This corporation [indicating on blackboard] will take care of research and development. It will have a director and two board members, the same way as the corporation in charge of manufacture as outlined earlier. I shall talk more about this phase because I am better qualified to talk about it than I am qualified to talk about the other machineries. One or two of these board members should be scientists, because scientists would have something to say about the function which this piece of machinery will have to perform.

In addition to these two pieces of machinery there may be another piece of machinery needed; and let me express the hope that it will not be needed. However, for the time being we have to envisage the possibility that it may be needed.

This would be an organization that could perform essentially the same functions which were performed by the project located in New Mexico. These functions include research, development, and manufacture; and since we might need a machinery for this function I shall, with your permission, put on the blackboard a third diagram representing a Government-owned corporation which will conduct our bomb manufacture, development, and research. I believe there should be a director, and two board members, all to be appointed by the President, and one of them ought to be a scientist, because research plays such a large part in future development.

Let me make it clear that these three pieces of machinery would not be capable of formulating policy. Therefore there is a need for a commission capable of formulating policy. I do not know how

many members it ought to have, but let us see how many members we need. I would say that these two board members [indicating] should take turns on this commission [indicating]. They are men with no executive responsibility, and have therefore time to study the functioning of their own corporation and to form an opinion of their own. Each one of the three corporations [indicating] would supply only one of its board members to the commission. These two corporations [indicating] would supply one board member each, and the same holds here [indicating]; so that you would have three board members serving on the commission who would have no executive responsibility but who would be men who are informed both about the technical problems and also about the qualifications of the managing directors of the respective corporations for the jobs for which they were appointed.

For reasons which I shall state later it seems essential that this commission [indicating], which is responsible for policy, should be tied closely to the Government. Therefore I am inclined to believe that we should have the Secretary of State or his representative, the Secretary of War or his representative, the Secretary of the Interior or his representative, and the Secretary of Commerce or his representative as members of the commission. In this way we may hope that the policy of the commission and the policy of the Government will be the same. If you wish you may add to this commission a number of public members, a representative of labor, of industry, and so on. How many you will need to add I do not know.

This is the picture which I visualize as representing the machinery which could perform the functions that need to be performed.

I shall not make any further comments on manufacture or on bomb development, but I would like to make some comments on the guiding of research and development.

I would like to explain why I believe that the Government must be in a position to do its own research and development rather than to rely on what research and development might be derived from universities or private industry. The reason for this is not my adherence to a particular social philosophy, but a reason which arises out of the nature of our special problem. In deciding along what line development should go we will have to make a choice. The choice is between these two alternatives: We might either go after the utilization of atomic power in the near future, and in that case we would make plutonium and use it for operating power plants in order to produce electric power. We could build such power plants in the very near future; and if we moved along this line we would have rather soon profitable applications of atomic power. However, while we would have atomic power soon, atomic power would not amount to much in the life of our Nation.

If we want atomic power to be an important factor in our national economy, we have to forget about these short-range objectives and we would have to guide the development along an entirely different line, develop different kind of manufacturing processes, refrain from using up in the next few years plutonium in power plants and aim to have 10 or 15 years from now atomic power available on a really large scale.

Why we cannot have both I do not feel quite free to explain, because I could explain it only if I told you facts which I cannot tell

you in open session, but I would very much appreciate an opportunity to talk about this subject, if it seems important to you, in executive session, where I would be free to explain that it is not my personal preference for Government-guided research and development, but the necessity of choosing between a long-range and short-range objective that makes me say that the Government will have to look after this task.

Mr. HOLIFIELD. May I ask the gentleman to please repeat his statement? I do not believe I caught the full import of it.

Dr. SZILARD. We have a choice between two different lines of development. We cannot have them both.

Mr. HOLIFIELD. Do you mean military and domestic?

Dr. SZILARD. No. I mean short range and long range. Use of atomic power could be attained in 3, 4, or 5 years. If we go along this line we will have atomic power soon, but we will not have it on a large scale. If we want to have atomic power on a large scale we have to renounce its use in the next few years and we have to guide the development into channels which will give us atomic power on a really large scale, some 10 years from now. If we utilized too soon plutonium in power plants we would not go along the line along which I think we ought to go.

Mr. HOLIFIELD. Your point is to retain it for seed rather than to use it?

Dr. SZILARD. This leads us into questions which I said I did not feel free to discuss in open session. If I have the opportunity to explain it in executive session I think I could say enough to convince you that it is not my preference for Government-conducted development, but rather a necessity arising out of the technical situation which makes me say that we ought to have Government-owned corporations authorized to carry the research and development which is needed.

Mr. HOLIFIELD. You believe, then, in full Government control of it as a matter of necessity, not as a matter of your own personal choice?

Dr. SZILARD. When you speak of Government control, let me say that as I understand the word, the Government should control an organization which can conduct development on a large scale along lines which the Government deems to be in the national interest, forgetting immediate gain and profit. I certainly do not believe that there should be a Government agency which is in control in the sense that it can prohibit other Government departments or universities or private industry from engaging in research and development.

Mr. HOLIFIELD. You mean control toward the acceleration of the development rather than toward restricting it?

Dr. SZILARD. I mean that the Government should have the power to carry out the needed development itself, but not the power to prevent other people from carrying out development work.

Mr. HOLIFIELD. But do you not believe that any private laboratory or university should make known to the Government any discoveries which it might make during that period?

Dr. SZILARD. I believe the Government ought to be kept fully informed by anyone who is working in this field. But Government control can be carried too far. According to the Johnson bill, the National Bureau of Standards could not conduct experiments without special permission.

The CHAIRMAN. Suppose we let the witness finish his statement.

Mr. HOLIFIELD. I am afraid I will forget some of these things.

The CHAIRMAN. You can put them down on a pad.

Mr. HOLIFIELD. All right, Mr. Chairman.

The CHAIRMAN. Proceed, Doctor.

Dr. SZILARD. As I said, what I am going to say now will apply only to the research and development aspect of our problem and not to the task of manufacture. As a scientist I am more concerned, and also more qualified to speak, about research and development than manufacture.

I believe that if we want to have a successful development we will have to incorporate into the organization of our Government-owned corporation in charge of research and development some features which are nominally operative in private industry. I believe that we will have to provide for some overlapping of work and a certain amount of competition within such a Government-owned corporation. I would like to indicate this also by a diagram.

This Government-owned corporation in charge of research and development could set up five or six branches, and it would be logical to locate them at the sites of great universities and institutes of technology. A branch might be located near Boston in the proximity of M. I. T. and Harvard; another somewhere near Columbia and Princeton; another branch perhaps near Austin, Tex.; a fourth branch might be in Los Angeles, where they have two universities, California Technology and the University of California, in Los Angeles, Calif.

What I am driving at is the following: If we want to avoid the mistake of putting all our eggs in one basket, it would be a fatal mistake to have a budget set for these branches by a central organization and have each work exclusively on the task assigned to it. Naturally the corporation will have to determine what budget each branch should have. I would like to see, however, this principle adopted (even though it might not be wise to write it into the law) that any of these branches should be free to use up to 40 percent of their budget, not for the task assigned to them, but for overlapping and competing with the work of the other branches. The men working at one site [indicating] may come to the conclusion that another branch located at another site is going the wrong way about the task which has been assigned to it by the central organization. In that case they ought to be free to use up to 40 percent of their budget to enter into competition with this other branch. I venture to predict that very often it would not be the branch selected by the central organization, but some other competing branch, which would deliver the goods. I am basing this remark on experience during this war in work which the Government conducted at various universities. Very often the methods selected by the central authority proved to be unworkable, and the method selected by some local group proved to be workable.

Mr. JOHNSON. You want 40 percent of the budget used for experimentation?

Dr. SZILARD. No. I would say it this way. The central organization assigns a task to a local branch and gives it a budget. I would say that it should be free to use 40 percent to go after some objective other than the objective assigned to it. For instance, an objective which was officially assigned to another branch.

I have not quite finished my statement, but it will not be long now.

The CHAIRMAN. Continue.

Dr. SZILARD. I would now like to make an attempt to visualize how these functions would be performed if the Johnson bill were passed. This, of course, is a guess, because we do not know who the men would be who would serve on this nine-man Commission. I am going to assume that those few men who sponsored and have spoken in favor of the bill will be the men who will serve on the Commission. If that were so, I think it is safe to assume that by and large the work of the Commission would be conducted pretty much in the manner in which the work on atomic energy was conducted under the OSRD, the NDRC, and the Manhattan District. In other words, I base my forecast on the experience which we had with those agencies in the past.

Mr. THOMASON. You mean, the military would run it?

Dr. SZILARD. No. The NDRC is not military; the OSRD is not military; and the Manhattan District is not entirely military. The Manhattan District had the advice of civilians acting as part-time advisers. It was not a purely military organization.

Mr. JOHNSON. Do you believe that the present lay-out would be contrary to your ideas?

Dr. SZILARD. No. What I meant to say was this. Assuming that the Johnson bill is passed and the men on the Commission are of the same type as the men who sponsor the Johnson bill—which is an arbitrary assumption, but I must assume something—then I am asking how would its functions be performed. I know how we operated during the war, and I can visualize how much of that would be carried over into peacetimes.

Mr. JOHNSON. In other words, you do not think it would be performed as well as it is under your lay-out?

Dr. SZILARD. I do not say it would be badly performed, but you can judge whether you are satisfied with the type of performance which I visualize or whether you will want a different type of performance.

If you will permit me, I will not talk about manufacture, because I know little about manufacture, but I will talk about research and development.

I believe there will be a tendency to carry out research and development, not in a Government-owned corporation which could try to enlist the most capable young men from our universities and induce them to work for the Government but rather by placing contracts. Contracts would be placed with universities and with industrial companies which have research laboratories. If that were done I believe the universities would fall short of their task, because they would fall short on the development side, and I believe that the industrial research laboratories would fall short on the research side. The industrial laboratories would not be able to attain the services of those spirited younger men who in the past have always preferred university or Government work to work in private industry.

Since it is much simpler to keep contact with a few big companies than to work with many small companies; I believe that the large companies which incidentally have also better facilities for development and research in their laboratories, would be given these development contracts. I believe that these companies would accept those contracts. I believe they would be offered cost-plus-fixed-fee contracts to develop what needs to be developed; and the Government

would tell the companies what to develop. I believe that the companies will not refuse such contracts. I believe they will accept them but they will accept them primarily for the following reason: The larger companies have a desire to watch this development. They want to be able to determine at what moment the development reaches a stage where it becomes profitable for the company to enter this field and start research and development at its own expense.

On the other hand, while these companies will accept the cost contracts they have nothing much to gain directly by the contracts. No patent rights will accrue to them; and in the circumstances I am quite sure that they will not put their best men to work on these contracts. They will save their best men to work on research and development within the framework of the normal business of the company, which is profitable. They will take the Government contracts because they have nothing to lose by taking them.

In saying this I am projecting into the future what is already going on at the present time.

I have talked now for a long time so I will skip what I wanted to say about manufacturing contracts and come to the point which worries me most at the moment.

I believe the most disturbing feature of the Johnson bill is the independence of the Commission from the Government and the fact that the Administrator is not appointed by the President. I believe that the greatest danger is that the operation of this Commission might adversely affect our foreign relations. If I have an opportunity to do so I shall be very happy to outline the different lines of our foreign policy which are conceivable. There are two or three different lines of approach in our relations with other nations which we might conceivably take, but we do not know at the moment in which of these possible lines of foreign policy we shall actually attempt to carry out in the future. The time may come when the Government of the United States, with the approval of Congress, may wish to establish collaboration with certain other countries and may wish to establish collaboration particularly in the field of research and development. Under the Johnson bill, if that time comes, this would presumably be carried out in this manner: The President would issue a directive to the Atomic Energy Control Commission and the Administrator would have to carry out the directive of the President.

What can happen under those circumstances is well known to those who have been associated with the Chicago project. We had such a case in the past. We had a directive which was presumably a Presidential directive, which was communicated to us, and instructed us to collaborate with a certain atomic energy project set up jointly by the British and the Canadians on Canadian territory. At the same time we received this directive, or shortly afterward, rules and regulations were issued by the Manhattan District which rendered this collaboration ineffective.

I am not saying that it is a good thing or a bad thing to collaborate with Canada. I am not voicing an opinion on this question. But I do believe that it is not a sound policy to have directives and regulations in conflict with one another; and that I believe would inevitably happen, or let me say it might conceivably happen, with disastrous results to our foreign relations, under the Johnson bill.

Let me repeat: I believe that our relations with other nations may be endangered if the organization which controls atomic energy in the United States is in a position to issue rules and regulations which render Presidential directives ineffective.

There are two more points about which I wish to speak, and I think I can speak of them shortly because I believe that others will take this matter up. I believe Dr. Anderson is going to testify today and may speak about them.

With reference to secrets, let me say that clearly the biggest secret was given away with the use of the atomic bomb, because knowing that such a bomb can be made is half of the secret. I believe that the other half of the remaining secret was given away when the War Department released the Smyth report, because that report clearly indicates the road along which any other nations will have to travel. If they do travel along that road they will step by step rediscover what we have discovered, and step by step they will obtain the same results we have obtained.

That does not mean that we have no secrets left. We have scientific secrets left and we have what you may call the know-how left. Almost all of the scientific secrets which we have left—and some are important secrets, I believe—relate to the development which may take place in the future. They have practically no bearing whatsoever on the kind of bombs we have used against Japan. This is one kind of secret. The other kind of secret is the know-how. The know-how is not a simple secret that you can write down on a piece of paper. It is something that is exceedingly difficult to transmit. I think the only way you can transmit know-how is to send a couple of engineers over to some other country. By taking blueprints along, explaining them and having consultations, they may be able to transmit the "know-how," but I am not sure even then whether it could be done easily.

In the past we had a very important secret, namely, the secret that the bomb existed. That secret was kept. It was not kept because employees of the Government were afraid of the Espionage Act. It was kept because we all understood it was important to keep it. I do not believe that secrets can be kept by any other method than by free cooperation of those who are in possession of the secret.

If a bill is passed which contains the type of security rules whereby the Commission could decide that what information should be transmitted between scientists who may work in this field at different sites in the United States. It will have two kinds of effects as to the rules which the Commission will issue, if they resemble the rules which we had during the war—well, there are two things I have to say about them. One is that it is impossible to keep them, and, the other that we do not want to keep them.

Mr. HOLIFIELD. I would like to have the gentleman elaborate on that a little bit.

The CHAIRMAN. We will give him a chance, of course. Go ahead.

Dr. SZILARD. The rules about which I speak regulated how much information we could give to each other. Certain men were allowed to know certain things; certain groups were allowed to know certain things. They were not allowed to know other things.

I do not know whether you ever tried to learn basic English. In talking basic English you must remember which words you have to

forget. You can learn basic English, but I do not believe you can learn basic English if every month a new list of words is issued to you containing new words which you may use and possibly old ones which you used before and which you must not use any longer. This kind of rules could not be obeyed if you wanted to obey them. But we did not want to obey them, because we had to choose between obeying these rules and sabotaging or slowing down our work; and we used common sense in place of obeying rules.

Hardly a week passed that somebody did not come to my office at Chicago from somewhere wanting to convey a piece of information to which I was not entitled. They usually said that they did not ask me to conceal the fact that I came into possession of this information, all they asked was that I conceal from the Army the fact that they were the persons who had given it to me. These men went to such trouble not in order to please me, but because they thought I needed the information for my work.

I can assure you that if you pass the Johnson bill and if it is possible to keep spirited men in this organization, they will go on violating these rules. What will be their position? I do not believe that they will be sentenced to 10 years in jail because they told each other a piece of "secret" information. I think, however, that they would be in no position to speak up and say for instance that the Administrator or the Commission is no good. I think they would not dare to do that, because if they did so, someone might remember that on such and such a date this man violated the rules by passing on to a coworker an exceedingly important secret, so important that no one could be told what the secret was. He could then, under the Johnson bill, be dismissed or sentenced to 10 years in jail. He might be dismissed not only from employment by the Commission but from any other Government agency.

So, this part of the security regulations means that no one in the United States might be able to criticize the Commission. Those who have not been in the organization do not know what to criticize, and even if they knew, their opinion would carry no weight. Those inside the organization would not criticize and risk being put in jail. We do not have such stringent regulations now, yet our men are intimidated. With the passage of the Johnson bill many of the younger men would not want to lose their civil rights and would leave this field of work. They will not go on strike; they will not declare that they will not work, but they will prefer to accept other employment. Those who remain will conform. They will do their job; and if they come to the conviction that their assigned work is not really the right one, that to do something else would be more important, if they come to the conclusion that the nine men on the Commission do not live up to their responsibility, that each one of the nine thinks that the other eight are doing the job, if they come to the conclusion that the Commission is no good, they will keep that knowledge to themselves.

I am not qualified to speak about for the younger men. I think that the backbone of this project will be the men below 45, a class in which I do not belong. I think it will be the younger man who will count; and I do not want to speak for them. Mr. H. L. Anderson, is here to testify and he can tell you of his own personal reactions.

So I will close with one request. This morning I received a telegram from the Oak Ridge and the Chicago atomic scientists and who wish to make a statement, and they have asked me to submit their statement to you. If the chairman would permit me, I shall not interrupt this testimony by reading their telegram, but instead will ask Mr. Anderson, who will testify, I believe, after me, to read the telegram at the end of his testimony so that we do not interrupt the present discussion. I propose to hand the telegram to Mr. Anderson and he will read it later, if that is agreeable to the committee.

The CHAIRMAN. He is going to testify later?

Dr. SZILARD. Yes.

I have finished my statement.

The CHAIRMAN. Doctor, as I understand your position, it is that if this committee decides that a commission ought to be set up to control and regulate the production of atomic power, it ought to be composed of representatives of other agencies of the government which you have named?

Dr. SZILARD. No; I cannot say that. I am not in position to make really any proposal. I had not thought about it long enough. But I would prefer the type of commission I have mentioned to what you have now in the bill.

The CHAIRMAN. You have suggested already that in the set-up that you put on the blackboard there ought to be personnel from other agencies, Cabinet officers, for instance.

Dr. SZILARD. I would prefer this solution to the one which you have now. But I do not want to imply that I believe that by taking this bill and amending it piece by piece, replacing one paragraph by another paragraph, and by juggling with amendments, it is possible to produce a bill that will have the approval of the majority of the scientists.

The CHAIRMAN. You do favor, if it is controlled and regulated, that it be done by an agency of the Government rather than private industry?

Dr. SZILARD. Yes, sir.

The CHAIRMAN. Are there any questions?

Mr. THOMASON. If I understand you correctly, then, you favor giving the secret of atomic energy to foreign countries?

Dr. SZILARD. No, sir. I think that discussing whether we should give away the secret or not is putting the cart before the horse. I should be only too glad to elaborate on this if I can make another statement today or some other day. The question is, What shall be our relations with other nations? After we have decided that, the question will be, What kind of arrangements do we want with other nations? If we know we can get those arrangements, then as a part of the arrangements we will give as much of the remaining secrets as is adequate.

Mr. THOMASON. Did I correctly understand you to say that you do not believe it is much of a secret anyway?

Dr. SZILARD. Even if it is not much of a secret, it is still something. There is no such thing as the secret of the atomic bomb. I have read the Smyth report and I know a little bit more than was put into the report. Hardly anyone knows all the details.

Mr. THOMASON. What was your connection with the project?

Dr. SZILARD. My work was, since March 1939, to develop methods of producing plutonium, one of the two substances which I mentioned.

Mr. THOMASON. For whom do you speak in your testimony?

Dr. SZILARD. I am testifying for myself only. But the Chicago group and the Oak Ridge group have both sent a statement which will be read by Mr. Anderson.

Mr. THOMASON. What is your connection with the University of Chicago?

Dr. SZILARD. I am employed at the University of Chicago under a contract with the Government.

Mr. THOMASON. In what capacity?

Dr. SZILARD. I can tell you my salary, but I cannot tell you my rank. My salary is \$11,500.

Mr. THOMASON. By whom is that paid?

Dr. SZILARD. By the University of Chicago, but it is reimbursed by the Government.

Mr. THOMASON. Then you are paid by the United States Government?

Dr. SZILARD. No; I am paid by the University of Chicago.

Mr. THOMASON. But you say that they are reimbursed by the Government.

Dr. SZILARD. As far as I am concerned it is the private business of the university where they get their money from.

Mr. THOMASON. What is your educational background in that field?

Dr. SZILARD. I have been working in the field of nuclear physics since 1934, first in London and then at Oxford. I started to work on atomic energy in March 1939 at Columbia University. In October 1939 Mr. E. P. Wigner and I approached Professor Einstein to get his help to convey to President Roosevelt the need for Government activity in this field. Dr. Alexander Sachs, in New York, with whom Mr. Wigner and I consulted, took Mr. Einstein's letter to President Roosevelt, and President Roosevelt appointed, at the request of Professor Einstein the director of the National Bureau of Standards, a representative of the Army, and a representative of the Navy to serve as a committee to look after the interests of the United States Government. The committee was later enlarged and finally attached to the NDRC.

Mr. THOMASON. In any foreign countries were you employed in this field?

Dr. SZILARD. Only in England.

Mr. THOMASON. You were born in Hungary?

Dr. SZILARD. Yes. I left Hungary in 1920. I studied in Germany. I was on the teaching staff of the University of Berlin from 1925 to 1933.

Mr. THOMASON. What were you studying at the university—physics?

Dr. SZILARD. Theoretical physics, primarily.

Mr. THOMASON. How long have you lived in this country?

Dr. SZILARD. I first came as an immigrant in December 1931, but returned to Europe and lived in England from 1933 on. I have not left the United States since January 1938.

Mr. THOMASON. How long have you been a naturalized citizen of this country?

Dr. SZILARD. Since 1943.

Mr. THOMASON. I believe you have some patents of your own in the atomic field, have you not?

Dr. SZILARD. I made certain inventions in the field of atomic energy which I communicated to the Government. I did not apply for patents until after the Government took over this work and then the Government applied for patents in my name and these basic patent applications are the property of the United States Government.

Mr. THOMASON. Your inventions have been patented by the United States Government?

Dr. SZILARD. Yes, the Government applied for patents.

Mr. THOMASON. Did you give those to the Government?

Dr. SZILARD. Yes; The Government offered me the sum of \$25,000, which I refused to take. What I was willing to take was \$330 of back salary for the months in which I worked at Columbia University and in which I did not receive a salary, and my actual expenses. This amounted to the sum of about \$15,000, or \$10,000 less than what the Government wanted to pay.

Mr. THOMASON. Did you refuse to give the United States Government copies of your inventions?

Dr. SZILARD. No.

Mr. THOMASON. Did you refuse to give the United States Government copies of your patents?

Dr. SZILARD. No; certainly not.

Mr. THOMASON. Do they have them now?

Dr. SZILARD. They own them.

Mr. THOMASON. What about your applications and your blueprints in connection with the patents?

Dr. SZILARD. The United States Government has everything that I have invented in this field.

Mr. THOMASON. You surrendered them upon condition that you retain copies, did you not?

Dr. SZILARD. Oh, yes. I have always asked to be permitted to retain copies of my own applications.

Mr. THOMASON. What personal rights did you retain when you surrendered your inventions and patents to the Government and retained copies?

Dr. SZILARD. No rights.

Mr. THOMASON. Did you not reserve some personal rights to do with those patents and inventions as you wanted to do with them?

Dr. SZILARD. No. The only right I reserved is to retain a copy as my own property to be kept in safe deposit with the university.

Mr. THOMASON. What did you do with them?

Dr. SZILARD. I do not have them.

Mr. THOMASON. What did you do with the copies?

Dr. SZILARD. I do not have them.

Mr. THOMASON. What became of them?

Dr. SZILARD. They did not give them to me.

Mr. THOMASON. You did have copies of the documents you gave the Government?

Dr. SZILARD. No. The Government drew up those patent applications, I only signed them; and the Government filed them in the Patent Office. So they belong to the Government. I just asked them to let me have a spare copy so I could refresh my memory as to what I had done.

Mr. THOMASON. What did you do with that spare copy?

Dr. SZILARD. I don't have it. I just asked for it.

Mr. THOMASON. You know what it is and you can reproduce it if you wish?

Dr. SZILARD. I could not very well reproduce a hundred page document.

Mr. THOMASON. Are you personally the author of those documents?

Dr. SZILARD. Yes. Either the sole author, or a joint author.

Mr. THOMASON. There is nothing to prevent you, under your agreement with the Government, from reproducing them?

Dr. SZILARD. No, but I cannot reproduce them from memory.

Mr. THOMASON. Can you in any other way?

Dr. SZILARD. No.

Mr. THOMASON. What would you expect to do with them if you had them?

Dr. SZILARD. I would like to keep a copy of my own invention. I think every inventor likes to keep a copy of his own invention, just as every author likes to keep one copy of the book he wrote.

Mr. THOMASON. What is the nature of this patent or invention of which you claim to be the author and which you later turned over to our Government?

Dr. SZILARD. I am sorry. May I hear your question again?

Mr. THOMASON. What is the nature of the inventions of which you are the author and producer and which you later turned over to the Government?

Dr. SZILARD. It is a system composed of uranium and graphite and is a method for producing plutonium, one of the substances manufactured in our present factories of which I spoke.

Mr. THOMASON. In its final analysis it goes to the final manufacture and production of the atomic bomb?

Dr. SZILARD. If you wish.

Mr. ARENDS. Do you think there is any defense against the atomic bomb?

Dr. SZILARD. There is no military defense. I think our vulnerability will be much less if we relocate 30 million to 60 million of our population. It may be necessary to do that unless the international picture improves.

There is one more thing that can be done. Certain key factories and vital installations can be placed underground. That would be quite an effective defense. A defense in the ordinary sense I do not believe exists.

The CHAIRMAN. Doctor, let me suggest to you that you make direct answers without any more explanation than you can avoid.

Dr. SZILARD. I did not quite understand you, Mr. Chairman.

The CHAIRMAN. I just want you to be as brief in your answers as possible.

Dr. SZILARD. I shall be as brief as I can without being inaccurate.

Mr. BROOKS. As I understand your testimony, you feel that the penalties in the bill will not help to retain the secrets in any way?

Dr. SZILARD. Who will betray the secrets? If you take a man who wants to betray those secrets—I do not know for what purpose he would do so—if he wanted to do it he would do it in the same manner as spies do.

Mr. BROOKS. So you feel that penalties would do no good. Would they have the effect, in actual operation, of driving away young men, especially, who did not want to be in an industry subject to penalties?

Dr. SZILARD. Let me put it this way. It will do very little good and it may do very much harm. I would not say that it would do no good.

Mr. CLASON. It is your opinion that this commission which is set up in the bill is too rigid; in other words, it will keep the whole subject of atomic energy within such close bounds that there is not going to be a possibility for development for domestic and industrial use which might otherwise result?

Dr. SZILARD. Yes. I believe that the bill will give the commission powers which they do not need. We can figure out what powers they need and give them the powers that they do need.

Mr. CLASON. If persons have been working on the Manhattan project for the Government at considerable salaries, and if they were not further employed by this commission and the Administrator, all of the time which they have spent, all of the research and all of the development which they may be capable of, might be lost to the Nation. Is that so?

Dr. SZILARD. Not quite. They left their records behind. What they have done would not be lost. The men would be lost; yes.

Mr. CLASON. If they were not given a license or the privilege of working on research and development they would have to seek other paths in which to earn a living?

Dr. SZILARD. Yes. Their past experience would be lost.

Mr. CLASON. And you would expect that any commission which carries on this work in the future would be smaller in number of employees and scientists than the number that were employed during the war?

Dr. SZILARD. Vastly smaller; yes.

Mr. CLASON. And therefore the effect of it, under the terms of the bill as it is now drawn, would be to prevent a great body of scientists, physicists, chemists, electrical engineers, and others, who might not be employed by the commission in the future, from conducting their research along atomic energy lines unless they happen to get a license from the commission?

Dr. SZILARD. Let me correct myself in this respect. I believe that the number of scientists employed will be smaller than during the war. I do not believe we will lose as much in number as in quality. If you have a hundred physicists in a group and you take the 10 best ones away, the other 90 will be of no use at all. It is loss of quality rather than quantity that I believe will take place.

Mr. CLASON. After listening to you it occurs to me that there is perhaps a lot of information in regard to this research in connection with atomic energy which has not been brought out to the knowledge of the public. I notice in an editorial today in the Washington Post a statement that there apparently have been conferences and consultations with persons who might know, and it might not be a bad idea for the Government to proceed with its research and development, as at the present time, under the direction of the War Department and give considerable study as to the type of commission or corporation which the Government might wish to set up to actually control the development of atomic energy. What would you say as to allowing the War Department to continue for a time under such legislation as may be necessary to protect the interests of the Government, and at the same time give Congress and the public an oppor-

tunity to find out what the entire subject matter is, in order that a proper commission or corporation might be set up?

Dr. SZILARD. I would be wholeheartedly in favor of it. I believe the War Department should be encouraged to spend, perhaps even more money than it spends at present. I think it should be encouraged to carry on until Congress has studied this matter. I am wholeheartedly in favor of this proposal in the editorial.

Mr. CLASON. We have been advised that \$600,000,000 was being made available for this Commission, or, in the absence of the Commission, the War Department, to use in the further study and development and research along atomic energy lines. Would you say that that is a sufficient sum to carry on until July 1 of next year?

Dr. SZILARD. I do not know whether it is sufficient, but I believe the War Department should be given any reasonable sum which in the judgment of the administration would be necessary to carry on; and they should be encouraged to carry on.

Mr. CLASON. It seems to me that \$600,000,000 is at least a good start toward anything that they might need.

With reference to this Smyth report to which you have referred, I gather the idea from your statement that if a person has possession of the Smyth report and that person is one who is a trained physicist and is in position to secure additional information from other trained scientists in other fields, he would be in position to work out the atomic bomb within a reasonable length of time?

Mr. SZILARD. He would not have all the information by reading the Smyth report, but he would have all the information which he needs to know how to go about to find that information which he still lacks. Therefore, I think that lack of knowledge is not a limiting factor, at least not one which would slow down seriously the development. It is more a question of the know-how a mass of technical details which it might take 6 months or a year to work out. But this perhaps will give you the answer: The Smyth report brings the reader up to date to the knowledge which we in the United States possessed in the late fall of 1942. Whether it will take other countries longer than us to develop a bomb will depend on two things: Do they have raw materials available, and can they find the technically trained personnel which is needed to operate factories?

Let me make my position clear in this. The statement has been made that to construct these factories requires high precision work. It has been said that the whole gigantic structure is like a Swiss watch and only the United States, or possibly Switzerland, can do it. It may be true that many of the constructions, and perhaps all of the constructions, require, according to their present design, high precision work. I am familiar at least with one of the most important branches, however; and the reason that high precision work is needed in this branch only is because of the particular design which was adopted. The design had to be perfected in a hurry. It was not a good design. It was a bad design because it required high precision work. You know the story of the man who writes a 10-page letter and then apologizes for the long letter, saying he did not have time to write a short one.

The CHAIRMAN. We have four other witnesses appearing on behalf of some scientific organizations, and we cannot give all of the time to this gentleman. He has had an hour and 15 minutes now. Make your answers direct, please.

Mr. CLASON. I gathered from your statement that in a period of time, from 2½ years up, it may be possible for another country, given capable scientists and research people, plus the necessary elements, to develop the atom bomb just as the United States did during that time?

Dr. SZILARD. I would say that it is more likely than not that another country will have it in 6 years. In 2½ years it is possible; it might not be probable.

Mr. CLASON. The question was suggested by some of your replies which rather indicated to me that you felt that atomic energy can be used in peacetime for industrial purposes and for other than military uses?

Dr. SZILARD. Yes. It will take 5 to 10 years before it can reach a large scope. We could do it right away, but it would not be important.

Mr. CLASON. In 10 years we will get some real benefit from this investment, for industrial and domestic purposes?

Dr. SZILARD. Depending on how good the machinery is that you are going to set up by legislation. If the development work is well guided, 10 years from now atomic power could be a very important factor in our national economy.

Mr. CLASON. Then would you say that the kind of commission set up by this bill would be one that would restrict the development for industrial and domestic purposes more than is necessary?

Dr. SZILARD. I cannot say that. It depends, of course, on who those men of the Commission are. If you can find men who during the day do hard work in their own business and during the night can study the reports on atomic energy development, if such men exist who do not need any sleep, then the Commission may function well, inasmuch as its members would be well informed.

Mr. CLASON. Do you expect General Motors, United States Steel, or other great corporations to go ahead with development and research leading up to production and manufacture so long as they had licenses from some Government commission which might shut them out at any moment?

Dr. SZILARD. I am afraid I cannot speak for any of those companies.

Mr. MARTIN. I would like to ask a question as to your opinion of this particular bill. I gather that you favor some sort of interim control but that you are opposed to this bill as a permanent measure.

Dr. SZILARD. I would very much favor some simple bill which would provide for an interim control solution to give Congress enough time to study adequately all aspects of the problem.

Mr. MARTIN. Could not this bill be used in that way?

Dr. SZILARD. I doubt it, more time will be needed before a good bill can be adopted and the delay may be too long.

Mr. MARTIN. Would you rather see speed in the matter of developing permanent legislation?

Dr. SZILARD. No, but the choice may be between either speed in developing permanent legislation or an interim bill maintaining the status quo until the final bill comes through.

Mr. MARTIN. I have one question on the atomic bomb. Can an atomic bomb be stored indefinitely without losing its power or usability?

Dr. SZILARD. The answer to this question is not a simple one, and I would prefer to give you the correct answer in executive session. It is not exactly a secret but it had better not be discussed in an open session, I believe.

Mr. ELSTON. To what extent could atomic energy be used by private industry?

Dr. SZILARD. At once, or later?

Mr. ELSTON. When it is developed.

Dr. SZILARD. I would suppose that the first application would be supplying electric power in remote regions where coal prices are high, or in mining regions where transportation of coal is difficult. That may be first type of use.

Another use, of course, is the use of the byproducts. During the manufacture of plutonium we produce a large number of radioactive elements which can be used by industry. Industry could use them for research aimed at improving its manufacturing processes, provided they are available.

Mr. ELSTON. Can it be used to run locomotives and steamships and automobiles?

Dr. SZILARD. When you produce atomic power you also produce radiations. You have to protect the driver and the passenger against those radiations. That might mean that an automobile would have to carry 50 tons of shielding material, and that would be rather on the heavy side. For ships this might be possible, but I doubt if it would be very important. Application of atomic power for locomotives I also would doubt.

So I believe that stationary power plants would be the first application. Very large airplanes might be a possibility. But applications for transportation are farther away than for the production of electric power.

Mr. SHERIDAN. Does anyone present have the entire knowledge of what you refer to as the know-how in connection with the production of atomic bombs?

Dr. SZILARD. Put it this way—

Mr. SHERIDAN. Put it my way.

The CHAIRMAN. Answer the question directly, please.

Dr. SZILARD. May I be permitted to give a correct answer rather than a short one. This is my answer. There are persons who have access to all information. But if such a person is unintelligent it does no good to him. If such a person is intelligent he will not try to accumulate all the available information. He will pick out what is of interest to him. So I believe that among those who have access to that information very few, if any, will know everything about the different manufacturing processes, and so on, simply because a scientist is not curious about everything; he does not want to know what he is not interested in.

Mr. SHERIDAN. Suppose that one person or a number of persons should be struck down; would that destroy the know-how procedure that we have?

Dr. SZILARD. No. I believe if some of those persons who believe they know everything were struck down it would promote rather than retard the development of atomic power.

Mr. PHILBIN. Do you know of any defense against it?

Dr. SZILARD. I would discount any statements emanating from either the newspapers or the Naval Affairs Committee of the House in this respect. But defense is possible by relocating our population concentrated in our large cities, and by putting underground some key industries, some vital installations, we might very materially improve the security of this country. I believe the time might come when we may have to do it.

Mr. PHILBIN. There is no scientific device or invention presently being considered that might be able to explode this bomb or offer protection against it?

Dr. SZILARD. I cannot say that no one would invent some such thing. But if anyone invents a device for detonating the bomb at 3 miles distance I would undertake to perfect in about 1 month a defense against the defense, so that it would become inoperative.

Mr. JOHNSON. Who is Mr. Wigner?

Dr. SZILARD. He is from Hungary. He has been in this country considerably longer than I have. He is a professor of physics in Princeton University.

Mr. JOHNSON. Is he a naturalized citizen now?

Dr. SZILARD. Yes, sir.

Mr. JOHNSON. Who is Mr. Teller?

Dr. SZILARD. He is also from Hungary. He was a professor in George Washington University.

Mr. JOHNSON. Is he naturalized?

Dr. SZILARD. Yes, sir.

Mr. JOHNSON. Is Mr. Weisskopf naturalized?

Dr. SZILARD. Yes.

Mr. JOHNSON. Where is Mr. Fermi from?

Dr. SZILARD. He is from Italy.

Mr. JOHNSON. The Kaiser Institute did a lot of inquiry into this thing before we got into the war; did they not?

Dr. SZILARD. I think it was in May 1940. They were going strong in May 1940.

Mr. JOHNSON. Did any of those men have any patents similar to yours, or do they have?

Dr. SZILARD. Mr. Fermi is a coinventor on some of the patent applications with me. He has also other inventions. I know a number of inventions that he made during the war for which the Government has applied for patents in his name.

Mr. JOHNSON. They were all turned over to the Government of the United States?

Dr. SZILARD. Yes; but I do not know whether he owns any patents or retained any rights in patents he may have taken out before he came to America.

Mr. JOHNSON. What about these others? Do you know whether or not they have any patents on any processes?

Dr. SZILARD. As far as Mr. Teller and Mr. Weisskopf are concerned I doubt that they have applied for any patents except patents based on inventions made during the war, which belong to the Government.

Mr. JOHNSON. Is there a group of scientists who were not connected with this project that were also studying atomic energy?

Dr. SZILARD. In this country?

Mr. JOHNSON. Yes.

Dr. SZILARD. I do not believe they could have studied it very effectively, but they may have patents. Paper is cheap.

Mr. JOHNSON. Is it your opinion that the present development of this is so dangerous that the Government should retain complete control of it and dictate who may do the experimentation and handling of atomic energy?

Dr. SZILARD. I do not believe that there is any serious danger representing a health hazard. If that were the main danger I would suggest that the Commission be headed by the Surgeon General. I do not believe danger of this sort deserves serious consideration.

Mr. JOHNSON. You are about 50 years old; are you not?

Dr. SZILARD. I am 47.

Mr. JOHNSON. You made the comment here that you thought that the development of this would be taken up by younger men. In other words, you think that it is only in its infancy; is that correct?

Dr. SZILARD. I think it is only in its infancy.

Mr. JOHNSON. And that full development will probably come after your working days are over?

Dr. SZILARD. In 5 or 10 years.

Mr. JOHNSON. The electricity which you say you can generate by atomic energy would be generated in remote places like the Rocky Mountains?

Dr. SZILARD. It would be more interesting to generate it in remote places; because where coal is available there is no need for such a power plant. If you have a hydroelectric plant you must have very long transmission lines. If atomic energy is used you could produce electricity close to the consumer.

Mr. JOHNSON. In small quantities?

Dr. SZILARD. No; not very small. Say a hundred thousand kilowatts. That is comparatively small.

Mr. JOHNSON. You could take a town of 75,000 and build a little plant and develop enough electricity in that little plant to serve that city?

Dr. SZILARD. I think so.

Mr. JOHNSON. Is that what you consider the big future domestic use of it?

Dr. SZILARD. Yes; provided we refrain in the next 10 years from using up the plutonium which we may produce.

Mr. JOHNSON. Did any of these men work in the Kaiser Institute before you came over here?

Dr. SZILARD. No one worked there at that time. I had some connection with it before 1933. It was before I worked in the field of nuclear physics.

Mr. HOLIFIELD. Doctor, I am very much interested in this commission and have been ever since the idea was brought out. Your reason for having four Cabinet members on this Commission is so that the unity of the development shall be in the hands of the Government rather than a separate Government commission or a commission appointed by the President which would be absolutely divorced, you might say, from the general Cabinet knowledge?

Dr. SZILARD. Both knowledge and intentions; yes.

Mr. HOLIFIELD. You think it is important, therefore, that the Secretary of State be on that Commission because of the international implications of the research and development and manufacture adaptation?

Dr. SZILARD. Yes.

Mr. HOLIFIELD. And you think that the Secretary of Commerce should be on it to protect the business interests of America in the future development for commercial application?

Dr. SZILARD. Yes.

Mr. HOLIFIELD. You feel that the general staff should be on from the point of view of military adaptation?

Dr. SZILARD. Yes.

Mr. HOLIFIELD. And the Department of the Interior because of the sources of uranium and plutonium?

Dr. SZILARD. Because our natural resources have to be conserved. My answer is "Yes."

Mr. HOLIFIELD. And your idea is that as to the other three members, one should be brought from those boards and serve for a limited time and the other members retained on that board?

Dr. SZILARD. Yes. One board member from each of the three corporations.

Mr. SZILARD. They would have leisure to study all questions—and then have an opportunity to bring to the Board their knowledge. They will have time to acquaint themselves with the details of the technical problems.

Mr. HOLIFIELD. In other words, you feel that that would bring to the Board current knowledge, actual, current knowledge of these three different phases that you have pictured on the Board.

Mr. SZILARD. That is correct.

Mr. HOLIFIELD. And the men would at all times have access to the technical knowledge from men who were actually in the work, and doing the job?

Mr. SZILARD. That is correct.

Mr. HOLIFIELD. May I ask you—if you will pardon me, I am not thoroughly familiar with these scientific matters of this kind as I would like to be—and I hope you will pardon the facetiousness of the question I am about to ask you, if you would have the extra men on this Board that you have indicated, whether or not they will be appointed from the State of Missouri?

Mr. SZILARD. Every one of them might be appointed from the State of Missouri for all we know.

Mr. HOLIFIELD. On the secrecy question here, you have made the statement that practically half of this secret was revealed in this explosion itself.

Mr. SZILARD. That is true; it was.

Mr. HOLIFIELD. And practically all of the balance in the Smyth report?

Mr. SZILARD. No; I said that half of what remained is contained in the Smyth report.

Mr. HOLIFIELD. Would you have issued as complete a textbook, as the Smyth textbook, had you been charged with that duty?

Mr. SZILARD. No. I would not; and I warned against its publication.

Mr. HOLIFIELD. I believe that you say that a man who is aware of the things that are in the Smyth report, he could take those general statements that are set forth, and with the knowledge of the explosion, and with the facts in the Smyth report, he would have a pretty full knowledge of what you were about, and how you went about it.

Mr. SZILARD. He would have a pretty fair knowledge of how to go about the production of an atomic bomb.

Mr. HOLIFIELD. In other words, this explosion, and then the textbook would give them sufficient information as to how to make an atomic bomb?

Mr. SZILARD. Pretty much so. I would say pretty much so.

Mr. HOLIFIELD. I want to now ask you in regard to a statement you made which it seems to me is very important. You said that during the development of this bomb certain Presidential directives, or directives that you had been given during the course of the Manhattan project, or these other projects that were given you, and also administrative regulations were also given you scientists who were well acquainted with these directives?

Mr. SZILARD. That is correct.

Mr. HOLIFIELD. And you made a statement it was impossible to obey the administrative regulations that were given to you?

Mr. SZILARD. No. I did not mean to say that it is impossible to obey them, with reference to our collaboration with Canada. Those regulations were such that we could obey them. They merely prevented communicating or collaboration with the British-Canadian atomic energy project in Canada.

Mr. HOLIFIELD. Regardless of where they were given you in the procedure in the work, it prohibited you—in other words, you were supposed to be prohibited from consulting with any other department?

Mr. SZILARD. That is right. That was the idea.

Mr. HOLIFIELD. As to the knowledge that that other department had.

Mr. SZILARD. That is correct. With reference to various groups working for the United States Government.

Mr. HOLIFIELD. Were those regulations impossible to obey from a scientific standpoint, because you had to have access to this other knowledge?

Mr. SZILARD. Yes. We had to have that information in order to make good progress.

Mr. HOLIFIELD. In order to get a complete knowledge of the project you were working on?

Mr. SZILARD. In order to be able to work with intelligence and get somewhere.

Mr. HOLIFIELD. They were based upon the idea that this was a wartime project, and it was necessary for the scientific information not to be given from one department to another department?

Mr. SZILARD. There was some idea like that behind it, that communication should not be allowed on a number of topics.

Mr. HOLIFIELD. But you feel, regardless of the penalties imposed in this bill, that if they went on with research and development, with any such regulations which would put restrictions on scientific research, which might be placed on these departments, it would not prevent them from passing this information to and fro?

Mr. SZILARD. I think they would go ahead and disobey, and take the risk of the penalty; they could not get very far otherwise.

Mr. HOLIFIELD. You think they would just go ahead and disobey them, and take the risk of incurring such penalty?

Mr. SZILARD. I am confident of that; yes.

Mr. HOLIFIELD. Going to the point of a person who from a criminal standpoint was one who would want to disclose this information, any

penalty that we might write into this bill would not have any bearing with that man, if it were a man, or a group, or otherwise, from a foreign government, which would prevent him from giving out the information which he might obtain by virtue of the risk of the revelation of this secret?

Mr. SZILARD. That is quite so. I do not believe it would stop him.

Mr. HOLIFIELD. In other words, we could not write a penalty that would prohibit anybody from disclosing this secret?

Mr. SZILARD. If they really wanted to do it I do not believe you could.

Mr. HOLIFIELD. Then in your opinion it is impossible for the United States to keep the eventual know-how and secret from getting out from where it may now be known, to another nation?

Mr. SZILARD. Another nation can reproduce these, by carrying out research work of their own so that if nothing leaks out from here at all, and if the United States were to sink into the ocean, still the other nations would succeed rather soon, just by reading the Smyth report, they would be able to go into this field and follow the road step by step to a successful conclusion. This is inescapable.

Mr. HOLIFIELD. How many copies of this Smyth report are there?

Mr. SZILARD. I have heard about 50,000 were sold, but I believe that one sold would be enough.

Mr. HOLIFIELD. I bought one at a book store in Washington for \$1.25 and then I found that I could have gotten it down at the document room for 35 cents after I had done that.

Mr. SZILARD. It received wide distribution.

Mr. THOMASON. How long have you been in the employ of the United States Government, Dr. Szilard?

Mr. SZILARD. Since November 1940, I have been working in the employment of Columbia University which had a Government contract.

Mr. THOMASON. Have you signed applications over to the United States Government for all of the applications for patents that you have developed?

Mr. SZILARD. This question is not a very clear one. I have assigned all of my relevant inventions to the Government. The Government has prepared a number of patent applications which I have signed and which were filed by the Government. But there are other applications prepared by the Government which I could not obtain a copy to study, and I am not fully informed as to their propriety, and those as of which I did not have full information, I did not sign.

Mr. THOMASON. Do you have eight inventions in connection with the atomic bomb?

Mr. SZILARD. Do I have eight of them? That might be right. I have no record of them.

Mr. THOMASON. That you refused to sign applications for patents?

Mr. SZILARD. No, I have not done that.

Mr. THOMASON. Of course, the Government cannot get those patents unless you sign those applications.

Mr. SZILARD. I think my position in regard to those applications is quite clear, that I simply wanted the proper information in regard to them.

Mr. THOMASON. The Government cannot get them until you have signed the applications?

Mr. SZILARD. I am not a patent lawyer. I find it difficult to form an opinion as to the propriety of some of these patent applications.

Mr. THOMASON. How many of them have you refused to sign an application for?

Mr. SZILARD. I have not counted the number of outstanding applications, but this is the situation: the position I take is that I shall sign any application as soon as I am confident that the oath attached to the application is proper; you see, I have to take an oath.

Mr. THOMASON. What is your objection to taking that oath after you have been in the employ of our Government in the development of the atomic bomb, and you have the know-how, as you call it, at least the secrets, and you have proved and perfected to your satisfaction eight inventions, and then you declined to sign an application for each of these patents so that these patents could be issued, and because of the oath that everybody has to take, everybody that is trying to get a patent, that is what they have to do. I am not trying to be critical of you, I want you to understand that. I am not criticizing you. I want to get the facts. I am simply trying to find out what the facts are in this particular situation.

Mr. SZILARD. I have no objection to taking an oath, but I must know that the oath is proper. After all, you cannot ask me to take an improper oath.

Mr. THOMASON. Will you tell us just what the situation is in that regard? How do you feel about that? What is the reason?

Mr. SZILARD. In some cases I do not know whether the oath is proper, that I would have to take. I have to take an oath that a specific application is my sole invention, or that it is a joint invention. I have asked that a patent attorney be cleared so that I may have proper advice on the matter. I think that is only a reasonable request that I be permitted to talk to a patent attorney with whom I could consult on these technical questions. I have been told recently that a patent attorney would be cleared, but I have not been notified yet in writing. Earlier, a year ago, I was told that the War Department would not clear any patent attorney, that there is no one that they are willing to clear for this purpose. Even though you say that I have been in the employ of the Government for many years I am not prepared to take a false oath. I do not feel that I should be called upon to take a false oath.

Mr. THOMASON. Nevertheless, you have refused and continue to refuse to sign these applications?

Mr. SZILARD. No. I have not refused to sign any application when I reached the conclusion that it would be proper for me to sign it.

Mr. THOMASON. While you were in the employ of the Government, and in full knowledge of the secret of the so-called atomic bomb, and you perfected to your satisfaction certain inventions in which the Government was interested, deeply interested as a matter of fact, you had presented to you an application for this patent and you refused to sign it.

Mr. SZILARD. I have told you several times, no, I did not refuse to sign it.

Mr. THOMASON. You declined to sign that because you did not like the form of the oath that is prescribed by law.

Mr. SZILARD. No; it is not the form of the oath, it is the substance of the oath which is involved.

Mr. THOMASON. What is it about that oath that you did not like and would not subscribe to, which every other citizen in this country who desires to obtain a patent has to subscribe to?

Mr. SZILARD. The fact that in the oath I have to declare that I am the sole inventor or a joint inventor, on this question I need legal advice on this question if it arises. I want the advice of a patent attorney on that, and I think it is only fair that I should have it. I am not a patent attorney and I am not prepared to decide questions of this sort alone.

Mr. THOMASON. You do not need much advice, and did not need much advice when you came to discover the great secret that has won this war, and yet you are not willing to turn it over to the United States Government.

Mr. SZILARD. Why do you say that? These inventions are the property of the Government. And——

Mr. THOMASON (interposing). I would like to ask you this——

The CHAIRMAN (interposing). Let the witness finish his answer.

Mr. SZILARD. I did not refuse to turn them over. I cannot accept your statement.

The CHAIRMAN. Mr. Elston.

Mr. ELSTON. Did not you, when you accepted employment in the Government, agree to turn over to the United States Government upon request any patents which you had developed while you were in the Government, which were in the interest of the Government?

Mr. SZILARD. Yes, and I have no desire to repudiate that whatsoever.

The CHAIRMAN. Thank you very much, sir. You have consumed 1 hour and 40 minutes, and we are very glad to have you testify, and I think we have been very much informed by your testimony.

The CHAIRMAN. Our next witness is Dr. Harold C. Anderson of the University of Chicago.

STATEMENT OF HAROLD ANDERSON, PH. D., OF THE UNIVERSITY OF CHICAGO, SANTA FE, N. MEX.

The CHAIRMAN. Dr. Anderson, will you come forward and take a seat, and just tell us your name, and make a statement about this matter.

Mr. ANDERSON. I should be very glad to do so.

The CHAIRMAN. Doctor, you have read this bill, and we would be glad to have your statement in respect of this bill. You can either stand up or sit down as you please.

Mr. ANDERSON. I am very happy to be here, Mr. Chairman and members of the committee.

The CHAIRMAN. May I ask you, before you start in with your statement, that you state your qualifications, and then proceed to your statement.

Mr. ANDERSON. I do not have it embodied in my statement and I will be glad to give it.

The CHAIRMAN. Just give us your background, your education, your experience in connection with scientific research and development.

Mr. ANDERSON. Yes; Mr. Chairman. I was born in New York City in 1914. I was educated in the public schools of New York City.

I received my A. B. degree from Columbia University in 1935. I received my B. S. degree in electrical engineering from Columbia University in 1936. I received my Ph. D. degree from the same university in 1940. I began work on the atomic bomb in 1939, as a research assistant to Professor Fermi of Columbia University, and I continued to work there until the work was transferred to the University of Chicago, to the Metallurgical University. I stayed there until September 1943—November of 1944, I am sorry, and then I went to work at the Los Alamos Laboratory on the Manhattan district project in New Mexico during the past year, and at the present time.

The CHAIRMAN. Thank you, Doctor. Will you now proceed with your statement?

Mr. ANDERSON. I am grateful for this opportunity to present this testimony before this committee.

As a young scientist who has played an active part in the development of the atomic bomb, from the very beginning to the present time, and who would be eager to continue to explore the full potentialities of this development, I would like to present testimony on certain aspects of the May bill which are of deep concern to any scientific worker.

This bill grants broad powers to a Commission in the administration of the security regulations which it may choose to set up. In accordance with the provisions of this bill violations of the security regulations set up by the Commission governing the dissemination of information relating to research on the transmutation of atomic species are punishable if such information has at any time, before or after the passage of this act, come into the knowledge or possession of any person (1) by reason of his official duties, or (2) pursuant to a contract with or license from, or in the course of employment by the Commission, the Administration, any other Government agency, their agents, contractors or licensees, or (3) in connection with certain activities specifically mentioned.

That these provisions can reach any scientist becomes clearer when we consider that an astronomer, making inquiries into the nature of the stars, requires access to information on atomic transformations because the energy production in the stars is believed to be derived from just such atomic transformations. Indeed, he might argue, and with good reason, that to help progress in his field he should be provided with full and detailed information on the atomic explosion in New Mexico since this was the first man-made star.

The medical researcher who will find application of radioactive tracers in his study of disease will likewise seek information and material and will be able to do so only by subjecting himself to the rules and punishments provided for in this act.

Since there will be, no doubt, as a result of the large expenditures of the public funds contemplated in this act, development of devices and techniques which will be applicable in other fields, workers in these other fields will seek enlightenment and become subject to the security provisions of this act.

The penalties for security violation which are provided in section 19 of the act deserve the closest scrutiny. It is provided that "any regulation promulgated by the Commission can, in addition to other

penalties, be ground for dismissal from employment by the Commission or the Administrator, or for dismissal at the direction of the Administrator from employment by other Government agencies; or agents, holders of contracts, or licenses of the Commission, the Administrator, or other Government agencies, without regard to criminal prosecution or conviction thereunder." Thereby, the due process of law is set aside and any person accused of violation of the rules may have his work and livelihood placed in jeopardy at the direction of the Administrator, without recourse to the usual means of protection under the law. Thus, the act admits that any person who receives the great benefits placed at the disposal of the Administrator and who for any reason, as by criticism or in some other exercise of his civil liberties, incurs the displeasure of the Administrator, may have these benefits cut off and be subject to loss of work and livelihood.

Under the cloak of secrecy and in the name of security the Administrator can conceal the inefficiencies and the faulty judgments of his rule. Persons on the outside will have no information which might be a basis for complaint; those who would have access to the information will be afraid to speak.

These are hardly the circumstances under which it could be possible to lure the young college student to take up the discipline of science. They cannot be expected to be viewed with enthusiasm by any scientist who by reason of his past service in development of atomic energy becomes subject to rules of the Commission, and in some cases without knowing what they are.

If we are to advance the national welfare, secure the national defense, insure the national safety, and promote world peace, we need to stimulate the progress of our understanding and pursue the development and utilization of atomic energy. The greatest progress in understanding comes from research coupled with the fullest and most free discussion and dissemination of its results and the related ideas. Frequently, the best ideas are inspired by inquiry into fields having only tenuous connection. Thus, the studies in the field of atomic transmutations gave the clue to the source of energy in the sun; and conversely, many of the studies of the astrophysicists and astronomers proved useful in the development of the atomic bomb. No one can predict how much harm can be caused the progress of science through the limitation of access to information and no one can be wise enough to know what knowledge can be limited without hindrance in the advance to the final objective.

The very existence of provisions for security in an act of law imposes on the Administrator a responsibility to make rules and make a show of enforcing them if only to demonstrate that he is being active and vigilant in his job. Even if he felt it was wise to have no security limitations at all in certain broad and fundamental lines it would be a bold step indeed to make this decision because of the criticism he might receive from some quarters. Thus, I believe that General Groves, the Director of the Manhattan District Project, was bold to have made public so many of the secrets of our work in releasing the Smyth Report.

I do not mean to infer that in the national interest a secret is never a good thing to have. But we have laws governing espionage activities and we have ways of keeping secrets other than by legislative action. In 1939, when the implications of the discovery of nuclear fission were

first considered, the group of scientists at Columbia University, who started active work toward the development of the atomic bomb, enforced secrets on themselves. Through the initial efforts of Dr. Szilard, an arrangement was concluded with the American Institute of Physics to withhold publication of all papers dealing with the pertinent subject in the field of atomic transformations. My own doctor's dissertation which bore on this subject was the first paper withheld from publication and still resides in a locked file under the stamp Secret.

At the Los Alamos Laboratory, where the atomic bomb was built, secrecy was guarded by the scientists themselves, a security body was set up and the scientific workers, for their own discipline, accepted a fine or punishment for each offense. Thus, a file safe which was discovered unlocked at night was punished by a fine equal to one-half day's pay or by the requirement to check out for 10 successive nights at the security office. The close secrecy which was and still is being maintained at the Los Alamos Laboratory is a tribute to the intelligence of the security offices in the consideration of the scientific needs and the wholesome collaboration they gained thereby.

In the interest of international understanding which lies at the basis of any arrangement to insure a world peace, it is essential to avoid a dictated security. In the eyes of a foreign government, the enactment of legislation which shields possible military activities of a government behind a cloak of secrecy, is in itself an act of aggression. It is fraught with just the dangers of mutual suspicion which we must endeavor from the beginning to wipe out, and it will prevent the free intercourse and mutual appreciation which we have to have if we are to deal with other countries on a friendly plane.

I appeal to the Congress to take care not to place in jeopardy the civil liberties of their constituents, to beware lest in their zeal to control they stifle the very object of their control, and to leave open the road to international understanding and world peace.

Mr. Chairman, may I read this telegram before or after questions? I have this telegram which was sent to Dr. Szilard, and I would like to read it.

The CHAIRMAN. You may read this telegram now.

Mr. ANDERSON (reading):

We, the members of the Atomic Scientists of Chicago and the Association of Oak Ridge Scientists at Clinton Laboratories, have carefully considered the provisions of the bill now pending in Congress known as the atomic energy act of 1945. We are strongly opposed to passage of the bill.

It delegates to a commission and an administrator, not responsive to the electorate, the authority and duty of determining and formulating, in addition enforcing all national policy in regard to atomic energy. Neither the commission nor the administrator are responsible in the asking or enforcement of policy to the President or any other authority. Further, they are virtually immune from outside criticism or review because their security regulations may prevent the disclosure of the actions or policies subject to criticism.

Some of the specific features which make the proposed bill objectionable are pointed out below:

1. Complete and arbitrary authority and power over all aspects of atomic energy, whose release has ushered in a new era of our civilization, is placed by the bill in the hands of nine commissioners who, once appointed, are practically speaking immune from removal.

2. Under the broad powers contained in the bill, the proposed commission and the administrator selected by it may restrict all scientific and industrial research in this revolutionary field to Government agencies, may place no restrictions whatever on such research, or may take any intermediate policy.

3. In the new fields, whose importance to our economic life cannot yet be foreseen, the proposed Commission and the Administrator may completely ban private enterprise, or may completely turn over development exploitation, and patents to private interests.

4. The proposed Commission may allow full and complete revelation of all present and future knowledge in the field of atomic energy, or may promulgate security regulations so stringent as to prevent discussion and interchange of information, the lifeblood of scientific progress, even between coworkers in the same laboratory, public or private. The scope of such regulations is not limited to those necessary for military security.

5. Under the proposed bill, the Commission has the absolute power to make grants to any person on such terms or conditions as the Commission or Administrator deems appropriate to its purpose.

6. The directives contained in the bill admonishing the Commission and the Administrator to use their broad and undefined powers for the promotion of general welfare and the advancement of science are unimplemented. No method is provided for their enforcement.

7. According to the bill, the Administrator and Deputy Administrator, who are responsible for the administration of both military and nonmilitary aspects of atomic energy, may be commissioned officers of the armed forces on active duty.

8. We believe that there is a great danger under the proposed bill of retarding the research and development of atomic energy. As citizens and as scientists who have worked to bring to fruition the promise of atomic energy, we believe that controls should and must be exercised by an administrative agency of our Government. The controls must be exercised for the military security and general welfare of our people, subject to international agreement for the preservation of world peace. We believe, however, that the limits and objectives of these controls must be defined by the people through their elected Congress. This may be accomplished only by a law drafted after the fullest discussion in Congress and out, of the meaning and possibilities of atomic energy and atomic bombs. It requires full presentation of the views of the armed forces, scientists, industry, commerce, labor, agriculture, and others whose lives and interests will be affected.

We propose that the present bill be abandoned and that steps be taken to prepare a new bill based on extended hearings and investigation. It should embody enforceable objectives and limitations on the controls to be exercised. If the demands for continuity of the work and military security require immediate action, we propose that Congress pass interim legislation enabling work and security to be carried on for 6 months in the present wartime manner.

Association of Oak Ridge Scientists of Clingon Laboratories: P. S. Henshaw, Chairman; W. E. Cohn, E. G. Bohlmann, S. G. English, H. S. Brown, R. P. Metcalf, J. G. Stangby, L. B. Borst, J. H. Rush, K. Z. Morgan, M. D. Peterson, R. N. Lyon; Atomic Scientists of Chicago: J. A. Simpson, Chairman; D. L. Hill, E. E. Rabinowitch, A. M. Bruce, J. J. Nickson.

Mr. CLASON. As I understand it, you agree to the conditions contained in the telegram?

Mr. ANDERSON. I did not say that I did, sir.

Mr. CLASON. I wonder whether you did or not.

Mr. ANDERSON. In the large, but not in specific details; no.

Mr. CLASON. In other words, you feel that it is necessary for the Government to have some manner of restriction and development of atomic energy?

Mr. ANDERSON. I would not like the Government to restrict research in any field.

Mr. CLASON. Would you say it would be better to carry on in accordance with the present program with the War Department rather than set up a new Commission?

Mr. ANDERSON. I would prefer to see a good bill passed which would permit work on a scale which would attract scientific workers of all competencies in the field.

Mr. CLASON. Did you envisage the Government developing this atomic energy not only for military purposes but for domestic and industrial purposes?

Mr. ANDERSON. I would envisage activities in all of these lines by the Government.

Mr. CLASON. In other words, you feel that the Government ought to have a commission so set up that the purposes for which the commission would seek out atomic energy will cover not only military proposals but also any industrial purposes or other purposes which might be of an advantage directly to the people?

Mr. ANDERSON. I think that is quite correct.

Mr. CLASON. If you set up an organization of that kind, would you expect it to be exclusively a research department of the private corporations and agencies?

Mr. ANDERSON. Absolutely not. I would not expect that.

Mr. CLASON. Do you feel that this bill, by virtue of the method in which it issues licenses and controls atomic energy for all purposes having to do with atomic energy is so restricted that it will prevent private individuals and corporations from going ahead with development as it would otherwise?

Mr. ANDERSON. I suppose the bill will be restrictive of certain development; that is my belief.

Mr. CLASON. Whereas the membership of the Commission—let us talk about that for a moment, the membership of the Commission; do you believe there should be several Cabinet members on it in order to have the people by their designated representatives always fully informed, whether they leave it to nine persons apparently unrestricted or not?

Mr. ANDERSON. Yes. I believe that is essential. I do not believe many people realize the far-reaching scope of this thing.

Mr. HARNES. Would the gentleman yield for a question?

Mr. CLASON. I will yield.

Mr. HARNES. Would you object to an advisory committee composed of elected officials from the House and representatives of the United States Senate to advise with the Commission?

Mr. ANDERSON. I would not object to any type of advisory commission. I believe, however, that there should be a close collaboration between the administration in the sense that it does deal with these international relations and the work of the Commission which would have to do with atomic energy.

Mr. CLASON. You would be perfectly willing that Members of the Senate and Members of the House should sit on the Commission, then, so that the people, through their duly elected representatives, would be directly represented thereon?

Mr. ANDERSON. I that, insofar as it may be a small enough committee, but I would not want it to be an unwieldy committee in numbers.

Mr. CLASON. How large a commission do you think it should be before it would be unwieldy?

Mr. ANDERSON. I am not prepared to say, but it seems to me that a Commission of nine is large enough.

Mr. CLASON. You suggested that if General Grove—first, do you understand that he let loose the Smyth report?

Mr. ANDERSON. The frontispiece of the report says he did.

Mr. CLASON. Would you, if this bill which has been proposed were put into effect, feel that if a person let loose such information that he would be violating the terms of the law and subject to these penalties which you have mentioned, feel that this would cover such a situation?

Mr. ANDERSON. That is a legal matter, and I am not prepared to pass judgment on that.

The CHAIRMAN. Mr. Johnson, do you have any questions?

Mr. JOHNSON. I have a few. Dr. Anderson, I noticed when you read that telegram you pondered over the first part of it for a little while. If it is a personal matter we do not want it in there, but if it is something that we ought to hear, I think that we should have it.

Mr. ANDERSON. No; the first paragraph is not a personal matter. It is addressed to Dr. Szilard. The first paragraph of the telegram reads as follows:

I understand that you agree to present orally the group statement on the May-Johnson bill. Please feel free to add your signature if you desire and have Nixon sign if he will do so. The statement reads as follows.

That is the part that I did not read. I am very glad to read it.

Mr. JOHNSON. You mentioned the matter of the dismissal of these scientific men by the Administrator. You do not believe that scientists should be under civil-service regulations?

Mr. ANDERSON. I certainly do not.

Mr. JOHNSON. Do you not think someone has to have the power of enforcing discipline and perhaps even firing or attending to the removal, having the power of removal of some of these scientists if the occasion should demand?

Mr. ANDERSON. I think it is correct; sometimes it appears that a scientist is not in a very good job for him where he can do his best.

Mr. JOHNSON. In that connection, will you tell me this: Whether there was any friction in the operation of the plant that you worked in?

Mr. ANDERSON. There is always some friction and gripes. Without that, I do not think you would get very much done.

Mr. JOHNSON. Was there anything that seriously affected the progress of the work?

Mr. ANDERSON. No, I really do not think there was. I do not think so.

Mr. JOHNSON. Is it your idea that at the present time we should have an interim bill and then have full hearings before we write permanent legislation?

Mr. ANDERSON. I think that it is of the utmost importance to arrive at a permanent bill at the earliest possible opportunity, not only to initiate and stimulate great progress in this work, and keep it going, but to prevent evaporation of the present personnel. On the other hand, I do not think that we should sacrifice in a poorly considered bill the possibility that this might never lead to fruition.

Mr. JOHNSON. It was stated here in the hearings that this bill was only a stopgap and there might be some permanent legislation affecting our relations with other countries, and the bill was designed primarily for immediate security until we could formulate a better bill in view of circumstances as we would then come to know them.

Mr. ANDERSON. I think that this bill is worse than our present condition under the War Department.

Mr. JOHNSON. Why do you say that, Dr. Anderson?

Mr. ANDERSON. I say that because I would prefer to see that we work during this time, and that it be continued during this interim under the War Department set-up until Congress has had time to consider carefully all the circumstances which it would wish to legislate and pass a good final bill.

Mr. JOHNSON. If the War Department continued the project, would that assure all the scientists that are now engaged in the work continuing in this mission?

Mr. ANDERSON. I am not sure that I can say that they would, but I rather think that the feeling of the scientists is that they are anxious to get back to their academic pursuits and unless—in fact one of the features that Dr. Szilard's plan does have is that it would provide that we would have Government laboratories in the vicinity of the universities, and this would permit close collaboration in the scientific world of these professors who are in the universities and the governmental work as well.

Mr. JOHNSON. Your idea is then that we should try to work out some plan that would capture the ability of these scientists and enable them to continue with their academic pursuits as well?

Mr. ANDERSON. I believe that is the better over-all plan, I think we have to have a plan which will keep the interests and the efforts of the scientists, who would now normally go back to university work, in this great field.

Mr. JOHNSON. Do you have any objection to the provision in the bill that provides for the licensing of the right to pursue this line of work to universities and things like that?

Mr. ANDERSON. No, I think that should be done.

Mr. HARNES. I would like to know what he means by that.

The CHAIRMAN. Let the reporter read the answer.

(The reporter read "No, I think that should be done.")

The CHAIRMAN. You may proceed.

Mr. HARNES. You think the Commission should be set up with full power and authority to control any scientific developments in this field, with the power to license anyone or everybody anywhere that was doing any work on it? In other words, they would have complete control of it?

Mr. ANDERSON. Yes, I think that the interests of Congress would be to provide legislation which will stimulate the work toward that end. There are dangers which I tried to point out in my statement, and I think that Congress should ask itself to take cognizance of those dangers in formulating the legislation.

Mr. HARNES. Do you mean this, that the Commission should have full and extraordinary power that this bill would give them, to either give to an individual or to a scientific group permission or to say to them that you cannot touch this field unless we license you?

Mr. ANDERSON. No; I would disagree with that point of view. I would prefer that the Commission be given no more powers than it is deemed necessary to carry out this kind of work in the best interests of the Nation.

The CHAIRMAN. That is precisely what we are trying to do.

Mr. JOHNSON. That is what the purpose of this bill is. That is all I have.

The CHAIRMAN. Mr. Martin, do you have any questions?

Mr. MARTIN. I have a few questions, Mr. Chairman.

Dr. Anderson, I would like to have your ideas over again about penalties. Did I understand you to say that you would leave the matter of penalties in the field of security regulations to the Federal laws which are presently on the statute books?

Mr. ANDERSON. Yes. That is precisely what I would do.

The CHAIRMAN. The espionage laws of the country?

Mr. ANDERSON. Something like that.

Mr. MARTIN. And not carry any penalties for violations of acts of that nature in this bill, or which would apply to people doing things like that?

Mr. ANDERSON. That is my belief. I do not believe they should be in here.

Mr. MARTIN. Just another question about this matter of the Commission's power to discharge these scientists. As I get it from your testimony, you objected to that power being placed in the Commission; am I right about that?

Mr. ANDERSON. I objected to the power insofar as it voided due process of law. I do not object to the power if there is some redress possible and it is handled in a regular and ordinary manner.

Mr. MARTIN. You mentioned another point about the matter of our procedure. You suggested that Congress make an intensive further study of this field to learn, I suppose, more of the features of the atomic bomb and the control of the work in that field. Do you have in mind in that point that we could in such a proceeding find out the nature of the atomic bomb as to whether it could be possible to successfully store it for long periods of time, and matters of that type, so we will know the general need for security provisions looking ahead, or do you have any ideas of that kind, or, on the other hand, do you have in mind something else?

Mr. ANDERSON. No. I believe there are certain pertinent points, and I believe one of those points which must be considered, and which most strongly indicates the importance of the point which Dr. Szilard commented upon, namely, that there is the question of conserving natural national resources. We cannot overlook the proposition of conserving the natural national resources in this country, particularly, of course in the field of uranium.

The CHAIRMAN. Just one moment. Off the record.

(There was a discussion off the record.)

The CHAIRMAN. On the record. The committee will have to recess at this time because we have to go on the floor. It is now 12:15, so we will recess until 2 p. m. Dr. Anderson, can you be back at that time?

Mr. ANDERSON. Yes. I can return at that time.

The CHAIRMAN. Very well. The committee will now stand in recess until 2 o'clock this afternoon.

(Whereupon, at 12:15 p. m., the committee recessed to reconvene at 2 p. m.)

AFTER RECESS

The committee reassembled at 2 p. m., pursuant to recess.

The CHAIRMAN. The committee will come to order. Dr. Anderson, will you come around?

FURTHER STATEMENT OF HAROLD ANDERSON, PH. D.

The CHAIRMAN. Mr. Johnson, I believe you wanted to ask a few more questions of Dr. Anderson?

Mr. JOHNSON. Not now. I believe I have asked all the questions I had in mind.

The CHAIRMAN. I want to ask the witness a few questions.

Dr. Anderson, in reference to the regulations that are proposed to be authorized by this legislation, of course, none of us know what they will be until they are written. But let us assume that after the Board is set up and licenses are issued to some university, the University of Chicago, for instance, or to some private industry, authorizing them to carry on experimentation and research, and it later develops that in issuing the license we issued it to somebody that was disloyal to this country, and turned out to be an enemy of this country, do you not think the regulations ought to be broad enough to allow the Board to remove that license fee?

Mr. ANDERSON. If you confine the use to the cancellation of the license, it might be, I might consider myself to be in agreement with that.

The CHAIRMAN. Let us assume that the Board makes a mistake and grants a license to the wrong party or the wrong industry, and they are not carrying on research work as the Government feels that it ought to be, or as I said they turned out to be German saboteurs, do you not think they ought to be allowed to eliminate them? In other words, to remove those licenses?

Mr. ANDERSON. It seems to me that there are laws which govern disloyal acts and acts of sabotage. I do not understand why that could not be applied in this case as well as in others.

The CHAIRMAN. What is the difference in a law by statute and a regulation which has the effect of law being applied?

Mr. ANDERSON. In my testimony I tried to point out that if the regulations were made which covered a proper field, then that is necessary, and there may be some reason for that, there might be some reason attendant upon those regulations, and I would feel that they were in the proper field of operation. It is my concern that the regulations might make certain misuse which would be the concern of the scientists which do the work in this field. I do not feel that the scientists in this field should be discriminated against in that way.

The CHAIRMAN. Dr. Anderson, you have not gotten around to my question yet. Supposing a wrong man gets the license, do you not think that the Board should retain the power under the regulation to revoke it?

Mr. ANDERSON. And if the man were considered to be a wrong man by reason of his disloyalty or sabotage activities, then I think that the F. B. I. ought to be called in.

The CHAIRMAN. That is an evasion of my question, young man, that I have asked you time and time again. It is a rather simple question and I cannot see why you cannot grasp it and give me a proper answer to it. I will ask you again, if a man was given a license as a licensee, and he turned out to be the wrong man, do you not think that we ought to retain the power under the regulation to revoke that license?

Mr. ANDERSON. No; I certainly do not think you should retain any such power. No, indeed.

The CHAIRMAN. You do not think it should.

Mr. ANDERSON. Emphatically no; I think that there are other means of taking care of that.

The CHAIRMAN. Well, at least we have your ideas on the subject at last. Mr. Johnson, do you have any questions?

Mr. JOHNSON. A few. Dr. Anderson, here is a thing upon which there has been some testimony. Is uranium and the byproducts of that so dangerous now that we should control it and say just exactly who ought to handle it?

Mr. ANDERSON. I do not think there are any more dangers than some of the other materials which we admit in the hands of workers in the field, and specifically I would say the matter of explosives which are in the field of research and industry.

Mr. JOHNSON. One witness made the point that the products and the method of making was one in which you had to make this which was so dangerous and in such a pioneer stage today that people might unwittingly be handling them improperly, and they could kill off a whole town; what can you say about that?

Mr. ANDERSON. Well, that possibility certainly exists; it is very possible. It is important that this be used properly and that those who use this material use them with due caution and exercise of care.

Mr. JOHNSON. Is that why you believe a license provision in this law will be proper or improper?

Mr. ANDERSON. I think that a license provision in this law would be a proper provision.

Mr. JOHNSON. That is the question I wanted to ask.

The CHAIRMAN. I would like to ask one other question: Do you believe that the control of this force ought to be left in the Government somewhere, or do you think that private industry could take it over and the Government let it go?

Mr. ANDERSON. I believe it ought to be left in the Government somewhere.

The CHAIRMAN. All right, sir. Thank you very much.

I have two letters here, one is a letter and one is a telegram, which I will read:

OCTOBER 12, 1945.

HON. ANDREW J. MAY,
*Chairman, Military Affairs Committee,
House of Representatives, Washington, D. C.*

DEAR CONGRESSMAN: I am enclosing copy of a telegram concerning the bill on atomic energy under consideration by your committee, which I have just received from Dr. J. Robert Oppenheimer, Dr. Enrico Fermi, and Dr. Ernest O. Lawrence. These eminent scientists are members of the scientific panel which was formed by the interim committee to advise it on many matters relating to atomic energy, including, specifically, legislation for postwar domestic control over this field. As you know, the interim committee, which was appointed by the Secretary of War with the approval of the President, was responsible for the preparation of the bill now before your committee.

These men have long been associated with the research on, and development of, the atomic bomb. Dr. Oppenheimer was in charge of the work in New Mexico on the perfection of the bomb itself. Dr. Fermi, who received the Nobel prize for physics in 1938 for his work on the neutron and other nuclear phenomena, has worked closely with Dr. Oppenheimer throughout the project. Dr. Lawrence, winner of the Nobel prize for physics in 1939 for his development of the cyclotron, was the leading figure in the development of the electro-magnetic process for the

separation of uranium 235. Because of the importance of their work on the bomb project, it occurred to me that you and your committee would surely be interested in having the views of these three scientists.

I am also sending a copy of this telegram to Senator Johnson, acting chairman of the Senate Military Affairs Committee, who introduced the companion bill in the Senate.

Sincerely yours,

ROBERT P. PATTERSON
Secretary of War.

SANTA FE, N. MEX., October 11, 1945.

SECRETARY OF WAR,
Chairman, Interim Committee on Atomic Energy,
Washington, D. C.

We would most strongly urge the prompt passage of the legislation now before Congress for the creation of an atomic energy commission. We know from our close association with the actual work in this field that delay will cost us heavily in efficiency, in accomplishment, and in spirit. We believe that with wisdom operations can be carried on within the framework of the proposed legislation safely, effectively, and in the best interests of this Nation. We believe that the broad powers granted the Commission by the legislation are justified by the importance and the perils of the subject. We think it necessary for the American people to understand in full the implications of the new technical situation, but we believe that the proposed legislation will make it possible for their desires and decisions to be responsibly and fully implemented. We assure you that in our opinion the legislation as presented represents the fruits of well-informed and experienced consideration.

J. R. OPPENHEIMER
ENRICO FERMI
E. O. LAWRENCE.

At this time we will call Dr. Arthur H. Compton.

STATEMENT OF ARTHUR H. COMPTON

The CHAIRMAN. Dr. Compton, we are glad to have you here as a witness. Of course, you know what we are discussing here today. We would appreciate you giving us your views on this matter in such a way as you look at it, and give us before that some testimony as to your experience and qualifications and then go into the matter that we have at hand. I wonder if you will be good enough to do that for us?

MR. COMPTON. My name is Arthur H. Compton. Thank you, Mr. Chairman. I am an American, born in Ohio, 1892, educated in this country and abroad. So far as the atomic project is concerned, my first important contact with that was as Chairman of the National Academy of Sciences Committee on the Use of Uranium in War, which had the responsibility for recommending to the Government the program which has been carried through leading to the construction of the atomic bomb. I was assigned first to the O. S. R. D.; later carried on under the Manhattan District the task of developing the method of producing plutonium. At the present time I happen to be on the scientific panel that advises the Secretary of War. I suppose the most important statement I have to make, and I am making my statement quite informally, is that the need for some kind of control is clear and obvious, and that control, I believe, may well be placed in the hands of a commission such as is set up by the May-Johnson bill.

It is, however, at the same time unfortunate that in writing up a bill that is designed for the development and control of atomic power it becomes necessary to emphasize particularly the restrictive clauses.

Having realized as we do, the matter of insuring the safety of the Nation and the welfare of the Nation, it does become important. The safety of the Nation is only very partially secured by any kind of restrictive legislation. The thing that is really important with regard to insuring the safety of the Nation in connection with atomic power is that we should develop our own strength. And that development of our strength means the encouragement of research and of industry. One cannot get very far in the matter of safety of our Nation in the modern world by any kind of restriction. If one recalls that the other nations which may compete with us in the modern world will at the same time get ready and go ahead strongly that statement becomes rather clear. In order, in a competitive world, that we may hold our place the situation is as it has always been that the strong nation is the one that is going to come out on top and survive, in that strength we must rely and that strength is not constructive in this case, which is born of over-all development and vigor in the industry in the field very much like the situation that we have known in the present war where our strength depended in large measure on our manufacturing ability in connection with gas engines. We had a great industry in that direction, and when wartime came on we were able to put it to wartime use. In a somewhat similar way when the next show-down comes it is going to be the nation that has the strength in that field.

Now the difficulty I see with regard to the present legislation in that regard is that whereas this is called a bill for the development and control of atomic power, almost all of the bill is concerned with the implementing of controls and almost nothing is connected with regard to the implementing of the development of atomic power. I think one has to take into account the fact that some years down the line, maybe 10, certainly with 20 years, we can consider the atomic energy industry in the field of shall we say at billion dollar a year industry. If we think of it now from the point of view of our military defense it is already in that category. But I am thinking now of the peacetime industry and the indications it seems to me are clear, and I believe that that estimate would be supported by the industrial leaders who have taken the present situation into account.

With that in mind it would be reasonable for our Nation to invest a considerable amount of its effort in the research and development leading to making such an industry effective. Now, of the sums indicated by one of the members of the committee this morning, that talked of in connection with the support of this work during the next year, which the greater part of that, of course, is in connection with our production for military purposes, only a small fraction in connection with research and development, I would assume that it would be a reasonable estimate to put something like \$50,000,000 or \$100,000,000 at least annually for the next 10 to 15 years into a program of developing peacetime industry leading toward a vigorous national situation with which we can have a background for competition with any other nation in the possible struggle that may come in the future.

As I now see the situation of the present bill, this bill is aimed toward control. The control is I think important that it should be there. One has to recognize the dangers of control, and the dangers are primarily the dangers of preventing those individuals and those industries from engaging in this work that should, for the national

welfare, be engaged in it. I do not mean by that that the research man who could be doing valuable tasks in the study of problems relating to the problem of atomic energy, will go out of that field into one relatively useless field. The actual situation is that the demands of the country for research are so many and are so important that there is only a delicate balance, and if a man finds that work in the present field is under restrictions which make it difficult for him to do his work effectively, he will more or less get out of that field into another field which he feels can be developed with greater profit to the national welfare, and it does not take very much to make that shift. When one faces the restrictions which are necessary, it is important that they be limited to what is necessary and not go beyond. I might say in that regard that I think that it is a very valuable feature of this bill it puts control of work in the hands of a commission for which this matter becomes the major interest, and does not leave it in the hands of, shall we say, a congressional commission or congressional committee that has perhaps changes in its personnel frequently and can spend only a small fraction of its time on problems of this kind. I like that part of the bill that provides and puts it in the hands of a commission. I think that the commission should be encouraged to spend as much time as possible in this type of work.

If it is at all possible, and it is not at all impossible—I think this has to be considered—that there are many arguments for making research in the field of nuclear research that are open—that is a traditional direction in which work of this kind has been leading and tending to go for a long time. No restriction may apply that cannot justify itself. Any restrictions from complete openness would be considered by countries outside of our own as a threat. They would wonder: Is this being done for purely military purposes? Thus a country that plans this freedom of restriction would make it possible for our scientists to do the work that they can do most effectively, and will keep us ahead in this matter.

Mr. HOLIFIELD. Mr. Chairman, may I be permitted to ask a question at this point, or should I wait until he has finished his statement?

Mr. COMPTON. It will not interfere with my train of thought at all.

The CHAIRMAN. You may proceed, Mr. Holifield.

Mr. HOLIFIELD. I am very much interested in your statement, Doctor. In making freedom of research possible, you would at all times allow the Government to know about that research and the nature of it and the findings of it?

Mr. COMPTON. Absolutely I would do that.

Mr. HOLIFIELD. In other words, it would be all right to write into the measure that type of protection that any research should be done not under the control of directives of the Government, but with full knowledge of the Government pertaining as to the lines of research and as to such findings as are made.

Mr. COMPTON. That would be strictly in accord with what a research man would envision and would want.

Mr. HOLIFIELD. That would be freedom to go ahead in a scientific way, but it would make available to the Government those findings?

Mr. COMPTON. I believe it would.

The CHAIRMAN. Would you yield for a question?

Mr. HOLIFIELD. Yes, Mr. Chairman.

The CHAIRMAN. According to that, Dr. Compton, if somebody came in and reported that there is a rattlesnake in the back yard, and does not do anything about it, it would not do any good?

Mr. COMPTON. I do not get the import of your question, Mr. Chairman, or the implication.

The CHAIRMAN. The implication is that we hear of the dangers in the rattlesnake, and the dangers that you scientists see, and if we get nothing from them as to what they want to do to cure it, that would mean that must not do anything about it except tell you, just tell you that it is there, and what I think they should do that it is there and tell you what we should do in order to kill it or take care of the situation.

Mr. COMPTON. I see your point, Mr. Chairman. That is the reason why I like to have this matter in the hands of a commission. I was trying to indicate some of the reasons which may lead to the desire to have a complete freedom. I do not think that that is the kind of matter that ought to be written into a bill. I do not want written into the bill that complete freedom of research should be there, because I do not believe that that is the kind of thing that can be put in or determined, or can be properly drafted and determined by legislation put up and set up in a bill, but I do think that is the kind of thing that should be considered carefully on its merits by a commission which the Congress and the President feel is qualified to pass on such matters. If in the national interest such a commission feels that freedom of research is desirable, then it should be within the limits of the legislation for them to make that research free, and to determine just how it should be done.

Mr. HOLIFIELD. In my opinion, Dr. Compton, such a purpose could be written into legislation, and so far as carrying it out in detail that is another matter. I would like to ask you this, by the very nature of the military need to experiment with this uranium and plutonium would it not be essentially desirable and possible for research to be accomplished in private without the Government knowing about it, particularly if they controlled the sources which the Government does of uranium deposits? Would it be possible for security in research and development in an effective way to be done without great laboratory equipment and without the need of the Government supervising individual equipment in that way and individual research in that way?

Mr. COMPTON. I do not believe that it could be carried on to a dangerous extent without making it necessary to obtain such materials or information that it would come to the attention of those associated with the Commission, a commission of this type that is set up here.

Mr. HOLIFIELD. I understand it, or at least as I do understand it all the information in connection with uranium deposits is known. As I understand it all the Nation's sources of uranium are pretty much under the control of the Government at the present time, of the United States, and they cannot go out and get this material unless the Government knows something about it. If this project is written into this bill and becomes a law, saying that as additional uranium deposits or deposits of materials from which uranium and plutonium can be obtained in reasonable quantities, are brought to the attention of the Government, it will not of necessity mean that the Government

will have to take over thousands or hundreds of thousands of acres of mineral land, but simply a prohibition against the production of the raw uranium ores and the use of it without the Government knowledge; would that not effectively and in a proper way control it?

Mr. COMPTON. I believe it would be possible to write a statement in the bill, and that statement has already been made in almost adequate terms, which would make it possible to control such experiments in terms of the amount of material used. We have one qualification, but here I am afraid one is getting into details that one should hardly bother with at this time—I will, however, mention it—namely, that one should not attempt to prevent small scale experiments by private individuals and of a private individual type, because those are the ones that may lead to very important new results. But I believe that that in intention at least is already being covered by the bill.

Mr. HOLIFIELD. All such experiments should be known to the Commission.

Mr. COMPTON. It would be very difficult to have every experiment known because any student in any chemistry laboratory can do elementary experiments with small amounts of uranium.

Mr. HOLIFIELD. Could they obtain that uranium if the Commission controlled the sources of that uranium? Could they obtain that without the Government having knowledge of the taking of such a small amount, even if it were conducted on a small scale operation?

Mr. COMPTON. Yes; on a small scale they could do so because it is possible to obtain small amounts of uranium out of ordinary granite, and therefore, they could obtain their material in that way.

Mr. HOLIFIELD. But not in dangerous amounts?

Mr. COMPTON. I would say not in dangerous amounts.

Mr. HOLIFIELD. Those are all the questions I have, Mr. Chairman.

The CHAIRMAN. Mr. Martin, do you have some question, you want to ask the witness?

Mr. MARTIN. I wanted to ask the witness his views as to the nature of this Commission control.

The CHAIRMAN. Has he not already stated that?

Mr. MARTIN. I know he has stated some of it, but I wanted to ask about the matter of penalties. Would you place in the Commission any power to impose such penalties as provided in this bill?

Mr. COMPTON. Personally I consider it unimportant whether the penalty is there or not.

Mr. MARTIN. You would not object to penalties if they were put into legislation?

Mr. COMPTON. I think the penalties are much too drastic, but I do not believe that the penalties of the drastic type would ever be imposed.

Mr. MARTIN. How would you give the Commission a complete control in the matter of the hiring and firing of employees on this project? Or would you do that?

Mr. COMPTON. There is a point there that I would agree with you and certainly with one of the witnesses this morning, that it becomes a very critical situation if a man can be released not only from his own job, but prevented from reemployment by any other similar employer on the basis of evidence which does not need to be brought out into the public forum, and that particular provision of this bill I think is indefensible.

Mr. MARTIN. Dr. Compton, now, in the qualifications of the personnel of the Commission, would you want to have the Commission made up of men who are scientists and qualified in that field of work, or would you advocate having the men supervisors, and the Commission supervisory in its functioning, and not necessarily qualified to be in this field of science?

Mr. COMPTON. As one who was in this field and no longer am—I have ceased to be in the field of active scientific work in the last few months—I think I can speak for the scientists more freely than they can for themselves. I think in that regard, I might say, that it would be unwise for obvious reasons, to have a commission at all exclusively of men of scientific background, but it would likewise seem to me to be highly unwise to have a commission on which there was no representation of men who understood the interests, the psychology, the motivations of the men who are working in the scientific field, which means that there should be men with scientific background at least, and background of actual research, some men of that type on this commission.

Mr. MARTIN. Then it would be unwise or possibly impossible to write into such a bill as this any specific designation as to the make-up of this board or commission? How would you get it into the law, the principle that you have just now expressed?

Mr. COMPTON. I might say that among the scientific men who are doing work on this project, one of the active concerns is lest the importance of having some scientific representation be overlooked, and that the only desire to have or rather a main part of the desire to have some scientific connection and composition is traceable to the fact that this point, together with the point that Dr. Szilard brought up for the need of representation in various parts of Government is something that should be taken into account. I might say that my position would be that one would have to rely upon the President and his advisers in the set-up of such a commission, and choose wisely, and an indication might be made, however, in the bill that due recognition should be taken of the need to have representation of various types.

Mr. MARTIN. Then from your point of view you would not feel it necessary to put into this bill any definite directive or restriction of the personnel of the Commission, leaving that designation to the President?

Mr. COMPTON. I would prefer, I believe, not to have specific instructions as to how it is to be composed.

Mr. HOLIFIELD. Will my colleague yield on that particular point?

Mr. MARTIN. I will yield.

Mr. HOLIFIELD. I want to understand this particular part. You mean, after making your plea for scientific men on this Commission, and after Dr. Szilard that men of Cabinet officer rank and other representatives of the heads of departments of the Government be on it, do you mean to say that you think it would be unwise to specify that at least three men of actual science be on this Commission? If I wanted to, and I am asking you if you—well, I am not asking you to approve of this thing, but if we wanted to put down after Secretary of State, the Chief of the General Staff, the Secretary of Commerce, Secretary of the Interior, and others, and then leave maybe two more appointments, say for one Member of the Senate and one Member of

the House, do you mean to say that such a balance to the Commission could not be written into the bill? Certainly, to allow the President to use his freedom on these three men of science who would be designated by the bill, and six others, one to be chosen by the Senate, one from the House, do you not think it would be wiser to write into the bill some type of balance in the Commission rather than a blank check with no one specified? I would like to have your ideas on that. I think that is one of the most important things that we have in this bill.

The CHAIRMAN. Mr. Holifield, will you let him answer your question?

Mr. HOLIFIELD. I will. I just wanted to state it fully.

The CHAIRMAN. I think if you will let him answer your question, he will do so.

Mr. COMPTON. It would seem to me wise to indicate in the bill that due representation from these various fields should be taken into account in the appointment. I can readily see that changed conditions might want to make the number of representatives changed from time to time. At the moment, for example, this is a very live research field. Thirty years down the line the research may be so far along that it is no longer an important research field. It may be more important in industry. It might at that time be more important to have emphasis in a different direction, but at least I would like to see an indication in the bill that representatives of the various parts of the Government, of research, and perhaps of industry should be included as the Commission is named, but whether the exact numbers should be included or precisely which representatives are to be included would seem to me to be a matter of secondary importance.

Mr. HOLIFIELD. Thank you. I just wanted to get your views.

Mr. MARTIN. I do not know, Mr. Compton, that I am qualified to go into these things as deeply as I would like, but I am not sure that I am clear as to the estimate of what the difference of weight between industry and research and military use would be, those three fields, I do not know what members of the official Government agencies are qualified, or as far as that is concerned, possibly to sit on such a commission. We are trying to write a bill now that may be faced with very different conditions of weights and balances in the very near future. That is why I wanted to find out how you felt about attempting to write into this bill some such restriction.

Mr. COMPTON. I would like to have in the bill an indication that it is important that some representatives from all of these groups, and that one of the groups should be a research group.

Mr. MARTIN. Is not one of your principal reasons to see that the research end is not suppressed?

Mr. COMPTON. That is correct, that seems to me at the moment to be one of the things which will determine whether the United States remains in a strong position or falls to a weak position.

Mr. MARTIN. My reaction to the testimony of the scientists so far before us here was that as a group you are more concerned with seeing that you are not suppressed or retarded or discouraged in your research and development work than anything else.

Mr. COMPTON. I think that is probably an accurate statement.

Mr. MARTIN. That is your principal concern at the moment, Dr. Compton?

Mr. COMPTON. Yes; I would put it more positively—that my principal concern is that the bill's intention—that it be made clear that the intention of the bill is to permit the development of industry in the field of atomic energy rather than to make the emphasis, as it now is, in the direction of controlling those who do the work in this field. That change in emphasis seems to me to be, if it is possible to do it, a very important matter.

Mr. MARTIN. Those are all the questions I have, Mr. Chairman.

The CHAIRMAN. Mr. Elston, do you have any questions?

Mr. ELSTON. Just a few. Dr. Compton, I take it that the penalty part of the bill that you particularly object to is the clause which makes it possible for the Commission to make its own regulations and then act as judge, jury, and executioner in the enforcement of them?

Mr. COMPTON. That is precisely it, Congressman.

Mr. ELSTON. I certainly agree with you in that connection. We have too many agencies down here today that are passing rules and regulations, and they are hidden in the Federal Register, and then they send people to jail for violating them, and nobody ever heard about them.

The CHAIRMAN. You are speaking about the OPA?

Mr. ELSTON. About the OPA particularly, and about a number of the others in general. Dr. Compton, you do not object to the severe penalty for giving away secrets of the atomic bomb to a foreign country?

Mr. COMPTON. Really, I do not, because if it is on the basis of intentionally giving it away, no; that, however, is perhaps already covered by the laws in regard to espionage.

Mr. FENTON. That would be treason, would it not?

Mr. ELSTON. It would not exactly be treason because treason is defined by the Constitution to consist of only in levying war against them, or adhering to their enemies, giving aid and comfort to them. That is somewhat synonymous with sedition. Since this might be giving aid to another country in times of peace, certainly the penalty should be equal to the penalty for treason. You do not object to a very severe penalty if it happened knowingly and willfully that someone should give away any secret in connection with atomic power or atomic energy to any foreign country?

Mr. COMPTON. Beyond the limits that are set by this Commission that is correct. When you say that, I think one must consider—well, in that case they are no longer secrets, I suppose.

Mr. ELSTON. In any event, if there is any penalty, Congress has the right to write it clearly and definitely as to the acts that should be punished?

Dr. COMPTON. I really do not see any difficulty with having a severe penalty for willfully and knowingly and, shall we say, with malice toward our own country, giving away secrets which have clearly been described as those which should not, in the Nation's interest, be given away. I might point out in that connection, however, on this, which was reenforced by a statement made this morning—the fact that the Nation's safety is not safeguarded by retaining these secrets. The Nation's safety is safeguarded primarily by building up our own strength, and it is really only a very minor part of our safety that is

concerned with giving away any of this information. I would support completely the statement, I believe, which was made by Mr. Szilard this morning, to the effect that the actual information as to how to make the bomb, even though given would not greatly affect the time at which the rival nation would be able to have bombs ready to drop upon us. But the thing which will greatly affect our comparative situation is the degree of encouragement and number of activities of a scientific and industrial way, that we set up in this country in this field. If we find that by making severe penalties, imposing close secrecy conditions on our men we are retarding the development of the work in our own country, then is the time that we must face the fact that we have gone too far. It may have already done us severe damage. So that I—while I do not think that those penalties are out of place, I would like to have us get away from the notion, because I would consider it an aspect very close to treason, and I feel it has very little to do with the national safety; national safety has more to do with what we do to encourage or discourage the development of work in this country along this line.

Mr. ELSTON. You feel that this bill, as drawn, will discourage rather than encourage the development of atomic energy in this country?

Mr. COMPTON. I think that is one of the difficulties. I do believe we should so tone down this bill. I believe it is a good bill and that it can be modified in such a way as to get rid of this difficulty; at least, I hope so. I think that is the difficulty, but I do not think it is at all insurmountable.

Mr. ELSTON. In any event you do not see any reason to set up an independent agency that gives more power, gives more power to it than any agency that has ever been given in the history of this Nation, do you, Mr. Compton?

Mr. COMPTON. Instead of answering that directly, may I say that if that agency is necessary to supply the safeguards required, it should be set up. At the present time I am doubtful whether the extremely broad powers can be justified. They seem to me to have little to do with the question as to whether the field of research and industrial development of atomic power is encouraged, and again it is the encouragement of the field of activity which seems to me to be the primary concern of this Commission.

Mr. ELSTON. If you gave this Commission the authority that is requested in this bill you would make it possible for the Commission to completely nationalize atomic power if they wanted to, on the other hand they could use it entirely for industrial purposes, could they not?

Mr. COMPTON. They would appear to have tremendous powers under this bill. Just where they would take them I would not know.

The CHAIRMAN. I do not know whether that was the question or not, I think it was a statement more or less.

Mr. ELSTON. I said if you gave this Commission all the authority that is requested in this bill you would make it possible for the Commission to completely nationalize atomic power both for military and for industrial purposes, would you not?

Mr. COMPTON. And to that I would say "yes." I merely affirm your statement. There was one aspect with regard to the placing of the Commission in a situation with regard to the national policy.

We have here a Commission which in its present form has very broad powers. I believe perhaps the powers have to be broad, though perhaps not as broad as they are now. But there is one aspect of that—this continues longer than the President continues, because the person on the Commission continues for 9 years. That means it is not impossible for the national policy to be carried on by such a Commission beyond a change of national ideas with regard to international policy. With the very broad powers now written into this bill for this Commission to control atomic energy, it might be carried on under these conditions in a manner which is not in accord with the rest of the Administration's policy. That is a hazard that needs to be considered.

The CHAIRMAN. Do you have anything further, Mr. Elston?

Mr. ELSTON. That is all I have at the minute.

Mr. HARNESS. I have this question too to ask the Doctor. Doctor, it is not clear to me just what we are trying to do here, we are setting up this Commission and giving all of this power in authority there for research and development of this atomic energy. Is it for the purpose of safeguarding any future development, or present development against some other nation acquiring it, or is it for our own safety in protecting us in the United States?

Mr. COMPTON. I believe—really, I am not the person to have you ask that question because I knew nothing about this bill until after it had come to your attention. But my impression is, I will say this, that it is important that some bill on atomic energy and work in atomic energy be brought into effect for our own internal, national welfare. It is dangerous to play with. We cannot leave it without restrictions.

Mr. HARNESS. Dr. Compton, is it dangerous to experiment with high explosives; that is most dangerous, is it not?

Mr. COMPTON. That is quite dangerous from the standpoint of the explosives; yes.

Mr. HARNESS. There is no restriction on that?

The CHAIRMAN. Oh, yes; there is. There are restrictions concerning the development of high explosives and the handling of them, and there have been for many years.

Mr. HARNESS. Scientists and laboratories can do all the experimenting they want to in connection with high explosives.

Mr. COMPTON. I would put it somewhat more closely in comparison with people playing with narcotics, that it is something that is very dangerous if allowed to get out of hand. I do think that the kind of control that we have in the case of narcotics might be a rather good example of what should be followed here.

Mr. HARNESS. Do I gather from that, then, that this development, and that this discovery is something that is dangerous and that it might destroy over a period of years our own people who play with it, and those who come around it?

Mr. COMPTON. The best answer that I can give to that is that in the several years that I have already passed during which we have been actually working with these large atomic bomb plants, some of them working at a very high level of density in all of our work there has not been one serious accident.

Mr. HARNESS. Dr. Compton, I did not clearly understand then why you say you have to have this control for our own welfare—be

specific, tell us something about what it will do to an individual which makes it important for us to have that sort of thing.

Mr. COMPTON. It is very possible to kill people with radiation burns, and I would say that that is the chief hazard.

Mr. HARNESS. Any more dangerous than the X-ray and electric energy?

Mr. COMPTON. By degree only, being perhaps thousands of times more intense than one has from X-rays. Both have the type of restrictions required, but in different degree. By that, however, the type of restrictions needed are comparable with this that we now have in the Pure Food and Drugs Act. I think the restrictions that are in the Pure Food and Drugs Act are somewhat similar to the ones that might be required here. I see no reason, for internal reasons, why the restrictions should be of a more severe type than those which would come into such a case. The only reason for this severe type of penalties or restrictions would perhaps be those with regard to letting information of a critical type get into foreign nations' hands. That would be the type of information that might be useful in connection with the construction of weapons.

Mr. HARNESS. There is no law that could prevent that anyway, is there?

The CHAIRMAN. As to that, there certainly is.

Mr. HARNESS. I mean, you cannot write a law that will prevent an individual from making a discovery. It might be right there in his brain, he might discover it right out of thin air, like you have discovered some of these other things. There is no law that will prevent them from discovering it.

Dr. COMPTON. No. It is possible, of course, if one wants to restrict the publication of the information.

Mr. HARNESS. We might restrict in a measure his dissemination of the discovery.

Dr. COMPTON. I would prefer personally in that regard to leave the activities in connection with publications in the hands of a scientific group that knows the importance of these discoveries, but that is a question that can be determined by the Commission.

Mr. HARNESS. Of course, you can gather, Dr. Compton, that I am confused about these things. I know so very little about these scientific matters, and it is difficult to get a picture of what we ought to do.

Dr. COMPTON. May I say again that I favor the idea of a Commission substantially now in the form presented in this bill which could, after the result of careful consideration as you are now giving it, determine what restrictions we should have for the Nation's welfare, and from that point of view, I feel it is good. It depends upon the personnel of the Commission to a great degree in any event.

Mr. HARNESS. This would be a blank check of authority to the Commission to determine what is good for the welfare of the Nation?

Mr. COMPTON. That would be a blank check. Whatever restrictions Congress wants to make of the extent to which they want to go is something that should be written into the bill. I have not been able to think of any such restrictions that I would want to place on them at this time.

Mr. HARNESS. Dr. Compton, I do not think I understood an answer to a question a few minutes ago just what you had in mind,

but something to the effect that in private industry or in private laboratories they could continue their research and study in this field, but it could not do any harm; is that correct?

Mr. COMPTON. I said that the amount of material they have would mean that the work they did in all probability would not do any harm.

Mr. HARNES. I just wanted to get that clear. In your opinion, in private industry or in private laboratories they could continue their research and study in that field but they could do no harm.

Mr. COMPTON. I believe that is correct.

The CHAIRMAN. Just a moment, gentlemen. We have a roll call now. We will recess now, and we will return and reassemble at 3:30 p. m.

(Whereupon, there was a short recess.)

The CHAIRMAN. Mr. Brooks, do you have any questions?

Mr. BROOKS. I have only one or two questions, Mr. Chairman.

Doctor, there has been a good deal of comment in the press and on the radio and elsewhere about the matter of whether or not the Nation should retain the secret of the atomic bomb. In the armed services in the past has it not been a matter of policy to retain our secrets, whether military or naval secrets, and not give them to other powers?

Dr. COMPTON. Yes.

Mr. BROOKS. Is there anything different in the atomic bomb in that respect that would cause one to come to the conclusion that we should not follow the normal policy?

Dr. COMPTON. With regard to the bomb itself, that is, the construction of the bomb and its effectiveness and all matters pertaining to it, I should say that it stands in precisely the same situation as other types of weapons. Atomic energy, however, has peacetime applications. The research which leads to the development of atomic energy and likewise to the improvement of atomic bombs has many other applications, and in that regard this differs from most of the other types of weapons with which we are familiar.

Mr. BROOKS. There is nothing in the potential peacetime usage of the atomic energy which would cause one to reach any other conclusion than to follow the normal policy of the Nation in maintaining its military secrets. Is not that correct?

Dr. COMPTON. With regard to those which are strictly military secrets, I would say, "yes."

Mr. BROOKS. Even gunpowder, if used for civilian purposes, and almost any weapon can have a civilian usage?

Dr. COMPTON. It has already been brought out that the so-called secrets leading to the development of the bomb, so far as they are concerned, were purely scientific information. They are so widely known that there is little of a secret to be released. The secrets that we have remaining are primarily concerned with technical know-how in connection with the production of the materials of which the bomb is composed and the construction of the bomb itself. Those remain secrets. So far as the growth of the field of knowledge and industry in connection with atomic energy is concerned, there is no reason why those should be made open, so far as I can see. But there is an important reason, so far as the national strength in the development of knowledge and industrial applications are concerned, in having exchange of ideas on purely scientific grounds.

Mr. PHILBIN. Are you aware, Doctor, that there are scientific developments to the extent that there is possibility of defending against the atomic bomb as a military weapon?

Dr. COMPTON. If you refer to a means of stopping the bomb itself, I am not aware of any. I would say that it is a possibility that should be investigated. But there is no reason that I know of why it would be easier to stop an atomic bomb than it would be a shell or a rocket or any other kind of explosive-carrying material.

Mr. PHILBIN. Science has not yet worked out any way by which any kind of bomb could be intercepted?

Dr. COMPTON. That is correct.

Mr. PHILBIN. As to the quality of the bomb itself, is it dangerous to have around? Is there any danger per se in having a bomb located close to habitation?

Dr. COMPTON. No. In making an atomic bomb explode it is necessary to do it intentionally. There is no reasonable possibility of its going off without careful preparation.

Mr. PHILBIN. So far as you know, there is nothing in existence now that can make it possible for us to be defended against it if used as a military weapon?

Dr. COMPTON. I know of no such possibility, and I do not see any on the horizon.

Mr. PHILBIN. That is all.

Mr. HOLIFIELD. Doctor, in your testimony I seem to see where you want to draw a clear line between the domestic use of this bomb and research and development for the purpose of domestic use and its military application. In order that I may understand your views, I want to ask you a few questions.

Let us assume that the production of this atomic energy is handled solely by the Government or Government licensees. Is it possible for them to give out a certain amount of this energy for domestic application?

Dr. COMPTON. Yes; it is.

Mr. HOLIFIELD. Let us take General Motors as an example. It is not necessary for that company to have an atomic energy production plant in order to place that energy in some kind of domestic application?

Dr. COMPTON. It depends upon the particular type of application which is desired. For some purposes it is not necessary for such an industry to have an atomic power plant. Perhaps it would be a great advantage for them to have it. But it is worth pointing out that it would not be at all necessary, in case they had an atomic power producing plant, for them at the same time to have the materials that would be necessary to compose the atomic bomb.

Mr. HOLIFIELD. In other words, there are two different fields. The atomic bomb is one field which is strictly military, you might say, and the other is the domestic application of atomic energy in the future for domestic purposes?

Dr. COMPTON. It is possible to separate those fairly sharply. It is true that some methods of producing atomic power might be transformed without too much difficulty into means of producing plutonium, which would be a possible source of an atomic bomb.

Mr. HOLIFIELD. You have no objection whatsoever to the Army using in a military way and keeping secret in a military way any

application in the way of constructing bombs or other weapons? You have no objection to that?

Dr. COMPTON. On the contrary, I think they should.

Mr. HOLIFIELD. But you want to divorce their complete control of scientific development in order that they may not have control over it because of the fact that you think it may minimize the domestic application. Do you think it would be wise to do that?

Dr. COMPTON. My belief is that the more freely we are able to discuss the scientific aspects of atomic energy the better will our Nation be defended; and that is primarily because of the increased knowledge that we will gain in our Nation because of the development of our atomic industry.

Mr. HOLIFIELD. It will be used in both phases?

Dr. COMPTON. It can be used in both phases; that is correct.

Mr. HOLIFIELD. I want to go back to the Commission for one question. Do you think that this Commission should be composed of part-time men or full-time men? Do you think, in other words, that the Commission can render a service commensurate with the importance of this affair and be composed only of part-time men?

Dr. COMPTON. I question whether as a scientist it is appropriate for me to give a positive answer on that. I would nevertheless give you my judgment for what it is worth, and that is that I would think it doubtful public policy to put a majority of full-time men on this Commission. The reason for that is that this Commission should consist to a large extent of men with broad interests. If a majority of the Commission consists of full-time paid employees, they will be passing really on matters in which they themselves have a direct interest. For that reason it would seem to me wise to have not many, not a substantial part of the Commission as full-time employees.

Mr. HOLIFIELD. Thank you. I want to ask you one other question. We had quite a discussion this morning in regard to patents. What is your attitude toward scientists retaining for their own private welfare or private financial interests patents on a thing that is fraught with such terrible world-wide consequences? Do you feel that any scientist should be allowed to retain patent rights or royalty rights on a thing as big as this?

Dr. COMPTON. With regard to control of patents I would say that the control must be in national hands.

Mr. HOLIFIELD. Let us say that Scientist A invents a method of procedure for the better production of this. Do you think that the Government of the United States should have to pay him a royalty for that knowledge?

Dr. COMPTON. It depends upon how that knowledge has been obtained. I would say that a person who makes an invention is entitled to fair compensation for the work that he has done in making that invention.

Mr. HOLIFIELD. I think that is so in the ordinary course of commerce; I thoroughly agree with you. But I am wondering if in this field, which has been developed mostly through Government money and which is fraught with so much world-wide consequences, those same private personal rights obtain.

Dr. COMPTON. So far as employment is concerned, if the man has already been compensated for his work in terms of salary or by some other method, then presumably the right to further compensation

no longer exists, because he presumably was employed so that he would make this invention. But if he has made the invention privately, I see no objection from the point of view of justice to appropriate compensation being paid him by the Government if it takes over control of his invention.

Mr. HOLIFIELD. Can you extend that into the military field? If this man invented some method of procedure which would be adopted by the military, do you expect the Government of the United States to pay him a royalty if it used that procedure in the construction of a superbomb, beyond that which we are now able to make?

Dr. COMPTON. I see no reason that the fact that it becomes of national interest lessens the Nation's obligation to pay the individual an appropriate amount for his services.

The CHAIRMAN. I doubt if that is pertinent to this issue.

Mr. HOLIFIELD. I think it is very pertinent.

The CHAIRMAN. We are not going to take patents away from anybody, unless they are military patents.

Mr. HOLIFIELD. That is what I am asking about.

The CHAIRMAN. The witness has stated his position. What more do you want?

Dr. COMPTON. I should emphasize this, however, that I do think that the Government should have a full right to take patents over and control them and to take them, if necessary, from the individual who has them, so that if this becomes a matter of national concern, if in the judgment of the Government it is of national concern, it has the power to take over the full rights to the patents.

Mr. PHILBIN. What proposals do you have regarding international control of atomic energy?

Dr. COMPTON. I would say that there are two stages of that. In the first place, the only type of international control that would seem to me to be successful would be to put in the hands of an international organization power to investigate what is going on in all the countries that belong to the United Nations Organization, and likewise the power to enforce any action by having ability to wage war with atomic weapons. I see no possibility myself of insuring that nations that have atomic weapons available will not use them if it comes to a desperate war. So that as for international control, it seems to me that in the first place the power of investigation by the United Nations, and, in the second place, the support of any action by the ability of the international organization to wage war, is inevitably called for by the present situation.

Mr. PHILBIN. Would that involve, in your opinion, necessarily, the disclosure of existing knowledge in the hands of our own Government and our own scientists to some international organization?

Dr. COMPTON. Eventually, yes. My own position on that would be, however, that until control can be securely set up it is essential for our Nation to look after its own defenses and maintain its own strength so we can reply effectively to any attack that might be made upon us.

Mr. DURHAM. Doctor, how long do you think it will take to develop this atomic energy?

Dr. COMPTON. If you mean, to the stage where one can secure atomic power as distinct from an atomic bomb—because there are two different stages there—a rough guess would be 5 years before

that stage would be reached. For an atomic bomb it would have taken twice that long if it had not been the emergency of a wartime development. That is my rough guess.

Mr. HARNESS. Doctor, after the war is officially over we will have no such control as is contemplated in this bill over business, radar, radio, high explosives, and other dangerous things. If you felt today that every other nation in the world, any of our potential enemies, knew as much about producing atomic bombs as we know today, would you still say we should have such a commission with all the powers that are granted in this proposed legislation?

Dr. COMPTON. I do not think that it is really necessary that this Commission have the broad powers that are given to it in order that the Nation's welfare should be secure under the conditions that you describe. The important point, as I said before, is that the Commission have the power to encourage the development of this field; and that power would be doubly important in case we were competing in an open field with other nations.

Mr. HARNESS. Don't you think that the ordinary scientist would want to pursue his studies in this field because of the remote possibility of its being used commercially, unless he was subsidized in some way by the Government that wanted the research made for military purposes and for national defense?

Dr. COMPTON. No. I apparently have not made myself clear: I do feel that if the field were free—it is from the scientific point of view—it is a matter of understanding what the world is like; and likewise, from the industrial point of view, quite in its own right, apart from the military aspect, it is a very interesting field and would, if left to itself, develop rapidly. I believe it can be developed more rapidly if subsidized and encouraged by the Government—considerably more rapidly.

Mr. HARNESS. That is the primary reason why you think there should be some further control?

Dr. COMPTON. That is correct. Associated with that development there should be control.

Mr. PHILBIN. To what extent do you think the Government should subsidize the development of atomic energy not only for scientific but for security reasons? How much money annually do you think the Government should provide for it?

Dr. COMPTON. Earlier this afternoon I gave the estimate that within 10 or 15 years I believed it would be industrially a billion-dollars-a-year business, something of that order of magnitude.

The CHAIRMAN. Mr. Voorhis, would you like to ask the witness any questions?

Mr. VOORHIS. No, sir.

Mr. PHILBIN. I think you may have misconstrued my question. The point of my question was to ascertain how much money you think Congress ought to authorize annually for research and development of atomic energy for scientific, industrial, and military purposes.

Dr. COMPTON. My reason for giving that figure was that if the United States were operating an industry they would presumably put into the development, roughly, the amount that would be eventually that annual turn-over, which would mean that they would roughly put into that development a billion dollars if they anticipated a billion-dollar industry afterward. On that basis, for purely peacetime development, one would expect the United States to put in

something of the order of \$50,000,000 or \$100,000,000 a year for the next 10 or 15 years. That is independent of the military requirements. The military requirements are already on the basis of, roughly, \$1,000,000,000 a year; and something of the order of \$20,000,000 to \$50,000,000 annually after that would be likewise appropriated for research and development. That would mean a research and development budget of the order of \$50,000,000 a year. That is only a part of the \$600,000,000 that was mentioned this morning as the present rate of expenditure, most of which goes into production for military purposes.

Mr. PHILBIN. That is all.

The CHAIRMAN. Dr. Compton, I do not want to detain you very long, but I would like to ask you just a few questions. One or two are general in nature. The first is this:

Do you agree that the President of the United States, regardless of the party he belongs to, is the person who ought to select and name the Commission.

Dr. COMPTON. Yes.

The CHAIRMAN. Do you agree also that, generally speaking, men in public office are honest and have patriotic purpose in the Government? Most men in the Government are honest, are they not?

Dr. COMPTON. We elect them because we believe that is true.

The CHAIRMAN. In other words, what we like to do is to assume that everybody is honest until the contrary appears. They mean to do their duty in public office generally and do what they think is about right.

Do you have any doubt about a commission being appointed by the President that would not be composed of honorable men?

Dr. COMPTON. The answer is that I have no reasonable doubt in that regard.

The CHAIRMAN. The very first section of this bill declares the policy of the Government with respect to atomic energy and the general welfare, and closes it with this statement in lines 14 to 19, on page 2 [reading]:

The primary objectives of all action—

And I call your attention to the word "all"—

all action taken under or pursuant to this Act shall be the promotion of the national defense, the protection of the safety of the inhabitants of the United States, the safeguarding of world peace, and the furtherance of the acquisition of knowledge concerning atomic energy.

Do you think that men who have the welfare of their country at stake, and who are under oath and acting as public officials, would not give reasonable encouragement to the acquisition of knowledge concerning atomic energy, when the Congress has declared that they shall do it, and makes it mandatory?

Dr. COMPTON. I believe that they would do their best.

The CHAIRMAN. The only question remaining would be competency?

Dr. COMPTON. Yes.

The CHAIRMAN. If you turn to page 5 of the bill you will find on the question of the administration of the act these words in line 19 [reading]:

In the conduct of its activities the Commission shall adopt the policy of minimum interference with private research and of employing other Government agencies, educational and research institutions, and private enterprise to the

maximum extent consistent with the accomplishment of the objectives of this Act.

Do you see any danger to private industry in that provision, from an act administered by reasonably honest men and reasonably intelligent men?

Dr. COMPTON. I would say that my difficulty with that statement is that it is a negative rather than a positive statement. It says, "shall adopt the policy of minimum interference with private research," and so forth. It does not say that it shall adopt a policy of encouragement.

The CHAIRMAN. We are assuming in the first section that what they are trying to do is to encourage research. It says that there.

Turning to page 17, where the question of the authority of the Administrator is provided for, it first provides for experimentation in the field of nuclear fission, the transmutation of atomic species, and then it has this proviso [reading]:

Provided, however, That it shall be the policy of the Commission and of the Administrator, in accord with the objectives of this Act, to utilize, encourage, and aid colleges, universities, scientific laboratories, hospitals, and other governmental, nonprofit, or private institutions equipped and staffed to conduct research and experimentation in this field.

There is the imperative "shall" again.

Dr. COMPTON. I think that is a very good statement. I like that sentence.

The CHAIRMAN. And you think that universities ought to be utilized in the development of scientific research in the future?

Dr. COMPTON. Yes; I think they should.

The CHAIRMAN. You mentioned the fact in your testimony that you were connected in some way with the National Academy of Sciences?

Dr. COMPTON. Yes.

The CHAIRMAN. What was your connection with that organization?

Dr. COMPTON. The official position was Chairman of the National Academy's Committee on the Use of Uranium in War. It was a committee appointed by the president of the National Academy at the request of the Office of Scientific Research and Development.

The CHAIRMAN. Do you think that the facilities of that organization ought to be utilized also?

Dr. COMPTON. It would be very wise, I believe, to bring them in in any way they could be used.

The CHAIRMAN. On page 21 of the bill the topic of control of activities is mentioned, and then you find on the top of page 23, line 1, this statement [reading]:

In administering this provision, the Commission and the Administrator shall interfere to the least possible extent with small-scale experimentation in research laboratories of nonprofit institutions.

You do not have any objection to that provision, do you?

Dr. COMPTON. No.

The CHAIRMAN. As a matter of fact, this bill, from your reading of it, indicates very strongly that the drafters of the bill were trying to provide a way in which this Commission could work along with private industry and private institutions?

Dr. COMPTON. I think that is correct.

The CHAIRMAN: And if the Commission is set up with proper personnel, capable and upright, there ought not to be any great danger of anybody suffering from it, ought there?

Dr. COMPTON. With the proviso that capable only means capable and qualified in the field which is being operated.

The CHAIRMAN. In other words, what you are suggesting is what I am thinking, that there should not be any Congressmen on it?

Dr. COMPTON. That was not my intention.

The CHAIRMAN. We might get politics in it if we had a Senator on one side and a Representative on the other side.

Dr. COMPTON. As a matter of fact, I have sat on more than one board with Members of Congress, to which they have contributed very effectively.

The CHAIRMAN. You have given us what I regard as a completely impartial and highly intelligent statement.

Mr. JOHNSON. I do not know whether this has been brought out or not, but, as I understand it, uranium is found in ledges in the mountains just like other kinds of ore. Is it found in the same strata or near the same strata as gold and silver and iron, for instance?

Dr. COMPTON. I am not well informed, Mr. Johnson, with regard to the occurrence of uranium, but it is widespread in its occurrence.

Mr. JOHNSON. Is uranium itself, without applying to it some industrial process, dangerous?

Dr. COMPTON. No; it is not.

Mr. JOHNSON. In other words, before there is any danger you have to put it through a process, capture it and confine it and then provide a way to explode it?

Dr. COMPTON. Yes; that is correct.

Mr. JOHNSON. The impression I got from the hearings was that any activity that has to do with uranium is dangerous. Is that a fallacy?

Dr. COMPTON. It is a fallacy. The only reason that one might consider it dangerous is because information might come out of it that might lead to something else, or something of that kind. But it is perfectly possible with safety to do experiments on a small scale with uranium.

Mr. JOHNSON. There are a great many commercial uses to which this element is put, which could be done in laboratories without any danger to anyone?

Dr. COMPTON. Yes.

Mr. JOHNSON. The only danger that has been exposed so far is the fact that you can put it together in a form where it is highly explosive. Is that correct?

Dr. COMPTON. Even that is exaggerated. Uranium, until it has gone through the process of separation to uranium 235, can at most produce atomic power and not atomic explosions.

Mr. JOHNSON. Then what do you think about the sweeping provisions of this bill which would allow the Government to take every possible source of uranium including any other metals mixed up with it?

Dr. COMPTON. It is justified, perhaps, on the basis that one does not want any possibility of an individual entrepreneur proceeding on such large scale developments of uranium as would make possible the accumulation of dangerous amounts of material.

Mr. JOHNSON. Is there any commercial use to which this element has been put now or before now?

Dr. COMPTON. There is a certain ceramic use. That is the chief use. It is used in making glass, in glazing porcelain, and matters of that kind. That is the chief use to which it has been applied. The production of radium likewise is one. Uranium ore is the source of radium.

Mr. JOHNSON. How long has that been going on?

Dr. COMPTON. Since about 1900.

Mr. JOHNSON. Is there any way in which any industrialist or mining concern or commercial outfit would ever get uranium and make it into a dangerous form without its becoming perfectly obvious to everybody around them?

Dr. COMPTON. The methods now employed are ones that would make it obvious. I would not want to say that methods cannot be developed, however, that would be otherwise. It would be more time consuming. I am thinking about what might be done in another nation rather than here; but even here a large industry might, if it wanted to carry on processes in certain buildings to which workmen would not have access in general, that might be dangerous.

Mr. JOHNSON. That is all.

The CHAIRMAN. Thank you, sir.

STATEMENT OF DR. J. R. OPPENHEIMER

The CHAIRMAN. Will you tell us something about your qualifications, your experience, and your connection with the subject embraced in this bill?

Dr. OPPENHEIMER. I have practically no qualifications, Mr. Chairman. I am a physicist who taught in California, in Berkeley and in Pasadena, before the war. In 1941 I became interested in the possibility of making atomic weapons, and since the inception of the laboratory at Los Alamos I have been its director. So I know a little bit about the making of bombs.

The CHAIRMAN. You may proceed with your statement, Doctor.

Dr. OPPENHEIMER. I have very little to add to the testimony which Dr. Compton has given and which has come out in the questions which the members of the committee have asked. But I think I may owe an explanation to the committee of the telegram which I sent the Secretary of War in conjunction with Dr. Lawrence and Mr. Fermi in which we urged the prompt passage of this legislation.

In the first place, there are two reasons why we would like to see legislation passed soon. One I might illustrate in the following way:

There are many things that ought to be done with atomic energy in a military and industrial and scientific way which are not being done now. One of them is a very small example. There are some people in southern California who would like to use the radiations from a small power unit to study biological problems to try to understand certain diseases and to try to find a cure for those diseases. They are not able to operate, not only because they have not the material with which to work, but because all of the information involved in the building of this particular unit is tied up under absolute secrecy at Los Alamos.

It is not, in my opinion, reasonable to ask the War Department to make fundamental decisions of policy on how such information should be handled. I do not think that the War Department is at present making such decisions, and information which might save lives and suffering is not being obtained because there is no authority to run the project. This is only one small example, but it is a true one.

The second reason is this: My own belief—and I think in this I speak for all scientists, or almost all scientists—is that the greatest possible future safety of this Nation against atomic weapons will rest in international control of atomic weapons. This is almost a negative statement. I believe that the people who have the responsibility for negotiation would prefer to do so with a satisfactory national organization. I have been assured of this, and I think it is true.

In addition to that, I would say a word or two about the bill. I did not have anything to do with the drafting of the bill, and I am not competent to judge of its adequacy.

It is certainly a bill which does not establish policy; it establishes a framework within which the policy agreed on by the Congress, by the American people, and expressed by the President, may be executed.

I share the confidence that the chairman has expressed in the ability of this Nation, in a matter of such great importance, to find nine reasonably intelligent and conscientious men to carry out whatever policy the country decides is right. I share his confidence that an administrator can be found who will carry out these policies in practice. No one that I have talked to would claim that the May bill makes it impossible to operate properly the many complicated and potentially dangerous elements in this project. The most that people claim is that it is not written into the bill just how these policies are to be formulated and how they are to be carried out.

In that connection I have one thing to add. The bill was drafted with the detailed supervision of Dr. Bush and Dr. Conant, with the knowledge and the agreement of the former Secretary of War, Mr. Stimson. I think that no one in the country carried a greater weight of responsibility for this project than Mr. Stimson. I think no men in positions of responsibility, who were scientists, took more responsibility or were more courageous or better informed in the general sense than Dr. Bush and Dr. Conant. I think if they liked the philosophy of this bill and urged this bill it is a very strong argument. I know that many scientists do not agree with me on this, but I am nevertheless convinced myself.

I would go one step further. It would in some ways be desirable to have a bill in which the powers of the Commission were much more carefully defined than they are in the May bill. I think that has not been done, for a good reason. It has not been done, because the subject is not only very important; it is very new. I think if we had tried to write a bill on atomic energy in 1941 everyone would have agreed that you could not do it, that the subject was not yet old enough. It is my conviction that the subject is still not old enough to write a bill under which operations can continue with the rapidly changing technical situation. Even if we forgot the matters of policy connected with industrial exploitation, the matters of policy connected with international relations, the dangers of war and the possibilities of further war, we would still have the fact that even the

science in which this is working is changing from day to day; and I hope it will change very much in the next 10 years, because it is in these changes that our real progress lies. And many, at least Dr. Bush and Dr. Conant, were very much impressed by the rapidity with which they had seen ideas change, by the rapidity with which they had seen new possibilities brought in. They would have found it unwise to write specific directives, such as control of this material and no control of that; let this experiment be done, but not this one; let this industry be uncontrolled and that industry be controlled—because they did not know, and I am sure I don't know, how to set these limits. I think, therefore, it is fair to say that the May bill has been written largely from the point of view that we must have confidence in the Commission; we must have confidence in the Government of this country. We are not in position to write detailed directives that will be binding for any reasonable period in the future. With the understanding that as the issues become clear it is appropriate to reconsider the legislation, that it is appropriate not to regard it as a scheme for all eternity, but as a measure which for the moment is the best that we could do. In that sense I think it should be supported.

I want to say one thing purely as a representative of scientists.

Scientists are not used to being controlled; they are not used to regimentation, and there are good reasons why they should be averse to it, because it is in the nature of science that the individual is to be given a certain amount of freedom to invent, to think, and to carry on the best he knows how. Most of the scientists with whom I have talked would like the assurances which are now in the bill, somewhat reinforced, about the intention of the Congress to direct the Commission not to interfere with scientific work except when there is a national hazard involved. This could not be said very much more strongly, but I think there are a few words that might be said, that the Commission should in no way interfere with or control research except insofar as the national safety and the national security are involved.

I believe that the War Department would be glad to support such amendments, and I believe it would do a great deal of good in reassuring the academic scientists of the country if such amendments were written in. There may be others. I do not want to go into details.

Mr. JOHNSON. Do you think the present bill is too sweeping and covering more than the necessity for security?

Dr. OPPENHEIMER. I am sure it is too sweeping, but I do not know how to make it less sweeping and still make it good. I am sure that if you say to the Commission, "Don't control anything," you will not have control. That has already been said.

Mr. JOHNSON. Do you think we could wisely leave it to the Commission to determine?

Dr. OPPENHEIMER. It seems to me that is the intention of the bill, and I agree with it.

Mr. HOLIFIELD. Would you be perfectly satisfied if a high Army officer should be appointed as the Administrator and a high Navy officer as Deputy Administrator? Do you think that such an appointment would be conducive to full and free scientific research in all the fields of atomic energy?

Dr. OPPENHEIMER. I cannot think of an administrator in whom I would have more confidence than General Marshall.

Mr. HOLIFIELD. Would you be perfectly willing to put the Administrator and the Assistant Administrator in the hands of the military completely?

Dr. OPPENHEIMER. I think it might be unwise, but I think it is a matter not what uniform a man wears but what kind of a man he is.

Mr. HOLIFIELD. That is very true; but don't you feel that if research and development were to be completely in the control of the military, it might be done along military lines rather than along civilian lines?

Dr. OPPENHEIMER. It might. It would certainly be so—

Mr. HOLIFIELD. Naturally, would it not?

Dr. OPPENHEIMER. No. I was going to say that if the administrators were chosen as representatives of the services to carry out work of consequence to the services, then it might be so.

Mr. HOLIFIELD. I am highly in favor of that. I think they should have control of all military applications; but I would hesitate to turn over all control of development and research and channel it into the hands of the military. They might not look upon civilian development with as complimentary a glance as others might.

Dr. OPPENHEIMER. That may be. You see, this legislation is legislation to get control of the project out of the War Department, not to put it into the War Department.

Mr. HOLIFIELD. I am not so sure of that.

Dr. OPPENHEIMER. That is what my friends of the War Department, for whom I have labored, tell me.

The CHAIRMAN. The War Department discovered the weapon. Why can they not keep the secret?

Have you completed your statement?

Dr. OPPENHEIMER. I am completely through, Mr. Chairman.

Mr. JOHNSON. Dr. Oppenheimer, this work has been done by a great many noted scientists?

Dr. OPPENHEIMER. Yes, sir.

Mr. JOHNSON. I think you ought to put into the record, if you know, who the men are who received the Nobel prize, who worked on this project.

The CHAIRMAN. Dr. Oppenheimer is one of them.

Dr. OPPENHEIMER. No; I am not, but there are many of my friends who are. There is the great Danish scientist, Bore. He contributed enormously. Sir James Chadwick, an English scientist; Dr. Compton, Dr. Lawrence, Dr. Anderson of the California Institute of Technology. I am forgetting many important names. There are many.

Mr. JOHNSON. That is all.

The CHAIRMAN. If there is nothing further, we thank you very much, Doctor.

Is Dr. Harold C. Urey present?

Dr. SZILARD. He is in Senator Taylor's office. He left word to call him if he was wanted.

The CHAIRMAN. He may put a written statement into the record.

Is there anyone else who wants to be heard?

Mr. VOORHIS. I would like to say a word, Mr. Chairman.

STATEMENT OF HON. JERRY VOORHIS, A REPRESENTATIVE IN
THE CONGRESS OF THE UNITED STATES FROM THE STATE OF
CALIFORNIA

Mr. Voorhis. Mr. Chairman, I recognize the temerity of an individual like myself asking to be heard after so many distinguished people have been heard. Everybody will understand that I am in no sense a scientist, but I am an American citizen and I am a human being and I am deeply concerned about this whole matter. I have read everything that I could get my hands on and have talked to all the people that would let me talk to them, including some of the scientists. I feel that the essential thing to be remembered by the American Congress in connection with this matter is that the tremendous advance in the field of natural science may readily become the most terrible curse that has ever been known unless advancement in the field of self-control on the part of human beings can in some measure catch up.

I would like to make one or two comments about the bill which is before the committee. The bill, as I understand it, is limited to the domestic problem. To my mind it is unfortunate that the bill does not carry a section on policy for the United States with regard to the international aspects of the problem. If it did carry such a section the suggestion that Dr. Compton made would be, to my mind, the one that ought to be carried. Indeed, what he said is almost exactly what is incorporated in a bill which I introduced.

To my mind, the principle that should govern our policy domestically is very brief—that the basic rights to atomic power should belong to the American Nation. By that I do not mean the right to development or use, but I mean the basic right to ownership of all patents in that field and the ownership of the original source of the power itself.

In saying that I believe that so far as the future is concerned I am advocating a policy which will offer the greatest hope for what people know as private enterprise of any policy that could be pursued, because, if I understand anything about this, the possibility of monopolistic control of it by a few great corporations might lead to a complete deterioration of our whole economy; and I see no way for that to be avoided except by national control.

I would like to say, Mr. Chairman, that in my judgment the board is all-important in this bill, but I do not think that board should be composed of part-time people. I think it should be composed of faithful, full-time employees of the United States Government, and I think they ought to be paid not less than \$50,000 a year apiece. I think it would be proper for the bill to prescribe that a certain number of those places be held by scientists. I think it is evident that some of the places should be held by people from the armed forces. I think it is of equal importance that the balance of the positions be filled by outstanding people who would, roughly, cover all phases of American life and population, because this is the American people's problem.

I shall not speak further about that, Mr. Chairman, but I would like to see the strongest possible emphasis given to a section already in the bill, that is found on page 20, where it says that the function

of the Commission and the Administrator is to adopt the policy of widespread distribution, so far as possible, of such licenses and consents on equally equitable terms to all qualified persons, etc.

I might call it an antimoniopoly section.

I would like to say very frankly that I am a very reactionary individual, Mr. Chairman. Some of the members may not believe that, but I am. Were it possible to move the hands of time back and to take out of the world some of the inventions and discoveries that have been made, I would do it. That is not possible. We have got to face the future as courageously as we know how. We have got to live with this new force in the world. There are two principles which, in my judgment, have got to govern: One, the most widespread dissemination of its benefits to the people, and, two, the prevention of a war in which atomic weapons will be used.

Mr. Chairman, upon that latter point, if I believed for a single moment that it were possible for the United States to retain in its sole possession any effective secrets about the production of atomic weapons and then to say to the rest of the world that we would never utilize those things in war unless some other nation broke the peace, I would be for doing that. I wish such a simple solution were possible. It is not. At the same time the overwhelming preponderance of evidence from people who know, is to the effect that no effective secret even now exists excepting that connected with the know-how of production, and that this will unquestionably be developed by other nations within a very few years.

Under those circumstances it seems to me that the most short-sighted policy that could be followed would be for the Congress, either by enactment of a bill or by failure to make clear its purpose, to set in motion an unlimited armament race in the field of atomic weapons which ultimately must lead to an atomic war, because the kind of armament competition which this would constitute would be the kind which could only be successful by a surprise attack made by some nation possessing these weapons.

I do not want us to give away our knowledge. I am not for that. I do believe we must use it with all the statesmanship at our command as the one instrument that might enable us to effect a genuine peace-keeping mechanism in the short time that remains to us while our Nation is still predominant. It seems to me that it is our move, and that we might save humanity. I believe that can only be done if World War III is somehow prevented. I want the country to go ahead with developments. I am in favor of our keeping ahead, but I want to make it clear to the world that we are trying to do that for the sake of the peacetime benefits, and that so far as America's use of this weapon is concerned, development is being carried on pending the time when it will be possible for us to get from all nations an agreement that if this knowledge is pooled among the nations they will every one agree to opening their laboratories, their colleges, their munition plants of every sort to an inspection by an international group in which, of course, our own people would be included. Under those circumstances all nations would know what was happening in other nations.

I cannot see that it would make any particular difference with regard to the know-how, but I think it would be the only way to create

an international situation in which agreements among the nations for the control of this terrible force could actually be enforced and kept.

In my judgment, it is either going to be a time in which we will succeed in the greatest crisis for statesmanship in all the world, or else we may learn at some future date what it was that Christ meant when he said "The meek shall inherit the earth."

I can foresee a time, unless that statesmanship is forthcoming, when the great nations of the world might destroy one another.

My testimony in defense of this position is not just my own, but the testimony of the very scientists who developed the atomic bomb. Ninety-six percent of them have joined in issuing the statements which follow and which I hope will be read not only by every member of the Military Affairs Committee but by every Member of Congress and every American citizen.

(The statements referred to are as follows:)

A STATEMENT BY SCIENTISTS OF AN ATOMIC BOMB PROJECT

1. We, as scientists who knowingly contributed to the development of atomic power and the atomic bomb, feel keenly the responsibilities we accepted in helping to create this force, first used as a weapon of destruction. These responsibilities are now shared by every person of every nation. Therefore, we feel that it is essential that every individual be made aware of the entirely new conditions this force imposes on the nations of the world and their relations with one another.

We cannot and do not presume to speak as international statesmen or politicians; however, as scientists who produced the weapon, we possess special knowledge of great pertinence in formulating our country's policy with respect to this epochal development.

2. No individual, group, or nation can keep new scientific discoveries secret as long as human minds can function anywhere. In this particular case, the fundamental principles of atomic energy and its release were widely known before the development of this project. The only remaining "secrets" are technical and engineering details of processes, plants, and devices. The fact, as announced in the Smyth report, that several different processes have been successfully employed on these projects, the fact that other independent attempts can be made with the knowledge that the goal is achievable, and the fact that many countries possess the scientists and resources which are necessary, make it a practical certainty that our efforts can and will be duplicated in other countries within a few years.

3. We submit that anything less than a single world policy with regard to atomic power and weapons can result only in catastrophe. The only way in which atomic bombs can bring security is by using them first. The tremendous industrial capacity of this Nation, of such tremendous importance in winning the war, will not be a factor in any possible future conflict involving atomic weapons, for no nation will dare to initiate war until it feels sure that it can accomplish complete and immediate annihilation of its enemies. Thus, no nation can find security in the preparation of stocks of atomic bombs.

4. We feel that participation by every nation in some plan for a single world control of atomic energy is an inescapable conclusion. This most certainly means a loss, in some respects, of national sovereignty. We do not propose to postulate any specific international mechanism for accomplishing such an end, but it appears to us that international control is the only way in which the misuse of atomic energy can be prevented.

Every war of modern times has seen the development and demonstration of some new offensive weapon; it seems obvious that some form of atomic-energy weapon is the ultimate and mankind has reached the point where it can no longer afford war. The world is too small, the power too great.

That the advent of the age of atomic energy signifies a revolutionary change in the nature of our civilization has been recognized, to a greater or lesser extent, by all men, but the crisis which we face will not be successfully overcome unless misconceptions are laid bare and the problem exactly defined. Either the leaders of mankind resolve the difficulties arising from the necessary integration of nuclear energy with the present international and national social structure, or the world will be faced with catastrophe.

As a prelude to intelligent thought, a myth which has already taken considerable hold in the public mind must be dispelled. We do not have and never have had a monopoly on the scientific ability, fundamental principles, or technological resources necessary for the large-scale release of nuclear energy. The important role of foreign scientists in project and preproject nuclear physics, the publications on uranium fission in foreign journals, the official Smyth report itself, all provide incontrovertible evidence of the truth of this statement. The dangerous delusion that the security of our Nation can be attained or even aided by secrecy is one that must be dissipated, for it will inevitably lead us into a line of action which will court the very disaster we seek to avoid.

Let us now suppose that, ignoring this fact, we embark on a course of narrow nationalism and irrational secrecy; what are the inevitable consequences? An atomic-armaments race proceeding with ever-greater acceleration; a deepening of mutual suspicion, distress, and fear; the growth of the psychological necessity for striking first in order to feel any assurance of safety; and ultimately war on a scale so horrible as to defy description. It is clear that the outcome of this policy will not be national security but world-wide chaos.

The only reasonable alternative is for us to lead all nations toward collective security. A World Security Council must be made the only custodian of nuclear power in the world. The prestige of the United States at this time will make it possible for us to insist on the adoption of all necessary safety measures; in a few years this bargaining power will have vanished, for many nations will have atomic bombs. An international technical panel responsible directly to the World Security Council should be set up. Its first duty be the investigation of all sources of critical materials; immediate and complete control of such sources by the Council should then be established. Provision should be made for further thorough geological surveys and the extension of control to new areas; no nation, whether or not it is a member of the United Nations, may be permitted to interfere with this program. Second, all nations must agree to complete and intimate periodic inspections of all scientific, technical, industrial, and military establishments by the panel, which is to make public all findings. The inspections must be universal to be effective; international inspectors must be backed by the full might of the Council. Third, all relevant scientific and technological advances, regardless of publication elsewhere, must be reported directly and immediately to the technical panel of the Council which is to be charged with responsibility of universal dissemination of all such information; all scientists should and will be honor bound to the implementation of such regulations. It is only after the adoption of such a policy as this that we of the United States can feel a reasonable assurance that the nuclear bomb will not be used for our own destruction.

There remains the danger of failure no matter how carefully the plans are drawn. But consider the alternatives: Either national security through collective security, or atomic war. Can there be any serious doubt that we must make a success of international control of nuclear power? Any feeling of choice in the matter is purely illusory. Our country today stands in a position of prestige and power never attained by any other nation. If we do not use this advantage in a manner worthy of our long tradition of freedom and democracy, if we do not take the first step in demonstrating our good faith and our hope for the future, our civilization is doomed. We must recognize at last that it is only through mutual understanding and trust that mankind can hope to banish forever the fear of war.

THE CONTROL OF THE ATOMIC BOMB

(A statement by scientists of a major atomic bomb research laboratory)

Man has entered the age of atomic energy. The explosion at Hiroshima on August 6 slammed shut a door on the past. We cannot go back; we dare not stand still. We must face facts as they are. What are these facts?

1. *There is no secret to be kept.*—It has been known for 40 years that this form of energy exists. The principles required for its release have been the common property of scientists throughout the world for the last 5 years. Each one of the advanced civilized nations possesses scientists capable of working out the details required for the accomplishment. Each one of the advanced civilized nations has access to some of the resources required for production of an atomic bomb.

All atomic bombs will not prove equally efficient but they will all be extremely effective compared to any weapons of the past. A nation does not have to make

the best bomb in order to be in a very favorable position for aggression. The retention of your technical secrets consequently offers no protection to this Nation or to any nation against atomic bomb attack.

2. *There is a possibility of world disaster.*—One bomb destroyed a small city and it was made obsolete by the next bomb. Bombs of the future will probably make obsolete those of the present. A few hundred bombs dropped throughout the world will destroy all urban civilization and all modern means of production. Atomic energy can force our unwilling regression to the status of primordial man. In the hands of the fearful or the stupid our knowledge may mean our downfall and our end.

3. *World security can be attained.*—All solutions to the problem of preventing world disaster depend upon one condition: No more than one group in the world may be permitted to possess atomic bombs. How may this be achieved?

We have atomic bombs now. We can try to conquer the world and thus eliminate competition. If we choose this course we must do so immediately and be prepared to police the world.

Atomic bomb manufacture by any group can be prevented by destroying all vestiges of modern science and technology, including scientists, libraries, laboratories, and industries. This must be world-wide to be effective. It means the end of modern civilization, but we will be sure of existence.

It is clear that we must acknowledge the fact that atomic energy is the world's problem. We must acknowledge that military protection is impossible. We must acknowledge that, since there is no real secret, what knowledge we have has to be shared by all for the good of mankind. We must acknowledge that the problem to be solved has to be solved jointly by all. We must acknowledge that new forces require new solutions unprejudiced by old notions.

Therefore, we must urge among the nations a cooperative unified control of forces which would otherwise destroy us.

That is all I have to say, Mr. Chairman.

The CHAIRMAN. That is a very fine statement, Mr. Voorhis, and we are very happy to have you here.

If there is no other witness present, the committee will adjourn until tomorrow morning at 10 o'clock. The hearing is closed.

(Whereupon, at 4:45 p. m., the hearing was closed, and the committee adjourned until tomorrow, Friday, October 19, 1945, at 10 a. m.)

(The following was submitted for the record:)

STATEMENT BY HAROLD C. UREY, TO THE MILITARY AFFAIRS COMMITTEE, HOUSE OF REPRESENTATIVES, RELATING TO H. R. 4280, ON THE CONTROL OF ATOMIC ENERGY

My criticisms of the May bill relate to the method by which the Commission and its Administrator are appointed; the terms of the Commissioners and its organization; to the powers granted to the Commission; to the security provisions of the bill. Also I believe the bill is drawn completely from a wrong point of view, and I wish to discuss this. My remarks will take up these points and attempt to make suggestions for improvement of the bill.

The members of the Commission are appointed by the President, with the advice and consent of the Senate, to serve for 9-year terms. They are expected to be part-time men. The Commissioners appoint an Administrator and Deputy Administrator, who will be full-time men. They are removable by the Commission. Because of the complexities of the problems of atomic energy, I believe the part-time Commission will have little knowledge of the whole field and the Administrator and Deputy Administrator will become, by various means, but largely because of their superior knowledge, the directors of the Commission instead of the reverse. Because of the extensive powers of the Commission, this places a very powerful individual—the Administrator—in a position not accessible to removal by elected representatives of the United States Government. This I believe to be fundamentally a bad arrangement.

I should like to make two suggestions in regard to this point. The first is that the Administrator be appointed by the President, with the advice and consent of the Senate, and that the Commission be advisory. The objection to this suggestion is that the Administrator may become a political appointment changing with

each administration. This could be guarded against by making his term of office 9 years with the provision that he could be removed by the President for proper causes. The second suggestion is that the Commission be smaller and be composed of full-time men appointed by the President and removable by him. Any administrative officers would then be under their control. If the appropriations for the work of this Commission are sizable, several full-time men of top quality must be expected to help with the administration. Further, I would suggest that salaries for these men be placed higher than \$15,000 and \$12,000, for I do not believe that we can attract the quality of men required for these jobs at these relatively small salaries.

There is a question in regard to the necessity for the broad scope of the Commission's powers. Many phases of these powers lie outside the experience of scientists, but it seems to me that the Commission needs to have control over hazards, control over all fissionable materials from the mine to ultimate destination, and control over security provisions. I do not believe that it is necessary for the Commission to own all mines and patents, nor do they need to have such broad powers for the condemnation of private property. It would seem to me that a nonexclusive license of all patents would be sufficient for the protection of the Government. Provisions that all patents owned by other persons must be licensed for experimental work and that all patents must be licensed for industrial or military work at reasonable royalties would be sufficient to protect the activities of the Government. It is difficult for me to see how we can attract industrial organizations into the development and exploitation of atomic power with the present provisions in the bill. If I were in charge of a large industrial organization, I would do my best to avoid any contact with the Commission for fear that such contact might result in the condemnation of valuable property of the company. No rewards are held out to industry to compensate them for this disadvantage.

The security provisions of the bill are almost fantastic. In particular, section 19 (a) makes possible very drastic punishment for violation of security provisions with no relief or, at most, indirect relief through the courts. These provisions will have a tendency to drive scientific men from the field. Life under the Espionage Act of the United States in time of war is very disagreeable, and it seems to me improbable that scientific men would readily live the rest of their lives under these conditions. Particularly, it is difficult for professors in universities who have the responsibility of instruction for young men, for these provisions would almost stop all discussion of scientific facts in modern physics at the year 1940. We recognize that with the international situation as it is, some security provisions are necessary. The objective should be a minimum amount of secrecy with a nonessential leak of information to outside sources. I believe that the lines should be drawn far to the side of free discussion. In any case, someone must draw the line, and the question is, who should do this? I believe the fears of scientific men in regard to the security provisions would be greatly alleviated if a security council were set up with a majority of the council being scientific men. Only scientists understand how severely scientific work is hampered by security rules. I am sure that the general public, and particularly, the armed forces, have little concept of this point. While scientific men appreciate these points, they also understand very well the problem of placing information on the hands of potential enemies. Witness the fact that the whole atomic energy problem was brought to the attention of the United States Government by scientific men on their own volition. I believe that we can trust them to protect the interests of the United States in the future as they have in the past.

In general, there are three serious objections that I have to the bill as a whole founded upon its method of approach to the problem.

1. This bill presumes an armament race and is notice to the world that we are starting such an armament race in atomic bombs. This will lead to disaster. The bill, if enacted into law, will hamper all attempts to secure international control of atomic bombs.

2. The bill offers no incentives for work on atomic energy. It seems to be the opinion of the drafters of this bill that both scientists generally, and industry, are very anxious to work on atomic energy. This, I believe, is definitely not true. Certain limited phases of atomic energy are of interest to a limited number of scientists, but most of the work that must be done to secure atomic energy for power or military purposes is drudgery in a scientific sense. It has no more interest for the man working on it than almost any technical job of the lowest grade. In order to secure maximum work, we must appeal to the emotions which prompt people to put effort into their work. This country has grown great upon

the methods of private enterprise. The patent laws have greatly stimulated American industry. The bill practically wipes out all private enterprise and patents so far as the field of atomic energy is concerned. Maybe it is unnecessary to have these motives, but I do not see how to replace them completely in the next few years. Hence, the whole approach to the bill from this angle, in my opinion, is wrong.

3. This bill, I understand, is essentially a War Department bill. Specific arrangements are made permitting the Administrator and the members of the Commission to be from the armed forces. Members of the armed forces will maintain this is wrong, but you will find, on analysis, that most of their development and research work is carried on by other organizations which they hire to do it for them. To leave the control of atomic energy either for military purposes or industrial purposes under the control of the Army or Navy, or both, will be fatal to rapid development in this field.

On the opposite side, the approach to the bill should be that it is primarily what it purports to be, namely, an atomic energy bill for power purposes and not primarily what it actually is—an atomic bomb bill. I would feel happier if it were sponsored by the Department of Commerce, which would place a proper light on this development work. Such an approach would avoid misunderstanding on the part of foreign countries in regard to the motives of the people of the United States in developing atomic energy, as well as keep our own thinking on the subject straight. We should recognize that we have a new frontier of great magnitude to develop, and we should consider carefully how we can get a maximum of energy from scientists, engineers and industry interested in a maximum effort in this problem. When the railroads were thrown across the country the United States Government made grants of land to them to encourage them in these undertakings. Had they not done so the railroads would not have been thrown across the United States as soon as they were, and the whole country would have been slowed down. The Government should be thinking of ways of granting subsidies to industry in order to secure its help and cooperation on this problem. In the airplane industry mail contracts supplied such incentives for its development.

In view of these criticisms I find it difficult to believe that any amendments to the bill could possibly meet my objections. The whole bill should be rewritten by other men who have an entirely different point of view about the whole program.

STATEMENT BY THE ASSOCIATION OF OAK RIDGE SCIENTISTS AT CLINTON LABORATORIES TO BE PRESENTED TO THE HOUSE OF REPRESENTATIVES MILITARY AFFAIRS COMMITTEE CONSIDERING H. R. 4280, ATOMIC ENERGY ACT OF 1945

The Association of Oak Ridge Scientists at Clinton Laboratories comprises more than 90 percent of the technical and scientific personnel at Clinton Laboratories and has a membership of more than 170 persons. The association has arisen spontaneously as a medium for the expression of the convictions of its members concerning the use to which the United States should put the atomic bomb and atomic energy. The members of the association have had ample opportunity to consider the course the United States must follow to prevent this great technological achievement from becoming a curse to humanity. The association stands as a tribute to the unanimity of opinion held by the scientists at Clinton Laboratories.

Members of the association had made known their desire to testify before the House of Representatives Committee on Military Affairs at the brief public hearings of October 18. Since this opportunity was denied its members, the association wishes to express its views for incorporation into the record of the Military Affairs Committee on H. R. 4280, known as the Atomic Energy Act of 1945.

As scientists who have aided in the development of the atomic bomb, we feel strongly the need for legislation which will enable the United States to maintain its position as a leader among nations. The scientific achievement we have accomplished places upon us a responsibility unknown to scientists in the world's history. Our knowledge has been restricted due to the necessity for military security to such a degree, that we now find ourselves perhaps no more than a thousand strong, unique among the citizens of the United States in our understanding of the force which we have created. We, alone, have had opportunity to consider the effects of atomic energy and the atomic bomb for a period of

years. It is our duty, therefore, as scientists and as citizens to emerge from the fields of our specialties and to take part in the efforts of our Nation to effect an enduring peace.

The world is at a cross road, and the United States may well determine which path the world will take. We citizens must determine in our own minds what course our Government shall follow, for it is the people of the United States and of the world who will suffer. A false step made by our Government may precipitate upon the world that worst of all nightmares, an atomic war. Such a war would bring ruin to all nations, victors and vanquished, for reprisal and retaliation would be the only courses open to the nation attacked. The bombs we have used are primitive compared to those which may be developed. The devastation of Hiroshima and Nagasaki will be repeated many times over.

The benefits which may accrue to mankind may dwarf those of the steam engine. We scientists have had no opportunity to develop the bountiful side of our discovery. Products and materials unknown, may in our time become commonplace. Industry will find many applications for these materials. Medical uses as important as the X-ray are well on the way. The generation of power by an engine requiring little fuel is perhaps only a few years away. A new era is dawning. The world is awaiting our efforts to turn our engine of war into an engine of peace. These peacetime accomplishments, if well directed, may well be used to found new industries and to combat postwar depression.

We may take the road of strict nationalism by which we preserve what we know, and race other nations for supremacy in military production and development. This, we feel, is the direction in which the May bill points. We may, on the other hand, attempt to make international arrangements concerning the control and use of the weapon, which will permit us to explore and develop the peacetime uses of atomic energy.

The choice is grave and the time is short, yet the time is not as short as to require us to take action without adequate study and consideration. It appears to us that the rapidity with which the May bill is being acted upon in Congress is such as to permit no adequate formulation of public opinion. The urgency is not such as to require our abrogation of the democratic process. We feel, therefore, that interim legislation should be passed, permitting the projects to continue on their wartime basis for 6 months. This would permit the people sufficient time to consider the choice and select the road they wish to follow. Since the people will reap the harvest, the people must sow the grain.

Our objections to the May bill are many. As scientists, we are unable to judge the legal aspects of the bill. We believe, however, that several provisions obstruct the peacetime development and use of atomic energy.

The scope of the bill covers "all activities connected with research on the transmutation of atomic species, the production of nuclear fission, and the release of atomic energy." This will mean that a very large fraction of modern physics, chemistry, biology, and medicine will fall within the jurisdiction of the act and, therefore, if not actually controlled by the Commission, can only exist through its sufferance. When coupled with the retroactive security regulations, this will act as a powerful deterrent to young men who might enter the field, or to industry interested in developing applications not connected with the development of atomic energy in appreciable amounts. The transmutation of atomic species other than those associated with fission or the release of atomic energy in appreciable quantities, should not fall within the scope of this bill.

The structure of the administration proposed by the bill appears to us unsatisfactory. Commissioners are immune to removal except after specified violations. The Commission consists of part-time men selected from civil life, Government, or the armed forces. The importance to the Nation and to the world of their task would appear to be ample justification for appointing the best men on a full-time basis. The relation of the Commission to the rest of the Government is not clear. It must act "in accordance with the basic principles established by the President in the promotion of international peace, the development of foreign policy, and the safeguarding of the national defense." No mechanism is described to implement these admonitions.

The Administrator and Deputy Administrator are twice removed from the will of the people. They are protected by the Commission which may set up such regulations as to prevent criticism. They may be members of the armed forces, interested only in military developments.

The broad powers of the Commission and Administrators will permit them to shape the nature of research, development, production, and use in this new field along highly restricted lines if they so choose. Their only limitation consists of

an admonition to "interfere to the least possible extent with small-scale experimentation in research laboratories of nonprofit institutions." The work may be restricted to Government agencies or may be unrestricted. There is no assurance that the policy may not change from time to time.

Security under this bill could be so administered as to stifle progress in the military development as well as the peacetime uses of atomic energy. Research in the physical sciences has never thrived where strict controls were imposed. The history of American science during the past few years is a case in point. During this period, American scientists have expended enormous effort in the technical development of the atomic bomb. The statement has frequently been made that there is no secret. The fundamental discoveries were made before the war when science still had an international structure. The very fact that our achievement is due to the exploitation of our prewar stock of fundamental information makes us aware of the scarcity of the fundamental discoveries made during the war. The national emergency forced us to choose between rapid development of a military weapon and free scientific pioneering. This choice was made knowingly at the expense of free inquiry. To keep its preeminent place in science, our nation must permit many of its scientists to return to fundamental research. To maintain national security, if a nationalistic approach to world peace is chosen, we must keep some of our leading scientists at the job of developing atomic energy. Conditions must be such that research, both pure and applied, can progress at a rapid rate.

If properly administered, the May bill could insure such rapid progress. It would require on the part of the Commission and the Administrators great restraint in the use of their broad powers. If these powers were to be applied in an adverse manner, as permitted under the provisions of the bill, twentieth century science would cease to exist. The scope of the bill is so broad and the limitations upon the Commission and Administrators are so few, that they can direct American science and technology in any direction they may choose. Whether this direction chosen is for the good of the Nation and civilization will depend largely upon the wisdom and integrity of one man. The Commission, consisting of part-time men, must lean heavily upon the advice and judgment of their Administrator. Once the decision is made, little can be done to alter the course of the Nation, for censorship and security regulations can be used in such a manner as to prevent criticism.

We believe that rapid progress in science, and strict security regulations involving particularly the compartmentation of information, are mutually exclusive. As the bill is constructed, the Commission may establish whatever security regulations it sees fit. These regulations need not stop at the limits of military necessity. Any regulations not required for military security will serve only to impede the progress of the work. Security regulations should be made known to the scientists involved, for to inform a man of a regulation only at the time he is accused of violating it is not living up to our American tradition.

We strongly urge that the May bill be withdrawn and new interim legislation be introduced to provide for continuing operation of the Manhattan District projects on their present basis. In the meantime, investigation and study of all aspects of the atomic energy development should be undertaken for the purpose of drafting permanent legislation which shall not violate the American tradition of government by the people.

Submitted to and approved by the Association of Oak Ridge Scientists at Clinton Laboratories in its meeting of October 24, 1945.

P. S. HENSHAW,
Chairman, Executive Committee.

STATEMENT OF W. S. AMENT, FORMERLY ENSIGN, USNR, NOW ON INACTIVE DUTY; AT PRESENT ASSOCIATED WITH THE NAVAL RESEARCH LABORATORY, WASHINGTON, D. C.

The United States should propose to Russia some such arrangement as the following: "You people know that we have a terrible weapon in our atomic bomb, and we have to suppose, since there are many events in your country that we do not see or hear of, that you have developed enormously destructive weapons which are unknown to us. Our people have become suspicious of the secrecy which veils your military development—as suspicious, perhaps, as you are of our secret production of the atomic bomb. We therefore propose, in order to wipe out the suspicions that are growing between us and to prove our claim

that we are a peace-loving Nation, that Russian scientists appointed by your Government will be given the privileges for all time of freely inspecting every military installation, factory, and laboratory in this country, and of freely reporting their findings back to your Government, providing our appointed scientists enjoy exactly the same privileges in Russia."

Our nuclear physicists say that any country can develop an atomic bomb even more destructive than ours by the expenditure of sufficient money and engineering ability. Therefore we certainly have much to gain and nothing to lose by making such a proposal as the foregoing one. For if the Russians do not accept the proposed agreement, our suspicions will be strengthened and we shall pour billions into atomic bomb and other military research—but this we are now doing anyhow, because our anxiety is already too strong for us to do otherwise. If the Russians accept in bad faith, we shall at least have gaged their strength and the first instance of official bad faith will serve as a loud alarm telling us to mobilize. And certainly no one will object if the Russians accept in good faith.

STERLING AMENT.

WASHINGTON, D. C., October 15, 1945.

Re atomic bomb.

MILITARY AFFAIRS COMMITTEE,

House of Representatives, Washington, D. C.

GENTLEMEN: To the great problem of elimination of wars and the consequent possible world destruction by the atom bomb, I am submitting herewith what I believe to be the only practical solution. This is contained in the basic psychological means as provided in paragraphs 5 and 6 of the attached. It is my opinion that no peoples of any nation will ever vote in the majority for war. With my terms in effect it will be the man who fights, pays, and dies in a war that will decide the issue by direct mandate. His answer anywhere, at any time, will be in the majority against war. I believe that no mechanical means can be found to counter this terrific atomic force, whereas my suggested conclusions can forever harness all danger. I am not in favor of any such idea as a one-world nation, or that we surrender our national sovereignty to accomplish the objective. With my plan in effect we are still left an independent nation. I further believe that any measures short of my suggestions, by the United Nations, will fail in its objective. You may feel that my views will be hard to put in effect. Granted; but so was the Constitution. Gentlemen, here is the one and only answer and, in the name of God, do not pass it up. Thank you for your consideration.

FRANK E. VANDERHOOF.

VANDERHOOF 13-POINT PEACE PLAN TO ELIMINATE FUTURE WARS AFTER VICTORY

(This plan presented to Congress, by Hon. Wirt Courtney, from Tennessee, as it appears in the Congressional Record of July 1, 1943, House of Representatives)

- (1) An organization or association to be formed among the United Nations, and those others which will have been freed from the bondage of Germany, Japan, and Italy.
- (2) These nations, large and small, shall be permitted to set up their own form of governments, without influence or demand.
- (3) These nations shall set up a new code of international law.
- (4) Present enemy nations shall not be barred from membership in such organization or association.
- (5) Each nation in association, to be acceptable to membership must adopt or write a constitutional amendment, waiving all right by power of their government to declare war, unless attacked by forcible arms. The association to decide what constitutes forcible attack.
- (6) All power to so declare war must rest with the people of each respective nation, by popular vote.
- (7) The armament of each of these nations shall not be in excess to that which will be necessary to maintain internal order. Size of each respective army to be determined by the association or union.
- (8) An international chamber of commerce to be organized with equal representation among these United Nations, to create markets and guide in the fair distribution of raw materials and manufactured goods. The main object of such

chamber is to eliminate competition among nations as much as possible. Tariffs of each member nation to be regulated by the association.

(9) The principal of freedom of religion must be a point of adoption among these nations. This to be the constitutional right of all the peoples of these respective nations.

(10) The principal of freedom of trade, of the seas, and in the air must be adopted.

(11) Any nations not joining this association or union, by adoption of agreement as set forth in paragraphs 5, 6, and 9 shall be cut off from international trade, postal exchange, and diplomatic relations with all nations of this association. Citizens of the outlawed nation will not be permitted to enter the boundary of any of the associated nations.

(12) Each nation of these United Nations, both large and small, shall have only equal representation in this association. Territorial claims and boundary disputes to be settled by the association.

(13) A sizable international police force or army to be maintained in readiness to occupy any aggressing nonmember nation. Also to see that the laws of this association are justly maintained.

FRANK E. VANDERHOOF.

STATEMENT ON ATOMIC POWER AUTHORIZED BY EXECUTIVE COMMITTEE,
METHODIST FEDERATION FOR SOCIAL SERVICE

The most destructive weapon in the history of warfare has been used by the United States. Tens of thousands of men, women, and children have been killed in one bombing. Great cities have been destroyed. The second bomb used was reported to be far deadlier than the first. Effective counterweapons have not been developed, and perhaps never will be. The question of war or peace is now a question of life or death for entire peoples—for mankind.

Temporary American monopoly over this weapon cannot guarantee the security of America or of the peace of the world. Peacemakers cannot emphasize too strongly that the atomic bomb is no substitute for international cooperation in general, or friendship with the Soviet Union in particular. In fact, the bomb makes that cooperation and friendship more imperative than ever. The bomb's use and discovery makes even more pressing the preservation and securing of the peace. But no one nation safely can be trusted with that task. This means that no one nation should claim or maintain an exclusive monopoly over that weapon.

Supposedly, the United States has today such a monopoly. But the scientists assure us that such monopoly is short-lived at best. The New York Herald-Tribune editorializes "that Britain, Russia, France, probably Canada, and some others could now produce atomic bombs in a reasonably short time if driven to the attempt." We are further told that, in order to win the race with the Germans to make the bomb, four processes were tried, three of which worked. Some other nation or nations might develop one of these processes or another one even more effective. The basic principles involved are already open knowledge. And as the Herald-Tribune again points out, it is futile to hope "that the genie can ever now be thrust back into the bottle."

How could the United States possibly gain by clinging to her certainly temporary monopoly? This could only serve to strengthen and spread hostilities, suspicions, fears, and hatreds between nations. It might well open the door to a mad competitive struggle in the development of atomic warfare. This would start mankind on the road to destruction and doom by splitting one world, in which peace alone is safe, into a divided world of two or more hostile blocs, a grim prospect indeed.

Fortunately, there exists an alternative. The alternative is that, under proper safeguards, the atomic bomb and its manufacturing processes be transferred to and controlled by the United Nations Organization and its Security Council. The President and the Government of the United States should make known a will to effect such a transfer and to effect it speedily. This would serve to clear the international atmosphere of ominously growing suspicions and fear. It would make clear to the world that our Nation has abandoned forever the fatal pattern of chauvinistic nationalism and isolationism. It would prove the sincerity of our professed aim to look, not to our isolated armed might alone, but to the new international organization, for the maintenance of world security. Thus can the atomic bomb be used to strengthen, not shatter, the precious fabric of international cooperation as begun through the developing United Nations Organization.

Now, not tomorrow, is the time to act—now, before the competitive armaments race has begun in full fury, now that the United Nations Organization and its Security Council have been set up in response to the overwhelming demand of the peoples that the catastrophe of recurring war be ended through sincere international cooperation and solid world organization.

* * * * *

Meanwhile, we should give consideration to the constructive possibilities of atomic power. Possibly the doors are opening to a new atomic age. President Truman has described the splitting of the atom as "the harnessing of the basic power of the universe." Monopolistic control over such power for the ends of private profit is as basically sacrilegious as would be similar monopoly for similar purposes over the air and stars. This vast new power must not get into the hands of vested monopoly interests or cartels to be used for private profit. It must, rather, be used and controlled of, by, and for the people as a whole. Such constructive democratic use of atomic power demands public or social ownership and control. It is in the hands of the awakened people to insist that such be our own Nation's policy.

ATOMIC ENERGY

TUESDAY, NOVEMBER 27, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to call, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Connally, Byrd, Tydings, Vandenberg, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser, and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The committee will come to order.

The Special Committee on Atomic Energy of the United States Senate is beginning this morning its public hearings on the entire question of the atomic bomb and atomic energy. Senate Resolution 179, by which the committee was created, stated that it shall be the duty of the committee "to make a full, complete, and continuing study and investigation with respect to problems relating to the development, use, and control of atomic energy."

(S. Res. 179 is as follows:)

Resolved, That a special committee on atomic energy to be composed of eleven Members of the Senate appointed by the President pro tempore of the Senate, of whom one shall be designated as chairman by the President pro tempore, is authorized and directed to make a full, complete, and continuing study and investigation with respect to problems relating to the development, use, and control of atomic energy. All bills and resolutions introduced in the Senate, and all bills and resolutions from the House of Representatives proposing legislation relating to the development, use, and control of atomic energy shall be referred to the special committee. The special committee is authorized to report to the Senate at the earliest practicable date by bill or otherwise with recommendations upon any matters covered by this resolution. The existence of this committee shall terminate at the end of the Seventy-ninth Congress.

For the purposes of this resolution the committee, or any duly authorized subcommittee thereof, is authorized to hold such hearings, to sit and act at such times and places during the sessions, recesses, and adjourned periods of the Senate in the Seventy-ninth Congress, to employ such experts, and such clerical, stenographic, and other assistants, to require by subpoena or otherwise the attendance of such witnesses and the production of such correspondence, books, papers, and documents, to administer such oaths, to take such testimony, and to make such expenditures, as it deems advisable. The cost of stenographic services to report such hearings shall not be in excess of 25 cents per hundred words. The expenses of the committee, which shall not exceed \$25,000, shall be paid from the contingent fund of the Senate upon vouchers approved by the chairman.

The CHAIRMAN. These hearings are going to be full, complete, and extensive. We want all the pertinent facts submitted to the committee so that our decisions may be based upon all the evidence which we can secure.

The release of atomic energy is certain to affect every phase of our life. Like the discovery of steam and of electricity, this may well hold the promise of tremendous benefits to mankind. It is essential that we exercise the best judgment of which we are capable in order to insure that atomic energy becomes a blessing to mankind and not a scourge.

All of us, I am sure, are anxious that the atomic bomb may never be used again in warfare. All of us want atomic energy used for peaceful purposes, to make life better and fuller.

We are conscious of the fact that no time is to be lost in dealing with this problem and I confidently hope that our hearings and deliberations will proceed expeditiously. However, we members of the committee feel impelled to bring out the relevant facts in the democratic manner. When those facts have been developed, then, and not until then, we will turn to specific legislation. We must have the basic data of scientific, industrial, economic, and social significance relating to the development of atomic energy, so that in weighing any proposed bill for its control and in making recommendations we will be in the position to contribute to the safety and welfare of our own country and the peace of the world.

The first witness before the committee, I believe, is Dr. Alexander Sachs, an early figure in this matter.

Dr. Sachs, will you identify yourself?

STATEMENT OF DR. ALEXANDER SACHS

Dr. SACHS. I am by profession, gentlemen, a practical economist, economic adviser, and consultant. I was previously economist and vice president of the Lehman Corp., of which I am still a director and a special economic adviser in my new capacity. Throughout the decade prior to the war I was associated with them.

I have also been interested in problems of national welfare and related problems, and from the very beginning of the great depression I had taken a much greater concern over its nature and development than other people were doing, and came to be known or nicknamed as the "Economic Jeremiah."

In the course of that, I had gone to Europe, and from the great crisis of 1931 my advice was sought by leading figures.

I was particularly a special adviser in an informal capacity to Lord Reading and Lord Lothian, who were concerned with the impact of the world depression on England.

I came back from that trip with a sense of foreboding as to the evolution of that great depression and a sense that its nature, as the collapse of the postwar reconstruction, was bound to affect us and was bound to undermine the political order of the world. I had so distinctly felt that that it became communicated in 1932 to Mr. Roosevelt, and so I began an association in which I continued through the years as an informal adviser without any special label. I tried to live up to a concept that he had formulated in connection with his reorganization message of January 1937 about certain assistants, that these should be men in whom the President has personal confidence and whose character and attitude are such that they would not attempt to exercise power on their own account. They should be

possessed of high confidence, physical vitality, and a passion for anonymity. I tried to live up to the last one, a passion of anonymity, and I have not myself participated in any self-reverentialness, feeling that my job was to be a person who was on tap and not to be one who was in the news or in any way trying to influence the course of events beyond that of trying to point out their implications and their consequences.

It was from the very beginning of 1933 that I sensed that the economic crisis was going to have political consequences. I had in 1932 written what I had passed on to the President-elect. The statesmen of the world continued to be overtaken by a sort of high-tension paralysis, like the trivial oscillations of the trench war battle fronts up to America's entrance in the great war, only to find that the imperious and menacing march of events swept aside the half-willed and half-thought schemes, and even attacked improvised defenses that were resorted to too late, as in the case of Germany to save Germany for democracy.

The outstanding feature of this great depression is that the economic concept developed since the Reformation and the great society developed since the fall of the Roman Empire have come to be threatened not by the destructive impact of external or natural forces, but by a disintegration from within because of an incipient failure of will and political wisdom.

Thus imbued in 1933, in connection with the National Recovery Act where I had been called in in my capacity as an economist, I had suggested that the best use for public-works money was to apply it to the reconditioning of the Navy and to the improvement of national defense.

Gen. Hugh Johnson, who was at the time an assistant in an economic capacity to Mr. Baruch, and who had gotten to know me from echoes heard of what he thought were always correct forecasts, had called me in; and I had urged upon him the inclusion of these provisions.

Senator Austin. What year was that?

Dr. Sachs. That was 1933, in the legislation of April and May.

Hugh Johnson was a little bit too humorous about it in thinking that I had put anything over, but the fact was that it was a very patent argument with the President that the advent of Hitler to power boded ill for all democracies, and that it was necessary that we take time by the forelock.

Hugh Johnson in the Blue Eagle, pages 197-198, credits me with having suggested that this provision about the availability of funds for naval construction be written into the NRA bill.

I have always been of the view that the real warmongering is done by the pacifists combined with a defeatism, and that one who is concerned about the protection of national interests without aggressive aids is the real practical pursuer of peace.

Later on—and I had been in the habit of reporting to the President regarding the progress of international developments—in 1936 he called me in to help in working out a solution on the problem of public utilities and power. I had proposed the idea of a power pool, and even then we discussed that in the event of danger we would want to have a mechanism for the coordination of private and public power.

The distinguished figures representing the public were Mr. Owen D. Young and Mr. Lamont, and I had been another one that was selected alongside those representing the public-utility interests and the governmental authorities concerned with power.

After Munich I had begun to send the President a series of memoranda, and it was at the turn of the year, in January 1939, that I had sent in a very long study on the international situation. In the preface to it, in the foreword, I described that memorandum and its predecessors. I had been discussing these things with him in 1936, and also in 1937 prior to the "quarantine" speech.

My role was, if you will, to be a reasonator for ideas that he had and also as a humble submitter of ideas. In this preface I wrote:

The orientation toward the crisis that has been developed in prior reports and needs to be borne in mind continually is that we are already in what Thomas Hobbes, who lived through the British civil war 300 years ago, justly called "war time-tract" and "war-weather": "For war consisteth not in battle only but in a tract of time wherein the will to contend by battle is sufficiently known * * *. For as the nature of foul weather lieth not in a shower of rain but in an inclination thereto of many days together; so the nature of war consisteth not in actual fighting but in the known disposition thereto during all the time there is no assurance to the contrary."

The thesis then was that the aggressor powers, the Nazis and the Fascists and their other allies—since Japan had already started this in 1931—were passing from the state of "white" war and limited war to totalitarian war.

On March 10, 1939, when I was asked by St. John's College to deliver a talk on the world situation, I prepared certain notes, a copy of which I sent the President. Those were "Notes on Imminent World War in Prospective Accrued Errors and Cultural Crisis of the Interwar Decades." That was a memorandum dated March 10, 1939, and the opening sentence was:

This interwar generation has been living on the edge of a smoldering volcano; and the predominant attitudes among both what is called "Right" and what is called "Left" have been variants of escapism, very much like peasants situated on the edge of a volcano who go on cultivating the slopes in the hope that the eruptions will not take place in their lifetime.

Then I reviewed the errors of the interwar period, and said:

The present period is too late for that reversal of error which prevents the consequences of error. The real "Munich" took place in 1936, in connection with the Rhineland. Then was the last opportunity missed for preventing that cumulative German aggression that was bound to culminate in a new and more terrible war by Germany. But what can and must be done for our salvation and safety is self-clarification and self-reorientation towards the onrushing dangers.

Then in the concluding sentence—and you must pardon the length—I thought it was my business to try to think these out, not try to be popular, I said:

There is still time for western civilization, and especially for the exceptionally and fortunately situated United States, to use the time drafts that can still be made on the Bank of History for the preparedness that has and will become more and more urgent and inevitable for all members of western civilization as a result of the past errors committed and in the course of the prospective unfolding aggressions of Nazi Germany.

That was in March, and the address was delivered in April before St. John's College on war imminence and the cumulative crisis of the interwar period.

It was in the following month, on April 15, 1939, that there was published in the *Physical Review* a note by Dr. Leo Szilard entitled "Instantaneous Emission of Fast Neutrons in the Interaction of Slow Neutrons with Uranium."

In keeping with the custom in scientific research, the date of its original sending was included, dated March 16, 1939; so it coincides with the time when Hitler seized Prague and by seizing Prague became the controller of the crossways of the continent.

The background of that was that at the turn of the year 1937 certain experiments had been concluded in Germany, and they were made available and made known. Dr. Niels Bohr of Denmark came to this country and spoke to his colleagues. Scientists are an international community. I think the word "international" is not as precise as it ought to be; it really is "transnational," across the boundaries of nations. They function in terms of common ideas because, after all, our heritage of common moral ideas and intellectual ideas dates for our world from the Reformation or the Renaissance, and it is a crystallization of the very Christian ideas and the pursuit of science irrespective of national boundaries, but as a human activity. These scientists depend upon the free flow of knowledge, the free flow of ideas. They had learned that there were completed in Germany experiments by Drs. Hahn and Strassmann regarding the fission of uranium.

What was done in this country represented a distinct advance because of the work of Dr. Szilard and the independent confirmatory work of another scientist, Dr. Fermi, a Nobel Prize man in physics of Italian descent who, under the conditions of fascism, found it inadvisable to return to Italy. The Nazi contamination had advanced so far that it became difficult for those who did not conform to the tribalistic notions of their sect.

The confirmatory work of Dr. Szilard and Dr. Fermi amounted to the suggestion that a chain reaction could be established in the process of atomic fission, and that chain reaction had implications for the type of energy for the kind of power that would be telescoped and concentrated in the process of disintegration.

Because I had been imbued with those ideas upon the nature of the world crisis, I was concerned with what was happening to the victims of nazism and fascism, and I tried in my own small way to be helpful during the period when the scientists had to leave.

I gave you at first some highlights of the "book of genesis" of my concern, and that is, if you will, the "book of exodus," the exodus of scientists who came to this country as a haven.

Prior to that, Dr. Szilard had worked in England at Oxford and Cambridge, at Oxford with F. A. Lindemann, who afterward became Lord Cherwell and played toward Mr. Churchill a role analogous to the one, in respect to this project, that I played toward Mr. Roosevelt.

In this phase of the exodus, the scientists were concerned not only with the progression of a technical problem, but with its political and moral implications.

There was another great physicist, who was a friend of Dr. Szilard and part of that group, Professor Wigner, of Princeton. There were a great many of them in Princeton, which became one of the great

centers. There was Professor Wigner, Professor of Theoretical Physics, and then there was Professor Einstein, whose theoretical work antedated the First World War, whose practical confirmation in the astronomical tests interestingly enough came just in the closing phase of World War I, as Prof. A. S. Eddington, of Cambridge, shows in his book on "Space, Time and Gravitation"—he was the head of that expedition.

Einstein, Wigner and Szilard discussed the problem; and I want to impress upon you gentlemen that, if I may refer to the Gospel of St. John—I happen to regard these testaments as equally significant in relation to basic ideas—"in the beginning was the Word." In the beginning was a moral idea and a political concern on the part of the physical scientists and this social scientist whom they brought in. They brought me in because they had heard that I was in a position to talk to the President and talk to him in terms of broad and fundamental concepts; and the idea was, how can this be brought to the attention of the President?

The Germans were organized to carry on experimentation without limit. The Nazis were not at all concerned about money expenditures. Ironically, despite all the beblinkered concern on the part of experts in my own field, economics, as to the terrible problem of reparations, the fact was Germany was spending on armament in any and every year, once it got going, more than was involved in the total amount of its remittances on reparations. Money was no object. They had these institutions. Many of the scientists were themselves refugees from work that they had been doing at these same institutions, the Kaiser Wilhelm Institutes of Physics and Chemistry.

The idea was that if they should be able to discover a concentrated power that could be used as an explosive, then the real safety of the United States and the rest of civilization would be gravely imperiled, because bear in mind that the essence of this period of foul weather internationally, to use Thomas Hobbes' expression of this wartime weather, was that the Nazis were rushing and not permitting the time for the organization of defense.

Therefore, these scientists, these physical scientists and myself, who was brought into the picture in the summer of 1939—and I had been introduced to Dr. Szilard by Mr. Stober, who was an economist; but I had known in a general way what was taking place because I had long been interested in theoretical physics and had followed publications in a general way—then felt that it was important to bring these matters to the attention of the President. We felt that it was essential that an opinion should be written by the one man whom the world recognized as the preeminent scientist of our day, and not only the preeminent scientist but, as the Senator this morning remarked, one of the greatest humanitarians, because he had left nazism before expulsion orders were given to him. He had anticipated the trend of events. He did have political foresight, and did see what it implied.

Dr. Einstein wrote a letter regarding this, dated August 2, 1939. I had also asked Dr. Szilard to write a memorandum describing the significance of the current and evolving scientific research, and that was a memorandum of August 15, 1939.

Then I sought for an opportunity to see the President. I had been in touch with him, but I felt at the time that the mere delivery of

memoranda was insufficient. Our social system is such that any public figure—you gentlemen in your work as statesmen, and the administrators in Government—are punch-drunk with printer's ink. You have to read so much that I felt there was no point to transmit material which would be passed on to someone else. This was a matter that the Commander in Chief and the head of the Nation must know. I could only do it if I could see him for a long stretch and read the material so it came in by way of the ear, and not as a soft mascara on the eye.

Then, of course, with the outbreak of the war it was not possible for the President. He had the problem of the existing neutrality legislation, as you recall, and only when that was solved did I accept an appointment, because it meant that then I could see him at leisure and read the material. I brought over the material to him, and met with him on October 11, 1939. I wrote the letter in anticipation of my seeing him so that I would be able to read it, and the opening sentence was:

With the approaching fulfillment of your plans in connection with revision of the Neutrality Act, I trust that you may now be able to accord me the opportunity to present a communication from Dr. Albert Einstein to you, and other relevant material bearing on experimental work by physicists with far-reaching significance for national defense.

Briefly, the experimentation that has been going on for half a dozen years on atomic disintegration has culminated this year (a) in the discovery by Dr. Leo Szilard and Professor Fermi that the element uranium could be split by neutrons and (b) in the opening up of the probability of chain reactions—that is that in this nuclear process uranium itself may emit neutrons. This new development in physics holds out the following prospects:

1. The creation of a new source of energy which might be utilized for purposes of power production—

naturally featuring first peacetime production.

2. The liberation from such chain reaction of new radio-active elements, so that tons rather than grams of radium could be made available in the medical field.

3. The construction, as an eventual probability, of bombs of hitherto unenvisaged potency and scope. As Dr. Einstein observes, in the letter which I will leave with you, "a single bomb of this type carried by boat and exploded in a port might well destroy the whole port, together with some of the surrounding territory."

In connection, then, with the practical importance of this work—for power, healing, and national defense purposes—it needs to be borne in mind that our supplies of uranium are limited and poor in quality as compared with the large sources of excellent uranium in the Belgian Congo and, next in line, Canada and former Czechoslovakia.

I also informed him that we had learned that in the wake of successful experiments by Drs. Hahn and Strassmann, one of whom afterward also joined the exodus, that the Germans, upon capturing Czechoslovakia, the seizing of Prague, had embargoed the export of uranium from Czechoslovakia.

I also mentioned the people who had been at work on this and who had been consulted:

Mindful of the implications of all this for democracy and civilization in the historic struggle against the totalitarianism that has exploited the inventions of the free human spirit, Dr. Szilard, in consultation with Prof. E. P. Wigner, head of the physics department at Princeton, and Prof. E. Teller of George Washington University, sought to aid this work in the United States through the formation of an association for scientific collaboration, to intensify the cooperation of physicists in the democratic countries—such as Professor Joliot

in Paris, Professor Lindemann of Oxford, and Dr. Dirac of Cambridge—and to withhold publication of the progress in the work on chain reactions.

The CHAIRMAN. Doctor, what was the date of the embargo on uranium?

Dr. SACHS. Right in April, right after the seizure of Prague on March 15, 1939.

Bear in mind that this world community was already functioning and included Professor Joliot, married to a daughter of Madam Curie; Professor Lindemann of Oxford, who afterward became Lord Cherwell and played this corresponding role toward Winston Churchill

As the international crisis developed this summer, these refugee scholars and the rest of us in consultation with them unanimously agreed that it was their duty as well as desire, to apprise you at the earliest opportunity of their work and to enlist your cooperation. * * *

In the light of the foregoing, I desire to be able to convey in person, in behalf of these refugee scholars, a sense of their eagerness to serve the Nation that has afforded them hospitality, and to present Dr. Einstein's letter, together with a memorandum which Dr. Szilard prepared after some discussion with me and copies of some of the articles that have appeared in scientific journals. In addition, I would request in their behalf a conference with you in order to lay down the lines of policy with respect to the Belgian source of supply and to arrange for a continuous liaison with the administration and the Army and Navy Departments, as well as to solve the immediate problems of necessary materials and funds.

There is one more document that is pertinent. One of the things that I brought together and submitted to the President, in addition to the scientific material, was, of course, this review of mine of the whole world situation on the imminence of war and the nature of this war, which is really a 30-year war, from 1914 on, for a world dominated by Germany with aggravations, of which there was one brief interlude, a brief armistice.

From 1931 on there was a resumption of war first in Japan in the seizure of Manchuria, and then came the succession of wars, the Italian war against Abyssinia, the interventionism by the Axis powers in Spain, the war against Austria, and finally the seizure of Czechoslovakia.

In 1936 there were lectures delivered on the history of science, reviewing the progress in sciences for the preceding approximately 40 years. The book was published by Cambridge University Press after Munich. It was published in 1938. Due to the work that I had done in England and my relationship to figures who consulted me—in addition to Lord Reading and Lord Lothian, there was Sir Josiah Stamp, a great economist, who had gotten in touch with me—I used to get these publications, as my interests included scientific work.

This book published in 1938 contained two lectures on the history of recent developments in physics, and the development of the theory of atomic structure by Lord Rutherford, whose work initiated the technical side of the physical research begun about the turn of the century.

Some of the greatest work of Lord Rutherford was done right nearby when he was professor of physics at McGill University, and it was for this work that he got the Nobel prize.

There were these two lectures prepared by Lord Rutherford, which after his death, were revised by an assistant of his, and then

there was a separate lecture, in addition, on Forty Years of Atomic Theory, by F. W. Aston of Cambridge, who died only a few years ago. You may have seen the notice.

F. W. Aston, reviewing the work that had been done in 1936 and describing what was being done in England and elsewhere, ended up his lecture as follows, and I showed it to the President with a view to high-lighting the fact that, like all things, there is an ambivalence in it, there are two poles of good and evil. The concluding paragraph is as follows:

There are those about us who say that such research should be stopped by law, alleging that man's destructive powers are already large enough. So, no doubt, the more elderly and ape-like of our prehistoric ancestors objected to the innovation of cooked food and pointed out the grave dangers attending the use of the newly discovered agency, fire. Personally, I think there is no doubt that subatomic energy is available all around us, and that one day man will release and control its almost infinite power. We cannot prevent him from doing so and can only hope that he will not use it exclusively in blowing up his next-door neighbor.

The President remarked, "Alex, what you are after is to see that the Nazis don't blow us up."

I said, "Precisely," and he then called in General Watson, lovable "Pa" Watson, another one of that period who has gone from us, and he said, "This requires action."

General Watson then went out with me, and the informal group was established.

Senator VANDENBERG. What was the date of this?

Dr. SACHS. October 11, 1939, sir.

He selected, with the approval of the President, one man representing the Army concerned with science, and one representing the Navy; Colonel Adamson for the Army and Commander—since Admiral—Hoover for the Navy.

Holding that as an expert I ought not to be injecting political views, I have throughout my work remained an associate regardless of party and other affiliations. As I have the honor to know ex-President Hoover, I was very pleased to find a namesake of his concerned with these scientific problems, as President Hoover during his incumbency as Secretary of Commerce did a great deal for the advancement of science and scientific research.

As the central figure, the President named a Government individual who was concerned with problems of science, the Director of the Bureau of Standards, Dr. Lyman Briggs, who rendered very great work during the critical period.

I got in touch with Dr. Briggs that very night, before having to go again to the White House to have some words with the President to report progress, because the potentialities of this were very much in the mind of the President, and he had communicated, "Don't let Alex go without seeing me again."

I saw him later that night, and the idea was to hold a meeting. A meeting was scheduled after this October 11 conference at the White House; a meeting was scheduled for October 21.

I reported to Professor Wigner, who throughout this period occupied a pivotal role because he is highly esteemed and was perceptive on what you might call the political problems. I reported to him in a letter of October 17 and I sought throughout the interval to broaden the group of scientists who were to attend that conference

Senator VANDENBERG. How about the Einstein letter you referred to?

Dr. SACHS. The Einstein letter of August 2, from which I quoted in part in my own letter, was left with the President, along with my letter.

The CHAIRMAN. Have you a copy of it?

Dr. SACHS. That is part of a record which I will leave with you gentlemen, which was a report I prepared immediately after the announcement about the use of the atomic bomb in August, which I prepared for the White House, the Department of Commerce—Mr. Wallace as the successor in charge of the Department that had such an important role—the Bureau of Standards, and the War Department.

The CHAIRMAN. Does that contain your letter?

Dr. SACHS. It contains all the documents, sir. It contains Einstein's letter, and it contains other memoranda.

I had throughout this period sought to be a historian, because the President said to me, "Pa Watson is going to be too busy to be a historian; you had better do that."

I made contemporaneous reviews, and would submit them as galvanizers of action.

I have a copy of Einstein's letter, a duplicate, which has his signature, and I will leave that copy with you.

Senator VANDENBERG. Could you state in a sentence or two the import of Einstein's letter?

Dr. SACHS. Yes, sir. [Reading:]

Some recent work by E. Fermi and L. Szilard, which has been communicated to me in manuscript, leads me to expect that the element uranium may be turned into a new and important source of energy in the immediate future. Certain aspects of the situation which has arisen seem to call for watchfulness and, if necessary, quick action on the part of the administration. I believe therefore that it is my duty to bring to your attention the following facts and recommendation.

He then describes the new phenomenon, and describes that the sources of supply are outside the United States; that the United States has only very poor ores of uranium in moderate quantities, and that there is some good ore in Canada and the former Czechoslovakia. As to that, he reports:

I understand that Germany has actually stopped the sale of uranium from the Czechoslovakian mines which she has taken over. That she should have taken such early action might perhaps be understood on the ground that the son of the German Under Secretary of State, von Weizsaecker, is attached to the Kaiser Wilhelm Institute in Berlin, where some of the American work on uranium is now being repeated.

In other words, there was political interest being taken in the work. So Dr. Einstein said that one of the ways in which the administration could be helpful was to entrust this task to a person—

* * * who has your confidence and who could perhaps serve in an unofficial capacity. His task might comprise the following:

(a) To approach Government departments, keep them informed of the further development, and put forward recommendations for Government action, giving particular attention to the problem of securing a supply of uranium ore for the United States;

(b) To speed up the experimental work, which is at present being carried on within the limits of the budgets of university laboratories, by providing funds, if such funds be required, through his contacts with private persons who are

willing to make contributions for this cause, and perhaps also by obtaining the cooperation of industrial laboratories which have the necessary equipment.

These scientists, as you see, gentlemen, were no doctrinaires, but indicated only a practical perceptiveness—using whatever means were available so that the Government and the Nation had a supply and had funds for going ahead with this thing.

The next meeting that was held was on October 21 in Washington under the chairmanship of Dr. Briggs of the Bureau of Standards, and there was a survey made of the whole situation. Many scientists were there, scientists who were not as much concerned as these refugee scientists, because, as I tried to explain, gentlemen, they just were not only interested in advancing science; they were interested in the imperiled position of the United States and civilization. They were imbued with a concern in the Quaker sense of the word, devoted interest and responsibility.

Many other scientists said: "This is very remote; we have got to wait and see; there are other lines of progress rather than the chain reaction that may be more attractive," and the discussion wandered all over the attractive side issues.

The job on the part of one who occupied this intermediary and catalytic role in behalf of the President, was to ask these gentlemen of science and Government officials, including the Army and Navy, to indulge—and I remember using a phrase by the Irish poet Yeats, echoing Coleridge—in a "willing suspension of disbelief."

The issue was too important to wait, and the important thing was to be helpful because if there was something to it there was danger of our being blown up. We had to take time by the forelock, and we had to be ahead.

One great advantage that we had was that these refugees, these scientists, themselves responded to that very spirit of freedom that brought the Pilgrim fathers over here, a freedom of speech in religion, if you will, free science and free thought, and were saturated by the idea that that motive which the regimented scientist would not have would itself lead them to make advances much faster.

In the wake of that conference, a subcommittee was appointed, notwithstanding these expressions of doubt. The subcommittee was presided over by Dr. Briggs, and on behalf of Keith F. Adamson, lieutenant colonel, United States Army, and Gilbert C. Hoover, commander, United States Navy, a report was written to the President on November 1, 1939, on the stationery of the National Bureau of Standards of the Department of Commerce, which reviewed the situation technically and culminated with this observation:

3. The energy released by the splitting of a mass of uranium atoms would develop a great amount of heat. If the chain reaction could be controlled so as to proceed gradually, it might conceivably be used as a continuous source of power in submarines—

I would not have wanted to limit it to this form, but a continuous source of power was the fundamental idea—

thus avoiding the use of large storage batteries for underwater power.

4. If the reaction turned out to be explosive in character it would provide a possible source of bombs with a destructiveness vastly greater than anything now known.

The military and naval applications suggested in paragraphs 3 and 4—

in this case he was expressing the not-quite-suspended disbelief of the representatives of the services. Voicing their greater skepticism, Dr. Briggs said that the military and naval applications—

must at present be regarded only as possibilities because it has not yet been demonstrated that a chain reaction in a mass of uranium is possible. Nevertheless—

and in this respect those representatives were willing to go ahead—

in view of the fundamental importance of these uranium reactions and their potential military value, we believe that adequate support for a thorough investigation of the subject should be provided.

There had been a previous adverse report that I had known about, which was given by a technical adviser of one of the services in the summer, and it was because of that adverse report—they didn't see any reason for being interested, although they wanted to be kept informed—that I was brought in to go directly to the Commander in Chief.

So they concluded:

We believe that this investigation is worthy of direct financial support by the Government.

But, alas, we had no money.

The Lea bill now before Congress, if enacted, would provide for carrying out important investigations of this kind in cooperation with the universities.

We recommend the enlargement of the committee to provide for the support and coordination of these investigations in different universities. We suggest the following be invited:

President Karl Compton, Massachusetts Institute of Technology.

Dr. Alexander Sachs, 1 William Street, New York—

that was my address at Lehman Bros., who were very kind to let me devote time, and did not ask me to tell them what it was about. Mr. Robert Lehman is particularly to be thanked for this, and a man who afterward became an adviser of the War Production Board, and later Deputy Chairman, Mr. Arthur Bunker, who was then executive vice president of the Lehman Corp.

The people who were asked to be added were Prof. Karl Compton, myself, Prof. Albert Einstein—I am reading this in order; I belong very much at the foot of any such list—Prof. Albert Einstein, of the Institute for Advanced Study, and Dean George B. Pegram, Columbia University.

As a sequel to the major finding and recommendation, the committee proposed that initial support take the form of:

(a) Supplying for immediate and experimental work four metric tons of pure-grade graphite, and

(b) If later justified, supplying 50 tons of uranium oxide.

Later on there were all kinds of difficulties about getting the supply, to which I referred, and in the following year there was another refugee, an industrial engineer by the name of Pregel, who made available very valuable supplies to Columbia University for the experiments of Dr. Szilard and Professor Fermi, for which he was thanked by Dean Pegram.

The first phase was to coordinate the group of physical scientists for the purpose of presenting the idea to the President. The second phase was the securing of action by the Government, and that was climaxed by a report, which was a go-ahead signal, that Dr. Briggs wrote on November 1, 1939.

If you bear in mind how narrow has been the time, how correct was the concept of the memorandum from which I read of mine of March 10, 1939, that the job was "time borrowing, the issuance of drafts on the Bank of History," if the work had not been thought through before the advent of the war, if the President had not taken action immediately after, if the report of the Bureau of Standards and its technical head had not come forth on November 1—the bomb came toward the end of the war; it abbreviated the war, but it came in 1945—you will realize that the time borrowing was very essential, and the organization and the finding of proper medium was the great task of the year 1939 and the year 1940.

While I was an adviser of the President, also, on problems of strategy, I was also a special consultant to General Donovan, of the Office of Strategic Services, and had written the first report on the work that was being done outside on problems of totalitarian economics and war economics, as well as strategy, before the organization of the Office of Coordinator of Information, which afterward became the Office of Strategic Services.

Through these connections I was able to keep in touch, and I was kept in touch on the basis of great confidence, with the White House on what was going on, so I knew what was happening, even to the very last. I discussed the problem of the form of the use of the bomb with the President early in November 1944, when I submitted a memorandum on the final phase of the European war. That memorandum contained a forecast that the war would end in April or May, and that there would be no lasting stand, that the whole German system would collapse.

Though I have kept in touch, my official role as the representative of the President continued up to the time when, as you will see, I submitted to him the idea that it must be given over to an organization in charge of all scientific development, and suggested Dr. Bush, of whose keen interest and ready aid I had learned in the course of the difficult months of 1940.

Many of the pivotal figures are not now alive; the President is dead; General Watson, who rendered very great service, is dead. I remember that to military and naval men who said, "Well, this is still so remote; what is this thing; let's wait and see," "Pa" Watson would answer, "But the Boss wants it, boys." That was the one theme song of "Pa" Watson.

He is dead, and the secretary who used to call me up and pass on my messages is dead.

These documents which fortunately were written, represent the only available record of the flock of events, apart from scraps; and the scraps that are available in the files are insufficient to give a correct picture. One gets a picture by reading some of the things that have been published, but there was a linear progression.

Like all things, it was full of set-backs, difficulties, and perceptiveness and willingness, doubts, and hesitations, and it required continuous prodding. Such work as I was able to do, I was able to perform because everyone knew I was not concerned about anything but the progress of the work, and had made myself anonymous.

If I may again quote the New Testament, there is a verse in 1st Peter, "Be ready always to give answer to anyone that asketh of you

the reason of the hope that is within you," and yet with meekness and fear I felt that I had to go on with this work, that I had this vision and it must go on; and so I sacrificed my time and concentrated on that. Later on, as a matter of fact, when the war broke out I resigned from my administrative post and became a private economic adviser so as to be able to devote myself to war work to a very large extent.

In the summer of 1941 I had given to the Navy a plan that was worked out with the aid of a great engineer, radiosonic buoys for the establishment of the Atlantic security lane for the lend-lease shipments. This was afterward adopted by the Navy through the technical work by Professor Huntsacker of M. I. T.

I want to convey this impression, that in the beginning there was a political concept and a moral concern, and that it was necessary to provide proper vehicles for action and also to get acceleration of action.

The third stage was the coordination phase of the university researches with limited governmental aid and pressure—these were words that I used at that time—as I was saying, limited governmental aid and pressure by Einstein and the writer for a new framework and an accelerated tempo for the project.

While a number of the university representatives were encouraged by the governmental interest, the fundamental tenor and the tempo of the work remained, on the whole, continuous with the past—that is, they were regarded as mere laboratory researches.

The time of this phase was approximately coincidental with what was called at that time the "phony" war. This was the time of the war which embraced the period between the fall of Poland and the Nazi invasion of the Lowlands.

You can well believe that the President during this period was pressed by, and preoccupied with, numerous internal and international problems.

Our liaison officer for the project, General Watson, orally conveyed to the President the general tenor of Dr. Briggs' report. While he had done that, he thought, when he transmitted it to the writer on February 8, 1940, that a more pointed conclusion was necessary. He added that he had asked for a special recommendation from Dr. Briggs.

Meanwhile, some progress was made in the coordination of the university researches by the coordinating committee mentioned in the concluding point of Dr. Briggs' report. The appointment of Dean Pegrum served to focalize activities in Columbia on this project, and frequent conferences were held thereby with the speaker and Doctors Pegrum, Fermi, and Szilard. This group used to meet often at the Columbia University Faculty Club.

In mid-November, this group projected an octet of experimental projects in the hope that the subsidiary questions could be cleared within a period of 6 months.

Based on notes that were made at the time, I find that the nature and scope of these subsidiary problems and the recommended personnel, all of them from nearby educational institutions, were as follows—I will not read that, but it included the leading figures in this country, people working on these problems.

However, I will say that the most important of the men who were brought in was Prof. Harold C. Urey, who won the Nobel Prize for his work on heavy water, and who later on became very important.

At the same time, the Columbia project became the recipient of governmental aid in the form of limited funds intended for the purchase of materials, as is borne out by the reply that Dr. Briggs made on February 20, 1940, to General Watson's note of February 8, 1940.

On the other hand, Dr. Einstein and myself were dissatisfied with the scope and the pace of the work and its progress. The writer conferred with Dr. Einstein at Princeton in February. I went out to see him there and there developed an inquiry as to the importance of the work that was being carried on at the time in Paris, work that had been described in a contemporaneous issue of Science.

We felt that it was very important that this free trade in ideas—to use Justice Holmes' words, one of his expressions given in one of his great and discerning decisions—that this exchange of ideas should be carried on because these things that were being reported served as links and as stimuli to future work.

I had asked him, Dr. Einstein, about the work of the French, and he reported about that, and he said that he thought that the work at Columbia was more important.

As I say, I evoked from him the statement that the work being done at Columbia was more important. He further said that conditions should be created for its extension and acceleration.

Accordingly, the writer sent, on February 15, 1940, to General Watson a plea for larger aid and an intimation that presently Dr. Einstein would give a favorable evaluation of the work which had been completed at Columbia:

(The letter referred to is as follows:)

FEBRUARY 15, 1940.

Gen. EDWIN M. WATSON,
Secretary to the President,
The White House, Washington, D. C.

DEAR GENERAL WATSON: Thank you very much for your letter of the 8th and the accompanying report of Dr. Briggs to the President, both of which will be treated as confidential. Had the recommendations from the second part of point 5 through points 6 and 8 been placed ahead of the more technical points 1-4, the practical meaning of the letter would have been clearer and more forceful—namely, that in the opinion of Dr. Briggs and his colleagues it was distinctly worth while to go ahead. Due to too academic a presentation, I feel that that practical point was lost.

As the last issue of Science contained a quotation from Science Letters bearing on work in Paris, and as, since our meeting, there has been even more searching and significant work in this country, I shall take the occasion to submit within the next month an up-to-date appraisal of the situation which, according to Dr. Einstein in a recent conversation, holds forth even greater promise than we had thought.

With kind regards and appreciation,
Yours sincerely,

ALEXANDER SACHS.

Dr. SACHS. Ensuing conferences which I had with Dr. Einstein prompted the suggestion that he prepare another review of the situation for submission to the President. I had felt that Dr. Einstein's authority was such that, combined with his insight and concern, it could affect the tempo of the work which then, to use a musical term, too slow, troppo lento.

His review, which was dated March 7, was written as a letter to me. I will read the opening and closing paragraphs of this letter dated March 7, 1940. It was addressed to me at my office at the Lehman Corp.

In view of our common concern in the bearings of certain experimental work in problems connected with national defense, I wish to draw your attention to the development which has taken place since the conference that was arranged through your good offices in October last year between scientists engaged in this work and governmental representatives.

He also reported that he had learned of the further work that was going on in Germany since the outbreak of the war, the work on uranium.

He pointed out that this work was being intensified in Germany. I shall quote a portion here:

I have now learned the research there is being carried out in great secrecy and that it has been extended to another of the Kaiser Wilhelm Institutes, the Institute of Physics.

However, when it comes to secrets—even under the totalitarian system, secrets come out. Under our freer system, things also come out. They come out even while we are taking terrific measures, and very rightly, they still come out. I refer specifically to the Minerals Yearbook of 1943.

On page 828, that book contains something which was very significant. In a very technical statement about uranium, it spoke about uranium production in 1943—

Senator TYDINGS. Was that our book, or was it a German book?

Dr. SACHS. It was our book, the Minerals Yearbook for 1943, on page 828.

At the very time that newspapers and editors were not even to breathe the word "atom," the Minerals Yearbook of 1943, page 828, said, with reference to uranium:

Uranium production in 1943 was greatly stimulated by a Government program having materials priority over all other mineral procurements, but most of the facts were buried in War Department secrecy.

Then, it goes on to say:

Most of the 1943 uranium supply was used by physics laboratories for research on uranium isotopes as a source of energy.

These technical books went everywhere, they were available, by the ordinary routine, to the technicians, who would not have to read between the lines.

Our secrets leaked out. However, the same thing applied in the hermetically sealed German system. It is inherent in the situation.

The only way in which secrets do not get out is if no one knows anything about them. Once it is known, it is out. The only reason they got no secrets from me was that no one knew that I had anything to do with it. The newspapers, which are always eager in trying to get stories, got nothing from me because they did not know I had anything to do with it, so they did not seek me out and they did not get the kind of denial that would mean an affirmation.

As I said, Dr. Einstein wrote me on March 7, 1940. He said that in view of our common concern in the matter, he wanted to make a report on the developments, what the developments were, since the outbreak of the war. He stated that research on uranium had intensified in Germany.

Since the outbreak of the war, interest in uranium has intensified in Germany. I have now learned that research there is being carried out in great secrecy and that it has been extended to another of the Kaiser Wilhelm institutes, the Institute of Physics. The latter has been taken over by the Government and a group of physicists, under the leadership of C. F. von Weizsaecker, who is now working there on uranium in collaboration with the Institute of Chemistry. The former director was sent away on a leave of absence apparently for the duration of the war.

Should you think it advisable to relay this information to the President, please consider yourself free to do so. Will you be kind enough to let me know if you are taking any action in this direction?

I shall skip the next paragraph. Then he wrote:

I have discussed with Professor Wigner of Princeton University and Dr. Szilard the situation in the light of the information that is available. Dr. Szilard will let you have a memorandum informing you of the progress made since October last year so that you will be able to take such action as you think in the circumstances advisable. You will see that the line he has pursued is different and apparently more promising than the line pursued by M. Joliot in France about whose work you may have seen reports in the papers.

And I have, throughout, followed the policy not only of having an expert on tap but of going to other people's experts to see what they were doing. When it came to scientific work, I was going to leave that to the scientists, I did not presume to act as a scientist. These memoranda written by Dr. Einstein, Dr. Szilard and the others, I did not presume, when I forwarded them, to act as a synthesizer for them.

I passed on Dr. Einstein's review of the situation to the President on March 15, 1940, asking for an opportunity to confer with him on the latest phases of the experimental work. That letter I have here.

(The letter referred to was entered in the record of the committee and appears below:)

MARCH 15, 1940.

The PRESIDENT,
The White House, Washington, D. C.

DEAR MR. PRESIDENT: As a sequel to the communication which I had the honor to submit to you on October 12, Prof. Albert Einstein sent me another regarding the latest developments touching on the significance of research on uranium for problems of national defense. In that letter he suggests that I convey to you the information that has reached me that since the outbreak of the war, research at the Berlin Institute of Physics, which has been taken over by the Government, was placed under the leadership of C. F. von Weizsaecker, son of the German Secretary of State.

In the realization that these further views of Dr. Einstein have a definite bearing on the favorable report submitted to you by Dr. Briggs as chairman of the committee which conferred with experimental scientists concerned and myself, I am enclosing his communication for your kind perusal. May I also ask whether and when it would be convenient for you to confer on certain practical issues brought to a focus by the very progress of the experimental work, as indicated in the concluding paragraph of Dr. Einstein's letter?

In view of your original designation of General Watson in this matter, I am transmitting it through his good offices.

Yours sincerely,

ALEXANDER SACHS.

Dr. SACHS. The reply of General Watson on March 27, 1940, was to the effect that the governmental committee was awaiting "a report of the investigations being conducted at Columbia University" and hence "the matter should rest in abeyance."

I did not feel that I could rest.

Senator TYDINGS. In abeyance?

Dr. SACHS. Yes. However, the sense of foreboding about Nazi aggression that had been voiced before the outbreak of the war—as

I disclosed previously—impelled the writer to relate the expectations of new invasions in the wake of spring to the instant project.

At the beginning of April, opportunity was afforded the speaker in the course of a visit to the White House to unfold views on the probable course of German aggression as encompassing in this war—as distinguished from the last war—the elimination of neutrals so as to secure complete control of the coast from Norway to France.

It had this bearing on the uranium project: It was suggested to require diplomatic arrangement for the shipment of uranium supplies in Belgium to the United States, instead of shipment on the eve of invasion to France, to avoid their probable capture by the Germans in their military onrush through France.

Taking the project as a whole, it was urged that instead of delimited aid in the form of specific material purchases or reimbursements for expenditures by universities, a fund be made available from governmental sources or by persuading foundations to allocate a fund in order that research could be planned on an adequate scale and on a long-term basis.

You see, I had also another thought in mind in making that provision or assertion that the late spring months were not too early for the planning of the enlargement of the research personnel.

This was because around April and May the scientists were being booked up for the next year's work in the universities, and if we did not take them then, we were not going to have them later on. So, our job was this, to divert academic talent from teaching to research, public research. Otherwise, the right kind of people, the people we wanted, would have completed their negotiations with faculties for the next academic year.

The tenor of these considerations and recommendations was embodied in an aide-memoire which was prepared in Washington and left at the White House. That was another memorandum that was left with the President to review the situation.

The fourth phase was the phase which I have called in this report, written immediately after the events, in the role which the President assigned to me, among other things, as one of the originators—what I mean was that I had had assigned to me, among other things, the job of acting as the contemporaneous historian—"efforts by the originators of the project to gain the adherence of the governmental and advisory group to organizational changes needed to attune the research to the urgencies of unfolding World War events."

The representations made to the President at the turn of the month, by me at the turn of the month, that is, in March and early April, as just summarized, led him within a few days to revert to and act upon the preceding correspondence that had been pitched in the same key.

Accordingly, on April 5, 1940, he acknowledged what had been conveyed to him by Dr. Einstein and proposed that a new conference be held in Washington between Dr. Einstein and the speaker on the one hand, and Dr. Briggs and the special representatives of the Army and Navy on the other hand.

The closing paragraph of that letter implied that the President wanted the research continued. That is, the preliminary questions about which a few in the coordinating group still retained tints of doubt were in his mind disposed of.

To General Watson was delegated the making of arrangements for the conference, but he, the President, wanted to be advised directly of the results of that conference.

Under even date, General Watson asked the speaker for a list of scientists to be invited, inclusive of suggestions by Dr. Einstein. The inquiries made by the writer of Dr. Einstein and other members of the coordinating group led to the submission by the speaker to General Watson of the requested list.

Throughout my work I was in touch with Dr. Szilard and Dr. Wigner of Princeton and Dean Pegrum of Columbia and, later on, also Urey.

Following the receipt on April 13 of the two letters from the White House of April 5, Dr. Einstein was written to on April 15. The letter opened up with a statement regarding the transmission to the President of Dr. Einstein's communication of March 7 to me.

It noted a contemporaneous impression that the efforts subsequent to the President's return from the Canal Zone trip—he had been on vacation—had contributed to the decision by the President—I had gotten in touch with him in the course of that trip and he had given me certain priorities so that this anonymous representative could go through and convey messages.

The message to the President so conveyed had contributed to the decision by the President "to adopt the procedure suggested" in the speaker's original communication.

Cognizant of the resistances in the group to the proposed enlargement of the organizational framework, the speaker urged Dr. Einstein to participate in person in the forthcoming conference. However, after a conference which the speaker had with Dr. Einstein at Princeton, it became clear that indisposition on account of a cold and also the great shyness and humility of that really saintly scientist would make him, Dr. Einstein, recoil from participating in large groups and would prevent his attendance.

So, he delegated me to report for him, too.

As a substitute, I had asked him to enable me to record the consensus of views in the form of a written communication to Dr. Briggs.

That communication, dated April 25, 1940, to Dr. Briggs, which Dr. Einstein signed, referred to the discussions he had had with Dr. Wigner and myself on the progress of the work of Dr. Fermi and Dr. Szilard.

The purpose of the letter was to impart a new impetus and to suggest an appropriate adjustment of the organization side of the research to the interlinked necessities of the emergent phase of the research and of the international situations.

I should like to quote from his letter, that letter.

I am convinced as to the wisdom—

The CHAIRMAN. Whose letter was that?

Dr. SACHS. This is Dr. Einstein's letter which I brought with me to Dr. Briggs.

I am convinced as to the wisdom and urgency of creating the conditions under which that and related work can be carried out with greater speed and on a larger scale than hitherto.

I was interested in a suggestion made by Dr. Sachs that the special advisory committee supply names of persons to serve as a board of trustees for a non-profit organization which, with the approval of the governmental committee,

could secure from governmental or private sources, or both, the necessary funds for carrying out the work.

Given such a framework and the necessary funds, it (the large-scale experiments and exploration of practical applications) could be carried out much faster than through a loose cooperation of university laboratories and Government departments.

You must bear in mind that this was before the fall of France and the Government executives had no money.

We were trying to take this thing out of where it was. This was the viewpoint of those who had shown an exercise of faith, of those who hoped for assistance, those scientists, as distinguished from other scientists who were more interested in what I called, in the memorandum to the President, a "bit-by-bit procedure."

Since they realized the import and pressure of international events, they wanted the thing lifted out of the somewhat monastic type of research that goes on in universities, a slow process, on a very limited scale. They wanted, we wanted, a greater scale and a much faster tempo.

Originally, the April meeting was scheduled by Dr. Briggs for April 22, and so far as nongovernmental people were concerned was to be limited to Dr. Einstein, Dean Pegrum of Columbia, and myself.

Then, by telegram of April 20, the meeting was postponed to the 27th. In the interim I begged to enlarge the group and I requested that an invitation be sent to scientists and executives in universities involved in the current uranium research.

That request was granted, as appears from my letter of May 11, 1940, to the President.

(The letter referred to was entered in the record of the committee and appears below:)

MAY 11, 1940.

The PRESIDENT,

The White House, Washington, D. C.

DEAR MR. PRESIDENT: In furtherance of your kind letter to me of April 5, the conference suggested by you was arranged and held under Dr. Briggs' chairmanship on April 27 between the governmental and nongovernmental groups concerned with the bearing of uranium experiments on national defense. With the conclusion of the first experiment, which was conducted at Columbia University by Drs. Szilard and Fermi, with governmental aid, the whole project is now entering upon a new stage. Assuming that the governmental committee will now, upon your inquiry, report in favor of further and larger governmental action, may I, in accordance with your own gracious expression of a desire to be advised of developments, submit the following considerations and suggestions:

1. With the invasion of Belgium by the very power which has organized the residue of its scientists for uranium work, the danger—alluded to in my original letter to you of October 11, 1939—that America may be cut off from uranium supplies of the Belgian Congo has increased. In addition, the successful completion of the above-mentioned preliminary experiment renders it practicable and advisable that the action to be taken shall be adequate and comprehensive.

2. Such action inherently involves not only larger financial support to be accorded by the Government but also the formation of an organizational framework under which the work can proceed with the flexibility required for a going enterprise. Interestingly enough, the latter practical aspect has been emphasized by Dr. Einstein in conversations with myself and was communicated by him in a letter to Dr. Briggs, of which I am enclosing a copy for your kind perusal and attention. In this communication you might find of interest the enclosed copies of two communications which I have received from Dr. Szilard, the first of which contains a synoptic statement of the implication of the work for national defense that was made orally at the above-mentioned conference of April 27, and the second an outline of the next tasks to be undertaken.

3. The resultant requirement for forming an organization for directing the work outside of governmental institutions and for assuring that work by scientists in the universities is carried out with due secrecy has to be dovetailed with the designation of persons to serve as trustees of a nonprofit organization that is to supervise the allocation of funds and to coordinate the various branches of the work.

4. These interlinked needs suggest to me that it would be desirable to bring one of your legal aides into the circle of discussion, along with General Watson, who is now serving so efficiently as a liaison for the representatives of the service departments and the Bureau of Standards.

In view of the urgency of a decision on these points, I should greatly appreciate conferring with you in the course of next week, at your convenience.

Yours sincerely,

ALEXANDER SACHS.

Dr. SACHS. That, then, is the background against which the conference was held, a background which was lit up by portentous international events. The second week of the month opened with the German invasion of Norway and Denmark on April 9; the third week witnessed counteroperations by the British, the landings in Norway on April 16 and April 18.

Since the concern for national defense and the survival of civilization motivated my mediation of the project between the scattered scientists and the President, it is understandable in the flux of erupting international forces that I should seek to transpose the laboratory questions to the larger theater of international policy and military operations.

Two contemporaneous crystallizations of that preoccupation are available. The first is a memorandum-letter prepared at my request by Dr. Szilard under date of April 22. The second is a self-addressed memorandum dated April 20, 1940, and bearing the title "Import of War Developments for and Application to National Defense of Uranium Atomic Disintegration."

Skipping the technical memorandum, I want to mention the—

The CHAIRMAN. Doctor, I am sorry, but we have to recess at 12 o'clock. So, if you will, we would like to have you bear that in mind.

Dr. SACHS. All right, sir; I will pick an appropriate place.

The memorandum-letter by Dr. Szilard aimed to describe the next phase of the research and its dual alternatives and their respective applications to national defense.

The first case deals with chain reactions in which the neutrons are slowed down so only a small fraction of uranium can be utilized.

In the second case, the neutrons are not slowed down and so the bulk of the ordinary uranium can be utilized. It is the latter case which has the greatest significance for national defense and particularly for the production of atomic bombs. The former significance would appear to lie in power production and would also present the complication that personnel handling such built and powered atomic engines would be exposed to the radiations.

The second alternative also presented a dual utility for concentrated power and concentrated explosives.

As to the second use, the concluding paragraph of that memorandum constitutes a most illuminating formulation:

A chain reaction of the second type would make it possible to bring about explosions of extraordinary intensity. If, for purposes of aggression, a bomb based on such a chain reaction were set off at sea near the coast, tidal waves brought about by the explosions might lead to the destruction of coastal cities.

The coincident memorandum of the writer was concerned with highlighting the bearing of the war developments on the organizational aspects of the uranium research, and evoking applications for naval warfare with a view to throwing into sharper relief the urgencies of providing more central direction and greater adequacy of scope and speed in the prosecution of the project.

I had previously been called in to discuss what would follow, what would be the results, if control of the Mediterranean was achieved by the aggressor.

In that connection there was an idea, a coincident idea advanced by a person who had been in the Army and who was concerned about this problem, a great friend of mine, Colonel Donovan.

Colonel Donovan and myself had independently perceived this fact, which was that the Mediterranean would be significant north-south, as distinguished from east-west. We saw that the democracies would be pushed out from the continent, that the next war would push France out as a power.

This conclusion did not require great foresight, neither did it require the memory with which I had been blessed.

The French military people engaged in the last peace conference had seen that.

Furthermore, in a book to which Clemenceau wrote the introduction—Clemenceau was a layman who had his own views about military strategy—you will remember he was the man who even wrote, "War is too serious a thing to leave it solely to the military."

Clemenceau had seen that this situation was fraught with difficulty and he expressed himself on it as a layman, with complete respect to the performance of the military—the layman having the advantage that he can synthesize the military considerations with the political considerations.

Clemenceau insisted, at the Peace Conference, "If you do not give the French the protection of the Rhineland, then the democracies will have no base of operations, no base of support."

You will remember the phrase "point d'appui," which means, you might say, jumping-off place—we agreed we would not even have a support on the continent. Therefore, the significance of the Mediterranean was going to be north-south and not east-west.

Following those discussions, I broached the problem of the supply of uranium for the United States.

I pointed out that the biggest supply of uranium was in the hands of the Belgians. I pointed out that even if they sent it to France it would not come to us, that we had to open diplomatic negotiations.

Incidentally, that industrialist I mentioned, Pregel, who at that time was in France and was a French citizen, had asked his own government to make arrangements with the Belgians and he had asked it in 1939.

That prescience on the part of these refugees, gentlemen, is not any special quality in time but rather it was because they were united by a political sensitivity with their specific expertness as scientists and technologists.

Now, the memorandum which I submitted to the President opened with a description of the meetings and the work that was being done by other scientists; by the scientists in England, men like Dirac and Dr. Charwick and Lindemann, and so on. That work would be avail-

able for collaboration with research in America. In other words, there was suggested at that time the idea of Anglo-American collaboration.

In a lecture in 1936 it was foreseen that there would be developed a new source of energy; we were aware, profoundly and humanly aware, of the dualism, the good and evil in it.

The memorandum then dealt with the tendency to reservations and understatement of the results of research and their implications, the effect of which on governmental representatives was to cause them to recoil from the very suggestions that were being pressed by Dr. Einstein and me for providing a larger and more resourceful organizational framework for adequate and faster prosecution of the task.

In the effort to overcome the tempo dampening and scale dampening that that very attitude entails, and that is the attitude of conservative hesitation, proper enough in an ordinary task but not for this kind of thing, which called for what I have described as "the willing suspension of disbelief"—the speaker submitted the following observations and considerations which in a later presentation to the President appeared to be contributive toward a resolution of the organizational difficulties.

I pointed out in effect that the action was forthcoming—I did not presume to give these as my results but as my observations from reading all these memoranda. As was my habit, I did not look at it as a scientist.

The present writer, as a nonphysicist—

this is a quotation from my memorandum—

would not of course venture an opinion alongside those cited. But as an economic historian and as a practical economist versed in the conduct of technological research, he has ventured to convey to the scientists mentioned and to the governmental authorities his hypothesis that the difficulties which loom so large now might well arise from the characteristic physical limitations of the pre-pilot plant operations that are carried on in the typical university laboratories. If the project is fraught with promise and importance for national defense, then it seems to him worth while to approximate very soon the conditions of industrial-pilot-plant operations. This might entail the building of equipment, machinery, and even the construction of adequately scaled and adequately protected physical plant.

Once we relate the uranium research to national defense, it should be regearred in type and tempo to the most advanced technological research that has been carried out by the American chemical and electrical companies.

I need hardly insert parenthetically that it was this scale of operation which was carried out with such distinction later on by General Groves. Returning to the memorandum:

What has taken place in Poland, Denmark, and Norway, and will doubtless go on through other European countries that will be invaded, is that the pacific-minded countries have not brought their national defense up to the quantity and quality required for technological warfare. When the import of the European war is assimilated by the American people and national defense is undertaken as a national enterprise, then we may be confident that we will match in war the progressiveness of our civilian technology and come to surpass it, which means surpassing the German military technology.

In the conviction then that "an adequate organizational framework is itself the precondition for the ascertainment and effectuation of the value of nuclear research for national defense," the speaker proceeded to sharpen the possible applications of that research for naval operation—

Senator RUSSELL. What was the date of that?

Dr. SACHS. April 20, 1940, before the invasion of France.

As I say, I proceeded to point out the possible applications for naval operations, on the assumption that the war would in time become global on the part of the Axis, inclusive of Japan, against the democracies, inclusive of the United States.

In that event, the applications in the dual form of telescoped power drive and magnified explosions should aid the United States to overcome "the disadvantage under which we labor due to the enormous distances between continental United States and our possessions, and between our possessions and the Japanese homeland."

This was not war-mongering; this was adjustment to the import of events as I saw them, as I followed this phenomenal development of mass effort.

If I may quote again from the Bible, from Jeremiah: "Take the wine cup of this fury at my hand and—drink it."

I could see that we would all be engulfed; that on the Continent, only Great Britain would be left; and that we would be the only continental insular power left in the universe and that then we would have to take action.

I saw that we must not let Germany go ahead with research on the kind of weapon they were working on, a weapon whose essence is the elimination of time for the defense, the elimination of that borrowed time we all needed so badly in this war.

Inasmuch as the attempt to relate the applications to strategic and logistic configurations presupposed naval data, Dr. Briggs' good offices with Admiral Bowen and Commander Hoover brought answers to questions submitted in a letter. This letter I do not have.

Now, the sequel to this was a new stage in this progress. You must bear in mind that this is not the linear progress that people have written about. You will remember that story in Alice in Wonderland, about the queen: You start with the end, you start with the sentence, and then you work back.

So it is when it comes to writing history. People might say, "We have got the bomb and we used it; therefore, it must have been present throughout."

There was no such straight line. It was a very zigzag line, and every bit of time and every urgency that was applied turned out to be indispensable. Every infinitesimal effort, even, became infinitely important in the course of the eventuation of what gave us the timely use of a weapon that did serve to shorten the war.

It did shorten the war, although it must be recognized that, strategically and otherwise, Japan had been completely beaten by naval and other action. They had been beaten by the Navy, by the air power. We must not, in our concern with these things, tend to eliminate the problem of the whole organization of our national defense. We needed those bases protected by the Navy to use for the bombing and that was the result of war operations by other war technologists.

However, it presents a new factor, a most vital factor—but I will not go into those questions. I will return to the history.

The conference of April 27, 1940, on organizational framework, the inadequacy we had then, resulted in new submissions to the President for a resolution of the difficulties.

The conference that was held on April 27 at the Bureau of Standards under Dr. Briggs' able and conciliatory chairmanship did serve to

dispel doubts that had been entertained by some members. It also marked further progress in evoking a willingness to entertain consideration of large-scale expenditures that might run up to six figures. That was fantastic alongside the cost heretofore, the thousands that were being spent and the money that was being furnished by those who were on the margin, who were spending out of their own pockets in connection with this work in corresponding amounts.

It had begun to run into six figures. Yet the majority, accustomed to the small scale of physical laboratories at the universities and the correspondingly reduced scales of the budgets of governmental scientific laboratories, did not appear ready to design a large scale and comprehensive program, and instead insisted on "bit-by-bit" procedures with ranked preferences and time deferments.

By the beginning of May the uranium research at Columbia, which was the pathfinding research, had reached the point where expansion was deemed advisable and desirable by the whole quartet of scientists concerned—that is, the direct experimenters, Drs. Fermi and Szilard and Dean George Pegram and Prof. Harold Urey.

After a number of conferences of the speaker with the Columbia group, a sort of minute was drafted as of May 10 embodying the consensus as to the successive stages. In this case, I myself did the secretarial work. I did not hesitate to be a glorified office boy.

The first point in this minute was:

The first large-scale experiment would have as its aim to demonstrate beyond any doubt whatever that a nuclear chain reaction could be maintained in a system composed of carbon and uranium. This would require about 100 tons of graphite and some 10 to 20 tons of uranium metal. It would also be necessary to design a rather elaborate mechanism to stabilize the chain reaction and to safeguard against overheating as well as the possibility of an explosion.

The second point was:

The next stage is to carry out a general survey of all nuclear constants in order to confirm the values previously obtained and to narrow down the limits of experimental error beyond observed values of the constants. This would strengthen the assurance of the group in the ultimate success of the experiment.

Then as preparatory ground for that experiment would come the advancing of structural details and the carrying out of technological tests on samples of materials which have to be used in large quantities in the ultimate experiment. This in turn would require getting bids for the manufacturing of the material in needed quality and quantity.

As to quality, the problem of refinement was throughout a very grave one; it was the industrial know-how which had to be acquired, as well as the fundamental scientific research.

In financial terms, the first stage would require expenditures of \$30,000 to \$50,000; the second stage would require from \$250,000 to upwards of \$500,000.

It was the speaker's view that in the interest of time, speed, and even of economy, the second could be prepared for while the first was going on, providing that adequate funds were made available to begin with. The proposal which had been submitted for a nonprofit organization directed by a mixed board of trustees seemed particularly suited to methodical and economical direction of the work.

The lack of resolution of the organizational difficulties led the speaker to submit an analysis of the situation and resultant recommendations in a communication to the President dated May 11, 1940, together with a note of transmittal to General Watson of even date.

The point of departure was—I am coming to the end of this section, that may serve as a terminal point.

The CHAIRMAN. Very well, Doctor.

Dr. SACHS. The point of departure was that, according to the advices given to the speaker by Dean Pegram, the graphite experiment, which had been partly financed by the Government, was a success. As the communication was coincident with the German march through Belgium, the invasion having begun on May 10, the situation adumbrated in the initial presentation of October 11, 1939, had come to pass.

I mean, the situation I had presented when I stated that we should acquire uranium supplies from Belgium had come to pass.

A problem of access of uranium supplies that would be needed on a larger and larger scale had been thrust forward.

This, in turn threw into sharper relief the need for a change of the organizational framework "under which the work would proceed with the flexibility required for a going enterprise."

The President was therefore requested to designate a legal aide to facilitate the establishment of a nonprofit body which would secure the resources for carrying on the work under conditions where the tenure of the research posts would be secure and their equipment and material be amply provided for. I have in mind here that large group of scientists that would have to be brought in at that period when they were looking for other university posts.

Along with that there should be provision for the necessary secrecy as distinguished from the normal eagerness and competitiveness in early publication of indicated results.

You must see that we had a job there. Even in getting the scientists, you had to take that into account, the fact that we were preventing them from having what is the biggest asset to the scientist—the knowledge that the results of his research will get published to all when he does an important job. He would not have that satisfaction—and you have to give them an adjustment in salaries.

This was no time to delay; if we delayed, then we would be losing the scientists.

Also, at that time—this was before the invasion of France—you would have to see to it that, so far as our publications go, the scientific magazines, such as Science, and the Physical Review, and related publications, that this work, in view of the potential value and the potential danger, was not made known to the potential enemy.

Is this a good stopping point, Mr. Chairman? I could go on. What do you say, sir?

The CHAIRMAN. Doctor, the Senate meets at 12 o'clock.

Dr. SACHS. All right, let me go on, then; this is a very short part.

The CHAIRMAN. All right.

Mr. SACHS. This is part 6 of this contemporaneous history, assembled at the end, in August. This is on the basis of what had been done with these reviews that were made, it is contemporaneous with what I have developed.

The heading is:

Resolution of the difficulties and resetting of the uranium research project into the new organization established by the President on June 15, 1940 for the direction of all scientific developments related to national defense.

The CHAIRMAN. What was the date that the small-scale stage ended and that you were to go forward on the large scale?

Dr. SACHS. Between May and June it was decided that we needed to go forward on the larger scale. The appointment of a new organization, the Office of Scientific Research and Development, came, I think on June 15, having been preceded by suggestions of such a scheme as I transmitted to General Watson.

Senator AUSTIN. This was 1940?

Dr. SACHS. This was in 1940.

In keeping with the practice of full confidence and cooperativeness with the Presidential representatives from the Government services to direct the joint committee on the uranium project, the letter to the President of May 11 was given a counterpart in the communication to Dr. Briggs of May 13, 1940. That is, I did not do anything with the President without sending a copy of it or speaking about it to Dr. Briggs, as the administrator-scientist, and to General Watson, as aide to the President.

My letter to Dr. Briggs drew attention to Dean Pegram's favorable report on the graphite experiment and inferred that the governmental committee would report favorably to the President on the project. That would be reported directly to the President and I was convinced enough and could discern that it would be certain to be recommended.

Recognizing that university research is inherently characterized by a "traditional discursive attitude and leisurely tempo," the contemporaneous facts of the invasion of Belgium threw into sharper relief the requirements of national defense. Applied to this project, those requirements were for a resourcefulness of operation and an acceleration of pace and also a secrecy that could not be had in the university projects, generally carried on with limited means and in an atmosphere of mutual interchange.

And I want to say here that the scientists, Dr. Szilard, Dr. Wigner, and Dr. Einstein, were all of the same view, that there had to be secrecy against leaks to the enemy.

In furtherance of the foregoing, another letter was written to General Watson on May 15, the second and revised version of which is included here.

[The letter referred to was entered in the committee's record and appears below:]

(Revised version)

MAY 15, 1940.

DEAR GENERAL WATSON: Confirming the intimation that I had the honor to convey in my letter to the President and in my covering note to you, I have just received a letter from Dean Pegram, of the department of physics of Columbia University, stating that the initial experiment "has now been concluded with satisfactory result," and that "the absorption cross-section of carbon was found to be encouragingly small * * * only about one-third of the upper limit previously reported in the literature." The detailed meaning of that has been set forth in the letters of Dr. Szilard of May 10 and of April 22, which I forwarded to the President; a copy of the latter was also sent to you. Please advise me before any conference on this is arranged.

In connection with an independent matter having to do with economic and fiscal policies for effectuating national reconstruction and defense, I should appreciate your expressing to the President my readiness to submit certain social-minded economic ideas that had interested him in 1933 and 1934, as to incentive devices for evoking large-scale plant investment for national defense and the training and reconditioning of the requisite skilled labor. To the original proposals drafted in 1932, there was added in early 1933—when submitted for the National Recovery Act—a provision authorizing public works' expenditures

for national defense, in view of the altered international situation. The ideas and proposals in connection with the original FHA plan submitted in 1933 were later expanded in the second FHA plan that, at the President's behest, was worked out for Governor Eccles' advisors. In keeping with the pattern of these earlier plans, the role of Government can be adjusted to specific requirements.

For the instant purpose, the organizational instrumentality proposed is the establishment of a Scientific Council of National Defense, composed of executives, engineers, and economists, acting in behalf of the Government, who should be invested with administrative powers for the testing and execution of technical projects of utility for national defense.

Yours sincerely,

ALEXANDER SACHS.

Gen. EDWIN M. WATSON,
Secretary to the President,
The White House, Washington, D. C.

Dr. SACHS. There was a telegram in between that letter and the revised version of it.

The letter starts out with a reference to a letter from Dean Pegram, of Columbia University, which I do not have. The substance of that letter from Dean Pegram as given to General Watson was as follows: "The initial experiment has now been concluded with satisfactory result; the absorption cross-section of carbon was found to be encouragingly small, only about one-third of the upper limit previously reported in the literature."

The main communication of the speaker contains the first adumbration of a plan similar to that later developed by the President for the direction of the scientific work related to national defense. The new suggestion was made in the setting of proposals which the speaker was evolving for submission to the President with respect to amortization and other incentive-tax devices for national defense plant construction.

It was my belief that industry had to be regulated and integrated for national defense and I had been asked to submit some suggestions and I made many suggestions in my professional capacity as an economist with reference to these problems, besides my interest in this uranium research.

For instance, in connection with the economic aspects of national defense, I make allusion here to the suggestion contributed by me under the National Recovery Act in 1933, for the inclusion in that Act of a provision authorizing public expenditures for national defense and naval construction.

In respect to the specific problem of an organizational framework that would carry forward uranium research on a bigger scale and at a faster tempo, the new recommendation of the speaker was as follows, against the background that the Government was then thinking of going to the Congress with a request for bigger appropriations.

For the instant purpose, the organizational instrumentality proposed is the establishment of a Scientific Council of National Defense, composed of executives, engineers, and economists, acting in behalf of the Government, who should be invested with administrative powers for the testing and execution of technical projects of utility for national defense.

In acknowledging that letter, General Watson on May 16 added an observation regarding the broader suggestion for a mixed executive and administrative group for scientific phases of national defense.

The CHAIRMAN. Was that group formed?

Dr. SACHS. That group was formed on June 15; there was an intervening communication and I had received an authorization after an O. K. and an encouraging word from the President to represent the Government in negotiations with the Belgian company representatives here for the acquisition of uranium.

The CHAIRMAN. Doctor, there has just been a quorum call from the Senate and I think we will have to stop at this point:

Dr. SACHS. May I read the last stage and that will complete the whole story?

The culmination of the foregoing phases of the uranium project came on the day following the German Army's entry into Paris. On June 15 the President established a new committee for the correlation of the scientific efforts of the country concerned with the problems of national defense and placed that committee under the chairmanship of Dr. Vannevar Bush, president of the Carnegie Institution of Washington, whose name I have mentioned in the course of my discussion here. This committee included representatives of the Army and Navy and distinguished scientists and, initially, was to be attached to the Council of National Defense, in keeping with the suggestions I had made.

Accordingly, the President advised Dr. Briggs on June 15 that "since the problem on which you are engaged is part of this larger picture," Dr. Bush was requested by him to take over the uranium project and to reconstitute the committee.

Now, I make my summary. Thus was found a larger framework in accordance with the tenor of the speaker's recommendations. Dr. Bush's committee after our entry into the war became the Office of Scientific Research and Development. Associated with him and Dr. James B. Conant, of Harvard, was the General Policy Committee, which included the then Vice President, Henry A. Wallace; Secretary of War Stimson; Gen. George C. Marshall; and Army and Navy representatives. The other group of the Army came in 1942.

The uranium project as initially presented by Dr. Einstein and the speaker in October 1939, having by the Spring of the next year been reported on favorably by the testing and coordinating committee that the President had appointed under Dr. Briggs' chairmanship, was thus launched on a permanent and progressive career in the wake of our decision after the fall of France to embark on expanding defense.

From then on it became invested with the importance, the resources, and the secrecy available to the Government of the United States in defense and later in war for the translation of an idea into a reality and into an instrument of national policy in war and peace.

The CHAIRMAN. Thank you very much, Doctor.

The committee will adjourn until 10 o'clock tomorrow morning.

(Whereupon, at 12:05 p. m., the committee adjourned until 10 a. m., Wednesday, November 28, 1945.)

ATOMIC ENERGY

WEDNESDAY, NOVEMBER 28, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to notice, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Connally, Byrd, Tydings, Vandenberg, Austin, Millikin, and Hickenlooper.

Also present: Edward U. Condon, scientific adviser, and James R. Newman, special assistant to the special committee.

The CHAIRMAN. We have with us today Major General Groves, who took such a prominent and leading part in this project.

We are pleased to have you with us, General. Will you go right ahead.

STATEMENT OF MAJ. GEN. L. R. GROVES, UNITED STATES ARMY

General GROVES. I have a short opening statement which I would like to read to the committee.

It is essential, in the highest national interest, that further development in the field of atomic energy be pursued under controls which will preclude the utilization of atomic energy in a way which would imperil the national safety or endanger world peace. Future activity in this field is so important to the national welfare, and potentially to the enrichment of our living, that control should be exercised by a special commission independent of any existing Government agency with the sole duty of supervising and controlling the development of atomic energy. The commission should have complete authority over all activities in the field, subject only to the approval of Congress and the President. The commission should be composed of persons of recognized ability whose actions would be unquestionably in the public interest. Broad discretionary powers and adequate funds are essential to its success.

The War Department will always have a vital interest in the use of atomic energy for military purposes. In the field of practical administration and operation, the Army can furnish invaluable assistance. Civilian and military personnel who have acquired knowledge and experience on the project should continue to serve to the extent that their services are useful. The commission should be in complete control of policy and should exercise general direction and supervision of all activities.

Because of the current uncertainty, we are daily losing key people whose services should be retained. Until that uncertainty is resolved by the establishment of a national policy, we are not in a position to offer acceptable commitments to these key people. Prolonged delay will result in appreciable loss of the present efficiency of the vast combination of plants, scientific talent, and engineering skill.

We must recognize the clear distinction between domestic control and international control. The two can and should logically be separated. Domestic control is necessary no matter what international policy may be eventually worked out for the United States and the world. It is necessary to protect America's tremendous investment in atomic research and development and to insure that this development will go steadily forward.

I would like to discuss for a few minutes what happened when these bombs were dropped over Japan. I don't know how much repetition there is in this, but I do not believe there is very much.

The atomic bomb mission which went overseas, headed by Major General Farrell, made no attempt at Nagasaki and Hiroshima to secure or estimate exact casualties. This was not possible because the mission did not survey the cities until over a month after the dropping of the bombs.

The best over-all estimates—and these come from the Japanese as they were given to General Farrell—of the dead and missing at Hiroshima are somewhere between 70,000 and 120,000; injured, between 75,000 and 200,000.

At Nagasaki, the dead and missing were between 40,000 and 45,000, and the injured about 40,000.

The figures at Nagasaki are much better than they are at Hiroshima because the authorities were able to act after Nagasaki because it hit one section of the city, the industrial section, and did not destroy all of the city and military governments. At Hiroshima there were a number of military targets, including army divisional headquarters, an army ordnance depot, an army transport base, an army clothing depot, all the public utilities, an oil storage depot, various textile and rayon plants, and Japanese Army headquarters, the commander of which was charged with the defense of that section of Japan against American attack.

Practically everything at Hiroshima for a radius of about a mile and a quarter from the point of detonation was burned as well as blasted. Up to a radius of 2 miles from the point of detonation everything was blasted, with some damage from burning. Between a radius of 2 and 3 miles, everything was about half destroyed. Beyond a radius of 3 miles, damage was fairly slight, with roof damage up to 5 miles. Glass was broken up to a radius of 12 miles.

There were about 20 masonry and steel structures left standing in the central portion of the city. However, the interiors of all buildings were gutted and all windows were out. Few bridges were destroyed; most were left intact except for handrails and sidewalks.

In the pier area—Hiroshima was a great military port—individual warehouses were collapsed. Intervening hills protected some nearby areas from the blast. Automobiles had roofs caved in, shelters were caved, and street cars were derailed and burned. About 4 miles away a fire was started in a forest on the mountainsides.

There were approximately 20,000 army personnel in Hiroshima at the time of the bombing, of which 80 percent were casualties. The Army headquarters, which I spoke about, had 9,000 men in the headquarters; of those, 7,000 were casualties.

At Nagasaki the blow was struck in a largely industrial area, which left a large part of the residential area more or less standing. The effects of the explosion in the industrial area were probably more spectacular and startling than Hiroshima; for example, the complete destruction of the huge steel works by blast and fire, and the destruction of the torpedo works by blast alone. Within a radius of 2,000 feet from the point of detonation, heavy industrial buildings, gas storage tanks, and many reinforced concrete structures were destroyed. The steel frames in all buildings in all cases were pushed away from the point of detonation. For a radius of 8,000 feet, Japanese workers' homes were completely demolished. Up to a radius of 2 miles, workers' homes had collapsed; roofs and walls were smashed, but were left partly standing except in isolated cases where exceptional shielding was given by local topography. Up to a radius of 3 miles there was some roof damage to tiles of heavy type. Glass and plaster damage was evident up to much greater distances.

Up to 2,000 feet, 9-inch concrete walls were destroyed. Up to a radius of 4,000 feet, brick smokestacks with 8-inch walls were displaced, cracked, and overturned.

The northern ordnance plant, at a distance of 4,000 feet from the point of detonation, had corrugated iron stripped from walls and roofs, window sash pushed out and framework overturned and destroyed. These were of light-steel-frame construction.

Fire damage was heavy throughout the area. The length of the burning area was 3 miles, with a 6,000-foot width in the northern part of the city.

The Japanese listed no destruction to shipping in the harbor, which was a considerable distance away, except minor damage to superstructures, which included broken glass. There were about 100 ships and small boats in the harbor, of which about a third were 100 tons in size.

Senator AUSTIN. May I ask a question at this time, Mr. Chairman?

The CHAIRMAN. Of course, Senator.

Senator AUSTIN. Have you any record of the examination of these two areas made since the time that you are now testifying about that would indicate whether there is a residue there of radioactivity in those areas?

General GROVES. Yes, sir; and there is none. That is a very positive "none."

I would like to read a statement from an eyewitness, which goes into that phase of it.

The CHAIRMAN. General, was that because of the way that the bomb was exploded?

General GROVES. Yes. The bomb was exploded at considerable height, and for that reason there were no after-effects from radiation. There were some radiation effects at the time of the explosion; they were instantaneous. No one suffered who was not exposed at that moment, and the casualties, as far as we can determine, resulting from that were relatively small.

The CHAIRMAN. If it is a permissible question, at Alamogordo, where you exploded from the top of a steel column, there was some radioactivity, was there not?

General GROVES. At Alamogordo we exploded it at a height of 100 feet on top of a tower, and there was residual radioactivity on the ground right below the point of explosion. That was of such a nature that you could walk through it, you could spend hours in there, but I would not have wanted to sit down and make my home in that area.

The CHAIRMAN. Would you want to own some of those cows, General, that they say changed their color?

General GROVES. They changed their color, but an examination of the animals shows they were not injured in any way other than having temporary gray hairs. They were streaked with gray.

This account was written at our request by a Jesuit Father, who was on a mission to Japan. He had formerly been in Tokyo, and his school was moved from Tokyo to Hiroshima.

As you know, the Jesuit Fathers, for a number of years—and I should say centuries—have been some of our most accurate reporters of world events. He prepared this at our request. I imagine he would have prepared it anyway and sent it back to the headquarters of the society.

He is a German named Father Siemes. This is his eyewitness account:

Thousands of wounded who died later could doubtless have been rescued had they received proper treatment and care, but rescue work in a catastrophe of this magnitude had not been envisaged. Since the whole city had been knocked out at a blow, everything prepared for emergency work was lost, and no preparation had been made for rescue work in the outlying districts.

Many of the wounded also died because they had been weakened by undernourishment, and consequently lacked the strength to recover. Those who had their normal strength and who received good care slowly healed the burns which had been occasioned by the bomb.

It was also noised about that the ruins of the city emitted deadly rays and that many workers who went there to aid in the clearing died, and that the central district would be uninhabitable for some time to come. I have my doubts as to whether such talk is true, and myself and others who worked in the ruined areas for some hours shortly after the explosion suffered no such ill effects.

He and a number of his fellow priests went from this outlying novitiate where they were living down into the center of the city to rescue their Father Superior who had been injured. I think they were in the ruins for about 12 hours, and from that time on they devoted most of their attention in assisting in the alleviation of the suffering, and certainly were exposed to anything anyone would be exposed to.

Senator RUSSELL. That was immediately after the explosion?

General GROVES. Within a few hours they got the word. It took about 12 hours going in and out of the city.

There has been something said of relief workers who were injured in the relief work. Those relief workers were in the city before the bomb went off, and they were just like any other inhabitants. They were in there because the Japanese had decided to evacuate all unnecessary population from Hiroshima. I think they felt that the city had been spared from bombing up to then. They did not know why, but they expected it to be bombed. They did not know it was being reserved, as it were, for this.

Senator MILLIKIN. May I ask, General, was Hiroshima on the list of cities to be bombed that were scattered over Japan?

General GROVES. No, sir; it was not on that list. That list was put out by General LeMay, and did not include Hiroshima. I don't recall whether it included any other cities that we were interested in or not. This is again from Father Siemes' account, and is his concluding paragraph.

Senator AUSTIN. May I ask a question before you pass forward?

General GROVES. Yes, sir.

Senator AUSTIN. There was one phrase in your testimony that causes this question, and that was "as soon as he heard about it," or words to that effect. Is it true that this priest did not know of the explosion until someone told him?

General GROVES. Oh, no, sir. He was, as I recall, about 4 to 5 miles from the explosion—or maybe 3—well into the suburbs. He was standing in front of the window when this bomb went off, apparently just looking out and seeing what a beautiful day it was. It was good weather, and there had been an air-raid alert, because of these three planes that had come over, but the Japanese had decided the three planes were photographic planes, and had apparently recalled the alert.

He was standing there looking out the window when the bomb went off and he saw this terrific light effect, and was scratched around his face and hands, I suppose by flying pieces of glass.

He did not realize at the time—for he thought it went off right over his head, and to him it was just a single bomb—he did not realize what had happened to the city until the refugees started streaming by. He did not know even then, and couldn't imagine that his Father Superior who was so far removed from him could possibly have been injured.

This is the final conclusion by Father Siemes:

We have discussed among ourselves the effects of the use of the bomb. Some consider it in the same category as poison gas and were against its use on the civilian population. Others were of the view that in total war as carried on in Japan there was no difference between civilians and soldiers, and that the bomb itself was an effective force tending to end the bloodshed, warning Japan to surrender, and thousands to avoid total destruction.

It seems logical to me that he who supports total war in principle cannot complain of a war against civilians. The crux of the matter is whether total war in its present form is justifiable even when it serves a just purpose. Does it not have material and spiritual evil as its consequences which far exceed whatever good might result? When will our moralists give us a clear answer to this question?

Senator RUSSELL. Before we get away from the question Senator Austin asked, do you intend to touch any further on the radioactivity?

General GROVES. I would be glad to right now.

Senator RUSSELL. I suppose the War Department has conducted an independent investigation other than that statement submitted by the priest?

General GROVES. Oh, yes, sir.

Senator RUSSELL. The first reports coming out of Japan were naturally highly colored and stated, as you have just related, that there were thousands of people who sickened and died several days after the explosion, and went so far as to say it killed all the fish in the rivers and created havoc generally.

What did the commission find?

General GROVES. I would like to explain first what the mission consisted of.

I have forgotten now whether it was after the Nagasaki bomb or after the Hiroshima bomb that I realized that this war was not going to last very much longer. I had always thought such would be the case once we dropped one. So I assembled in this country a special group to go over to investigate what had happened in Hiroshima and Nagasaki. Some of the group came from the Marianas where General Farrell was, and the whole group went over under his personal guidance. We sent essential medical scientists of the highest repute in the United States, headed primarily by Col. Stafford Warren, who is, in normal times, one of the leading authorities, a professor at the University of Rochester.

We had the full support of General MacArthur's headquarters over there and assistance in going into these cities once we were landed in Japan.

They made very careful studies. They talked to the Japanese doctors and the military, all of whom had order and who faithfully carried out those orders to cooperate in giving us all possible information.

We are still studying those facts and figures, and I think I can make some positive statements. First, there was no radioactivity damage done to any human being excepting at the time that the bomb actually went off, and that is an instantaneous damage.

The CHAIRMAN. General, you don't make any point of congratulation on that result, the fact that that didn't happen, do you? If there was radioactivity, there wouldn't be anything morally wrong with that?

General GROVES. No; we hoped to avoid that, and we did avoid that; but I think that is something that if it was a choice between radioactivity on a few Japanese or even a number of thousands of Japanese or a case of saving 10 times as many American lives, I would go the American way on that question without any hesitation.

The CHAIRMAN. It seemed to me that the War Department had made a great deal of the fact and sought to emphasize it time after time, that there was no harm from radioactivity.

Of course, if you are simply telling the fact, that is one thing, but its very reiteration seemed to me to indicate that there was some feeling on the part of the War Department that there was something morally wrong if it had. I just wanted to get your view on that.

General GROVES. There would be no feeling, as I say, on my part, on anything that would have shortened this war by a single day.

Senator RUSSELL. My question was not intended to indicate that I thought there was anything morally wrong if the radioactivity had been very disastrous; but thousands of people all over this country are living in tremendous fear of this atomic energy and its use. I thought it would be well to develop just how far the effect of the radioactivity would go.

General GROVES. I would like to go into that, if it is agreeable to you gentlemen, now.

As I say, our facts disclosed that nothing happened of that character excepting at the time the bomb went off, and that the number of casualties from that were relatively small. Nobody knows what the casualties were or how they were made up; but all the investigations by men who were in there to investigate and get the facts, not

to come out with an answer, indicated very clearly that that was the case.

Now, at the time the bomb went off, a person who was within a certain range could be affected by radioactivity; but in the normal case, he would already have been killed by the effects of the explosion or by the tremendous heat, and that is the real thing to think of. If he was right on top of the bomb, he could be killed in a dozen ways, all of them equally fatal; and as he removes himself from that exact point, certain of these possibilities are removed.

It really would take an accident for a man, the average person, within the range of the bomb to be killed by radioactive effects.

Senator MILLIKIN. Mr. Chairman, may I ask a question, please?

The CHAIRMAN. Yes, Senator.

Senator MILLIKIN. General, is there any medical antidote to excessive radiation?

General GROVES. I am not a doctor, but I will answer it anyway. The radioactive casualty can be of several classes. He can have enough so that he will be killed instantly. He can have a smaller amount which will cause him to die rather soon, and as I understand it from the doctors, without undue suffering. In fact, they say it is a very pleasant way to die. Then, we get down below that to the man who is injured slightly, and he may take some time to be healed, but he can be healed.

Senator MILLIKIN. Does that come about through treatment or through time?

General GROVES. Through time. Radioactive effects are like X-rays. They depend upon the intensity and the time. Anyone who is working with such materials, who accidentally becomes overexposed, just takes a vacation away from the material and in due course of time he is perfectly all right again.

Senator MILLIKIN. Let me ask you, would the effect be different had the bomb exploded in the ground?

General GROVES. If the bomb had exploded on or near the ground, that is, within a hundred feet or so, the effect would have been the same as at New Mexico, I believe; there you would have had lasting effects for a considerable period of months. You would have had a considerable number of radioactive casualties, and I think that you would have had an area which should have been banned from traffic.

The first mission given to our organization that went over there was to determine that the cities of Hiroshima and Nagasaki were 100 percent safe for American troops, and to know absolutely that that was a fact so that the men themselves would know that everything was all right.

Senator MILLIKIN. General, can you tell me the largest size regular bomb that was used in the Pacific area at the time of Hiroshima and Nagasaki?

General GROVES. No; I really do not know, Senator.

Senator MILLIKIN. Can you give us a reference point, some sort of bomb that was in use, and tell us how many of those bombs it would have taken to produce the same result in those cities?

General GROVES. I am sorry, I cannot tell you exactly. I believe that at that time they were using against Japan a bomb which must have had about 1,000 pounds of explosives in it; against Okinawa,

possibly up to 10,000 or 15,000 pounds of explosives. I may be in error on these figures, but I can tell you that taking the heaviest type of bomb they had that a rail of a thousand planes would not have been as effective as this one bomb in actual damage done to the cities—no comparison.

Senator MILLIKIN. One thousand bombs of the type they were using would not have produced a similar effect?

General GROVES. That is correct. At Tokyo, which had been bombed repeatedly, and I don't know how many times or how many bombs were dropped there, there were a great many burned-out sections, but it also had a great many usable sections. The casualties at Tokyo I understand are greater than they were at Hiroshima or probably as great as in both of these bombings, but the effect was not the same.

Senator MILLIKIN. Are the cities comparable, so that you could draw a comparison?

General GROVES. In physical damage, I would say that it would take maybe as many as 2,000 planes to equal the effect of 1 of the bombs; but in the effect on the people, there is a much greater effect. I think the Japanese officer who was assigned to aid General Farrell at Hiroshima presented that thought in the best possible way. He stated that when it came to the fire bombing of Tokyo and the high-explosive bombing, there was something you could do about it—that the bomb fell and you took your chances; a small number of people were killed with each bomb, and you could get out and save some of your property. In general, it was something that you could stand up against. But he said when it came to the Hiroshima bomb it was unendurable, and I think that is the real statement; that it is an unendurable bomb to anyone, and particularly to someone who did not know it was coming. How much the surprise element had to do with our success I don't know, but I am a great believer in military surprise, as is everyone; and this was the greatest surprise since the Trojan horse, and it ended a war just as suddenly.

Senator MILLIKIN. May I ask you, what was the percentage of loss on our plane flights in that area?

General GROVES. I do not know, Senator. Due to the cooperation of various services, such as the Navy Special Rescue Service, and the supreme care that was exercised, I think that our loss rates were getting better all the time. After all, these planes were flying a tremendous distance, and just in the normal time of flight they were bound to have accidents. How many men were lost there, I do not know.

Senator MILLIKIN. Passing the question of time in shortening the war, I was trying to determine the lives that we saved just in point of the air missions that would be required to produce the same amount of damage.

General GROVES. In that, I don't know that you could get a real figure, but I think we could get that from the War Department for the record if you would like to have it. I think that the real saving in life came in regard to the attack on the beaches. The Japanese, from all that we can find out, had no intention of quitting this war even if we had bombed by normal means and destroyed every city in Japan. The people on the beaches of Kyushu, in the caves there, were perfectly prepared and expected to stand there and die—men, women, and children—and take as many Americans with them as they could.

Senator MILLIKIN. Your point is that the psychological effect created by this bomb served to pull them out of the war, whereas the same amount of damage, the same number of casualties produced in other ways might not have pulled them out of the war?

General GROVES. That is absolutely correct.

Officers I have talked to, who have toured Japan under the conditions as they are now, state that this bomb created a fear throughout all of Japan that was just indescribable, and that that was the first real propaganda that they could understand; maybe they had gotten a lot of leaflets, but this was something they could understand, and it went all over the Japanese press, and they knew that it was the end. Of course, it was a tremendous point for the Japanese Government and the ruling classes to lean on as a face saver to get out of the war.

Senator MILLIKIN. Thank you very much.

The CHAIRMAN. You and I have talked about Churchill's estimate of what he thinks was saved this country and England.

Do you agree with his estimate, and will you state it for the record?

General GROVES. As I recall, it was 1,000,000 Americans and 250,000 British. I don't know what the basis of his estimate is. I think probably that it is a little high.

All that I can say definitely is that probably, if you figure on the number of divisions that had been announced as making that landing, and think of the number that were on Okinawa and that this was the homeland, you can estimate quite properly that the casualties that would have been suffered—and I am speaking of the serious casualties, not the ones that are just for a day or two and not the ones who are disabled for life due to illness of various kinds—could well have numbered into the hundreds of thousands, possibly up to Churchill's figures, and certainly enough so that everyone who had a boy over in that theater, or expected to have one, was dreading the day of that landing on Japan. I don't think that that dread was unjustified at all.

Certainly, the military authorities in their plans and in their estimate of the situation never felt that the landing on Japan would be a push-over in any sense of the word. They felt that they were going to fight to the last cave.

Senator VANDENBERG. What was the Hiroshima date, General?

General GROVES. August 5.

Senator VANDENBERG. And what was the date of the test in New Mexico?

General GROVES. July 16.

Senator VANDENBERG. So that as soon as this bomb had been developed to your satisfaction as a success, there was no delay in its use in the war itself?

General GROVES. There was no delay. I would be glad to tell you of the delays that we had from the time that we could have done it. The whole bomb depended on when we could get the material. The mission that I gave to the scientific laboratory at Los Alamos, N. Mex., under Dr. Oppenheimer, was that I wanted a test of that bomb as soon after we got sufficient material to them for the test and it could be processed and put into the bomb. My recollection is that they were 3 days late. In other words, they had a few things that they had not solved ahead of time. That mission had been given

to them over 2 years before. I felt it was a master performance on their part.

Part of the bomb for Japan was sent over there, as you know on the *Indianapolis*, and part of it followed by air. The bomb was ready to be dropped, or could have been ready to be dropped on the 31st of July. It had to be assembled overseas in part. We had to wait for weather, so that it was really from the 16th of July until the 31st, and in that time we had to assemble enough material and ship it.

Our production of material was going up on a very sharp curve, and we had enough for the first time. The delay in the use of this bomb was 5 days, and that was due to weather.

Senator VANDENBERG. Up to July 16, you had not been prepared to proceed?

General GROVES. Oh, no, sir. We did not have enough. We couldn't. In other words, we could have fired our first bomb on July 16, and the second on July 31 in the Marianas. If we had had a second test in this country, which we would not have had under any circumstances, that could have saved the time of travel from the United States over there of about a week. So that the second test could have been on July 24.

Senator VANDENBERG. So that completely dissipates the stories that were general in this country, that there was a long and substantial delay in the use of the bomb for international political reasons?

General GROVES. Those stories are completely without basis in fact.

Senator HICKENLOOPER. General, coming out of the Los Alamos test were the stories of the effect of the flash and the light on the eyes of the observers at great distances.

Did the priest who wrote this report make any statement as to any effect on his eyes at that comparatively close distance?

General GROVES. He did mention that eye effect and talked about a girl who was much closer than he was, and how she was blinded temporarily from the flash just as you are if you happen to look at a welder on a street-car track as you drive down the road. You are temporarily blinded, but your eyes soon recover, and you are all right.

We have had no results that I know of that indicated any real eye effect. There would possibly be some, but if they were minor, just a few, I would not know it. There were certainly not any great number or I would have known it.

Senator HICKENLOOPER. It seems to me I recall from reading some of the stories that have appeared in articles and in the newspapers that the observers at Los Alamos were unable to view the first flash even through darkened glasses.

General GROVES. That is correct. I think the best example of that were the observers who, I believe, were 27 miles away. Those were the observers who had worked with it and were not necessary to the test, and they had a vantage point out there. They were provided with the equivalent of welders' helmets with the glass that is in them, and they could view the explosion through those.

The ones who were looking directly at it at the time of the explosion, which were approximately 90 percent, were just sort of temporarily blinded just as you are when a flashlight bulb goes off, just that same feeling, and the result was that they could follow right along and see what happened. Some of the men in their excitement,

having had 3 years to get ready for it, at the last minute forgot those welders' helmets and stumbled out of the cars where they were sitting, and did not have the helmets in front of their eyes. They were distinctly blinded for maybe 2 or 3 seconds, and in that time they lost the view of what they had been waiting over 3 years to see.

Senator HICKENLOOPER. How far away were they?

General GROVES. About 27 miles, as I recall. It may have been 20, but I think 27.

I was at 10 miles and looked at it as soon as I could turn around after it went off. I looked at it through dark glasses. That was probably a fraction of a second, or maybe a little bit more. At that time I could look at it, and it was perfectly all right through a piece of smoked glass.

Senator RUSSELL. What equipment did you give the crew of the plane that carried the bomb?

General GROVES. They had special glasses of the polaroid variety that they could twist to change from almost full light down to no light at all, and they were supposed to be screwed down to the complete no-light basis.

Senator HICKENLOOPER. It seems curious that this priest could be 4 or 5 miles away from the center of this explosion without anticipating it and suffer no particular ill effects from his eyes.

General GROVES. I think the answer to that is that when we saw the thing go off in New Mexico, although we had figured out and told ourselves that we were going to have this tremendous light and should watch our eyes and all of that, we did not really believe it; it was so far beyond the human experience, seeing this tremendous light in the sky, that it just gave you a strength of light many times that of daylight, so we over-emphasized that effect and thought it was more dangerous than it was. In the same way, it was so overpowering that I was not particularly interested in the blast or the noise effects of this explosion. In other words, most of us lost the keenness of observation that we should have had for such a thing because we were so dumbfounded by this light effect, although we had expected it and said, "That is what is going to happen."

Senator MILLIKIN. Can you tell us of the heat reactions, if any, felt by the observers in New Mexico?

General GROVES. The only heat reaction that I recall was just a sort of warm glow. Some people claimed they felt it on the backs of their necks. We were all lying on the ground faced away from the explosion, and they claimed they felt some; but I did not feel any.

Of course, for a considerable distance around all the vegetation was seared off. There wasn't any left.

Senator MILLIKIN. What is the heat generated at the moment of explosion?

General GROVES. I would prefer not to answer that in open hearings, sir.

Senator MILLIKIN. Let me ask you one more question.

In your opinion, had Japan lost the war strategically at the time of the bomb?

General GROVES. I think Japan lost the war—and of course I am not speaking for the War Department here—at the Battle of Midway, but they didn't know it and would not admit it, and their people did

not know it. It took something to knock them out of the war. They were still fighting, and they had no expectation of quitting even if they had lost the war.

The CHAIRMAN. General, it occurs to me that some foreign agent might spread this radioactive material around a city, and you would not know it was being spread because you could not see it, and it might kill a whole population.

General GROVES. You would know it, because everybody who used X-ray film would know it was all fogged, and you would have almost immediate warning because they are using X-ray film constantly. Every person with a camera would find it out as soon as he tried to develop a picture. The photographic film would tell you immediately.

The CHAIRMAN. Suppose some enemy were to drop an atomic bomb or atomic rocket on you. Would there be any danger of radioactivity?

General GROVES. If they dropped one on a city and exploded it close to the ground, there would be radioactivity there that would have an effect.

The CHAIRMAN. Do those rockets that the Germans used over London explode near the ground?

General GROVES. I don't know just where, but some exploded, I believe, on landing. I don't know where most of those exploded, but I believe the world knows today that the way to get maximum explosive effects is to get up in the air, depending on the size of the explosion. For that reason, if they want explosive effect, they will certainly set it off up in the air.

If we had set that bomb at Hiroshima off when it hit the ground, the damage would not have been nearly so great. It was designed to be set off so as to give us the maximum possible explosive force.

The CHAIRMAN. I think those rockets that went over London exploded on contact. If they were loaded with atomic material and it spread out, there would have been considerable danger then from radioactivity?

General GROVES. There would have been considerable danger, but the total damage done to London would have been much less than if the rockets had been exploded in the air; so the real fear would have been in the case of a fuse that did not work and did not go off when it should have up in the air, but then would have been a much less favorable result from the explosion. I say "less favorable" from the standpoint of the enemy dropping it.

The CHAIRMAN. General, relating the bomb to approximately the same size that was sent over Hiroshima, suppose one dropped upon Washington. Could you estimate the amount of damage and relate it to Washington?

General GROVES. Related to Washington, if that bomb had been dropped, say, in the center of the Pentagon, there wouldn't be any Pentagon left.

The CHAIRMAN. That is a big result.

General GROVES. That would have far-reaching consequences.

If it were dropped in what would probably be the goal of any enemy dropping it in Washington, so that it hit on the Federal triangle and destroyed the offices of the Government, it would have destroyed an area maybe 2 miles in diameter so there wouldn't be much left there.

Of these big Federal buildings that are well built, many would have their walls standing. All of the limestone and marble on the facing would have been blown off. There is not much question of that, but the concrete and steel structure might still be standing.

All interior partitions would be gone; all the windows and window frames would be gone, and in general you would have a number of buildings standing just as you see them in the picture of Hiroshima, everything flat in between, and maybe 2 feet deep in rubble of all varieties, with these walls standing there but absolutely unusable.

The normal house that most Washingtonians live in would be completely destroyed in that area. It wouldn't be findable.

The area of real damage, where there wouldn't be much left, would have extended from the Capitol to the National Cathedral at Massachusetts and Wisconsin, or something of that general order.

It would have gone over across the river into the Pentagon area, and have blown out all the windows and window frames of the Pentagon, and probably blown out most of the interior partitions. It would not have destroyed the Pentagon, but it would probably have done a tremendous amount of damage.

Senator VANDENBERG. It wouldn't have wiped out our deficits, would it?

General GROVES. I think it would have taken the Treasury out, excepting the lower vaults; but, in general, there just wouldn't be anything left.

You would have found all of your headquarters in municipal government would be gone. At Hiroshima, as a rule there were about 400 firemen in the town, or 450, and about 25 were left fit for duty immediately after the explosion. That is typical of what happens to all your municipal affairs.

In the United States, it would have taken probably about 30 minutes to start organizing relief, and every man that could walk would be helping someone else. The Japanese did not handle it that way, and that built up their casualty lists.

The better disciplined our people are—that is, the fact that they know such a thing might come now automatically gives them a defense against it—and anything that is in the nature of an organized body gives still more power to resist and to lighten the losses that occur in such a catastrophe.

Senator VANDENBERG. General, if you had to start from zero today, with nothing except your experience and knowledge, how long would it take you to produce a bomb?

General GROVES. You mean with the same full authority I have had in the past?

Senator VANDENBERG. Yes.

Senator CONNALLY. Do you mean with the installations?

Senator VANDENBERG. No; I mean all installations are out; he has got to start at zero.

General GROVES. But knowing what we do today?

Senator VANDENBERG. That is right.

General GROVES. I would say if we had complete authority and freedom from interference by suggestions from lots of people, we could do it in probably 2 years' time as compared to the almost 3 that it took us.

If we had that interference I think it might take anywhere from 5 to 10 years, because it is so easy to say, "We have got a better process; you should build the better process and get more efficiency, or you can do it faster," or something else, and by the time you get through settling those matters, the time has gone.

Senator VANDENBERG. Would you be willing to state what our total investment in atomic energy is up to this time?

General GROVES. I would be willing to state, but unfortunately I do not know the figure. I should say, offhand, the figure of \$2,000,000,000 that was given in August was very close. I think by this time it is probably about, I should say, a little over \$2,000,000,000, maybe \$2,100,000,000, something of that order. I would be very glad to supply that figure.

Senator VANDENBERG. Would you state the total employment in the United States on this enterprise?

General GROVES. The maximum direct employment either by us or our contractors who were working directly for us was 120,000 peak.

There were, in addition to that, all the suppliers of goods who were furnishing on a unit-cost basis. These are not included in that; it might make up a total of 200,000 people, maybe 225,000.

With respect to the operational forces, operating our establishment, the peak of those was somewhere in the order of about 55,000—between 50,000 and 55,000.

Senator VANDENBERG. Now, in dealing with the problem we have to consider, among other things, that we have some Federal cities on our hands, have we not?

General GROVES. Yes, sir.

Senator VANDENBERG. Will you state for the record what they are and, very briefly, what has been done there?

General GROVES. At Oak Ridge, Tenn., we have a town, or a city I think would be a better way to put it, which had a maximum population of 78,000. We have discontinued certain work down there, trying to economize where we can, remembering that money is now controlling where time was before. So that I should say that it would compare in size with the normal city, residential city of, maybe, approximately 50,000. That is 100 percent a Government city.

Senator VANDENBERG. That is the city you built right up from the ground?

General GROVES. Yes; right up from the ground in every way, including every facility considered to make up a city—amusements, stores, and everything else.

Senator VANDENBERG. And the Federal Government owns the whole thing?

General GROVES. The whole thing is owned by the Federal Government; yes.

Senator VANDENBERG. What else?

General GROVES. Hanford, Wash., at Hanford Engineering Works, at what was the site of Richland, Wash., a small town.

There we have a city which is designed to house, I believe, about 5,000 workers and their families. Just what the total population is, I cannot say. I imagine it would be about 15,000 to 18,000. The houses there are different from the ones which you saw in Tennessee. They are probably of better construction but they were also cheaper to build because of the locality.

Senator VANDENBERG. Now, is that a Federal city?

General GROVES. That is a Federal city, the same way, on Government property, everything owned by the Government.

At Los Alamos, N. Mex., the town there is more like the normal military reservation. It has housing for married people and it has quarters for bachelors and the unmarried. It has a large military population, mostly enlisted men who were young scientists who came into the Army and whom we picked out by reason of their records and brought into the work. They were people without whom we could not have done this job. We had a total of about 3,500 of these men out there at Los Alamos.

Our problem there is much more serious than at the other two places. We can house the people we need at the other points but we cannot house them at Los Alamos,, the people we should have there right today.

They were brought in there during the war but they will not come in time of peace without some provision for their families and we are faced now with what we are going to do with that establishment.

Due to the uncertainty we are losing the people; we are faced with a very desperate situation.

That laboratory was designed to develop the bomb, all the theory connected with the bomb, the designing and the engineering of it, and to take the pieces that were made elsewhere, as well as some that were made right there, and assemble them into the final bomb; to do some of the final processing of the material as it came from these two plants.

Generally, that laboratory was to develop all the technical details that went into our operations overseas. They furnished the men who were our technical detachment overseas, which was a combination, like everything else in this project, of the American people, made up of Army officers, enlisted men, Navy officers, and civilians, both scientific and highly skilled mechanics of a type that is far beyond what you would normally refer to as a skilled mechanic.

Senator VANDENBERG. Now, is it your contention, General, that in the adequate continuity of developing atomic energy, it is going to be necessary to maintain all these enormous installations?

General GROVES. It is going to be necessary from the standpoint of—but before I answer that, I would like to add that, in addition to those things that you have generally been made aware of, we have certain laboratories that are Government-owned. We have one in Tennessee, which you went into that afternoon. That is a very important laboratory. We have one near Chicago, in the outlying districts of Chicago.

The CHAIRMAN. That is the Argonne?

General GROVES. The Argonne; that, also, is a Government laboratory, although it has been operated for us by the University of Chicago.

Then, we have these various laboratories in universities where, while they are university laboratories, we have been supporting them. We will have to continue to support them if we are going to stay in the lead in this field, because the universities cannot afford to support them, in the first place. In the second place, the universities will

not wish to work on certain problems we are vitally interested in, because they are not of particularly scientific interest as a whole.

The CHAIRMAN. Is that not the reason, General, that you have lost some of your personnel?

General GROVES. Oh, yes.

The CHAIRMAN. Some of these scientists who have done a wartime job of making an explosive will want to get back to something that they consider a little more constructive, will they not?

General GROVES. They wish to get back to the type of life which they chose as young men. They chose to be academic scientists because they like the life. When a man chooses his profession considering all the financial rewards and considering how hard he is going to have to work, and considering the surroundings, and he chooses an academic profession, he would like, in the main, to get back to it. They still feel that the academic profession is more attractive.

The CHAIRMAN. General, going back—

Senator VANDENBERG. Excuse me. Can we have an answer to the question, General?

General GROVES. Did I dodge it? I am sorry.

Senator VANDENBERG. No; you wanted a little more prefix to it. You remember what my question is?

General GROVES. Yes. I would like to amplify a little the situation I am faced with at Los Alamos.

There we are trying to establish this scientific laboratory which will be of a highly secret order. It will have there the heart of the weapon and everything else, as it has in the past.

In order to have scientists of the caliber we are getting—we are getting good men there despite all the handicaps that we have in getting men—we are not getting some of them, we are losing some we would like to keep, but we are getting good men and we hope that we will have an operating laboratory.

To get those men, we are having to encourage them to come and we are encouraging them in two ways.

The first way is that, in addition to working directly on this weapon for us, they are going to be given the equipment and they are going to be given the time to engage in certain fundamental research that they would be doing if they were back in their home universities. That is part, as far as I am concerned, of their salary. We are merely giving them that much time to do the work that will enable them to keep on doing our job with the fullest of interest.

These men have very active minds, they border on the genius type and unless we do that, we just cannot keep these men, we cannot keep them doing it willingly and with pleasure and, I think, with efficiency. In other words, we cannot keep them working toward one goal all the time without ever taking their noses off that particular grindstone. They should have that opportunity of doing their own work, and we are going to furnish that.

We are also going to furnish them with housing that will enable them to have their families there and to have the proper housing for the supporting cast, which is enormous.

These scientists will need the technicians; they will need the technicians to do the wiring for them, so that they can devote their time to

what they are being paid for, which is scientific endeavor and not the rigging up of their own experimental equipment. This is the custom in most university laboratories. You see these very high-grade men having to spend time worrying about wiring up things that they could buy if the budget permitted them to buy.

Now, what we have to keep operating, in my opinion, at the present time is this:

We have to keep operating everything from the standpoint of having a sufficient supply of bombs on hand until somebody makes up his mind as to what is to be the future of this work.

If we shut down a plant, there is no telling what the cost of that shutdown will be. It is possible it can be restored in 6 months' time, that the cost there would be five million or ten million dollars.

How long it will take us to get the personnel back even in time of war is a question. We, of course, have our lists of everybody who worked or is working for us and, naturally, we would send out and call them and get them back.

But we do not know about the equipment. We have never shut down a plant like this. We are shutting down certain sections in our plant in Tennessee and we are shutting down the sections that we feel aid the least and the shutting down of which would enable the greatest saving in money.

In other words, if we can save 35 percent of our money, maybe we will only lose 10 percent in production.

However, when it comes to shutting down the remaining works at Tennessee or the Hanford Engineering Works, we are making a decision that cannot be easily corrected—in fact, a decision which may not be possible of correction. I do not know whether certain of these buildings and equipment could be shut down without having to replace certain parts. I know that we would have to replace certain parts; just how many, nobody knows and nobody will know until we shut down and try to start again.

It is not like some other weapons, like a gun which we can cosmoline and put away and say that we can always clean it up in 30 days and we would have that gun in shape. We cannot do that.

We cannot shut down the Los Alamos laboratory and ever assemble a laboratory like it again, except in time of war. We cannot stop our work at the Clinton laboratories and start up again because we would have lost the personnel—there is not much in equipment there.

With regard to the work at the Argonne, we would lose the momentum we now have and it would cost a tremendous lot of money if we had to get that momentum back.

Senator VANDENBERG. How are you operating? Are you still operating under war appropriations?

General GROVES. We are still operating under war appropriations and those appropriations, of course, run out next July 1.

Senator VANDENBERG. Have you made a budget estimate for the next fiscal year?

General GROVES. No, sir; I have not, because I had hoped that that would be done by some other agency.

We are preparing now, in view of the fact that legislation has not been passed, we are starting in now to get together a general idea of what it will cost.

I cannot possibly give you any figures today, because we are still trying to decide what is going to be done on the major decisions, the ones that will affect us for 5 and 10 years. We cannot do that until we have somebody who will make up his mind about it.

Senator VANDENBERG. So, if I understand you, speaking generally, you would anticipate not only the desirability but the basic necessity of substantially maintaining your present establishment in peacetime?

General GROVES. Yes, sir; as it now stands. That is, with the reduction we have already made in Tennessee and with a distinct saving in personnel as time goes on, because we are getting savings. Naturally, we are watching and seeing where we could do with less personnel. As we learn more about the process we are able to do that and as the time factor becomes of less importance, we are also able to do a great deal more.

For instance, we no longer have to rush materials through; we can take our time about it and it does not cost us anything to have material in process, whereas before it was costing us days of war.

Now it merely means we can get it any time; but the pressure of time is gone.

Senator VANDENBERG. Speaking generally, is this going to be a billion dollars a year, half a billion, or do you have some figure in mind?

General GROVES. I would hate to speak because you might remember the figures [laughter] but I should say that it will be less than a half billion.

Senator HICKENLOOPER. I was just wondering, General, with regard to this matter of safety. How long would it be safe for a fellow to walk around with a radioactive dime in his pocket?

General GROVES. I don't know, Senator.

Senator HICKENLOOPER. Do you think it would be safe?

General GROVES. I wouldn't carry it. [Laughter.]

Senator MILLIKIN. General, am I correct in interpreting your remarks to the effect that you favor the maintenance of the essential parts of your set-up until Congress decides upon its policy?

General GROVES. Yes, sir.

Senator MILLIKIN. You are not advocating a permanent maintenance?

General GROVES. No, sir; I am not advocating its permanent maintenance; the permanent maintenance of the essentials of our present organization.

I am advocating it until such time as Congress passes some legislation. I am advocating it beyond that point to the time when the body that is given the responsibility over this thing has a chance to really understand what problems it is going to be faced with.

Senator VANDENBERG. Regardless of what kind of action Congress takes, is it your view that it is necessary to maintain it? If I understand you, if we are to maintain our momentum in the field of atomic energy, regardless of what Congress does, you say it is going to be necessary substantially to maintain an institution approximately of the present magnitude?

General GROVES. No; I think that it is possible that that can be cut considerably in magnitude, within a period of, say, 2 years.

In other words, our first problem is to get adequate supplies on hand and then we will be in a position where we can say that now we can start cutting down on that establishment.

Senator AUSTIN. May I ask a question?

The CHAIRMAN. Certainly, Senator.

Senator AUSTIN. In your view, does it make any difference, with respect to this minimum amount of facilities, whether the ultimate control of this production is in the hands, you might say, of an institute that is operating as a private enterprise, with its own horde of trustees that are self-perpetuating and thus released from Government; or whether it is to be continued to be operated by Government through some agency set up for that purpose and always under the control of the Government?

Whichever role we should decide to take, whether public ownership or private ownership, there is a minimum below which we cannot afford to drop, in your view. Is that right?

General GROVES. That is correct; but I cannot imagine the Government failing to continue to have a controlling voice in this problem because it involves the whole existence of the Government and of the people that make up that Government.

Senator CONNALLY. General, at that point, I assume that your theory is that it is no more necessary to keep an Army and Navy than it is to keep other essential war or aggressive agencies and weapons in a distant part of our national defense. Would you not say that it is just like maintaining—spending hundreds of millions of dollars—maintaining the Army and the Navy?

I assume that your idea is that so long as this thing has all its potentialities it is pretty well demonstrated to be in the interest of the Government to maintain these plants and control this instrumentality until some new policy is adopted; is that right?

General GROVES. I think that this is an integral part of our national defense.

Senator CONNALLY. That is right.

General GROVES. And it is not only an integral part but it is absolutely essential to our avoiding national suicide.

To me it is not a substitute for the Army and Navy, but it is certainly part of the integrated force—I hope a well-balanced force—of whatever is needed to protect the interests of the United States.

Senator CONNALLY. I would like to ask you this question. Furthermore, would it not be wholly impracticable to turn this over to any private corporation? Do you not think that the Government itself ought to keep the whole of it?

General GROVES. I feel that this is so important that it must be retained under complete governmental control and that private industry should have no rights whatsoever with respect to this, excepting those rights that can be given without interfering with the welfare of the United States.

Senator CONNALLY. Thank you.

Senator TYDINGS. Have you any estimation offhand as to the number of employees that you think would be required to operate permanently the establishment that you describe, beginning 2 years from today?

General GROVES. I should say offhand that it would get down below 35,000.

Senator TYDINGS. For all these plants?

General GROVES. For everything.

Senator TYDINGS. How many do you have now, roughly?

General GROVES. Roughly, we have now, I believe, about 45,000.

Senator TYDINGS. So all you see in the picture is the possible reduction of about 10,000 employees when you reach the 2-year level which you have described?

General GROVES. Yes; but I also see a great reduction in the subsidiary employees who are furnishing materials of one kind or another, so that the impact on the country will be less.

Senator TYDINGS. Are they Government employees or private?

General GROVES. You mean on furnishing those materials?

Senator TYDINGS. Yes.

General GROVES. Private.

Senator TYDINGS. So that the governmental picture as of today is 45,000; and you see it 2 years ahead from now as being about 35,000?

General GROVES. The governmental picture is a lot more than that at the present time. I was speaking of operating only. We are still trying to finish certain things which are almost finished so that we will have a well-planned process.

Senator TYDINGS. What I am trying to get at is: What is the over-all governmental picture—governmental employees as of today and what you think it will be in 2 years?

General GROVES. I should say the over-all governmental employee situation is that we will cut it almost in half within 2 years. It is about 70,000.

Senator TYDINGS. And you think that 2 years from now, if the plan you have in mind is carried out, it will be 35,000?

General GROVES. I think under 35,000. As I said to Senator Vandenberg, I hate to submit my successors to something that will be worrisome in the future.

Senator VANDENBERG. Well, is this figure you are making a figure that would include the operation of the Federal cities?

General GROVES. Yes, sir.

Senator VANDENBERG. And it includes the necessary employees for that purpose?

General GROVES. Yes, sir.

Senator TYDINGS. May I ask you one other question? The expense of operating that plant today, the over-all governmental expense of operation today on the 70,000-employee basis, plus the cost of acquiring materials, and so forth, the operating of all the plants you now have, how will that figure compare with your figure for 2 years from now? Will it be the same cost, will it be half, one-third, or two-thirds, in your opinion, of what it is today?

General GROVES. I think it will go down to probably half or two-thirds.

Senator TYDINGS. You mean it will go down two-thirds?

General GROVES. No, sir; it will be, at the end of that time, between 50 and 60 percent of what it is today.

Senator VANDENBERG. That is, without inflation? [Laughter.]

General GROVES. Of course, if you are going to raise all the civilian salaries we had better make it all military, so that the pay rates won't go up. [Laughter.]

Senator VANDENBERG. General, I would like to ask you one more question—if I may, Mr. Chairman?

The CHAIRMAN. Yes, sir.

Senator VANDENBERG. Assuming an international decision to outlaw the use of atomic energy for military purposes, in your opinion could the world be successfully policed in respect to that objective?

General GROVES. I don't know. It all depends on what the attitude of governments is. I don't think it could be policed as of today unless the United States is ready, on the drop of a hat, to start an offensive, aggressive war against somebody who has taken the first step toward preventing the inspection that will be necessary.

I don't think—you are really getting me out of my field—but personally speaking, as an individual—I don't believe that the people of the United States would ever be willing to enter on an aggressive war to destroy another nation because some agent of the United States Government said that he was not allowed to go and look at a certain city because they said, for example, that the roads were bad or they had an epidemic of smallpox in that area.

Now, that is what we are faced with. We have got to have inspectors who can go everywhere, who can go into every man's house—not quite into every man's house but, in general, nose into everyone's business throughout the world.

Now, we can do a lot and be reasonably certain that things are going on as they should be by other means, maybe, by watching certain trade movements and the like. But it is impossible, unless you have complete and free access to every nation in the world, a willing access of the type that we give any foreign national in traveling in this country in general. It will be necessary also to have that access include every one of our industrial plants. It will be necessary for them to poke into all the rooms where we are developing a new piece of commercial equipment and it will be necessary to have the shrewdest and sharpest people to do that job.

It is awfully hard to think of anyone who is of that caliber who could ever forget his national loyalty. I certainly would not be willing to recommend any man that I thought was capable to be one of these international inspectors who would forget for one minute that he was a United States citizen with all the loyalty that means.

Now, of course, I have been educated and brought up on the United States' first principle.

The CHAIRMAN. Just a minute, General. That implies that the inspector you would recommend, if he found in the making of a joint inspection in this country that, we will say, in the laboratories of one of our big corporations that there were some secret works going on—is it your thought that you would reprimand that man if he reported to an international inspection service what was going on in that laboratory?

General GROVES. You mean—no; I would not reprimand him. I just say that if I were that inspector I would always be thinking about the United States, as well as the international organization.

The CHAIRMAN. You would also think about the obligations that the United States undertook, to open up to an inspection service, under a solemn agreement that they would? You would reprimand this United States inspector who was a member of an inspection panel of, we will say, six members who joined in a report, we will say, to the United Nations Organization that there was some secret atomic-energy work going on, we will say, in Princeton, N. J.?

General GROVES. No; but I would hope not to have anything to do with it, Senator, myself, personally.

If there were secret work going on in the laboratory of one of our big commercial organizations and that secret work involved, say, a new design of an automobile that was being kept secret for trade purposes, I would hate to be a party to encouraging some foreign commercial spy in getting information about that. It is so hard to draw the line as to what is atomic energy and what is something else.

The CHAIRMAN. We are talking about atomic energy, weapons of war, and not automobiles.

General GROVES. But, to me, it means this: As I say, any inspection service has got to be free to go into every crook and nook and cranny of the United States, to be certain that any work being done is not work on atomic energy.

That means that we are all going to have them; if they decide that I am working on atomic energy and they say that I must have some notes at home, it means that they can come up and search my house.

That is the degree to which you have got to go if you are going to depend on that service. That is so because when the scientists developed this thing, the theories on which this was done, practically all of them, were based on theoretical blackboard work and you would have to be able to inspect those blackboards.

I think you have got, maybe, to change the world from feeling loyalty to nations. We had a civil war in this country and it was based on loyalties, and you do not drive those loyalties out of a man's head overnight. You cannot just say that everybody in this country now is going to owe allegiance to some international organization.

Now, we may do it. We may come to it. It may be the solution. But, at the same time, we have to have the feeling—we may be misguided in that feeling—but we have to feel that the other nations of the world will come into this with just the same desires as we have.

Senator VANDENBERG. Now, assuming that we do try to discriminate between the development of atomic energy for war purposes as distinguished from peaceful purposes and suppose we allow a general world-wide development of atomic energy for peace purposes, is it possible to develop atomic energy for peace purposes and stick to that with complete fidelity—

General GROVES. No, sir.

Senator VANDENBERG. And yet be just as ready, the day after tomorrow, to turn it into a war weapon?

General GROVES. We can. The real secret of this development does not lie in the work that was done at Los Alamos, which was the development of the bomb itself; it was in the preparation of the material, that was the hard job.

Now, I am not taking away anything from Los Alamos. They did a magnificent job but it is something that if we had to do over again—supposing I was an outsider and was in some other country and I was told to duplicate that job. My real worry would not be the work at Los Alamos, but the work that led to the development and to the successful operation of the separation plants.

There was involved not only the development. We had to learn how to operate and that took us a long, long time.

We were on the brink of failure; in fact, we were over the edge on the failure side many times and for long periods of time.

It is that that is the real thing which I would like to see kept. Now, in other words, that means that you cannot separate the peace and the war. They are just so closely interlinked that you just cannot separate them.

While you may say that we can use it for peace and if we start out for war we will do something, I say that you have got to be prepared to go into an aggressive war at the drop of a hat, at somebody's say so, and without even waiting to assemble Congress in special session because it would take too long. We would have to change from peace to war pretty fast and get to making enough bombs before they could put our bomb-making capacity out of business.

Senator HICKENLOOPER. In other words, there is no difference between the material and its use for peace and industry and public health and fields of that kind and its use as a weapon? The same material is used for both purposes?

General GROVES. It is the same. It is in a different form, as you know. I think I have shown you all those various steps in these processes, where they take the material and change it from one salt to another and do that all the time and that does not take very long with modern chemistry.

Those things can be studied and they are being studied and these processes can be discerned, they can be learned from very small amounts of the material. It can be done by sneaking out some of the material and they can develop all of our processes and be all ready to go when the time came.

Senator TYDINGS. Right along that same line, suppose that the leading nations started on the production of atomic energy for peacetime purposes and that they had plants which produced it and it was beginning to be utilized to run ships or automobiles or electrical plants or whatever it might be.

They would then have plants that were making the elements that go into a bomb. I imagine that it would not be a very difficult procedure, after assembling all the elements, to build the apparatus that would make the bombs. As I understand it, the problem is to get the elements.

General GROVES. That is right.

Senator TYDINGS. So, if we do have an atomic-energy-operated world, all the inspections will be pretty much dissipated—the value, rather—because once the development of atomic energy is assured to different nations and the means for producing it is set up, it is a very short step from there, both in time and in mechanics and intellect and everything else that enters into it to change that into making a bomb with it?

General GROVES. That is correct. If that came to pass and I had anything to say about the inspections, I would want an inspector of my own in every plant that this material was being used in for the production of energy and I would also want somebody in there watching that man to make certain that he was still my man.

Senator TYDINGS. You would still want another man watching him?

Senator VANDENBERG. In view of all these complications, have you thought this thing through as to a recommendation?

General GROVES. You mean, as to what to do?

Senator VANDENBERG. Yes.

General GROVES. I feel that the step proposed by the President, as announced in the agreement or announcement signed by himself and Mr. Attlee and Mr. King was the correct step to take.

In other words, we have now got a weapon which can destroy an enemy very suddenly and punish him to the point where it would be a long, hard pull if he is going to win out. I don't believe, necessarily, that we will have a push-button war in which somebody will press a line of buttons and then the war will be over. But I do think that whoever is hit by what comes from that line of buttons is going to be at a terrific disadvantage. He is going to have the equivalent of 5 or 10 Bull Runs on the first day of the war.

Senator TYDINGS. With three Pearl Harbors thrown in.

General GROVES. I was not mentioning Pearl Harbors.

Senator VANDENBERG. That is around the corner down there [indicating corridor]. [Laughter.]

General GROVES. That is what is going to happen. I think that the discipline of the people is going to tell whether they quit like various nations quit in this war or whether they are going to go on fighting no matter how dark that day looks to them.

The CHAIRMAN. In that event, maybe there will not be enough people left to compose a coroner's jury if we had that kind of devastation.

General GROVES. I think the thing we are faced with is that this can be a terrific blow in the early stages of a war. It is a terrible temptation to anyone who wishes to start a war, as Japan did with us. It could give them a tremendous advantage in the way of a sudden surprise attack which would come without all the diplomatic palaver that went on in this case.

For example, using Japan as an instance, they would have come in 1935, or something like that time, when supposedly everything was lovely between us, but they would have made up their minds that we were an obstacle to a Greater Asia and therefore they were going to put us out of business.

Senator TYDINGS. General, coming back to this question of inspection, I take it from your remarks that inspection might be feasible and beneficial in the early development of this energy and before atomic energy gets into what might be called civilian use.

I take it that after that point was reached and atomic energy was being used on a wide scale, let us assume, it seems to me that the value of the inspection decreases correspondingly as civilian use of the atomic energy increases, because it would be so widespread, so much of it here, there, and every place. Is that correct?

General GROVES. I would say that perhaps the value would not decrease but the possibility of doing it would become just hopeless.

Senator TYDINGS. Yes.

Senator BYRD. General, the answer you gave to Senator Tydings' question was that you said it was hopeless. I presume you have been doing considerable thinking on the feasibility of inspection?

General GROVES. Yes, sir; I have.

Senator BYRD. Have you called upon the officers for a report on that subject?

General GROVES. Not for a report, but I have discussed it individually with a great many of them.

The CHAIRMAN. It is my information that a great many of them, officers and generals, will discuss that phase and we hope that we will have the best of their thinking on that proposition within a short time. I just wondered as to how deeply the War Department had considered the subject.

General GROVES. We have discussed the subject. On all such matters we have discussed them very closely with a number of scientists. As you know, we have a great many hundreds and even thousands of them and we do not discuss everything with all of them. After all, we still have work to do and so have they.

However, we try to get a cross section of their views and opinions as to how just such a thing can be operated. We also try to get their opinions on a great many other things—when we get into something that involves science as a whole we try to get the views of their representatives.

There is one thing I would like to take this opportunity to correct and that is this: I do not feel that there is any real difference between the War Department and the scientists.

I say that because the War Department does not want to put the scientists in a strait-jacket, they want every possible advance in the country scientifically, as well as in all other fields of knowledge.

The scientists, on the other hand, do not wish to disclose things that should not be disclosed to foreign governments.

I think that that is really their standpoint on that. I had hoped today to be able to read to you an extract from a letter written by one scientist to another of which he sent us a copy.

The CHAIRMAN. Before you go into that, General, I would like to go back to your estimate of 2 years that you made in answer to Senator Vandenberg's question.

Assuming that we were starting from scratch with what we now know about it today and suppose that we wanted to get into production, I want to ask you this.

Have you taken into account the following factors:

First, on the assumption that the safety of operating personnel is to be disregarded, would that period of time be considerably shortened? It would, would it not?

General GROVES. I think, if safety of operating personnel is to be disregarded, it may be.

I would also like to add that when I said 2 years I assumed that we knew what had happened but that we did not have the experimental work done and that we had to repeat that. In other words, that we threw away our notebooks, as it were. If we did not do that, that time, maybe, would be shortened. Well, it would still remain almost 2 years, but it would be a lot easier.

The CHAIRMAN. I would like to go into that because that seems to me to be a very pertinent subject for further inquiry.

I think one of the things you have to determine is the possibility of other nations getting going on this project.

That leads me into another subject I want to inquire into, namely, if certain countries were to announce, tomorrow, that they had it, I wonder if it would change your views any.

Now, you have the assumption that if safety of personnel were disregarded entirely it would cut down the period somewhat?

General GROVES. It would cut it down in this country, if we could do that.

The CHAIRMAN. In other words, if we built those buildings without any regard for safety factors or if we just took an empty factory building, any empty factory building, or put up a great big shed or a great big tent just to cover you from the weather and without any regard to the cities you built around this project which took, of course, a good deal of time, you could then really bring it down to the basic factor of building some complicated machinery, could you not?

General GROVES. No; because you would have a cleanliness affair. Now, if you take the work that you saw at Tennessee, the two big plants, there were no unusual safety factors built into those plants. They were built that way because they had to be in order to start operating.

The CHAIRMAN. But we developed four processes in 3 years, did we not?

General GROVES. Yes, sir.

The CHAIRMAN. Now, assuming that we took the best process and proceeded from scratch on that—that is, when I say “scratch,” I mean with the knowledge of how to go about it—without regard to safety and using flimsy buildings without building any city and using one process that will work, that has been found to work before, does that change your 2-year estimate?

General GROVES. Yes; if we built one, the 2 years would probably become 3 years because you could not accomplish what we did if you built one process. It might become 4 years.

The CHAIRMAN. But today you know the best process, do you not?

General GROVES. Yes, I know.

The CHAIRMAN. Knowing the best process and concentrating on that, would it shorten the time?

General GROVES. No, sir; it would increase the time.

The CHAIRMAN. In other words, you have got to use all four processes?

General GROVES. Not all four, but it would increase the time because of the whole over-all picture. I am taking it from the time we started until we have a bomb that would work. I would rather not explain the details of that in an open hearing.

Senator HICKENLOOPER. General, if we disregarded the safety factor of the personnel, would not the morale of the personnel have something to do with the efficiency?

General GROVES. I do not think—knowing what I do know of American citizens—I do not think that we could operate this thing, even with the most highly disciplined troops, without regard to safety.

Senator BYRD. You have had no operating accidents?

General GROVES. We had no operating accidents throughout this project that were directly attributable to the unusual nature of the material that was a fatal accident. We had one after the bomb was exploded. We then had one which we should not have had; there was no reason for having it.

It was like all accidents, industrial or home accidents. If you do not turn on the light when you go down to the cellar, you are going to start having accidents; that is something that's too bad, but that is the way most industrial accidents happen.

Senator HICKENLOOPER. But even in the case—General, let us assume, in order that we may have an extreme assumption—let us assume that we had slave labor or impressed labor of one sort or another. Would not the morale factor of the impressed labor, knowing that their safety was not being taken into consideration, reduce their efficiency almost to the point of zero?

General GROVES. I would say that the best example of that is to read what the American prisoners did in that machine shop in the Japanese prison camp. There the Japs found out that impressed labor ceases to be of value when it is for anything but plain physical labor, like shoveling dirt. Where you get into highly complicated technical processes, where one man can turn a valve and turn it back again and nobody can tell that he did it unless he has a terrific amount of equipment such as we have for registration, it is just too bad.

Senator HICKENLOOPER. And you cannot stand for sabotage in this business.

General GROVES. That is right. Sabotage is a very serious problem. We have had some cases where a man made a mistake and that mistake was extremely costly. I think it would be very difficult to operate without the highest morale on the part of the workers and without the highest degree of intelligence and capacity.

Senator TYDINGS. Going back to the question of inspection again because, after all, sooner or later we have got to determine what to do to protect ourselves and the world, I take it that you are looking ahead 15 or 20 years, to what we might say would be the normal evolution of atomic energy.

With that viewpoint, according to your statement as I understand it, you consider that as of doubtful final value; and that your opinion is that some approach to it, similar to President Truman's statement, is the best thing we have been able to conceive for the future protection of our own country and of the world?

General GROVES. I think so. That will lead to inspection of a certain type. That approach, in my opinion, leads toward the opening of international frontiers and a free interchange of people and essential ideas.

With that free interchange I think that it is impossible for a dictator to exist, except in a very small place, like a city. For example, you may have a city dictator but he cannot become a national dictator with a capacity of waging war and drawing the whole world into it.

To me the important thing is the opening up of all nations to freedom of travel and that, you might say, would be an inspection service, but you would not say that if we had inspection we would be safe.

You would be expanding that. You would have not only scientists, but you would have engineers, you would have nationals of all types traveling back and forth and spreading the doctrine of how the rest of the world lives.

I think that would do more toward obviating wars than anything else because then a man would say, "Why should I starve over here when I can go to another country and be treated decently?" The better men would tend to migrate and the thought of war would be less and less in their minds.

Senator TYDINGS. So that the real hope cannot be pinned too strongly on inspection alone?

General GROVES. No, sir.

Senator TYDING. Inspection simply implements a plan for the control of atomic energy?

General GROVES. I believe depending on inspection alone would be like depending on having most of these bombs alone and saying, "Here, we have got 10 times as many bombs as anyone else has, so we are absolutely safe." We are not absolutely safe. It may have a very strong influencing effect.

I think, in the same way, an inspection service would be a great influence and, as far as we are concerned in our own country, would be quite effective, but I do feel that we cannot depend on it unless we are willing to have every house subject to inspection without warning or without warrant.

Senator MILLIKIN. May I ask a question?

The CHAIRMAN. Yes.

Senator MILLIKIN. General, assuming that there is inspection and assuming that it is reciprocal and assuming that to make it efficient involves a large number of inspectors who would be privileged to go through all our industrial processes and laboratories and that the same privilege would exist in all other countries, what would be the effect on the private enterprise economy of the world?

General GROVES. I don't think there would be anything private anymore because if, for instance, you have got a new type of automobile brake, you would have to explain it to every other nation.

You might say that that possibility might not be included; but as soon as they can pry around and they start finding out things it will be so.

I think the history of the General Motors proving ground, for example, showed that. They had, they found out, to bar the public to keep their competitors from finding out what they were doing.

Senator HICKENLOOPER. As soon as somebody locks a door to an inspector, that places the building immediately under suspicion?

General GROVES. Yes. If I were running that inspection service, I would want to know what was going on in that building.

Senator HICKENLOOPER. Whether it was work on industrial power or atomic power, the inspection would have to be held to find out?

General GROVES. Oh, yes. It may be something that somebody is making; for instance a better microphone. I would say: "I wonder how it fits into this bomb. I want to use it. Maybe they are making a special type of fusing for that bomb."

Senator HICKENLOOPER. May I ask another question?

The CHAIRMAN. Yes.

Senator HICKENLOOPER. General Groves, I would like to ask you, is there any encouragement at this time—

Senator VANDENBERG. I don't think so.

Senator HICKENLOOPER [continuing]. For the development of a reasonably adequate defense against the atomic bomb within the reasonably near future?

General GROVES. I know of none. I think the only defense is to stop the carrying vehicle before it can launch the bomb.

The CHAIRMAN. How about its being planted by sabotage around our cities?

General GROVES. As to its being planted by sabotage, I think that that means that you have to know enough about what is going on if you want to have complete protection.

There again you have got to have a corps of inspectors that will go into every room, you might say, of everybody's house and see if they have got the ingredients for the bomb.

Senator HICKENLOOPER. My point is this: There is no encouraging answer when it comes to defense now to detect a bomb in the air and explode it, for instance, or destroy it before it reaches its target once it is launched?

General GROVES. No way. I see no hope of that and none in the future. You must figure, in this instance, that you have got to stop them 100 percent. It is not sufficient to stop half of them. You have got to stop them all and no one, I think, has yet been ever able to devise a perfect defense line.

Senator HICKENLOOPER. You can detect it with radar, the approach of it if it is coming, just as a metal object; but there is no way of detonating them or reaching them?

General GROVES. You could detonate them with high-powered artillery, but some of them would get through. As you know, the attack by the German buzz bombs—a great many of those were shot down but some of them got through; not enough of them to do enough damage when they got through, so they could stand that. But these bombs, you have to stop them.

Senator VANDENBERG. I would say your answer is, "There is no encouragement—period."

General GROVES. There is no encouragement—period.

The CHAIRMAN. Assuming that 40 of these were planted around 40 of our centers of population and were detonated in some mechanical way, of what value would 10,000 of these bombs be to us, distributed around the country ready to launch at an aggressor?

General GROVES. I would say the value would be that although we had suffered a loss through the damage of 40 such bombs—

The CHAIRMAN. Which might mean 40,000,000 people?

General GROVES. Which might mean 40,000,000 people; but the rest of the people would still win the war.

The CHAIRMAN. How would they know where to launch the 10,000 we had?

General GROVES. It is a little hard for me to conceive of someone just exploding such bombs without at least letting us know who it was.

The CHAIRMAN. Well, let us assume that country A takes over country B, a small country. This small country, for all you can find out, these 40 bombs come from this small country. On that suspicion, are you going to launch the 10,000 bombs at country A?

General GROVES. If I were running the Government I certainly would not hesitate very long on that, because you are faced then with the need of an instant decision which would mean the life or death of the United States and you could not sit down and have a jury trial to determine whether that country did it or not.

The CHAIRMAN. But they might be innocent.

General GROVES. Well, if they are innocent—

Senator RUSSELL. They are out of luck.

The CHAIRMAN. In other words, it is too bad for us or too bad for them, the innocent country?

General GROVES. Yes, sir. But it is just like anything else. If you are driving an automobile across the street and a child runs across

the street and you instinctively turn the wheel and run into another car and kill somebody in that car, it is too bad for that person in the other car.

The CHAIRMAN. I don't think any system of morality I know of would work.

General GROVES. In other words, I feel that it is very difficult when you take a hypothetical question, to know just what all the background is going to be. That is what would determine it, the background. I cannot imagine not knowing who was responsible. I personally feel that if that was done the nation responsible would tell us.

The CHAIRMAN. If we had an inspection force, the feasibility of such an event as I have described would be, you might say, considerably lessened, would it not?

General GROVES. Considerably lessened; yes, sir.

The CHAIRMAN. From that point of view inspection would be zero plus, some factor, anyway?

General GROVES. Yes, sir. That is what I said to Senator Tydings. I hope I made it clear that I do not oppose inspection because I feel that the steps the President is taking will lead eventually to some type of inspection. But I would say that you cannot make inspection 100 percent perfect.

The CHAIRMAN. Don't you think that it would be easier for us to act before other nations got it?

General GROVES. I am very much in favor of rapid action on this and that has been the policy of the War Department straight through, that everything should be done to get this thing settled and on the way as soon as possible.

The CHAIRMAN. Rapid international action as well as domestic?

General GROVES. Oh, yes, sir.

The CHAIRMAN. One more question, General, and then we have got to adjourn.

This stuff we are making now, as you know, has a peacetime use for experimentation, making it serve a use for good instead of for destruction?

General GROVES. Yes; we hope it has. We think it has. We do not know yet, but we think that we will find the way through that problem.

There is no question in my mind that it is going to come.

The CHAIRMAN. So, to consider our production day by day as simply for bomb-making purposes is to throw it a little out of focus, is it not?

General GROVES. Yes, sir; although we do not know yet. In the end, I think that the atomic bomb will be considered as a byproduct of the atomic age.

The CHAIRMAN. Thank you, General Groves.

We will adjourn until 10 o'clock tomorrow morning.

(Whereupon, at 12:05 p. m., the committee adjourned until 10 a. m., Thursday, November 29, 1945.)

ATOMIC ENERGY

THURSDAY, NOVEMBER 29, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Connally, Byrd, Tydings, Vandenberg, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. General, I believe you had finished your formal statement.

General GROVES. Yes, sir.

The CHAIRMAN. Are there any questions which you want to ask, Senator Hart?

Senator HART. No; I was not here during all of his testimony.

The CHAIRMAN. Of course; you had to attend a meeting of the finance subcommittee.

Senator Hickenlooper?

Senator HICKENLOOPER. I would like to ask the general a question or two, if he cares to give an opinion on this matter. If this is a matter that you feel you prefer not to answer, it will be perfectly all right. If you can, I would like to have it answered.

Assuming our present state of advancement in the atomic science, assuming that we kept on within reasonable degrees of scientific progress vigorously advanced, what in your opinion would be our opportunity of keeping reasonably ahead of any other nation for a period of time?

In other words, could other nations catch up to us in spite of all the time and scientific effort that we might put into this thing, based on our accomplishment?

STATEMENT OF MAJ. GEN. L. R. GROVES—Resumed

General GROVES. Other nations can catch up to us on fundamental science within a reasonably short period. They can catch up with us eventually on our present state of technological advance, engineering, and operation, assuming that we remain stationary.

The CHAIRMAN. Pardon me; I did not get that last answer.

General GROVES. I will be glad to repeat it. On the basic fundamental scientific knowledge, other nations can catch up with us with-

61

in a comparatively short period, say 2 years, and that assumes that other nations will make a really serious effort. They cannot do it by just sitting there with a handful of men and spending a few dollars. They have to spend a lot of money and put their best people on it. There has to be a lot of people, and they have to be supported. They cannot take the time to build their own apparatus. They will have to have it made by mechanics instead of professors.

On the development of that basic information into the information that is necessary to produce a bomb, including the separation of the material, the making of plutonium, and the development of the bomb, they can catch up to where we are at the present time within a period of years.

I testified before the House committee, in response to a direct question on that point, that one nation could catch up and produce a bomb, if they did it in complete secrecy, probably within from 15 to 20 years—more likely the latter. If they did it without secrecy and with a great deal of help from the United States and from England and Switzerland—and I say Switzerland because she is a manufacturer of precision machinery—it could be done in 5 to 7 years, probably seven.

Now, that would be catching up with us to where we stand today.

Senator HICKENLOOPER. Assuming that we go forward from where we are today on advanced research and intensive research into this fission field and the whole field of atomic energy, is it reasonable to assume that we could keep several steps ahead for a long period of time, ahead of the accomplishment of any other nation, if we devoted time to it?

General GROVES. I believe that we can keep ahead of any other nation in the world for all time to come, provided that the rules are the same for the two nations.

Senator HICKENLOOPER. That does not mean, of course, that they cannot build a bomb that would blow up?

General GROVES. That is right, and it also means this: When I say that the rules are the same, if we have secrecy and they have secrecy, we will be ahead. If we have free and open distribution of every bit of knowledge we have, and they have secrecy, they eventually are going ahead because they will finally find out something that we don't know and we won't find it out.

Senator HICKENLOOPER. I have one other question, if you would care to comment.

Do you consider the development of the atomic bomb or the atomic fission in this country, eventually resulting in the making of the bomb, to be entirely a question of scientific calculation plus mechanical development, or are there some other elements that went into that besides those scientific and mechanical things?

General GROVES. There were the scientific developments and there were the decisions as to which route to take to get those developments. Those decisions are probably not so important now as they were at that time, because people know that we were successful.

Then there is the other factor, and that is the operation. These plants do not operate themselves. It took many months before we could make one of our processes work in operation. You could take one element of it and it would work. That was the electromagnetic plant, but it did not work satisfactorily as a complete process until the

best management and the best advisers we could get on the problem had worked and worked at that problem for many months.

Senator HICKENLOOPER. Is it a fact that it requires an unusually high degree of fidelity in personnel as well as scientific and mechanical development?

General GROVES. It requires all the qualities that any employer wants in his personnel up to the utmost. It requires skill, ingenuity, faithfulness, and carefulness that is hard to equal elsewhere in the world.

Senator HICKENLOOPER. Thank you.

The CHAIRMAN. General, you say that they can catch up on fundamental science involved within a comparatively short period. I believe you said that period was 2 years. It has been my understanding that the fundamental science has been encompassed in the Smyth Report.¹

General GROVES. No; I don't believe that is correct, sir. The Smyth Report gives the fundamental science that was known or could be easily deduced. It did not give all the fundamental science.

There is always the question of what is fundamental. Here you have something that stretches over a tremendous field, and the question is: What is fundamental?

It is just like the framework or the bone structure of the body. What is the fundamental framework?

The CHAIRMAN. But the Smyth Report received world-wide distribution, did it not?

General GROVES. Yes, sir.

The CHAIRMAN. That would be my conception of fundamental principle.

General GROVES. If that is your conception of fundamental, if that is the definition you apply to fundamental, then it is already known and was known back in 1939.

The CHAIRMAN. In other words, the problem now is to take the theoretical principles which are known and put them into application?

General GROVES. Yes.

The CHAIRMAN. That is, we have the "know-how" of doing that.

Now, do you think it would take 2 years for them to get to the point where they would start to develop the "know-how"?

General GROVES. I believe it would take them 2 years to get to the point where it would be feasible to get into the actual development of plants, start that phase of it, and to me that is the fundamental knowledge.

The CHAIRMAN. You have two other estimates. You say that if we gave help it would take them 5 to 7 years. What do you mean by giving help, which would reduce it from the estimate of 15 to 20 years?

General GROVES. I mean this: We would give them various engineering developments, how to make certain things, how certain machinery was made, the exact design and exact specifications, the metallurgical processes, as well as the analyses—everything that a man has to know in order to do the job.

¹ A General Account of the Development of Methods of Using Atomic Energy for Military Purposes Under the Auspices of the United States Government, 1940-45, by H. D. Smyth, chairman of the Department of Physics of Princeton University and consultant to Manhattan District, U. S. Corps of Engineers; published by the U. S. Government Printing Office, August 1945.

The CHAIRMAN. Well, it seems to me if we gave that, they would be able to go ahead and do it in a very much shorter time.

General GROVES. No; the only way they could do that would be to have us send over American labor to do the job for them.

The CHAIRMAN. This 15 to 20 years, 5 to 7 years, and 2 years—just so that we will have the record straight—are estimates by you?

General GROVES. Yes, sir.

The CHAIRMAN. That estimate would seem to me to encompass a pretty detailed knowledge about the industrial manufacturing, engineering, and scientific fields in the various nations to which you applied the estimate. What I am getting at, General, is that it is a guess, isn't it?

General GROVES. Yes, sir, it is a guess.

The CHAIRMAN. A pure guess?

General GROVES. It is my guess, based on my knowledge of what it took us, and I certainly had the opportunity to have a better basis for the guess as to what it took us than any other individual.

With respect to other nations, some of them we know something about; others have had a wall around them and it has not been possible to know what is necessary in order to make the guess. But we do know, we have looked into the problem, we have consulted and I have personally discussed the problem in its various phases with everyone with whom I could come in contact who had any basis of knowledge.

The CHAIRMAN. I have some more questions on that, because I think this is a very important point.

As to the countries on which you have not had such full information, the guess would be worth a good deal less than it would in others, would it not?

General GROVES. I think that follows naturally.

The CHAIRMAN. Of course, you know that the scientists who worked on this have a different estimate of the factors involved?

General GROVES. I know that some of them do, and I know that some do not. I believe that the answer to that really falls within how closely they were acquainted with the industrial problems with which we were faced in this country as opposed to how much of their time was devoted to the purely scientific phases.

I would also like to point out that when you say my guess may be in error—which I admit fully, naturally—it may be in error in the other direction. It may be that instead of this being 20 years it should be 40 to 50. A good many people who know and have been in some of these countries tell me they don't think they could ever build it, because they could never get, under their present system, men with courage enough to go in and make the mistakes that are necessary to produce such a thing as this.

The CHAIRMAN. I presume you would agree that no country of any size is holding back on this problem, and, for purposes of prestige and purposes of equalization, if you please, they are not sparing any efforts from here on. You don't think they will go about this lackadaisically, do you?

General GROVES. I have no information which would lead me to believe that they are pursuing it with the vigor that the United States pursued it, or anything approaching that vigor. They are still ap-

proaching it from the standpoint, you might say, of the attitude that was taken in Germany from 1939 until the end of the war. It has not reached, as far as I know, the point where anyone has started really to do anything. They are still talking and still working in their laboratories; they are still collecting scientists; they are not putting behind those scientists, or over them, or in front of them, the management and the engineering and the drive that are going to accomplish anything in a hurry. They are going to build up their stocks of fundamental knowledge, their basic science, and the things that build onto that science, so that later they will save some time; but they are not yet, as far as I know, making the determined effort that is necessary in this work to make it a success in a short time.

The CHAIRMAN. Haven't I read something in the papers about England starting a plant?

General GROVES. You have read a good deal of discussion, and it depends on which paper you read; but as far as I can tell and as far as I know, and I think my information is accurate, England has not yet made any step comparable to what we did.

The CHAIRMAN. You stated that we could keep several steps ahead, and I think we ought to make it clear for the record.

As Senator Hickenlooper said, they don't have to go ahead of where we are now to make it somewhat uncomfortable.

General GROVES. I am glad you brought that up, because I meant to comment on that, and that is that in this affair it certainly will not do us any good to be a few steps ahead if they are right up behind us and they have enough; so it is not sufficient just to say, "Well, we can always be ahead of them."

The CHAIRMAN. When you say, "Keep a few steps ahead," I presume you mean a bigger explosive and a bigger detonation?

General GROVES. Yes, one that may be cheaper and may be in greater quantity, particularly cheaper in production.

The CHAIRMAN. Of course, cost has never been a factor in the making of warfare. Isn't that true?

General GROVES. I think costs sometimes have a good deal to do with it. Our country has so much economic power, they have to decide what we will do with that power. In our case, during this last war, despite all of the economic power of the United States there had to be a military decision made by the President on the advice of his military advisers that the effort that would go into this project should be devoted to that rather than to something else. No country is rich enough to embark on such a project as this without realizing that it affects its economic structure.

The CHAIRMAN. Of course that theory does not hold water. There was Hitler. I remember that Mr. Miller, who was the financial attaché at the Embassy, made a speech in this country before the war that there wouldn't be any war because Hitler could not afford it.

The Kaiser was supposed not to have been able to afford it, either.

I don't follow your theory that cost or money has anything to do with the making of war.

General GROVES. Money does not as such, but the economic power does; and when I speak of that, I speak of the factories, the raw materials, and the labor.

The CHAIRMAN. Wherever they are found in abundance, plus a determination to proceed, you have a situation on your hands in which

there are unknown factors, of course, but nevertheless you can come to the conclusion they are going through as far as they can.

General GROVES. I have no doubt but that they will go through if they decide that they want to, and then it is just a question of how soon they can. I also understand that most of these nations state that they are unable even to subsist without money from the United States, so it is a little difficult for me to see how they can embark on something of this scale so blithely.

I think they have to consider how they are going to handle this, how much they are going to reduce the rations of their people, and possibly how much money they are going to have to borrow from the United States to build these plants with which to attack us.

Senator HICKENLOOPER. Have you finished, Mr. Chairman?

The CHAIRMAN. For the present, yes.

Senator HICKENLOOPER. May I ask the General a question?

Let's assume that some other nation or other nations, no particular nation, could build pilot models and experimental models in which they could produce small quantities of this fissionable material.

Does it necessarily follow that because they can produce these small models in fairly sizable laboratories, for instance, that they can thereafter easily go on and build quantity production models with any great speed?

General GROVES. Not unless they are a lot smarter than we were.

Senator HICKENLOOPER. In other words, there is a difference between the experimental models that produce very small quantities and the quantity production plants that produce this material in sufficient quantities to be usable as an explosive?

General GROVES. There is a great difference, and I think you saw at Clinton the preliminary pilot model for the Hanford Engineering Works.

Senator HICKENLOOPER. Yes.

General GROVES. Now, the difficulties in the problems that we were faced with there in the Hanford Engineering Works are just not comparable. They merely sort of gave us a little guide as to what might be done.

Senator HICKENLOOPER. In other words, when you built the pilot model you certainly did not know how to advance to production?

General GROVES. It was like having a headline to a newspaper story that was going to run three columns and you had the headline only.

Senator HICKENLOOPER. Reverting to the question of our keeping ahead of other nations, I assume that if they reached a point of production of this material that we have reached today they would be producing bombs that could blow our cities to pieces.

If we went forward from today, on the basis of knowledge that we have, it is reasonable to assume that the main advantage we might get from the scientific development would be, perhaps, an exploration of the field of new and different materials that would be fissionable and possibly, although it may be remote, the discovery of some more adequate defense against the atomic bomb. Is there experimentation and development along those lines?

General GROVES. I think that at the present time we have merely scratched the surface of knowledge, and we are in the same position

as some other sciences were a few hundred years ago. For example, in the lifetime of all of us we have seen the tremendous advances in the equipment for medical services. If you go to a doctor's office now, he has everything that is necessary to make a good guess, at least, as to what is wrong with you, whereas formerly, a hundred years ago, he did not have those facilities.

We are now in the same position in this field that medicine and medical treatments were in several hundred years ago. We don't know, but maybe we have gone a lot beyond that point. Maybe we have learned everything, but we have no reason to suspect so, because the more we work the more we learn things. We have not reached any slowing down on learning.

Senator HICKENLOOPER. It is interesting to note that we have not developed any defense, figuratively speaking, against the slingshot except to go farther away or put up a wall; but they can still throw the missile over it.

General GROVES. We can always, of course, if the world should ever get into such a horrible position, disperse. It would be a terrible thing economically to have to live in an armed camp. What we hope, at least I personally hope, will come within a reasonable length of time is a freedom which such wars; but I don't believe that freedom will come by ignoring the tremendous impact of this as a military weapon.

Senator MILLIKIN. Mr. Chairman, may I ask a question, please?

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. General, roughly how many separate items go into the making of one of these plants? Is it in the order of thousands?

General GROVES. Well, many, many thousands. I think the best answer to that, that really gives you what you want, is that at the Hanford Engineering Works, the Dupont Co. had over 10,000 sub-contractors, each of them supplying a different material and not raw materials or basic materials. They were supplying subassemblies, you might say, as if they were in the automobile business.

Senator MILLIKIN. Each one of those items involves a technique that is the result of long experience and oftentimes of exclusive "know how." Is that not true.

General GROVES. I would say not each item, but a great many of them. In fact, of the 10,000 probably 50 percent at least required special "know how." Some of them required "know how" which with all of the power and knowledge of American industry, took us more than 18 months to learn.

Senator MILLIKIN. In many cases you took advanced technology that made them advance still further.

General GROVES. Advance much further, and far beyond what they thought was practicable. I think a good answer to that, in clearing up that point, was a statement made to me by a gentleman I met some months ago who manufactured a certain type of material which is in common use, but in the normal plant you use, say, 100 pounds of it a year, which would seem a large consumption. This gentleman told me he received an order from the Hanford plant which instead of being 100 pounds per year might be said to be 10,000 pounds per year. He replied and said, "You don't need this; you are throwing away,

Government money; why do you need it," and the answer came back: "Supply that material."

Without the 10,000 pounds it would not have worked, because you cannot, in this complicated affair, use certain materials when you need a higher grade. They just will not work.

Senator MILLIKIN. Would it be correct to say that thousands of these items represent a reflection of technological skills that have been built up in this country for many, many years, in many cases for many generations back, not only as to the particular firm that is making the item but the workmen and the craft traditions that have been passed on?

General GROVES. I think the answer there would be not only thousands, but probably tens of thousands of items.

Senator MILLIKIN. Leading now to the end point toward which I am driving, anyone that wants to do the same thing has either got to duplicate that same technology in that same way, or possibly in an expedited way as much as it can be expedited, or borrow it or assemble it from around the world. Is that correct?

General GROVES. That is correct.

Senator MILLIKIN. Either way of doing it would be a difficult way of doing it, would it not?

General GROVES. Yes, sir; unless they had world support for doing it.

Senator MILLIKIN. And it would require a long, long time?

General GROVES. I believe so; yes.

Senator MILLIKIN. With a rather technical and highly skilled overall direction which in itself, you suggest, may be lacking?

General GROVES. There is nothing that is harder to get than competent management, I think, as everyone who has tried to operate knows, and not only top management, but down below in what would normally be termed the subsidiary positions.

Senator MILLIKIN. If a country that figured on making this bomb commenced to reach out and pull in scientists that specialized in atomic energy, and if they started buying specialized machinery here, there, and in other places over the world, we would find out about that in the normal course of events, would we not?

General GROVES. We would. That comes back to the point I stated, that if they went out and told the whole world, it would be 5 to 7 years; but if they tried to do it all themselves, it would probably be 20.

I think there is another point there which will clarify it. I have discussed just how a nation would proceed on such a thing. I believe the first thing they would do would be to start educating their workmen and their management so that they could operate such an affair. Now, you cannot pass on the ability and the skill of management, or of scientists, or of any other highly skilled workmen, in, say, 5 years, and then liquidate the men—because you never know what problem is going to come up. You cannot pump a man dry unless it is something that is simple, like a formula.

I believe that certain formulas, for example the one for bitters, have been kept in the family as a trade secret, and no one has achieved the knowledge of that secret. That could probably be told in half an hour, but you cannot tell the secrets and the knowledge that are necessary to operate a thing like this in half an hour or in half a cen-

tury. You have got to build up your men and build them up so that they have the capacity to do the job.

Senator TYDINGS. General, assuming that in any one of the big nations the funds were available, the material was available under reasonably conceivable conditions, and with a degree of good fortune in discovery, we will say, how long would it take any of the leading nations in your judgment to reach the point that we have reached in this country with reference to the atomic bomb?

General GROVES. Depending upon which country you take, because there is a wide variation between them—

Senator TYDINGS. I didn't want to take one particularly, for obvious reasons, but say any of the three or four leading countries.

General GROVES. It would depend on what knowledge they had and what their industry was. In a country in which people were interested in it, if they did it in complete secrecy, it is my opinion it would take from 15 to 20 years; if they did it with the help and assistance of ourselves, England, and Switzerland, they could do it some 5 to 7.

Senator TYDINGS. Your guess would be, as between those two propositions that it looks as if you have a margin of safety in some cases of, say, 12 to 15 years?

General GROVES. Yes; I think that in any case we have a period of at least 5 to 7 years in which the problems of the world can be settled to such an extent that we won't immediately start dropping these bombs on each other.

The CHAIRMAN. Senator Tydings, before you came in, the general testified that was a guess.

Senator TYDINGS. I understand.

General GROVES. There is a more complete discussion, Senator, in the record.

Senator MILLIKIN. Mr. Chairman, I would like to pursue that just a step further.

Aside from Switzerland, Sweden, Belgium, France, what other nations could help a nation?

General GROVES. England.

Senator MILLIKIN. England, I assume, is with us.

General GROVES. Those are the principal nations, and I believe that you can almost limit it to the United States, England, and Switzerland, with possibly Sweden. It is the machine industry that is necessary. Certain things could be done in Switzerland or in the United States that cannot be done easily elsewhere.

Senator MILLIKIN. France used to make a lot of small items of various kinds.

General GROVES. Yes; and Switzerland has also been a center of high-grade machine tools of special design. You find a great many of them in this country, particularly in any plant that has been in operation for a number of years and has accumulated a number of special Swiss machines.

Senator MILLIKIN. Do you think of any other countries? I think we ought to have that pretty clear on the record.

General GROVES. I don't know what was taken out of Belgium and France by the Germans. Those two countries could supply certain assistance, no doubt, and I believe they would if they were paid for the assistance.

Senator MILLIKIN. Did you say France and Germany?

General GROVES. France and Belgium. Germany, of course, could supply technicians, management, engineers, and scientists.

Senator HICKENLOOPER. Doesn't Czechoslovakia have a highly developed machine industry?

General GROVES. It has certain things.

Senator CONNALLY. Mr. Chairman, I want to ask a question.

General, it is not your fault, because you have been prodded into it by members. I think it unwise to take up each one of these countries and particularize and estimate how long it would take. It might indicate an intention to have a contest with them, or cause some unfavorable reaction.

I submit that to the chairman as worthy of consideration, at least.

The CHAIRMAN. It might be better, I think, Senator, if we generalize.

General, we have no compact with any country mentioned whereby the country has agreed not to proceed either to do it themselves or help anybody else, have we?

General GROVES. I think anything of that kind I would prefer to discuss in closed session, sir.

Senator HART. May I ask a question, Mr. Chairman?

The CHAIRMAN. Certainly.

Senator HART. Following that same subject of your estimate, you did not mention supplies of raw materials as being in the picture. Is there anything that is not already in the record that you would like to say on that point?

General GROVES. Not in an open hearing, sir; and I would like to make it clear, Mr. Chairman, particularly in view of the presence of newspaper people behind me, that the fact that I would prefer not to discuss certain things in open session does not mean there is anything there, because either affirmation or denial is something that I would prefer to avoid. The fact that I have said I prefer not to answer does not really mean I know the answer. That is important for the benefit of the press, sir.

The CHAIRMAN. We have gotten to this point, General. I think it is safe to say that we have no such agreement with Switzerland, for instance, not to engage in it or experiment. I think it is well for people to know that.

Senator MILLIKIN. I would like to say, for the benefit of Senator Connally, that I opened this subject of nations that might be in a position to contribute material for the making of the bomb without reference to any particular nation, without having as an end purpose an alignment against any nation, and it seemed to me it was very important that we know in our consideration of this problem just who is in a position to give effective help in the construction of an atomic bomb.

There was no reflection on any country; there was no insinuation or implication on my part that it might be used by or against any country.

Senator CONNALLY. My attention was attracted to the fact that you mentioned a whole lot of countries and left out some. I submit that it doesn't require a hand pointing to a sign that this is the so and so country, because by elimination anyone could determine what country you are talking about, and that is what I am objecting to.

Senator MILLIKIN. Senator, I am objecting to the proposition of smothering simple, open facts of what nations are in a position to contribute to the making of an atomic bomb.

Senator CONNALLY. We don't expect them to contribute to us to make an atomic bomb. We are going to have to make them ourselves.

Senator MILLIKIN. I think it is agreed that if anyone else makes them, we will lend the money to make them.

Senator HART. I would like to observe for Senator Connally's benefit that the questions were altogether founded on the state of industry in these various countries.

Senator CONNALLY. The state of industry in manufacturing automobiles or bombs? We are talking about bombs.

Senator HART. No; the general industry.

Senator CONNALLY. Bombs are what we are supposed to be investigating.

Senator HICKENLOOPER. I have a great deal of faith in General Groves' discretion, which I think he has proved, and I don't think General Groves would answer anything he thinks is detrimental to the public interest. Therefore, I felt perfectly free to ask him such questions as he would care to answer, and he has answered them.

Secondly, I believe that the answers elicited about these various countries are probably as well known to every other country in the world as they are to any of our people, and I could see nothing dangerous or inimical to our interests in either the questions asked General Groves or his answers given.

The CHAIRMAN. General, this weapon is not just a new weapon of war, is it?

General GROVES. I don't follow the question, Senator; I am sorry.

The CHAIRMAN. Well, there has been some statement made that this is just a new weapon of war. I know you don't agree with that.

General GROVES. Oh, I think the term usually used is that this is "just another weapon."

The CHAIRMAN. My mistake.

General GROVES. Anyone who says that, with all due respect to whoever he may be, is just ignorant of the power of this weapon; and I think the more people think about it the more they realize the importance of this and that it is not just another weapon. I think they realize that it ended the war with Japan, and sooner than it would have been ended otherwise, and that if we had been able to drop it sooner it would have ended the war just as promptly.

The CHAIRMAN. In other words, it can be a decisive weapon of war.

General GROVES. I don't know that any weapon is decisive, excepting the will of the country to continue to fight, when that is broken. But as a weapon, it is very important.

The CHAIRMAN. In view of that statement, do you not think that your former statement that you can see no desire upon the part of other nations to go ahead with this is perhaps open to some question?

General GROVES. I didn't say that I didn't see any desire, I believe. At least, that was not my intention.

I said, or wanted to say, that I did not know of any nation that was now really going after it hard, but that they were still proceeding along the lines of laboratory research on a limited scale and had not done what we had done, which was to attack this problem with real

vigor as if they really meant to get somewhere. They are still wandering around, discussing and arguing as to what is the best method.

They have given wild estimates, such as an estimate that appeared recently from a very distinguished gentleman of one foreign country, to the effect that any nation could have this bomb within 6 months.

Well, I just say that that is an absolute impossibility. It is that kind of discussion that is going on.

The CHAIRMAN. That was Professor Oliphant of England.

General GROVES. That was the press report that came over.

The CHAIRMAN. Well, he wrote an article of recent date in Nature, which is a British scientific magazine.

He is the fellow who discovered the basic tube that made radar possible, is he not?

General GROVES. I don't know much about his career at that time. He is a distinguished physicist and a man of tremendous scientific ability.

The CHAIRMAN. He did; he discovered the basic principle of the radar tube. It was his statement that you referred to.

General, I understand we killed about 500,000 people in areas in Germany, and of course pretty well wrecked her desire to fight, with the air attack.

Reverting to your testimony of yesterday that if we killed 40,000,000 people here you thought the war could still go on, do you think we would be able to wage effective war with 40 of our cities laid waste and 40,000,000 people killed?

General GROVES. I think we would wage war for quite a while on that basis if we still had the will to win, and I think anyone who travels over the United States and knows the strength of American industry and the ability of Americans feels that we would continue to fight for a long time.

I think the war years of 1861 to 1865 show that the American people do not stop fighting, no matter how hard they are pressed or what the conditions or the odds are. I don't think the Americans have changed much since that time.

The CHAIRMAN. Of course the 40 cities would contain the bulk of our industrial industry. Wouldn't that have some effect on the ability of the Nation to wage war?

General GROVES. It would have a tremendous effect, and I did not want to say yesterday that it would not make conditions very hard for us; but I did wish to make the point that we could still go on fighting and that we wouldn't necessarily quit. I don't know just particularly when we would know what we were faced with. If our people have courage we are not going to stop just because of somebody destroying a great deal of our potentialities. We would always be faced with the problem, "Is it worth while to go on?"; but England was faced with that problem and they decided to go on. It was the courage and determination of a few people in England that carried that balance over. Maybe if they had all been willing to quit they could have quit very easily.

The CHAIRMAN. General, do you want to give us some cost figures for the record on these various projects?

General GROVES. I can give you general cost figures, I think. I do not remember those figures exactly, because they are rather large. If you want to give me a little time to hunt, I will try to hunt fast.

The CHAIRMAN. Perhaps you can furnish those for the record. We would like to have those inserted in the record.

General GROVES. All right, sir.

(The following statement was subsequently submitted by General Groves and made part of the record:)

MANHATTAN ENGINEER DISTRICT GENERAL OVER-ALL COSTS

1. Diffusion plant

(a) The cost of research and construction of the diffusion plant was approximately \$545,000,000, of which about \$45,000,000 was spent on research by various plants and universities. The one major university working on research was Columbia, and the amount expended there was approximately \$11,500,000.

(b) The monthly bare costs of operating this plant under the initial conditions have been approximately \$6,000,000. These costs should increase appreciably as the plant continues in operation. (These costs do not include the cost of Government-supplied materials or the indirect costs of housing and transporting employees.)

2. Electromagnetic plant

(a) The cost of research and construction of the electromagnetic plant was approximately \$350,000,000, of which about \$33,000,000 was spent on research with various plants and universities. The one major university working on research was California, and the amount expended there was about \$14,000,000.

(b) The monthly bare costs of operating the entire plant have been approximately \$12,000,000. These costs should decrease appreciably in the future. (These costs do not include the cost of materials supplied by the Government or the indirect costs of housing and transporting employees.)

3. Metallurgical, Argonne and Clinton Laboratories, and other institutions

(a) The total expenditures on the activities at the Metallurgical and the Argonne Laboratories through June 30, 1945, were about \$17,000,000, of which about \$550,000 was spent on construction at Argonne. (These costs do not include the costs of materials furnished by the Government.)

(b) The total expenditures on the activities at the Clinton Laboratories through June 30, 1945, were about \$25,000,000, of which approximately \$12,000,000 was spent on construction. (These costs do not include the cost of materials supplied by the Government or the indirect costs of housing and transporting employees.)

(c) The total expenditures on related and closely coordinated activities at other institutions to June 30, 1945, were approximately \$4,000,000.

(d) The cost of production of metallic uranium at Iowa State College (where production of uranium ingots continued until the spring of 1945) amounted to about \$2,000,000, not including the cost of raw materials furnished by the Government.

4. Hanford engineer works

(a) The total cost of the Hanford engineer works, including housing facilities, is approximately \$350,000,000.

(b) The present operating costs are about \$3,500,000 per month. (These costs do not include the costs of certain materials furnished by the Government.)

5. Los Alamos laboratory

The total expenditures on the activities centering on Los Alamos laboratory have amounted to about \$60,000,000, of which about \$26,000,000 was spent on construction. Military pay is not included in these figures.

6. Housing

(a) Oak Ridge: Expenditures on housing facilities, including necessary roads, utilities, schools, and shops, at Oak Ridge total approximately \$110,000,000.

(b) Hanford: The total construction cost of all housing facilities at Hanford was approximately \$48,000,000.

(c) Los Alamos: The total cost of housing of all types at Los Alamos was approximately \$4,500,000.

7. Industrial accidents

(a) The cost to the project of industrial accidents to workers and their subsequent care was about \$1,441,000 up to August 31, 1945. This cost included com-

pensation benefits, medical payments by insurance companies, and that portion of plant medical operating expense assignable to industrial accidents; it is broken down as follows:

(1) Total cost in connection with construction:

- (a) Compensation benefits, \$1,577,000.
- (b) Medical payments, \$757,000.

(2) Total cost in connection with operation:

- (a) Compensation benefits, \$938,000.
- (b) Medical payments, \$1,169,000.

(b) The total accident experience of the Manhattan Engineer District is 62 percent lower than comparable experience of private industry. The National Safety Council's "Award of honor for distinguished service to safety" was presented to the Manhattan Engineer District on December 9, 1945, in recognition of the record made "in achieving and maintaining low accident rates at the Manhattan District facilities throughout the country under the urgent demands for speed in the unique processes attending the development of the atomic bomb."

The CHAIRMAN. General, what are the prospects for the development of bombs of considerably greater destructive power than those produced so far?

General GROVES. I think I can answer that one. It is a little hard to answer in open hearings, but I think it is of sufficient importance so that it should be in the open.

The CHAIRMAN. I asked the question, General, on the basis of the preliminary conference we had in which you said you thought you could answer that question.

General GROVES. I think—and I am speaking now primarily on the basis of the normal course of development, and not on any basis that there is something we know and have not disclosed or anything like that—we have built and fired three bombs. We have done this in a hurry. Our mission was to get a bomb that would go off with power. When we first started, various people talked about enormous sizes. In order to get the thing done, I stated that our goal was to have a bomb that would be the equivalent of at least a thousand tons. That was not the goal; that was the bare minimum.

Senator JOHNSON. Was that a thousand tons of TNT?

General GROVES. The equivalent; yes, sir. As announced by the President, the bombs were of the order of 20,000 tons of TNT.

Initially we all thought we could get something in the order of 10,000 tons of TNT, and I believe that I stated that the various scientists, as they started to work on this and started to wonder about how sure they were of their figures, kept putting in factors of safety, so when we came out at the end some of them even thought it would be below a thousand tons; but it actually had about 20,000, or in that order.

Senator TYDINGS. 20,000 tons equivalent?

General GROVES. Yes, sir; they are always equivalent.

Now, as to the prospects of developing bombs of considerably greater destructive power, I think they are promising; but I would also like to point out that when you go beyond this size of bomb you start to wonder where you are going to get a target that will require the full effect of this bomb. At Hiroshima we had such a target. In other words, it landed and there was space enough so that all of its destructive energy could be used. At Nagasaki we did not have that opportunity. We had a long, narrow target, and the bomb was bigger than it had to be. There was a lot of wasted energy that went off to the sides. If you remember how that river looked, the width of the

target varied. I think there were some points where there was actually no development at all.

Senator BYRD. Were the two bombs of the same power?

General GROVES. They were of the same order; yes, sir.

Senator BYRD. You would say the same amount equivalent of TNT.

General GROVES. Yes, sir. No one knows what the exact amount is. We made an attempt to determine it, but you couldn't prove it. We have not discussed, Senator, the bombs in detail, and I would prefer not to discuss them in open hearings.

Senator CONNALLY. General, does the power of the bomb increase in proportion to the size or amount of material in the bomb?

General GROVES. I don't mind answering that one here.

Senator CONNALLY. Leave it to secret session, if you like.

General GROVES. I would like to leave most of it in secret session, but there is one thing that I think should be made known, and that is what happens in an explosion anyway.

What really happens is that you develop an explosive force, and then that blows apart.

Now, the question is if you put too much material in there it doesn't all explode because it is blown apart before it has an opportunity to explode, and there is a definite limitation on just saying, "Well, you made one bomb of this size; let's put two of them together and have twice as much material and we will have twice as big a bomb."

Senator CONNALLY. If you have any hesitation, don't answer any of these questions; but there was an old theory of chemistry or physics of which I have a very hazy recollection, that you don't get any more power out of something than you put in it. Is there in these atoms a latent power that is just there that needs touching off? I am speaking industrially now, more than about this theory of ruining everything with bombs; automobiles, and everything. Do you get any more force out of the bomb than you have to put in it through all these manufacturing processes and expenditures of fuel and energy and so on? If that is a secret, don't tell it.

General GROVES. I don't know the exact answer because I have never figured out how much energy we put into it; but I think it can best be expressed by this illustration: If you dig coal you get a certain amount of heat out of that coal. Whether you used up more or less energy in digging that coal, what you would get out of it would remain the same. In other words, there is something in here which if we start to explain would be getting us into some of Einstein's theories and a few other things which I would find trouble in explaining, and I am sure you would not be able to understand my explanation. Essentially there is something that is already there which we take advantage of. We don't compress this energy and put it all in one package as it were; it is there.

Senator CONNALLY. Well, it is the old idea of the indestructibility of matter, on which I was basing my question.

General GROVES. This might be based on the theory of the equivalence of mass and energy.

Senator CONNALLY. That explains the whole thing to me, General.

Senator RUSSELL. General, the papers tell us that some of the scientists are of the opinion that if a large number of these were exploded over the world that it would reach out into the elements in the atmos-

phere, and any other elements, and start splitting atoms there which would set the entire world on fire, and instead of being a world we would just be a new star and all life on the planet would be extinguished almost automatically.

Do you have any theory on that to give us?

General GROVES. My only theory is that I don't worry about it, because if it happens it will be all over and we won't have that to worry about. We won't have to explain that one, but the theory is not concerned with getting a number of these bombs but with getting one that is big enough to do that. No one knows what that size is. It is all highly theoretical.

The CHAIRMAN. That is where this thing was 3 years ago?

General GROVES. That is correct, but 3 years ago there was an agreement among the better nuclear physicists that these theories were correct. I don't believe there is that agreement now. It is more or less the kind of thing that they will discuss as a possibility when they are just sitting around talking; theoretically they may be able to prove that such a thing is possible, but the best advice I have, and I certainly don't hold any personal views or knowledge on the subject, but the best advisers tell me that they are not a bit worried, and I, personally, am not worried. I feel it will be beyond my lifetime, and then I will let the next generation worry as to whether they are going to blow themselves up or not.

I think there are many other things that a crazy man who had power behind him, and who got enough crazy people with him who all wanted to commit suicide, could do to destroy life on this earth as well as by this means.

Senator RUSSELL. There is one other question. Yesterday you implied that you had some doubt as to the practicability of a thorough world-wide inspection or checking on the production methods or use of atomic energy. Is that due to the difficulty in exploring all the places where this energy might be developed, or just on your opinion that the people would object so strenuously to the measures that would be necessary that it would be impossible?

General GROVES. I believe it is both. In other words, if the people object too strenuously they can stop thorough inspection. This country has never been able to have thorough inspection on certain things.

Senator TYDINGS. Prohibition is a good illustration of that.

General GROVES. So are the moonshiners in certain sections of the country where you might say the people were not so solidly against the Government as they were with prohibition, but you have that problem and also it takes such an awful lot of people.

I didn't say yesterday that inspection wasn't something that should not be done. I pointed out the difficulties of it because I did not like the idea of anyone feeling that it was something that with a wave of the hand you could accomplish and have effective inspection.

I do not believe that it is safe to say that inspection gives us a 100 percent guarantee. It is just like all inspection of all kinds. It is the reason that an airplane on reconnaissance can tell you if they see something, but they can't tell you something isn't there if they don't see it. That is true of everyone who is out looking for things.

Even in the days when cavalry was of real importance in this world of ours, we had to have infantry go behind the cavalry to make certain

the cavalry had not missed some of the military information that we wanted to have. You have got to look at every foot.

In this case you have got to look much closer than is generally spoken of. You just cannot go to the big industrial plants and say, "What is going on here," and then walk out.

Senator RUSSELL. You have shown us various little gadgets where if you would hold some piece of some radioactive element you would have certain reactions. You don't think it is possible to have any machine or development expose the place where any work of this nature might be done?

General GROVES. No, I don't think that is possible at this time. You could get certain things, there is no question; but other things you could not get.

The CHAIRMAN. Those certain things would be necessary in order to make an atomic explosive, would they not?

General GROVES. No; I don't believe so, Senator. I believe that it could be fixed up. In other words, you could put shielding on certain things.

Senator RUSSELL. You don't think you could fly over in an airplane with one of these machines and tell?

General GROVES. No, sir. Just how much you can do with that no one knows. After all, we were faced with the practical problem a few years ago in trying to find out what was going on in Germany, and we had many theories presented as to how we could find that all out; some of the theories were good, but you could not do it. After all, you have got to have the men who are going to make the inspection come back. Certain things can be done by a general, broad inspection; but I believe also that there is one thing you could do to defeat broad inspection if you intended to. Certainly if you are going to conceal or try to get away with something, the first thing you would do would be to start fighting on the inspection method that was used.

Remember that all nations would probably find out what type of inspection methods were used, and then they would go out to beat those methods.

Senator RUSSELL. We have heretofore, I believe, used only uranium in developing this energy. Has any extensive research been made with other elements to determine whether or not it would be practicable to use them?

General GROVES. I think the answer to that is that our goal was to get a bomb, and we went after that goal and have done a considerable amount of research in trying to build up knowledge. We built this bomb with inadequate knowledge, particularly inadequate scientific knowledge. Every time we could guess at the answer, we guessed at it without knowing why that was the answer, and we have consistently tried to fill in those gaps in knowledge.

We are working on that today with the purpose of trying to know all that we can about fission.

There is a great deal of talk in various places about how ultimately you can split other atoms, and ones of more common material. They have talked about how fine it would be if you could split hydrogen and oxygen, and then nobody would have a monopoly on the air.

We don't know how to do that yet, and I don't think anybody even has a real glimmer of an idea. It may come in fifty or a hundred

years. I don't see it coming within a few years; if it does come, then that will be something to be faced by the people who are then responsible.

But we are not neglecting the advancement of science. We are doing everything we can to encourage it and to encourage it in our own laboratories and at our own expense.

The CHAIRMAN. General, is this material uranium radioactive in the ground?

General GROVES. Yes, it is to some extent.

The CHAIRMAN. Airplane surveys with a suitable detecting apparatus would register the presence of uranium on contact in low flight?

General GROVES. That would all depend on the shielding of the uranium on the ground. You see, when it is down in a mine or down several hundred feet, it is shielded by the earth in between. But it would also depend on the equipment.

No one that I know of has yet been able to locate uranium deposits by flying over them in low airplane flights.

If you put a piece of uranium in a room, you could probably find it if you could get up close enough. It is the same thing with some of your detecting equipment which is such that, when you hold a luminous dial in front of it, it registers, and the man who designed the equipment says, "That is a fine piece of equipment; look what it registers." Then I held my hand in front of it and it registered the same way. That is the size of it.

If you get apparatus that is too delicate then you find it goes out of order. It is one thing to have delicate apparatus in a laboratory where it can be very carefully protected from shock, and it is another to mount it in an airplane and send it through the air and really know what you are getting. You could get suspicions, but you would get a great many false suspicions.

I think eventually something may be possible on that, and certainly if I had any responsibility for inspection, it would be one of the methods of attack that I would take to try to get that knowledge. I think that eventually something can be worked out.

The CHAIRMAN. General, I have just one more question. If, perchance, by intense work it were possible to develop this process for central heating within the next 2 years, assuming that hypothesis, it would be impossible to use it until the international control problems were settled, would it not?

General GROVES. You mean to use it in the United States?

The CHAIRMAN. Yes.

General GROVES. No; I don't know of any reason.

The CHAIRMAN. You would have to put guards around it?

General GROVES. Yes, and I don't care whether it is under international control or not. I think you would want guards around it, for you have got too much money in there alone not to have guards, and real guards, too.

The CHAIRMAN. Thank you, General.

Senator CONNALLY. Mr. Chairman, I just want to say this: I think the general has made a very fine and splendid exposition of this matter and I want to congratulate him on the great work he has done in connection with the whole program and its development.

General GROVES. Thank you, sir.

The CHAIRMAN. I might say that the general has done a splendid management job in the last 3 years and has accredited himself most favorably.

Senator JOHNSON. Before the witness leaves, Mr. Chairman, I desire to say this: I concur in what the Senator from Texas has said.

But going back to the question of detection, this committee saw the finest instruments that science can devise within 12 feet of tremendous radioactivity, and the instruments were in no way affected. A dime was borrowed from the Senator from Iowa and inserted in that machine, and when it became radioactive and was placed near that machine, it went completely crazy.

Senator TRIDINGS. The machine or the dime?

Senator JOHNSON. The machine. That indicates to me, at least, that it is going to be pretty hard to detect radio-activity with any kind of device, because there you had a perfect example of the difficulties of it. Just a concrete wall shut it off.

General GROVES. I think I said earlier, particularly if I knew what the rules of inspection were, that I could hide the material so that the inspectors would not find it; I think that any nation would have enough representation on that body of inspectors so that they would know.

Senator JOHNSON. That is particularly true with respect to the material when it is reduced to a chemical compound, where there is very little or no radioactivity present?

General GROVES. I think in various portions of the process it would require less shielding, but the shielding is not an impossible task; I would rather undertake the shielding than I would undertake the separation, or, particularly, undertake the detection.

Senator JOHNSON. That is all, Mr. Chairman.

The CHAIRMAN. Thank you, General.

General GROVES. Thank you, sir.

The CHAIRMAN. Professor Urey.

STATEMENT OF DR. HAROLD C. UREY, PROFESSOR OF CHEMISTRY,
UNIVERSITY OF CHICAGO

Dr. UREY. My name is Harold C. Urey. I am professor of chemistry at the University of Chicago. During the war I was at Columbia University in the city of New York and was director of the SAM Laboratory. SAM was code for "SpeciAl alloyed materials," which in turn was code for the laboratory doing the research on the diffusion process for the separation of the uranium isotopes and for the production of heavy water and other materials. I did not work directly on the production of the atomic bomb but on materials used in its production. Altogether I have worked about 5 years on this problem.

The CHAIRMAN. I notice, Doctor, that you would not state it, but, for the record, I believe you are a Nobel prize winner.

Dr. UREY. That is right.

The CHAIRMAN. And that award was made upon the basis of your successful experiments on heavy water?

Dr. UREY. That is right.

The CHAIRMAN. In 1932?

Dr. UREY. Yes; in the fall of 1931, reported in 1932.

The CHAIRMAN. Thank you.

Dr. UREY. The Smyth report gives a history of the whole Manhattan project from the very beginning in 1939 to August of this year. This report is very well written and does not need expansion. It states what was done and by whom and when it was done. Hence in this testimony I shall not refer specifically to the various methods used or not used in the production of the separated isotopes of uranium or for the production of heavy water or their uses. Since all production figures, costs of production, comparison of relative advantages of various methods, etc., are classified as secret, it is impossible to say more about these processes than is already published in that report.

Suffice it to say that the diffusion method was very successful for the separation of Uranium-235 and that the exchange method was very effective in concentrating heavy water but that all methods for producing this latter substance were not sufficient to produce this material in large enough quantities for large-scale use. Exact figures on production and costs would better be secured from the Carbide & Carbon Chemicals Corp. and other operating companies rather than the director of research in any case.

If the committee will secure clearance for classified information I would be glad to appear before the committee again in order to discuss technical facts which it wishes to have and which I am competent to give. Today I wish to discuss the over-all situation relative to atomic energy and the atomic bomb as I see it.

One: Facts in regard to atomic energy and the atomic bomb.

Atomic energy is stored within the nuclei of atoms and has been so stored since the beginning of the earth, solar system, or universe, perhaps. It should be referred to as nuclear energy, but popular usage has probably fixed the term atomic energy in our vocabulary. The amount of energy liberated in the fission of uranium or plutonium is pound for pound about 3,000,000 times as great as in the case of coal burned in air. An improvement in a fuel or explosive by so much as 20 percent would normally be a remarkable one. The factor of 3,000,000 is so great that the significance is not comprehended immediately. We have some conception of what 1,000 miles is but no conception of 1,000,000,000 miles. Even a large source of power after decades of development amounts to about 100,000 times the power of a horse. It will be some time yet before the people of the United States really appreciate that on December 2, 1942, a radically new source of energy for peacetime purposes was first discovered and that on July 16, 1945, a radically new explosive first appeared. This latter event changes the entire military position of the United States, as well as those of all other countries and in fact makes the defense of this country more difficult.

Senator VANDENBERG. What is the significance of the date December 2, 1942?

Dr. UREY. That was the first time that a spontaneous pile producing heat steadily without explosive characteristics was produced at the University of Chicago.

The atomic bomb which fell on Hiroshima destroyed what was reported to be 4 square miles of the city. The area of total destruction in the case of Nagasaki was reported as 10 square miles. If the third bomb of this type to be exploded was a definite improvement on the

first and second bombs we may confidently expect considerable improvements in the future.

The CHAIRMAN. Improvements, Doctor?

Dr. UREY. It depends on how you look at it. If 10,000 bombs were made and each were properly placed and if each should destroy 10 square miles, these bombs would completely destroy about the entire area of the States of Indiana and Illinois. This weapon transcends all other weapons in destructive capacity.

Scientific men have repeatedly stated that there is no defense against the atomic bomb and that there cannot be any decisive defense. Such statements come from men who have studied offensive and defensive military devices throughout the war. However, such studies are not necessary and probably are not as convincing as observations on other weapons for which defenses are known. A defense is known for machine guns, for example, armor plate; nevertheless machine guns accounted for many casualties in this war. Defenses are known against submarines; nevertheless they sank large tonnages of ships in both the Atlantic and Pacific Oceans. Defenses against airplanes are known, but they destroyed the cities of Europe. And thus we could tabulate many weapons both great and small. Similarly, we may expect countermeasures to the delivery of atomic bombs and countermeasures to the countermeasures, but in spite of this the atomic bombs will do damage in future wars commensurate with their destructive capacity.

In another way we cannot even expect as good defenses against atomic bombs as against other weapons. Forts, trenches, tank traps, armor plate, armored ships, and planes are able to absorb some punishment from the weapons used against them in warfare as it was before July 16. It is not to be expected that such defensive measures against atomic bombs can be taken except at expense so great that they could not be applied to all the vital points or to all the population of a country.

It is necessary to accept the fact that there is no decisive defense against the atomic bomb.

The atomic bomb could be smuggled into a country and used to mine our cities unless we practiced the greatest vigilance, so great in fact that our liberties would be seriously curtailed.

The bomb could probably be delivered by plane, rocket, pilotless plane, or other means. It could surely be delivered in ways that would not disclose the military power from which it came. It would be delivered from points at considerable distance from the target.

Atomic energy for peacetime purposes is possible but it is not developed to so great an extent as the atomic bomb. For peacetime uses we do not wish to secure the three million-fold effect that was attempted and secured in the bomb. Though small amounts of fuel will be required, industrial power uses will still require apparatus of the size and complexity of steam generation plants and the cost of securing power from atomic fuels will probably not be less than that for power from coal for some time. Power for special purposes such as for naval vessels, where competitive costs are not so important, will undoubtedly be the first practical application of atomic power. Many other uses as tools for research, and many techniques and devices of use throughout industry will be possible and will surely become available if ade-

quate effort is put into this side of the problem. However, I believe that the whole peacetime use of atomic power does not have comparable importance to us as a nation nor to the world as a whole as does the problem of avoiding the use of atomic bombs. I believe we could well forego the large industrial power developments of atomic energy if this would aid, as it may, the control of the atomic bomb.

Two: The course of a probable armament race and the subsequent war.

I wish to present the probable future course and development of atomic bombs, assuming that no prohibition of the manufacture of such bombs on an international scale is introduced and also assuming that a war does not break out during the course of the development.

In the first stage of this development we shall have bombs but no one else will have them. This is the present situation. We feel safe and secure, but the people of other countries do not. We know that we have no intention of attacking other countries, but they probably cannot be expected to take us at our own evaluation. If the situation were reversed we would be very much alarmed and with good reasons. Others undoubtedly are alarmed now and believe they are alarmed with good reason, too.

In the second stage we shall have a fair-sized stock pile of bombs and other countries will begin to get a few bombs. Ours will be the best unless the scientists and engineers of other countries discover and develop some better ideas that we may have overlooked. In this stage we may have sufficient bombs to destroy the cities of any probable enemy and they will not be able to retaliate. I cannot help but wonder whether we shall be as harmless at that time. Surely other countries will hardly think so.

In the third stage both we and other countries will have sufficient bombs to destroy each other's cities—and by and by all will have about equally effective bombs.

As this situation develops tensions will increase slowly at first and finally beyond anything we have ever seen, or experienced. In a few years we will begin moving our families far from big cities and industrial plants if we can afford to do so. Finally, every ripple on the international scene will make us wonder whether the atomic bombs may not arrive before morning. Testifying before a Senate committee is an unusual experience for me but it will be much more exciting when this building becomes an important and probably target for atomic bombs in that future war. Of course a scientific laboratory would be an important target, also. But probably the most important targets will be those that result in the killing of the greatest number of people.

The CHAIRMAN. You aren't inferring that if they landed one here we are the most important people?

Dr. UREY. Well, the scientific and governmental leadership of a country is very important indeed, and perhaps my estimate is not quite right. This, I think, will be one of the important targets in a future war.

We might start such a war, or another country might attack us. In either case the country attacked would probably have concealed the launching sites for its atomic bombs and hence would be able to retaliate and destroy the enemy's cities. So with all cities destroyed

on both sides we start a war with ordinary weapons and finish it in that way. Of course an enormous supply of material would have to be accumulated before the war, for with industry crippled it could not support the war while it was being fought. Unless great care were taken we would have lost our governmental, industrial, and scientific leaders. But I could go on with this for a long time and that would be unnecessary since none of us know just what course such a war would take. However, any course that it took would be disastrous for victor and vanquished.

But we have the atomic bomb and hence hold a trump card. How should we play the hand? Where can we interrupt this fatal chain of events most effectively for our own selfish advantage and perhaps to the advantage of every other country? The obvious answer is at the end of the first stage when we have lots of bombs and others do not, if we can judge exactly when that will be. We can blow the enemy's cities off the earth and take possession of the earth, occupy it with our armies, and begin the job of running the world according to our own ideas. This is a large order and one that I should like to avoid. In fact, I would stumble into it only by mistake or be forced into it only by overwhelming necessity.

My choice of time to do something about this threatening series of events is now or preferably 3 months ago, if it were only still possible. Atomic bombs must not be made by any country and they must not be stored any place in the world if we are to have any feeling of security in this or any other country on this all-too-small planet. We are making bombs and storing them and are thus a threat to other countries and are guilty of beginning the atomic armament race. If continued it will lead to dire disaster.

Three: The problem of control.

Can we control the atomic bomb by agreement between sovereign states? Japan armed herself and fortified islands of the Pacific in violation of her promises. Germany did similar things. The whole course of the League of Nations, which was a series of agreements between sovereign states, showed how ineffective such methods of control are. I would not trust the word of any foreign power if it stated that it would not make atomic bombs and I most emphatically would not expect any foreign power to trust this country. I believe that we would live up to our agreement, but I would not expect that others would believe it. And as time moves on, circumstances and people change and a time will come when abrogation of treaties will occur or treaties will be ignored or even used to deceive other peoples. I do not believe that this type of control is feasible for political and historical reasons.

Could we turn the bombs over to the United Nations Organization for safekeeping or use in emergencies? I would suppose that other countries might insist on some atomic bomb plants and their extensive accessory plants being located in other countries than the U. S. A. Also they would probably suggest that bombs be stored in other countries than ours. Also the big powers would insist on equal numbers of bombs in each of their countries or on some 5-5-3 formula. Or perhaps bombs could be stored in central Africa. In this case we would all become afraid of central Africa. I believe that there would be no satisfactory place to store bombs.

Also bombs would not be useful in an emergency. I cannot see how bombs could have been able to have solved the Spanish, Ethiopian, Manchurian, Czechoslovakian, and other troubles with which this war was begun. Further, we now have a supply of bombs. How could they be used in the Indonesian difficulty or the Chinese civil war? These bombs could have been used to destroy Madrid or Rome or Tokyo, but no one would have given such orders when the difficulty started. Only when the lines are drawn and the war ready to start could the atomic bombs be used and then an atomic-bomb war would come. Perhaps not so suddenly as otherwise but it would come nevertheless.

I believe that we should attempt to establish a control over atomic energy under the United Nations Organization which would be so effective that no person or group of persons in any nation could manufacture atomic bombs without detection and without being brought to trial and punishment. This means a sacrifice of some of the national sovereignty of this and other countries. I would rather submit to this, with police officers armed with sidearms able to arrest me for violating a law not to make atomic bombs, than to be threatened along with an entire city with destruction by atomic bombs from United Nations Organization planes for a similar violation. Also, I believe either of these would be better than an atomic bomb war. Of course the control must cover all countries of the world.

I believe that it would be technically feasible to determine whether a country as large as the United States were making atomic bombs, providing that inspectors could ask any questions and receive answers to them, could visit any scientist or engineer and see his work, inspect any plant or facility that they desired. It would be necessary to watch the movements of scientists and engineers, mines, ores, special materials and types of apparatus, and the appearance of any new developments. The existence of the Manhattan project and its general purpose were probably known by thousands of scientists in this country, and the extent of the operations and state of advancement would have been known had they been allowed to receive answers to questions. An inspector might have asked where any of dozens of prominent scientists were; and if he were told and then visited any of these, he would soon have learned what was being done and the approximate state of the work. Of course, any refusal of the privilege to visit or inspect personnel or facilities would be a suspicious act and also lead to disclosure. Covering up activities on such a broad scale would be very difficult.

In considering the problem of control there are two assumptions that might be made: First, that there would be no peacetime large-scale power plants; and second, that peacetime power plants would be permitted on a large scale.

Senator VANDENBERG. You mean power plants with atomic energy?

Dr. UREY. That is right. In order to secure power for industrial purposes from atomic energy, it is necessary to have very large scale plants. If these large-scale plants were all in existence, as they might be some 10, 20, or 25 years in the future, they would contain considerable amounts of fissionable material that could be used for bombs. It would then only be necessary to withdraw the material from these plants and manufacture this material into bombs.

This would be comparatively easy and would be much more easily concealed than if such plants did not exist.

If we have no large peacetime plants of this kind, and if it were necessary then to do a development job on somewhat the scale of the Manhattan project, I think the whole development would become quite obvious to any inspectors in the country; and I say that because the development of the Manhattan project was quite obvious to all our scientific friends not working on the project during the past few years.

The CHAIRMAN. Doctor, do you know of any invention in history, or any improvement in science, that was ever suppressed in peacetime use?

Dr. UREY. No; all weapons have been developed by other countries in time. The only case in which such things are not done is in the case of very backward countries. I don't think we need to worry very much about China and India getting atomic bomb plants; not for some years, anyway. But in the case of industrialized countries, I think that it is not possible for us to say how long it will be before they could produce them.

Great progress can be made in a relatively short time in a country that has an extensive system of technical education.

Senator JOHNSON. Reducing your "relatively short time" to years, how many years, Dr. Urey?

Dr. UREY. My guess is that it will take 5 or 10 years for other industrial countries to secure atomic bomb plants. It depends somewhat upon which country, and it depends upon the effort that is put forward.

When the bomb exploded, the most important fact was known. From that point on, any foreign country could move with confidence, and this is a great advantage; whereas we had to feel our way along on this problem, set up many alternative methods for doing this work, follow many lines of research, many of which were discarded. The foreign country at the present time would be able to set up its production sites, its bomb-production laboratory, and establish with confidence such laboratories as we had at Columbia, Chicago, California, and Los Alamos; and this would be a very great advantage.

Of course, my opinion as to how long it would be is a guess on my part, but I think that we should not think of a longer time than about 5 years. It may be longer, but I think it would be best to be pessimistic, or optimistic, depending on which way you regard the low side at the time.

Senator CONNALLY. Let me ask you one question.

You were talking awhile ago about the situation where we would not have any peacetime industrial use for the bomb at all and had none of those factors.

If we didn't, wouldn't it require, for the manufacture of bombs, such a large plant and equipment that it would be easily detected by these inspectors if there were somebody trying to bootleg the bomb?

Dr. UREY. I don't know whether you went to Oak Ridge or not.

Senator CONNALLY. No; I didn't.

Dr. UREY. The plants that are located at Oak Ridge, particularly the diffusion plant, are the largest chemical plants I ever looked at. It would be difficult to build that plant in pieces; it must be built as one unit. In order to build such a plant we need railroads, many roads,

a large accumulation of people, and above all, we need concentrations of scientific men and engineers. Probably the scarcest commodity that is involved in producing these big plants is the scientific and engineering talent, and so the whole development becomes a very big thing which would be quite difficult to conceal.

Senator CONNALLY. That is what I was getting at; that of course if we had the industrial development it would be a simpler process for them to abstract materials and go off somewhere and make the bomb. But if we did not have the industrial development, you could not hide a plant that was making the bombs, could you, from an intelligent inspector?

Dr. UREY. I don't believe so.

Senator TYDINGS. Doctor, would I be diverting you if I asked some questions on what you previously brought out, or would you prefer that I wait until the end?

Dr. UREY. It makes no difference to me.

Senator TYDINGS. Assuming that other countries had learned to make the atomic bomb, using the Jules Verne imagination, would this circumstance be possible: Let us assume that any enemy country with atomic energy in its possession desired to stage a Pearl Harbor raid again in 15 years. Let us assume that they came to the city of Washington and hired three garages in three different places in the city and operated trucking lines, say, to Leesburg, Va., Baltimore, Md., and Richmond, Va., and operated these trucking lines for 6 months; and that on Pearl Harbor day of the future these trucks were driven back from their runs and in each of them was an atomic bomb that had been gotten in surreptitiously from a ship on the coast, or what not, and these trucks were put in three different garages in the city of Washington, and with time devices were exploded simultaneously during the night and killed the President, the Vice President, and Members of the Congress, the Cabinet, the Joint Chiefs of Staff, and similar other persons.

That is a very farfetched illustration, but that is not without the realm of possibility, is it?

Dr. UREY. I should say it would be quite possible.

Senator TYDINGS. Just as Pearl Harbor astounded our imagination when it happened, it could be done; there our fleet was caught flat-footed, so to speak. That would be the logical Pearl Harbor of the future under existing conditions, wouldn't it?

Dr. UREY. I should think so. I would say that exactly what you outlined would be wasteful. It would not be necessary to have atomic bombs in each one of these trucks. Three or four would be quite sufficient.

Moreover they could probably be brought in in pieces, piece by piece, and assembled at strategic points, and then as you say, set off with an alarm clock.

Senator TYDINGS. Then we would have no President, Vice President, or anybody in charge temporarily under our constitutional form of government, and if, simultaneously with that, other attacks were made at other places, from carriers at sea, or whatnot, we would have a demoralization far beyond any comprehension of which we are now capable.

Dr. UREY. The people of all the other cities of the United States would be very anxious to get out of them immediately, because they would be afraid that those cities were also mined in the same way.

Senator TYDINGS. The fear which I have just expressed for my own country would be the fear of any other country if international tension were developed to a point where war was possible?

Dr. UREY. I would suppose so.

Senator TYDINGS. Thank you, Doctor.

Dr. UREY. There are difficulties in connection with the possibility of inspection. Industrial executives would not like the idea of having inspectors come into their plants and find out all about what they were doing; but what alternative is there?

I believe that when the alternative of the possible destruction of the industrial plants of our large country is brought home to these people, that they also will realize that the loss of a few industrial secrets is really a small price to pay for the security of this country and for their own industrial enterprises.

The atomic bomb only high lights the fundamental difficulty caused by modern wars. Other high-caliber weapons by themselves would also bring disaster to all countries. In addition other weapons such as bacteriological warfare, destruction of crops by chemical or bacteriological methods as well as others may easily prove as destructive in the future as atomic bombs are now. Any international control should include all weapons and other means of waging wars.

Four: Our present situation. At present we have no method of international control and no international organization sufficiently strong to enforce control of atomic energy. We do not know whether we are moving toward an atomic armament race or toward such international control. In the first place, let us assume that it will not be possible to secure an international agreement, at this time, in regard to the manufacture of atomic bombs. In this case, we must make atomic bombs, we must make them larger, we must make them efficient, we must develop what defensive measures we can. We can and we must devise means for delivery of such bombs to possible future enemies. If this is to be the case, peacetime applications are relatively unimportant and need not be considered.

In the second place, if we do not make bombs, that is, if there is international control, then the peacetime developments become important. There are many things which can be done that would be of great value to the citizens of this country. There is the possibility of power, which is not of paramount importance because of our store of other fuels. In addition to that, there are many possible peacetime applications of the details of the work that has been done in connection with the development of the atomic bomb. In case adequate international control is secured, it will be unnecessary to keep anything secret from any of the rest of the world. If there is an adequate international control preventing the manufacture of atomic bombs by any country we should publish everything we do in the field of atomic energy, since only in this way could the control be made effective. We should have the maximum liberty for universities and private industrial companies to work on this problem.

In the third place, we must consider the interim period, which in any case must obtain before we can go from the present situation in

which we are making atomic bombs on a modest scale either to one in which we make an all-out effort to make more and bigger bombs or to one in which no bombs are made by us or anyone else. This is a very difficult situation, for the manufacture of atomic bombs will cause suspicion on the part of other nations and may prevent international control while failure to make bombs might lead to a weakening of our military position if such control proves impossible.

I should like to add a brief insert at this point, if I may.

Much of the thinking and discussion on atomic energy is confused and often contradictory. Because of this situation, no legislation with regard to the domestic situation can clarify our muddled thinking and arguments. Only a rapid solution of the international problem will be effective.

The War Department does not know just what line of development to take at present, and any commission would be in the same situation. Moreover, it seems doubtful if both the military and peacetime work can be carried on at maximum speed. We can hardly afford to keep as large a group of scientists and engineers on this problem as we have during the war because of the urgent necessity of catching up with other lines of development.

I refer particularly to the need of training new men in sciences which has been so largely neglected during the war.

Five: Secrecy. In our present situation it is not possible to decide with confidence what degree of secrecy should be imposed on research, development, and manufacturing facilities. The fundamentals in regard to atomic energy are generally known, as are the general facts in regard to the direction we took in developing the bombs. Our present secrets are not of decisive value in an atomic armament race, but they are not negligible either. I estimate that the time required by other countries to secure atomic bombs might be decreased by about 25 percent if we published every detail of our scientific data and manufacturing procedures. Another competing country would be saved very considerable effort and cost by such publication. We must remember that secrecy hampers our own scientific effort very greatly. It seems most likely to me that complete publication of our present results and any secured in the future would be of more value to us in an armament race than it would be to any potential enemy.

Again the situation on secrecy calls for maximum efforts to clarify the international situation in regard to control of atomic weapons and other heavy arms. Obviously we should not attempt the control of atomic bombs only, for if this were done a war would start with the use of ordinary weapons and be continued with them until the atomic-bomb plants were in operation and the war finished with these weapons.

The secrecy conditions within the Manhattan project are, as nearly as I can learn, quite exceptional as compared with those in other scientific projects engaged in the work of the war just ended. There has existed and now exists almost a mania for secrecy not only with regard to the late enemies of the United States but also with respect to our own allies, our own citizens, our own elected representatives, other branches of our armed forces, and the scientific and engineering men engaged in the work. Those of us entangled in this net did not know whether this was necessary and mostly still do not know the detailed facts

in regard to the desirability of this constant interference with the transfer of information. My own belief is that it was, and is, largely unnecessary and that it did, and will, impede the progress of the work on atomic energy. This subject is one which may frighten us but it should not lead us to apply methods which all experience shows will stifle development, drive the best men from the field, and shift all rights to knowledge to those with least experience in the application of that knowledge.

I may say that I do not wish to place the blame for this situation on any particular group. It has existed from the very beginning of the work on atomic energy for over 5 years. I believe that it developed gradually, and to some extent universally, because of the very exceptional character of atomic energy and the atomic bomb.

Before the war we were all more nearly sane in regard to this question of maintaining secrecy in regard to scientific developments than we are now. The military have been accustomed from the beginning of history to keeping operational decisions secret. This is entirely feasible. Such things as the exact date of D-day, the point of attack on the coast of Normandy, the number of troops and ships to be employed are matters which can be kept secret and which obviously should be kept secret. Moreover, no advantage is to be secured by not keeping them secret. Moreover, these secrets can be told easily in a few words so that any reasonably intelligent spy can transmit the information.

The problem of maintaining secrets of this kind has led to definite methods of preventing any probable loss to the enemy. Thus compartmentalization of information has arisen. Individuals reporting to a higher echelon are not allowed to discuss their work with each other except when permission is granted by higher authority. Moreover, each individual is given only the information which in the opinion of the higher authority is needed for his own work. All of this type of organization is that needed for espionage work.

In World War I, and in World War II particularly, science has demonstrated its great effectiveness in developing weapons of war, methods of defense and operational methods and the military have come to appreciate these contributions to the art of war. But no one has had so great a field day as the "security officer." What vast numbers of "secrets" he has had. What great stacks, in fact tons, of secret documents. How he has risen to the occasion in compartmentalizing all these scientific espionage agents and controlling the movements of personnel and documents. And he has not realized that his methods are not applicable, that his efforts obstruct the work beyond anything that he can comprehend, and that all his efforts are bound to be futile in the end because scientific facts are the same and can be learned by the careful student of nature on both sides of any international boundary.

Perhaps the committee would appreciate some examples of what we mean by "compartmentalized systems" of controlling information.

The laboratory of Columbia University had the problem of separating the uranium isotopes. That in Chicago worked on the so-called piles. In connection with the work on piles, and especially the work at Los Alamos in New Mexico, the exact conditions which would lead to the explosion of our materials were studied and finally well understood.

The separation of the uranium isotopes did not require any such knowledge as that, and hence all flow of information from the metallurgical laboratory at Chicago and between the University of Chicago and the laboratories at Columbia University was interrupted and prevented. But at the same time, if material accumulates in our diffusion plants in sufficient quantities and in the right places, either an atomic explosion might occur or radioactivity of great intensity might be produced, both of which would be destructive of the plant and of the personnel involved. Of course, if any accident of this kind occurred we would lose our operating personnel which would make it very difficult to continue the work.

Throughout this time, great efforts were made, particularly by the Carbide & Carbon Chemicals Corp. which operated the plant, to secure for their own men the necessary data which would enable them to determine whether the plant that was being built might be explosive or not. Up to the last contact I had with this problem, no such permission was given. Competent men, Dr. Teller and Dr. Smith, were assigned from Los Alamos and Chicago, respectively, to the construction company, and they were expected to decide as to whether the plant would explode or not. They are very competent men.

We managed to get the plant built, and there was no difficulty of this kind, but throughout the whole period the operating company found themselves building a plant which might have been explosive, and had no way of securing information that would enable them to decide that question.

A similar situation, I am told, occurred in the case of the electromagnetic plant in which a solution of Uranium-235 made up in water would have been explosive, but the people operating the plant had no information which told them that such would be the case. By a rather rare accident and by a break-down of compartmentalization, this difficulty was discovered in time.

I could go on with many other illustrations of this kind. I might say one that I think was a little amusing occurred at the beginning of 1943, when I learned that the du Pont Co. was told not to inform me in regard to their method for the production of heavy water. I knew this because of my contact with my very good friends at the du Pont Co., and I also learned it by the backyard-grapevine route by which information leaks around compartmentalization barriers.

The lack of necessity for that has always appealed to me as quite remarkable, for the method they used was merely boiling water through apparatus that is standard apparatus used in the chemical industry. It was not a problem in which I was personally greatly interested, but I was greatly annoyed by the fact that that information was interrupted.

Recently there have been questions about the cost of heavy water which are not known to people who would plan and think of using it. It is quite a vital item of information to the research man on a job as to whether a material he proposes to use is expensive or not. Also the amount of Uranium-235 which might be available for their plans were matters which they were not allowed to have.

These are a few samples. I could carry on examples of this kind; they could be brought up by the hundreds.

Senator HARR. May I interrupt you there?

I think you said something which you would not wish to have misunderstood.

You were talking of the risks that were involved in certain plants; risks to personnel, I take it, because of what you term these extravagant methods of secrecy. Of course, there were risks all through, and no accidents did happen, which shows that very excellent provision was made to guard against them, and free insurance was carried, so after all you don't wish to be understood as saying that none of the personnel involved should have been facing such risks as those which are rather minor as compared with the risks which the men in uniform are taking, do you?

Dr. UREY. No; in a war we all expect we will take risks, and these problems were surmounted; but had accidents of this kind occurred, it would have seriously interrupted the work. How would we keep the personnel on the project? All the men would have walked out of the plant if they had realized there was such a great risk. At least it looks that way to me, and it was the opinion of the operating company that that was a serious difficulty they faced. It wasn't a matter that in a war you need to worry too much about a few human lives. Many are being lost, but it was important that the work should continue to go on.

Senator HART. Yes; but, Doctor, did you mean to say that that condition is what you consider an extravagant method of secrecy?

Dr. UREY. It is one illustration of what I think are the extravagant methods of secrecy.

Of course, the important part of this side discussion is not what was done in the past. I am perfectly willing to let the Pearl Harbor investigation take care of such matters, but if this constant frustration of scientific and technical men by artificial barriers to the flow of information is continued in the future, it will be a very discouraging feature to many scientific people. They will prefer to work in fields where no such interference with the information which they need occurs; and that is the important thing for us—nothing of the past, just what is the bearing upon the problem of future development.

While operational secrets can be told in a few ordinary words, scientific facts can only be told in many pages of highly technical discussion. Within a large scientific project the distribution of information is a very difficult problem. The reading of the German documents on atomic energy must be done by men who understand the subject matter. Scientific details are difficult to transmit to others, even to other scientists. For this reason compartmentalization of scientific information is unnecessary and only obstructs the necessary dissemination of information among men who need it. Of course, if scientific information were freely published during a war it would be of value to the enemy, since this gives us an opportunity to study the scientific details.

Certain types of information in our problems partake of the character of operational secrets, that is, the fact that a problem is being investigated, probable dates of completion of phases of the work, amounts of production, sizes of weapons, general processes being used, nature of critical materials used, and so forth. Some of these were made public in the Smyth report.

I think we were entirely justified in making those public in the Smyth report, for most of the information was of the type that would

have leaked very quickly in any case, and perhaps already had leaked before the Smyth report came out. Unfortunately, most of these cannot be compartmentalized without, at the same time, treating scientific data in the same way. Also certain information of this kind bears on public policy and during peacetime should be available to the public. Thus the rate of production of bombs and the number stored should be known to the people in the same way that the size of our Army and Navy is known to them, and in both cases is then necessarily known by the governments and peoples of other countries.

Before the war the distribution of scientific information was not restricted in any way unless it related to the detailed construction of weapons or defenses against weapons. We should go back to this same situation in the postwar period, since the advantages to be gained from a free science so greatly outweigh the immediate advantages of a few temporary secrets that no other course would be sensible.

Specifically, secrecy regulations under the assumption of no international control should be limited to the mechanical details of the bomb and certain details of construction of plants. It should not cover any scientific facts whether or not they are necessary for the construction of the bomb and plants. Only in this way can work on the improvement of the atomic bomb and on industrial uses be done effectively.

Moreover, as a matter of public policy, our capacity to produce atomic bombs and the number stockpiled should be known by the people of the United States. To keep such matters secret would be comparable to having a secret navy or army. Making these matters public will inform all other countries of our strength in this respect, but unless we intend to abandon an important aspect of our present system of government, these facts should be known.

Senator HICKENLOOPER. Mr. Chairman, may I interrupt?

The CHAIRMAN. Yes, Senator.

Senator HICKENLOOPER. Doctor, I do not mean to take issue with you on this argument about the number of atomic bombs except to raise this question: I cannot quite follow the desirability of announcing to every other country the exact number of our store of atomic bombs, assuming that we elect to keep a store of them. It would seem to me to be a whole lot like the moving-picture versions of the detective who counts the number of shots in the crook's revolver, and when he shoots six times goes in and gets him.

When the other nations, assuming we want to use this for war purposes, know we have a thousand of these bombs, or 500 of them, or the exact number, they might be able to perform the best defense possible against our use of them by merely dispersing their population and their industry until we shot all of our 500 bombs, and then know that we, at least at that moment, did not have any more.

That argument would appeal to me as being against the announcement of a particular number of bombs, as differentiated from statements concerning the size and number of our ships, for instance, or our military forces—information readily obtainable by any good spy.

Dr. UREY. Well, atomic bombs are a weapon of such a large magnitude that they represent something of the order of magnitude of capital ships in their importance.

I would also, along with my idea in regard to people of the United States knowing what number of bombs we have, believe they should

know how many ships we have in our Navy or how many soldiers in our Army.

I am only saying the atomic bomb is a major weapon, not a minor one at all. It is equivalent to an entire air force, or an entire navy or an entire army, and the people of the United States should know whether they are building up an army, a navy, an air force, or a stock of bombs.

Senator HICKENLOOPER. Well, I agree that the widest information should be given on these things, but I believe that perhaps we announce very glibly the number of ships we have and the size of our Army because we know anybody can find it out anyway.

In the case of the atomic bomb, which is a major weapon and perhaps for the time, anyway, a controlling weapon, there might be a little different element of human nature in there that would dictate whether we should conceal the fact if we elect to go on with the atomic bomb as a war weapon.

I hope we can arrive at a solution where we do not have to. If we elect to use it as a war protection, I conceive that it could be concealed just as we conceal the number of battleships and carriers we have, and, if we could do it successfully and hide them so no foreign agent could find them, I have no doubt but that we would be concealing the exact number of bombs.

Dr. UREY. My own idea would be the matter of whether we considered ourselves at war, or in an armament race where we expected to get into war, or considered ourselves at peace. But if we are at peace, my argument applies. If we are essentially at war I would agree with you.

Senator HICKENLOOPER. Thank you, Doctor.

Senator JOHNSON. Mr. Chairman, may I interrupt?

I understand your position, Dr. Urey, as being opposed to all military secrets, not only the atomic bombs, but every other kind of military secret.

Dr. UREY. Well, that is a rather broad statement.

Senator JOHNSON. Well, that is what I understood from your prepared statement.

Dr. UREY. No; I say that if we are going to engage in an atomic-bomb armament race, the things that should be kept secret are the details of the bomb, as we do in the case of all other weapons.

We do not tell the details of our bombs, or the details of our planes, or the details of our ships and things of that sort.

But also we do not suppress the scientific data upon which all of these things are constructed, and the same distinction is the only one that I ask in the case of the atomic bomb.

Senator TYDINGS. But what you say, Doctor, with a great deal of emphasis, as I got your testimony, is that we ought to try to establish a line between what might be classified as purely scientific research and development as differentiated from its application to weapons.

Dr. UREY. That is right.

Senator TYDINGS. In other words, to take a far-fetched example, if Einstein's theory is discovered, or if the philosophy or formula for the splitting of the atom is discovered, that should be passed along?

Dr. UREY. That is right.

Senator TYDINGS. But you are not attempting to say that all of the application of that theory to the actual mechanics of producing the weapon should be publicized?

Dr. UREY. That is right.

The CHAIRMAN. Then your point is, as I get it, that it would not be possible to develop—to use the Senator's illustration—an Einstein theory in the compartmentalization treatment of scientific matter?

Dr. UREY. A genius such as Einstein would probably bring forth his theory of relativity without a great deal of discussion with many scientific colleagues; but most scientific work is not done that way. I may say that the development of the theory of relativity was not done entirely that way, either. A professor of the University of Chicago tells me of the seminars they had in Berlin at the time Einstein was working on his theory of relativity, and I have no doubt but that Einstein found those discussions exceedingly stimulating at that time.

But somebody of that kind may from time to time bring out a startling piece of work without a great deal of stimulation from his colleagues, but that is very rare. Nearly all scientific work proceeds by one man making a discovery, moving the subject forward by a small amount, publishing his data, presenting it at a scientific meeting, everybody discussing this thing, and someone in the group goes home with an idea of his own that might be slightly different from that of the man who presented the work. Then he starts to work and he presents some paper, and somebody else picks up another idea. This constant interplay of many minds working on the problem is what makes the whole field of science go forward. If we must have secrecy on this problem within the United States in the next coming years, all compartmentalization lines should be destroyed so that we get as much discussion among the scientific people within the project as possible, so that a maximum number of good ideas can be brought forward.

That is my objection to the compartmentalization. If we must have secrecy, then the whole project should be in one unit in order to bring as many minds into one group as possible.

The CHAIRMAN. Did you protest this compartmentalization while it was going on?

Dr. UREY. I think, as I said, that the scientists somewhat helped it along. I believe that it started about in 1940, which was my first contact with it, and it was certainly in full swing at that time.

I believe the scientists dropped into it themselves because they did not realize how damaging it was, nor to what proportions it could grow, and only after swimming in this molasses for years have they come to realize that this sort of thing stifles their efforts and frustrates them more than they ever imagined when the thing started.

Senator HART. Doctor, I think I understand you better now. You are arguing against the continuation of the methods of employing secrecy which we carried on through the war?

Dr. UREY. That is right.

Senator HART. You are not particularly finding fault with the fact that they did carry them on during the war?

Dr. UREY. The whole job on the development of the atomic bomb was done, I think, very well. I could go through and find fault here, there, and some place else, but if you were to turn the whole thing

back to the beginning and try it again I don't know whether we would have done any better or not. I doubt it.

I am not complaining primarily concerning the things that were done in the past, and I am distinctly not blaming any particular person or any particular group. I think it is a thing into which we all dropped for a rather natural reason because of our appreciation that we had in our hands a very important development.

I am only saying at this time, "Let's not do it in the future; let's get out of our tank of molasses and make some progress in a much more effective way than we have done in the past."

Senator TYDINGS. But you even limit that statement to the qualification, as I get it, that the theoretical or scientific development, or the art itself should receive freer consideration; but as to the weapon itself and the technique that goes into it, you are not complaining of the secrecy imposed on that?

In other words, you want science free to explore without disclosing what it has done in the way of this weapon?

Dr. UREY. That is right.

TNT, trinitrotoluene, is a substance which we can investigate in chemical laboratories and find its properties all we wish to. But just as soon as it is being made into bombs, then we do not publish our results, and the same thing should be done in this field.

Senator TYDINGS. It is inherent in your testimony that the degree to which we transmit scientific knowledge should be international; that is, there should be reciprocity.

If we find that scientists are working in other countries under the restriction of their governments to transmit nothing to our science. I imagine you would approach the freedom of the interchange of ideas with more hesitancy than if there was a freedom everywhere.

Dr. UREY. I would say this: If we must have a competition on this subject with foreign countries, then we ought to have as large a degree of freedom in the United States as possible in order to get the maximum benefits. But of course there is no reason, if we are going to compete seriously with another country, why we should give them information and they not give to us.

Senator TYDINGS. You are requesting an interchange of international knowledge within the limits that could be exchanged without impairing our national safety?

Dr. UREY. That is right.

Senator JOHNSON. Dr. Urey, I think I understand your position much better now. The paragraph that threw me off was your second paragraph under "Secrecy," wherein you state [reading from a copy of Dr. Urey's prepared statement]:

* * * the situation * * * calls for maximum efforts to clarify the international situation in regard to control of atomic weapons and other heavy arms. Obviously we should not attempt the control of atomic bombs only, for if this were done, a war would start with the use of ordinary weapons and be continued with them until the atomic bomb plants were in operation and the war finished with these weapons.

That paragraph led me to the conclusion that you did not want secrecy with respect to any of the weapons of war.

Dr. UREY. I would say this: If we can secure an international control which we believe is adequate and can trust, it will necessarily lead to control on other weapons than the atomic bomb. Inspection

would immediately disclose the developments on other weapons as well as the atomic bomb.

If that were the case, if we could secure such control, then we should publish every single thing we do. If we cannot get that control, then we must have a certain amount of secrecy within the framework of our own group, and I am only pleading that in this second case the compartmentalization rule be broken down so that all people working on the various phases of this project can know about it.

Senator JOHNSON. I agree completely with that statement. However, until we get the international control in the satisfactory position such as you describe, I think you are making too much of a distinction between peacetime and wartime. I think we are continuously at war and must consider ourselves to be continuously at war until we have stabilized peace, the international peace to which you referred.

The argument which you made about everything being satisfactory in wartime, and not satisfactory in peacetime refers to the kind of peace that we have been enjoying, which is nothing more than a temporary armistice, an unstable peace.

Dr. UREX. That is exactly the reason why I plead so repeatedly for rapid movement on the international scale so that we can make a decision as to what we ought to do. I don't believe we can make any decision as to what we should do at the present time.

Senator TYDINGS. You are not advocating that we carry out anything you say tomorrow?

Dr. UREX. No.

Senator TYDINGS. You are simply projecting it as a possible premise upon which we might proceed when the circumstances permit it?

Dr. UREX. One of our difficulties is that none of us knows whether we should try to produce atomic bombs in great numbers at the present time, or whether we should not develop them at all and pay attention to peace.

What you do in one case will be quite different from what you do in the other. Until that situation is clarified, you cannot make up your mind what you ought to do.

In the first case, if we don't have to make bombs, we can publish everything we do. In the second case, where we must make bombs, we still must get as much freedom to the groups working on this in the United States as possible to get a maximum effort in the field.

Senator TYDINGS. Have you thought of this angle—and evidently from your testimony you have: All countries manufacture, perhaps in peacetimes, disease germs which can spread epidemics in hostile populations. I assume that many countries on the face of the earth during the war kept laboratories where these germs were made and could be dropped if any other country started that.

It was not done, for the very obvious reason that there was the fear that the other fellow might have a worse bunch of germs or a better bunch than you had yourself.

Have you given thought to the fact that if we have a store of these atomic bombs, it might stop the other man from using the atomic bombs that he has, because retaliation would come sooner or later, and even though he got the initial advantage by a surprise attack, if we had some bombs all over the country and the transportation facilities available so that atomic bombs would eventually be dropped on him, too, that the horror of the whole thing might restrain him?

Dr. UREY. I have thought about that a good deal. I don't think I would trust it. Take the case of poison gas. We undoubtedly did not use poison gas for humanitarian reasons. Perhaps the Germans did not use it for fear of retaliation; but back of the failure to use poison gas was probably a judgment that incendiary bombs were more effective than poison gas, and hence the effort went into the production of incendiary bombs rather than the production of gas in Germany.

Having proceeded along this line, they had not gotten ready to defend their population against poison gas, and hence did not wish to start it later.

I think it is very likely that the analogy, for example, to poison gas is not good. In the case of bacterial warfare, I don't know. Turning bacteria loose in the world is dangerous, because if you produce a very large diseased spot in some part of the world, the diseases have a natural way of spreading to places where you don't want them. Atomic bombs, the ones we drop, will not spread back on us.

Senator TYDINGS. No, but the other country has the germs to bring back on you, in the form of another atomic bomb.

Dr. UREY. Yes.

Senator TYDINGS. I think, if we had a large stock of these bombs, and some possible enemy had a large stock of these bombs, there would be a hesitancy on their part to start a war with us because of the inevitable retaliation that would come.

I am wondering whether you have pursued that very far, and what your opinion on it would be.

Dr. UREY. My opinion is that it would not be a sort of protection which I would like to trust.

Senator TYDINGS. Have we got anything better for the time being?

Dr. UREY. The only thing that appears to me to be worth while as a means of trying to avoid the destructive effect of atomic bombs is to try to induce the other governments of the world to agree to an outlawing of the bomb and to backing it up with an inspection to find out whether the outlawing is obeyed, and also with some means of bringing violators of law to justice.

I believe that means we must not manufacture bombs, because that enables us to introduce an inspection system. If we are manufacturing bombs at various places, I don't know how we would introduce an inspection service.

Senator TYDINGS. You made that clear in the first part of your remarks. I believe you looked ahead for 20 or 25 years to the period when probably five or six nations would have an ample store of these bombs.

The CHAIRMAN. He didn't say 20 or 25.

Senator TYDINGS. I am just assuming that.

The CHAIRMAN. He said 5.

Senator TYDINGS. Well, let's assume 20, 15, or 10, and they all have a large stock of these bombs.

Now, if that situation should come to pass, there would be no hope in the world that a war would be fought without atomic bombs.

Your assumption is that we ought to try the other thing and see if we can work it before we face that alternative, if it is humanly possible. That is the general line of your reasoning, isn't it?

Dr. UREY. That is right.

Senator TYDINGS. The other may not work. The alternative may not work, it may fail, but you think it is better to explore it and try it

than it is to rely on the day 20 years from now when there will be no restraint and every nation will have these bombs available?

Dr. UREY. Yes. Toward the end of this statement I have pointed out the difficulty of keeping scientific men on the job of making atomic bombs.

Scientific men don't wish to work on destructive weapons; they would rather work on constructive things. If they have a choice—and we still have a choice in this country to work on what we wish as individuals—they will drift into fields of work in which they will see constructive results of their scientific work. As a result, I don't know how you are going to maintain research on atomic bombs, except in one way. You will have to see that the international situation develops in such a way that each individual scientist is convinced himself that that is the only thing that can be done to defend the United States, in which case he will go to work on atomic bombs. I don't believe any artificial method will get an active development of atomic bombs except that feeling of necessity in the heart of every man that has to work on them.

Senator TYDINGS. Would you say, from your contact with fellow workers in the scientific fields—and imagine that contact is on a rather wide scale—that it is the universal opinion of the men who have built this Frankenstein creation, so to speak—and I say that with a smile, not with criticism—that the hope of the world lies in finding some means of dealing effectively with the atomic bomb so that its probable use will be prevented, and that any other thing that is allowed to drift means the ultimate destruction of the whole earth, let us say 50 years from now when it has gone through its whole evolution? Is that your thought?

Dr. UREY. That is right. I do not see this line of argument. The atomic bomb is exceedingly destructive. A picture in a morning paper shows what area of Washington would be destroyed by one atomic bomb. It is very destructive.

Second, there is no defense for it, and therefore we must make a large number of bombs.

The last step, somehow or other, does not follow logically in my mind from the first two. I do not believe it is a solution to the problem posed by the first two statements, and I would like to see us propose something that is at least a partial or a possible answer to the first two statements.

Senator TYDINGS. In other words, the ultimate conclusion of the first two statements is so horrible that you are not willing to accept that as a final answer without working with all your might and main to find, even though you fail, an alternative?

Dr. UREY. Well, making a lot of bombs is no defense to us; it is only the retaliation that you mentioned, Senator Tydings, that is the only defense involved in it. It still will not prevent our cities from being destroyed and people from being killed.

Senator TYDINGS. Scientists share your view, don't they?

Dr. UREY. I think they do.

Senator TYDINGS. Those I have talked to do, and I wonder if your experience was the same.

The CHAIRMAN. Doctor, I don't want to delay you unduly, but I wish to ask you the question I asked General Groves yesterday. You were probably in the room.

If country A was to take over country B, a small country, by fifth-column methods, and the attack was to come from country B although promoted by country A and although we had no proof of that fact, the only retaliation we could have would be on the basis of suspicion, would it not, that maybe country A did have something to do with it?

Dr. UREY. Yes, sir.

The CHAIRMAN. Now, it is possible that country A might be suspicious, but maybe, on the other hand, it would not have anything to do with it because a small industrial country might get these bombs to do the job.

Dr. UREY. I don't know what we would do in such a situation. It is a very difficult thing to answer. To attack the first country because you suspected them of having something to do with country B would be immoral, to say the least. I suppose that our country in that case would have to make some sort of a decision, and maybe just attack country A. I don't know.

The CHAIRMAN. We might be wrong?

Dr. UREY. And we might be wrong.

Senator TYDINGS. You heard General Groves testify, Dr. Urey, that in a war in the future, let's assume 25 or 30 years from now, between major powers we might have 40 large industrial cities partially or totally destroyed, and probably 40,000,000 people killed and that we would still fight on.

Do you care to comment on that statement, to enlarge on it?

Dr. UREY. Well, I mentioned in my direct testimony here that I feel in such a case we would have to have very large stores of material before the war started in order to be able to continue it.

Mostly we have fought our wars recently by letting someone else hold the enemy for a year or so while we built plants to make materials with which to fight a war, and then as the war progressed we kept up an enormous production to fight that war.

I don't see how we could possibly follow that pattern in such a future war.

Senator TYDINGS. That is gone.

Dr. UREY. That is gone. We would either have to have a large store, or else hope the other fellow was in exactly the same position so that we could fight it out on equal terms by much more limited methods of warfare than have obtained in this war.

Senator TYDINGS. But if the atomic bomb is in production among three, four, or five of the leading powers and there is a surprise attack on a big scale, the modern conception of Pearl Harbor 25 years from now, and our population is in the stage it would be in with the killing going on, what is your conception of what would take place after that surprise attack had pretty well been carried out with moderate success, let us say?

Dr. UREY. I would like to make a further assumption, namely, that our atomic bomb launching sites were not destroyed. We would destroy the other fellow's cities next. I think after that that the war would languish. I think we would all be so busy taking care of our own homeless and wounded people, probably without leadership, for our leaders would probably go with the first Pearl Harbor attack, that we wouldn't pay very much attention to the war for quite a long time, and neither would our enemy. That, I think, would be the probable outcome.

Senator TYDINGS. We would hunt the open spaces, wouldn't we?

Dr. UREY. We would hunt the open spaces and try to get enough to eat to take care of ourselves, and it would be pretty much of a stalemate from that time on.

The CHAIRMAN. If we had 100,000 bombs and if you adopt Senator Tyding's example that he gave about the trucks that would come into Washington, for instance, it is possible that we would not know who planted those and so we would not know at whom to launch the hundred thousand. What would we do—throw them widespread?

Dr. UREY. It would be an anonymous war, and I think it would be the greatest mystery of a long time as to "Who done it?"

Senator HART. I, like Senator Johnson, am afraid I misunderstood you.

In the first paragraph of your discussion on secrecy, you said that you thought we had more to gain than we had to lose by publishing everything that we know right now.

Dr. UREY. Yes, sir.

Senator HART. To me that sounds considerably like our noble experiment of the early 1920's, when we tried to get the world to disarm by example. It didn't work.

Would you wish to enlarge upon that, Doctor?

Dr. UREY. I told Senator Johnson that if we must get into a definite armament race I think we will have to have secrecy around the borders of the United States, as it were, and so that statement is somewhat inconsistent with what I have said there.

But in reply to your analogy, I would say this: There is a very great damage to scientific effort imposed by these secrecy conditions. You see, it isn't a clean-cut decision. We wish to get a maximum amount of effort and development on our side, and to minimize the effects of leaks to the enemy, and some place between the two postulates of publishing everything we do and keeping everything carefully compartmentalized and secret, there probably is an optimum position, and I think the optimum position lies far toward the side of making public our scientific facts, but probably not so much of our scientific or industrial "know how." That is, where I would place the maximum is probably close to the side of maximum publication.

Senator TYDINGS. Are you doing anything with the powers that be to achieve such a policy of a little more freedom in scientific research, and making headway?

Dr. UREY. I have been asked by General Groves to serve on a committee looking toward the declassification of scientific documents that have accumulated on this project during the war. My argument before that committee sounds very much like the one that I am presenting to this committee.

Senator TYDINGS. I imagine, then, there is an agency set up working on this problem to see how far, within the limit of what is conceded to be the Nation's interest, scientific freedom can be granted without jeopardizing our security.

Dr. UREY. That is right.

Senator TYDINGS. So that problem is being worked on?

Dr. UREY. That is right.

The CHAIRMAN. When was that committee set up?

Dr. UREY. Oh, I should judge about a month ago. There was a meeting of the committee on Monday preceding October 16, which was a Friday.

The CHAIRMAN. About 30 days ago?

Dr. UREY. Yes.

The CHAIRMAN. It wasn't set up before the War Department prepared their legislation on this subject?

Dr. UREY. No.

The CHAIRMAN. Go ahead, Doctor.

Dr. UREY. Six: Specific provisions for prospective domestic legislation.

I might say that that is a field in which I have a few suggestions to make, but I am sure the gentlemen on this committee are far more skilled in matters of this kind than I am.

The commission, in whatever form it is set up, should be responsive to the President and the Congress. This is especially important in the case of the control over atomic energy, which is moving very rapidly and involves so many points of foreign and domestic policy. Two forms of organization would seem possible to me.

A director of atomic energy might be established, appointed by the President, with the advice and consent of the Senate, and removable by him, as are Cabinet officers. This director is bound to exercise vast powers, and some check on his activities is desirable. This might be supplied by the use of the courts, though they are likely to find themselves uninformed on such a complex technical problem and hence unwilling and unable to review acts of the director which may be regarded as arbitrary by persons with whom he deals. In order to avoid this difficulty it may be possible to establish an advisory and appeal board.

A second form of organization would seem desirable to me. A full-time commission of, say, three or five men, with the Secretaries of War, Navy, State, Commerce, and Interior as ex officio members. The full-time members should be scientists or engineers and should be appointed by the President, with the advice and consent of the Senate, and removable by the President, just as Cabinet officers are. The commission could then appoint its administrator, with the approval of the President, who again should be a civilian without any other loyalties. This administrator should be a civilian for two reasons: One, he should owe allegiance to no other authority than the commission, and two, he should have had experience in handling men and organizations on a peacetime, nonmilitary basis.

Either the director, in the first case, or the administrator, in the second, should be men of broad experience, with the ability to handle very large problems, such as those which will occur in the case of atomic energy control. If it is feasible to do so, the salary should be high enough to attract a man in competition with industrial positions.

The powers of the director or commission should be adequate for this problem, but any blanket grant of powers should be avoided. Amendments to laws are always possible; and if the original powers granted are not sufficient the Congress can extend the first grant of power. Since this development has been carried through with Government funds, it is only reasonable to attempt to avoid monopoly by private persons. At the same time, the control should not be so strict that development is stifled by lack of incentives.

The director or commission must have the following powers:

One. The right to know where and by whom scientific, development, or industrial work on atomic energy is being done.

Two. The power to make rules and regulations covering hazards incident to such scientific, development, and industrial work and the power to inspect establishments to determine whether such rules and regulations are followed.

Three. The power to keep inventories on all fissionable elements and their separated isotopes. Ownership of U-235, Pu-239, and other elements of similar fissionable properties should reside in the Government.

Four. The right to use all patents and other information for work on atomic energy. The patents should be made available on a compulsory license basis.

Five. Certain legal and business powers dealing with organization of corporations, making contracts, etc.

Six. The right and, in fact, duty of licensing fissionable and other special materials on an equitable basis to private persons for use in research.

Seven. The right and duty of encouraging research, development, and manufacture of atomic energy and equipment for peaceful purposes.

In addition to these, other powers may be necessary. I believe that the Navy and Army should be permitted to carry on experimental and developmental work on phases of atomic energy having to do with national defense. The commission should also be permitted to conduct such studies.

I believe that the commission should not operate its own research and development laboratories but should secure the development of atomic energy through private laboratories or by letting contracts for such research and development with private persons. This suggestion runs counter to opinions of other people, and some explanation is necessary.

I may say that I am not sure I am right about this; that is just my opinion.

The commission, if it had its own laboratories, would be making grants to private laboratories and its own laboratories. It would immediately get a proprietary interest in its own laboratories and almost certainly would favor these laboratories relative to private laboratories. I believe that there would be an almost unconscious tendency to divert the work on the more promising lines to its own laboratories. Such things have occurred in the past in the minds of a number of people, and the effect is to make people in the private institutions very wary of any contact with the commission and its favorite "pet" laboratories. I noted with satisfaction that both the Magnuson and Kilgore bills on a National Science Foundation specifically required that the Foundation should not establish its own laboratories.

The Commission or director should have the power to classify information in accordance with the requirements of the Espionage Act.

Severe penalties should be provided for violation of regulations relative to safety hazards, diversion of fissionable materials, or failure to keep the commission informed relative to research or other work on atomic energy.

I believe that there should be no specific penalties for violation of matters covered by the Espionage Act but that the penalties of that act should apply to the work on atomic energy as it applies to other activities.

In order to secure maximum effort on atomic energy, every effort should be made to make conditions for individuals and institutions such that they will be attracted to this work, and this means that these conditions shall be as favorable for work in this field as they are in other fields of research and development. Specifically, penalties which can be applied in arbitrary and unusual ways should be avoided. I am a believer in free enterprise and do not believe that this system should be completely abrogated in this new field of energy utilization.

Finally, I wish to add one brief remark on conditions necessary for the development of atomic weapons. Scientific men are not particularly attracted to work on destructive weapons but would rather devote their talents to constructive development. The enthusiastic work during the war on weapons of all kinds by scientific men was done because all of us realized that this country was in great danger and not because the work was particularly interesting. As we enter a peacetime situation, it will be difficult and probably impossible to keep the more capable and brilliant men working on weapons of war. I believe that this would only be possible if these men are convinced that such work on weapons is absolutely necessary for the defense of this country. Again, I urge that all possible efforts be made to secure international control of atomic and other weapons. If these efforts are made and fail, our scientific men will rally again to the support of this country. Otherwise, I believe that the overwhelming majority will be attracted to other fields of effort.

Senator HARR. Doctor, would you add the management and governmental operation of those big plants to the powers you have laid down for the commission?

Dr. UREY. Yes; I think they shall have to operate those plants.

Senator JOHNSON. Doctor, in the proposals that you make for the specific provisions of prospective domestic legislation which you name, are they based on conditions without an international agreement or with an international agreement?

Dr. UREY. I should say that it doesn't make so much difference. I am assuming that the commission or the director will do what is needed in view of the developments in regard to this field.

If in the one case it is necessary to develop atomic weapons, I should think that a director, an administrator, or a commission would take their orders from the President of the United States and direct their efforts in that direction; and that would be done.

If, on the other hand, peacetime applications are necessary, they would direct their efforts in that direction as well.

Senator JOHNSON. Then you are not in conflict with the President's message to Congress making the domestic controls entirely independent of the international controls?

Dr. UREY. I am not, sir.

Senator JOHNSON. That was his procedure.

Senator RUSSELL. You of course read the joint statement of the President, Mr. Atlee, and Mr. King as to international control?

Dr. UREY. Yes.

Senator RUSSELL. Do you care to comment on that as to whether you think that is the best approach to the problem?

Dr. UREY. I think that is the way we should move on that problem. I was very glad to see that statement. I was only sorry it was not issued 3 months before. What is needed is as quick a follow-up with effective establishment of such a commission as possible. Immediate steps should be taken. I don't know whether those are being taken or not.

Senator RUSSELL. You are convinced then, Doctor, that a system of international inspection can be thoroughly effective in preventing the use of atomic energy as a weapon?

Dr. UREY. As General Groves has told you, I think it might break down and might not be perfect. I think that that is a danger we will face no matter what we try to do. No matter what scheme we try to work, out, there will always be the possibility that there will be imperfections in it.

I believe that the international inspection, providing the countries of the world agree that it shall be done, should be feasible. I cannot imagine that the inspection would work if the countries of the world have it imposed upon them in some way or other from without against their consent.

I am assuming we would secure agreement from the major industrial countries of the world; and if that agreement were given, then I think it would not be difficult to tell whether the large-scale development we have in this country were going on.

Senator RUSSELL. If it developed that any one of the nations refused to assent to that proposal, and refused to have anything to do with international agreements on this subject, do you think we should continue to manufacture these bombs?

Dr. UREY. Yes; I don't see anything else we can do. I think we ought to indicate to the other countries of the world our great willingness and great desire to discontinue our manufacturing, our willingness to dismantle our present store of bombs, and to disperse them into only peacetime uses, and that we ought to indicate to the world our willingness to do that if any adequate machinery can be set up for control.

Senator JOHNSON. Dr. Urey, on page 5, along the line of the question which you have just answered, the last paragraph in part II of your statement, you say:

My choice of time to do something about this threatening series of events is now or preferably 3 months ago, if it were only still possible.

What is the particular significance of "3 months ago"? That takes us back to the 28th of August, if your paper is dated today.

Dr. UREY. I wish very much that the President, Mr. Atlee, and Mr. King's statement had been made in August instead of now. I believe our international situations are being poisoned day after day because we are accumulating a supply of bombs. At that time we had no supply.

Senator JOHNSON. Prior to August 5 or after August 5?

Dr. UREY. I think after August 5.

Senator BYRD. Would you destroy, Doctor, the bombs we have made?

Dr. UREY. I would indicate a willingness to the people of the world to dismantle those bombs.

Senator BYRD. What do you mean by "dismantle" them?

Dr. UREY. There is an explosive charge which is fissionable material, and there is an auxiliary mechanism to set it off. I would take it all apart. I would take the material, and dissolve it and put it in the form of ordinary chemical substances, and tell everybody exactly where it was under those conditions.

Senator BYRD. We would have to destroy them so far as they could be used?

Dr. UREY. I would not destroy the fissionable material; it is valuable for other purposes.

Senator BYRD. Then that would be available to be put together?

Dr. UREY. Oh, yes, after a time.

Senator BYRD. Actually we would have bombs which the other nations would not have.

Dr. UREY. We would have material from which we could make bombs in perhaps six months.

Senator BYRD. And you propose to keep the other nations from having that same material?

I am trying to find out whether you would put this country on an equality with other nations.

Dr. UREY. The point is that if we do not intend to make the bombs, if the conditions were imposed that we were not to make or have large industrial plants and have only a limited amount of fissionable material in the country, I would judge that what fissionable material we have at the present time comes within those limits.

Senator BYRD. In other words, other nations should get the same amount of that material?

Dr. UREY. Surely, if we can get an international control we must expect that other nations will go forward to the same extent we think we ought to.

Senator BYRD. You have to start the use of this atomic energy to get that material. They would have to start the preliminary processes?

Dr. UREY. Oh, yes.

Senator BYRD. And then you would want them to stop at that particular point and not go further?

Dr. UREY. Yes.

Senator BYRD. It seems to me that is quite a weakness in your argument.

Dr. UREY. Let me point out this: If we ran these piles at rather limited power, we would produce all the radioactive materials that we could use for medicine, for industrial research and things of that sort. That would be a very valuable peacetime effort, but still would not accumulate for anyone a large stock of atomic bombs.

Senator BYRD. We are faced with this partial situation: Before action can be taken, we will have made a good many bombs. They will be in existence.

Dr. UREY. Yes.

Senator BYRD. Now, if we are to be on an equality with other nations, we have got to destroy those bombs or put them in some other kind of condition, and then permit the other nations to do what we have done.

Dr. UREY. Yes. There is no possibility of securing an agreement with any other country unless we are willing to establish a level and expect them to reach it also.

Senator BYRD. In these preliminary stages where you set this material back for some other conditions than what it is now, then the other nations can go that far and no further. That would be hard to police and inspect, it seems to me.

Dr. UREY. Perhaps you went to Oak Ridge; did you?

Senator BYRD. Yes.

Dr. UREY. You visited the pile down there?

Senator BYRD. Yes.

Dr. UREY. That pile is a very nice-sized pile for experimental work in the production of radioactive materials, and so forth, and it is not a very big plant, as you have seen. I think it would be feasible.

This would be my opinion, and certainly it would be subject to review by others than myself, that if we had piles of something of that order of magnitude in other countries, it would not be a serious threat to the peace of the world and would come within a level of activity which could be controlled by inspection.

Senator BYRD. But I am speaking of the actual bombs that will be made before this agreement you mentioned could be effectuated. They will be in existence, and something has got to be done with them. They have got to be destroyed or put in some other form, or something, and whatever we do in that respect we have got to permit other nations to do.

Dr. UREY. There is no level to get down to, except that we admit to other peoples the same rights we ask for ourselves.

Senator BYRD. You would not destroy the bombs?

Dr. UREY. I would not destroy the material, but dismantle the bombs.

Senator BYRD. Then we should permit other nations to go as far as we go in this preliminary stage in making the bombs. You have just said we could make them in 6 months if we had that preliminary.

Dr. UREY. That is a guess on my part. I did not work on that part of the problem.

Senator BYRD. What I mean is that we still have got that element of danger in existence, haven't we, under your plan, because of the fact that we have got the bombs or will have more bombs when this thing is finally settled.

Dr. UREY. If your argument is correct, Senator Byrd, and we can only control the atomic bomb by pouring fissionable materials down the Mississippi River and let it go, I think it is worth while to destroy it completely rather than run the risk of atomic bombs, if that is the only way it can be done.

Senator BYRD. I have not made any argument; I have taken no position. I am trying to find out what your plan is with respect to these bombs that are in existence, and I think that is a very important question. They must be destroyed, or something must be done with them. We must permit other nations to have exactly the same opportunity that we have had toward the manufacture of the bombs.

Dr. UREY. That is right, the same attitude, and if necessary we will have to destroy the materials of our bombs as well.

Senator BYRD. I think that is a very vital question in this whole matter, as to what you are going to do with what you have already got in existence.

Dr. UREY. And the more we have got, the worse the problem is.

Senator JOHNSON. Dr. Urey, the members of this committee and, insofar as I know, no one else unless it be General Groves and some of the people at the top, know exactly the amount of the compound that we have that is ready to go into the development of bombs.

It seems to me your paper displays a lack of faith that others might have in us.

Now, how are you going to convince the world, for instance, that we don't have a sizable amount of this compound stored away which can never be detected, never be discovered, that we are holding back from the world? You do not seem to think that the other nations will have very much faith in the United States' good intentions. Now, how are they going to have any faith in the amount of this compound that we have on hand, and I am not talking about the piles; I am talking about the compound that is ready to go into the manufacture of bombs?

Dr. UREY. In regard to the question of good faith between nations, I feel about it like I do when I make a contract with my brother. I love him, and all of that, but I put it all down on paper just the same.

I may feel that a country is intending to deal with us honorably, but at the same time I propose to make laws and regulations so that there will be no question about enforcement. That is just one remark on one side of it.

As to how much we have, a scientific or engineering man from any foreign country, if he visited the plants in the United States, could determine their capacity from the figures that we have on them, and I think it would be very, very difficult to deceive him in regard to how much we have made.

If we wish to convince him how much we have, the records on the plants will be adequate to do so.

Senator TYDINGS. This may be oversimplification, but as I have listened to your testimony very carefully here this morning, I take it that as a scientist who has been with this from the time it was born up until the time it was a grown man, so to speak, and who has looked ahead to see its possibilities, your testimony is predicated on the fact that we have at last invented a weapon which, if used with its ultimate evolution of further development, might conceivably destroy civilization?

Dr. UREY. Yes, sir.

Senator TYDINGS. And might conceivably wipe out a thousand years of progress?

Dr. UREY. Yes.

Senator TYDINGS. And faced with that alternative and the knowledge that sooner or later other nations will probably be in a position to do what we today can do, it is your considered opinion that international agreement is necessary for the control of this element, that everything that we can do to implement the success of that agreement by inspection or any other thing that may be conceived of is necessary, that that process may fail, that it may be a fond hope that will never be realized, but it is the only alternative to the complete destruction of all that we have worked to achieve.

Am I correct in that summary?

Dr. UREY. That is a very good summary.

The CHAIRMAN. Are there any further questions of Dr. Urey?

Doctor, on behalf of the committee, I want to thank you most sincerely for the careful and studied statement that you have made, and I am going to take advantage of calling you back again for further testimony at the proper time.

Dr. UREY. I will be very glad to appear.

The CHAIRMAN. We will meet again at 10 o'clock tomorrow morning.

(Whereupon, at 1:05 p. m., the committee recessed until 10 a. m., Friday, November 30, 1945.)

ATOMIC ENERGY

FRIDAY, NOVEMBER 30, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Connally, Byrd, Tydings, Vandenberg, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. Dr. Langmuir is our first witness this morning. Will you give your name to the reporter and the official position that you occupy in industry?

STATEMENT OF DR. IRVING LANGMUIR, ASSOCIATE DIRECTOR OF THE RESEARCH LABORATORY, GENERAL ELECTRIC CO.

Dr. LANGMUIR. My name is Irving Langmuir. I am associate director of the Research Laboratory of the General Electric Co., and have been in that laboratory since 1909, engaged mostly in fundamental scientific research in physics and chemistry, but also have had considerable experience in industrial research.

Senator VANDENBERG. I think the record ought to show that in spite of the doctor's modesty he is also a Nobel prize winner in chemistry.

Dr. LANGMUIR. Yes, sir, in 1932.

The discovery of the accessibility of atomic energy opens a new era in human affairs. If used for peaceful purposes, it promises to be of untold and unpredictable benefit to mankind. But, if it should again be used in warfare, it threatens to annihilate a large fraction of the human race and to give to an aggressor nation a complete domination over all populations which are permitted to survive.

International control of atomic energy and, particularly, of all possible manufacture and use of atomic weapons is thus of the utmost urgency. Since such progress toward an effective world government can only taken place gradually through successive steps which build up world confidence, it is imperative that we devise adequate but sound legislation for the control of the knowledge and of the processes which we now possess in the field of atomic energy.

I propose to analyze the proper objectives of such legislation and of the forms that it must take if it is to be effective.

96002 O - 49 - 8

Peacetime applications of atomic energy: Much of the discussion of the human value of atomic energy has been based on the thought that such energy may displace coal and oil as sources of industrial power. This, I think, is a relatively trivial matter. Even if coal or oil cost nothing as fuels, this would not have a very great effect on our civilization: we would not use our automobiles much more and our electric power bills would not be cut as much as they already have been within the last 15 years by the improvements that have occurred in power production.

The greatest benefits that will accrue to mankind from our new knowledge of nuclear reactions will more probably come through its indirect effects in speeding up progress in science. We may now expect a series of great discoveries in biology, in chemistry, and in physics. Through such better understanding we may have better means of preventing and of curing diseases, such as cancer. We may similarly develop new or better and cheaper chemical materials and alloys. It is probable that most such benefits can be had by relatively small scale production of the new radioactive products that are by-products of the manufacture of plutonium.

Large-scale atomic power production will probably first be important for ship propulsion, but even this will be of vital importance only for naval ships or submarines if these still prove to be of value in an atomic age.

Our present ability to obtain vast stores of energy from the nuclei of atoms forever eliminates any danger from the exhaustion of coal and oil reserves, but this is something that, in any case, would not be important for a century or so.

The threat of atomic bombs: We now have atomic bombs and no other nation has them. As long as this condition exists we are in a secure position.

England and Russia, however, have already announced plans to produce the substances that will give them atomic power. Such materials could also be used to construct atomic bombs.

France, Switzerland, and Sweden are other nations which might successfully undertake programs aiming at the production of atomic power or atomic bombs.

It has already been brought out by all scientists who have worked in this field and have spoken about it that there is no "secret of the atomic bomb" which can be permanently kept. The Smyth report and the fact that successful bombs can be made by several processes enable any nation attempting to build bombs to concentrate on one process and to start work simultaneously on separate phases of the problem.

The laws of nature await discovery by anyone properly qualified and equipped. Thus, all the basic scientific knowledge needed for the construction of atomic bombs can surely be obtained by any of several nations. The difficult technical processes that are involved in the manufacture have been, so to speak, "right up our alley," but we must remember that the Russians long ago held the world's record for long range airplane flights and that during the war they devised and built in quantity tanks as good as the best made in Germany.

They are now engaged in the construction of a large experimental plant, of the order of \$100,000,000 to operate a blast furnace with

oxygen instead of with air. They have plans for using oxygen for all their blast furnaces at a possible cost of \$2,000,000,000. Such undertakings prove an ability to carry out large complicated projects like that needed in the development of atomic energy.

We must consider also that the Russians have continued the training of scientists during the war to a far greater extent than we have. Furthermore, they have available, in any atomic energy program, the knowledge and technical skill of German scientists and technicians. Russia certainly has ample resources in uranium.

If Russia decided that the incentives were great enough, she could mobilize her resources on such a program, just as she did between 1934 and 1939 in her preparations for war with Germany, and getting her people to forego a higher standard of living, devote 10 percent or more of her total production capacity to a 5 year atomic energy plan. Before the war the United States devoted about 0.04 percent of its national income to research and this increased to perhaps 0.5 percent during wartime. That is excluding the atomic bomb project.

National prestige at home and abroad may well induce nations to undertake atomic energy programs. A still greater incentive, however, can be furnished by the feeling of insecurity which results from our possession of atomic bombs and from any failures we have made or may make in the future in establishing the "atmosphere of reciprocal confidence in which political agreements and cooperation will flourish."

The insecurity which Russia may feel as to our possible use of atomic bombs may well be based on a misunderstanding of the American people and of our Government. But we also have much misinformation regarding Russia. What can we expect when, according to a recent letter from Moscow by Edgar Snow, there are only 260 Americans in all of Russia and only 2,000 Russians in the United States? How many Americans read or speak Russian? The Russians have recently taken a great step in fostering understanding by starting to teach English to all Russian children.

We can better understand Russian doubts about our policy of holding atomic bombs as a "sacred trust" by asking ourselves: What would American public opinion now be if we had had no atomic energy development but, near the end of the war, atomic bombs had been dropped on Berlin by the Russians without warning? Would our insecurity have been entirely relieved if the Russian Government, a few months later, had announced that it held an increasing stock pile of atomic bombs as a sacred trust?

It is thus reasonable to believe that the insecurity, which Russia may feel for the future, acts at the present time as a very powerful incentive to build her own atomic bombs.

If, in this way, an atomic armament race develops, I believe the Russians will produce their first atomic bombs in about 3 years. Thereafter, however, there is a definite possibility that the Russians might accumulate atomic bombs at a far faster rate than we do. The following factors give them certain advantages in such a race:

1. They have a larger population and it can be regimented, and is willing and has been trained to sacrifice living standards for an extensive defense program.

2. They have a remarkable system of incentives which is rapidly increasing the efficiency of their industrial production.

3. They have no unemployment.
4. They have no strikes.
5. They have a deep appreciation of pure and applied science and have placed a high priority on it.
6. They have already planned a far more extensive program in science than any contemplated by us.

These conclusions are based in part on my own observations of scientific work in Russia made when I attended the two hundred twentieth anniversary of the founding of the Academy of Sciences of the U. S. S. R. in Moscow and Leningrad last June.

Ever since 1933 the Russians have lived in a state of insecurity. During the war, as their armies became victorious, they looked forward confidently to an end of their insecurity. In June I found that all the scientists with whom I came in contact expected a long era of peace in which the devastated industries and territories could be repaired and then their standard of living could be raised to a level as high or even higher than that in America.

The atomic bombs in August must have shattered such hopes and brought back a state of insecurity like that of the years 1933 to 1939. I believe the impairment of the relations between our two nations since that time is a reaction to their disappointment regarding future security.

The security which we now possess through the possession of atomic bombs will thus be short lived. It will probably end completely within 5 or 10 years if an atomic armament race continues.

I believe all of the United Nations now desire future security above almost anything else. During this period of 5 or 10 years it is of vital importance that steady progress be made to develop means for the effective world control of atomic energy. Any steps that reduce insecurity will tend to remove incentives for an all-out atomic armament race and will thus extend the time available for the working out of the completely effective control mechanism. It is thus essential that such steps be started as soon as possible and that they be followed as rapidly as possible by other steps that will develop world confidence.

The November 15 declaration by President Truman and Prime Ministers Attlee and Mackenzie King is a most constructive program aiming at this world control of atomic energy. I hope that the Governments of the United States, Britain, and Canada make immediate contacts with the Russian Government to secure, if possible, their tentative agreement instead of relying solely on the more cumbersome machinery of the United Nations Organization.

I believe that this declaration will receive the wholehearted support of all Americans. The council of the National Academy of Sciences on November 15 approved unanimously the declaration of that date.

Although I believe that this program will ultimately succeed, we cannot now foresee how long the step by step progress toward effective world control of atomic energy will take. In the meantime it is essential that we have adequate but wise national control. The proper objectives of legislation designed to this end may be considered under the following headings:

1. The legislation should conform to and support the program aiming at world control as outlined by the November 15 declaration.
2. Security regulations which attempt to maintain secrecy in any fields of fundamental science must not be contained in this legislation.

Any such secrecy as we had during the war under military control would stop nearly all progress in those sciences. We may hope that other nations will reciprocate in an exchange of scientific information but whether or not they do, it is to our advantage to see that fundamental scientific knowledge is published as soon as possible.

At the June meeting of the Russian Academy of Sciences many Russians, as well as scientists of other nations, expressed the view that fundamental science had always been international in character and that everyone had profited by the cooperation and good will among scientists. All expressed hope that such cooperation would always exist.

Even during wartime the secrecy regulations in matters of fundamental science were not lived up to. Most of the scientists working on the atomic bomb project frequently had to violate the regulations to exchange information with one another in order that the work could get ahead effectively. In peacetime such regulations would be completely unworkable for any attempts to enforce them rigorously would drive all able scientists out of the field.

As an example of the ineffectiveness of military security regulations even during the wartime, I should like to tell of an experience of my own.

I had had only a trivial connection with the atomic bomb in some consultations I had at two of the laboratories during 1942 or 1943. I had been invited to Russia in May 1945, had accepted through the Soviet Embassy, had received my passport, and was told that the American delegation would be taken to Russia on a C-54 plane with transportation arranged by the State Department and by the President. The day before we were scheduled to leave two Army officers, who did not know on what grounds the request was based, asked me to decline to go to Russia. This would have meant that I would have had to invent excuses on my own responsibility. Since there appeared to be direct conflict between the War Department and the State Department, I refused to withdraw my acceptance at the request of the War Department and demanded that the matter be taken up with the State Department canceling my passport if necessary. I wholly disapproved of the manner in which this matter was handled. When others interceded and the War Department was made to realize how little I knew of the atomic energy project, I was finally allowed to go. Other Americans, however, who had been invited, were not permitted to go after having accepted.

This, of course, the Russian Embassy knew. They knew also that no physicists were among those who accepted the invitations.

When I reached Russia I was told by the English group that eight British physicists, who had accepted the Russian invitation, had had their passports canceled after they had reached the airport ready to fly to Moscow. All of the scientists and the whole of the British delegation were much incensed at these tactics. They believed that the passports were canceled because these men had worked on the Tuballoy project, which is the equivalent of our Manhattan project. I also heard the opinion expressed that this action must have been taken at the request of the American Government because no one outside of the American Army could be so stupid.

The English newspapers gave great publicity to the cancellation of the passports and called Prime Minister Churchill to account

before the House of Commons. This was all known in Russia, but it was never published in American newspapers.

I believe that these attempts to maintain secrecy resulted in giving to the Russians the very information which the Army most wished to keep from them. Any sensible Russian scientist knowing of these facts would have believed that we were developing an atomic bomb and were keeping it secret from the Russians.

3. Everyone agrees, I believe, that security regulations are needed at present to cover the manufacturing processes for making the materials used in the atomic bombs and, particularly, the details used in the construction of the bombs. These, however, should not go beyond those which are common in the manufacture of war weapons.

4. Fundamental research in nuclear physics should be stimulated and supported in universities, in Government laboratories, and in industrial laboratories. This may perhaps best be done through the machinery that will probably be set up through the science legislation, such as that proposed in the Kilgore-Magnuson bill.

5. Research, engineering, and development of better methods of manufacture of materials capable of releasing atomic energy should be planned on a large scale.

6. The peacetime utilization of atomic energy requires that the Government should furnish to research workers in this, as well as in other countries, materials such as radioactive substances and sources of neutrons of moderate intensity. This will greatly increase the rate of progress of scientific knowledge in this field. The results of all work done with these materials should be published.

7. As I pointed out previously the development of atomic power is of secondary importance. Exploratory, large-scale experiments should, however, be made to find what the possibilities are. It will probably be many years before profitable large-scale developments can be made from these experiments.

That ends the prepared part of my statement, but I would like to add a few more paragraphs.

The CHAIRMAN. Go right ahead.

Dr. LANGMUIR. Much fear has been expressed about the possibility of control of atomic power by monopolies. I think this will not be a possibility for many years. At present and for a long time to come, it is not an attractive field for industry. The possibilities should be explored, but obviously all rights should be retained by the Government.

Later, it might be necessary to help industry get started on applications of atomic power, if and when such developments become desirable, which I think will only occur after we have some form of international security.

I would like to add an eighth section.

The organization of the board to control atomic energy and the form of its administration is something that I do not feel qualified to pass judgment on. These are matters that our Senators and Representatives must decide.

I do feel, however, that the organization should be one which encourages cooperation on the part of scientists and places upon them a full share of the responsibility for planning and carrying through scientific programs. In particular, the scientists should participate in

the establishment of all security relations, for they are more likely than others to understand the harmful effects of unduly severe restrictions.

I spoke in one section about coordinating the work of the atomic energy board with that of the National Science Foundation, which may be set up under the Kilgore or the Magnuson bills when they become law.

There are two ways in which that can happen. First of all, it is very important that work in fundamental nuclear physics should be continued. The National Science Foundation will naturally have an organization that will be able to plan such work through universities and other laboratories, and it seems unwise to duplicate any such work through two organizations. Therefore, it seems to me that this organization of an atomic energy control board should operate through any science foundation for fundamental research work on nuclear physics.

Dr. Urey yesterday thought that it would be undesirable for the atomic energy board to operate laboratories. I think that is perfectly true, for laboratories such as those can be operated by the National Science Foundation.

However, I think we must recognize that any manufacturer of materials for atomic power or bombs will continually need research work of a semiskilled kind, which should be done in intimate contact with the production facilities. In other words, any organization that manufactures these materials should have connected with it a laboratory which studies processes and even develops new methods or the possibilities of new methods, and so it would be very essential for this board to operate laboratories in connection with those industries.

The other point where coordination is needed between these two boards is in regard to the training of scientists. Any extensive atomic-energy program means that we must have students coming along who are enthusiastic to work along the fields of nuclear physics.

The CHAIRMAN. Doctor, you would agree that the move taken, as reported in the press this morning, about deferring young men who have peculiar scientific ability, was a good one, would you not?

Dr. LANGMUIR. It is excellent and very important for these reasons, it seems to me: It is a very important part of the atomic energy program to coordinate the work with that of the National Science Foundation.

I have attended one of the hearings of the Kilgore-Magnuson committee and have been very favorably impressed by the way they have gone about these hearings, having 4 weeks of hearings, bringing in the best scientific opinion with free discussion.

Scientists have been almost unanimously agreed on the importance of the Government supporting and stimulating research on a very large scale under present conditions. There have been minor differences of opinion among them, but largely on the matters of administration which are things that automatically come down to Congress to decide and the President. I believe that whether or not the particular form of the board is a matter of discussion, it seems to me that that is a matter of relatively minor importance.

Most of the scientists I think would favor the control of the foundation residing in the board largely of scientists who chose their chairman, but if that proves to be politically unfeasible or unworkable, if it couldn't pass Congress, for example, or would be vetoed by

the President, it seems to me in no case must such legislation be prevented.

The most important thing is that we have adequate support. The particular form that proves to be workable is a matter in which I think the scientists are only moderately qualified to express opinions.

Speaking of the educational program for training men in nuclear physics, it seems to me there again we see how vitally important it is not to have secrecy in fundamental science. Think of a professor trying to get students interested in starting research work on nuclear physics when the professor perhaps has been connected with the project and knows a lot of things which he cannot tell the students because of security regulations. The students would know that immediately, and the professor would have to explain that that is a thing which he could not talk about; yet perhaps that is the thing that the student wants to work on, and it would absolutely stymie the whole educational program if the professor were not allowed to talk freely about fundamental science as well as other fields. Otherwise, students would be diverted from that field and would likely work in a field where they could discuss things freely and receive scientific stimulus.

This smashing of the cyclotrons is another feature that goes along with secrecy. I think it is a great mistake. In the future, it seems to me that will be compared with the burning of the books in Germany, or with legislation that occurred years ago forbidding the teaching of the theory of evolution in one of our Southern States. That is totally unnecessary. The cyclotron is not a device by which you can make atomic bombs; you can simply gain knowledge. Interference with the gaining of fundamental knowledge is always an unwise procedure.

I attended the hearing yesterday and heard Dr. Urey's testimony, and there are a few points there that I would like to touch upon and amplify to some extent.

In general, I agree completely with everything Dr. Urey said. He mentioned that in an atomic armament race there would be three stages. I would like to consider that there might be a fourth stage, and I would like to tell you what that is.

The three stages he spoke about are these:

1. We alone have atomic bombs. We are then secure at that time.
2. Other nations also have atomic bombs, but they haven't enough to destroy all our cities; but we have enough to destroy all of theirs. We are still relatively secure, and nobody is likely to start an attack under those conditions.
3. Two or more nations have enough bombs to destroy all cities, perhaps 10,000 bombs of the kind that we have now. That will probably come in an armament race. Retaliation, however, would be expected and that would be a deterring factor, but perhaps not decisive.

As was mentioned yesterday, and I think discussed by General Groves, 40,000,000 people might be wiped out in the United States by an attack of that kind, and it would not help us much to destroy 40,000,000 people in the Nation of attack.

The CHAIRMAN. Do you believe, Doctor, that any nation which suffered that kind of catastrophe could proceed with a war?

Dr. LANGMUIR. No; I think it would be crippled for perhaps hundreds of years, and with far less than 40,000,000 people. The 40,000,000 people that would be killed would be those that are in cities where

industries are located. The whole of the Government would be wiped out, all our railroad terminals would be wiped out, and we would have to go back to living, as in the case of colonies, on the farm to survive as best we could. We might fight atomic bombs with pitchforks, but it is not a good means.

When we have lost 40,000,000 people it may be that the other nation still has again as many atomic bombs; so, if we start to construct plants to build such bombs, they would be destroyed one by one. It would be complete annihilation of the whose existence of the country as such.

There is, however, a fourth stage which would automatically come sooner or later in any unlimited armament race. We can confidently assume that there are going to be discoveries made in this field. They may be made 4 or 5 years hence. They may be made 10 or 15 years hence, but it is almost certain that we will have atomic bombs a thousand times as powerful as those that now exist by means that are now undiscovered.

It could be done by a cheaper means of production. Instead of producing 10,000 bombs, it is conceivable that by cheaper means of construction you could have 300,000 bombs.

That would be enough to treat every square mile in the United States the way Hiroshima was. There would then be no retaliation. There wouldn't be 60 percent of the people left; there might be 2 percent of the people left, and under those conditions you can see what happens in the world.

Having wiped out one nation, the aggressor nation would then feel it necessary to control all others. There would be only one nation that could exist, and it has to operate the world possibly as a slave factor, or if they are troublesome wipe them out altogether.

It is a perfectly horrible state of affairs to look forward to, and yet it is the thing that will inevitably come sooner or later.

We cannot predict what discoveries are going to bring. We cannot predict whether we will be the one who gets to the fourth state first. It may be even a small country that succeeds in doing that by discovering bombs a thousand times more powerful, and perhaps cheaper. If they discover that first, and if they become aggressors,—and they are almost sure to become aggressors, because the state of uncertainty of the world at that time would simply be intolerable—you would be almost forced to take action under those conditions before the next fellow gets to that stage where he could destroy the entire nation in one blow.

Dr. Urey gave a very excellent discussion of the effective methods of world control and said, and I agree with him, that inspection will be one of the things that will be necessary, mutual inspection, inspection which is desired by all nations and not forced upon some nation but really desired for their own security.

One of the things that will be important in the preliminaries of the discussion is exchange of scientists on an informal basis first, and later a closer and closer cooperation.

When I was in Russia in June, I found that the Russian scientists spoke far more freely than we were allowed to speak. We were told we could not say certain things, but the Russians frequently told us the very things we were not allowed to tell them. There seemed to be

no restrictions on this field of pure science. We didn't get into industrial applications, for that was not in the field of the Academy of Sciences.

When you go to Russia and you find that Kapitza, Fersman, Frenkel, and Joffe—all of those men who are working on problems that have nothing to do with atomic energy—when Joffe tells me and shows me the cyclotron started in 1938, work on which was discontinued during the war and is now just starting again, and tells me the cyclotron will be finished in December of this year—and he is the most prominent physicist that has had anything to do with nuclear physics—when you see that, you are convinced they are not carrying through a Manhattan project.

Later, if we had international control and if our scientists could visit one another, it would be obvious that if any large scale atomic project were under way, scientists would disappear and it would be impossible to reach them. That would be one of the first indications and one of the most powerful things in international inspection and control. Later, it would have to be followed up by visits to factories.

As Dr. Urey pointed out, if you were going to have factories that make these fissionable materials—uranium 235 and plutonium, on a large scale for power production purposes, and those plants could be converted within a short time, possibly within a time so short it could hardly be detected, if those could be converted in a short time to the production of atomic bombs, the difficulties of inspection are tremendously increased.

If there are no such large factories, it would be relatively easy to find that a factory is being built for large scale production, for that could be seen by simple observation from the air. With the disappearance of certain physicists and the construction of certain mills for the making of all kinds of materials, it would be relatively easy to find.

Others will feel the same need for security that we do in that field, and if we reach a point where through agreement with other nations it seems we might have international control, it may well be that others will agree that control would not be satisfactory if we have large plants for making plutonium for peace time purposes or allegedly peace time purposes, like atomic power, while they have practically none. That would not mean security for the other nations.

Under those conditions, as Dr. Urey pointed out, it would be far better for us to forego completely any production of atomic power. But I want to go a step further; I say we ought to be willing and even consider that possibility now that when the time comes that it looks as though international cooperation or inspection would be possible, and if at that time it appears that the destruction of our plants, the renunciation of any power applications, the destruction of the bombs that we have and even all reserves of the fissionable material that could be used for peace time purposes was advisable, it may be highly desirable to destroy all of that in order to put ourselves equally on a basis with other nations.

We, of course, would not do that until we were satisfied that the control mechanism is adequate.

Senator MILLININ. I did not understand, Doctor, to what you referred when you said we should destroy something.

Dr. LANGMUIR. In order to be on a par with any of the other nations that might want to agree with us, we cannot be on a par if

we say 5 or 10 years hence, have a stock pile of bombs that we have accumulated during 10 years. It would not be sufficient to take the plutonium out of those bombs and say, "We are going to use it for power purposes," because within six months we could put it back into bombs.

It seems the only way we could be on a par with another nation that had not been manufacturing these materials on the same large scale that we have, in order to accomplish that result, would be to offer to destroy the whole thing, drop it all in the sea, destroy our plants, destroy our bombs, and destroy all reserves of materials in spite of the fact that they probably will cost us \$5,000,000,000. Five billion dollars is not an unreasonable price to pay for any adequate form of world security, and we must all look to having world security because the alternatives are simply appalling.

Senator HICKENLOOPER. As I understand it, you are discussing that phase of it solely from the standpoint of a military weapon, a military threat. In other words, you would not carry it further and say that our country having more automobiles than any other country in the world, we should destroy our automobiles down to the number existing in another country?

Dr. LANGMUIR. I am talking merely about the atomic bomb at present. The point is that you cannot have atomic power, or that you cannot keep plutonium which you have stored up and made during 10 years. You cannot put that anywhere in the world where it will not destroy the security of every nation. You could not agree to put it in Africa. You could not hold it in Canada. You could not do anything with it except completely destroy it.

The CHAIRMAN. You would not want the Security Council to hold it?

Dr. LANGMUIR. I wouldn't, because it is no good for police action. I don't say we should do this now. I say, if it should turn out that security or satisfactory world security should depend upon the destruction of that, then, for heaven's sake, let's destroy it. It would be a cheap price to pay.

However, if it progresses ahead fast enough, it may be we can come to some agreement which we cannot now foresee, but in five or ten years we may easily come to some agreement where it is decided to retain it only if we have safeguards that will prevent it being turned into atomic bombs.

Senator HICKENLOOPER. Wouldn't we run afoul of the very human tendency in the history of progress that no material advancement has ever been discarded by the human race?

Dr. LANGMUIR. This is quite a unique thing. It is a million times more dangerous than anything we have had before. That is the dominating factor.

Senator VANDENBERG. Suppose you could not get a satisfactory agreement. Then, what would you do?

Dr. LANGMUIR. Then I certainly would not give up the atomic bombs. I think under that condition you would have a 50-50 chance of being the one that wins the next war, maybe. But that is not satisfactory; there is no security in that. This whole insecurity problem is intolerable and will remain so, and sooner or later the nations will all agree that that has got to stop.

For that reason, we must make sacrifices, and it would not be too much to have us sacrifice in order to give security to other nations, to put ourselves on a par with them. In fact, I cannot conceive of an agreement with any other nation by which we would not start off as equals.

Senator AUSTIN. Mr. Chairman.

The CHAIRMAN. Senator Austin.

Senator AUSTIN. Taking your testimony as a whole, in connection with this process you are developing now, isn't it the logical conclusion that we should go back to the position we were in before this discovery?

Dr. LANGMUIR. I don't think we can do it now. I was saying that all of these things should be done only when we have reached and obtained and perfected a mechanism which would give security, international cooperation, and development of the UNO to a point far beyond where it is now. Only when we can get in return for this action security to ourselves should that be done.

At present, if we should destroy our atomic bombs or our reserves or stop making it, we would be looked upon as suckers by some of the other people in the world who have no intention of doing any such thing. We would be the laughing stock of them and they would go ahead and take advantage of that position. We have to have security, or the promise of security, but the possibility of security may depend on that very thing, on our willingness to go back to equality with other nations that have none or have very little.

If it comes to that, then we should be prepared. We do not have to decide these things now, but I want to see this legislation designed in such a way that we preserve the freedom of action. Congress has got to decide these things now. All it can do is pave the way now going in the right direction, but we should have the vision ahead of us, and in that vision we should preserve our freedom of action. We don't, if we stop making bombs; and I don't think any nation now would expect us to stop making bombs, because they would not do it, if conditions were reversed. But we ought to stop making bombs if and when world organization progresses to a point where everyone wants security so much that they are willing to make real sacrifices.

Senator JOHNSON. Dr. Langmuir, how do you compose your two different viewpoints? On the one hand, you say that this country should appropriate \$5,000,000,000 for scientific research; on the other hand, you say that this country should destroy \$5,000,000,000 worth of the products of science.

The scientists, according to your testimony, have made the world extremely insecure. Science has made, according to your statement just now, aggression inevitable and yet, at the same time, you say that we ought to keep on pouring money into science.

Dr. LANGMUIR. Science is not a thing that we make; scientists don't create science in that way.

Senator JOHNSON. But you create atomic bombs, and now you want to go and throw them in the middle of the ocean because they have made the world insecure.

Dr. LANGMUIR. In order to get security—in other words, we buy something by that. It is a price. You cannot get security for yourself without giving to other nations.

We have no security now for the future, because we are in stages one or two. We are now secure, but we can foresee the case that this security is only temporary, that the time will come when not only we but no nation is secure, and we must do something about that. We must start now to do something about it, because otherwise disaster lies ahead, probably a worse disaster for us than anyone else.

Senator JOHNSON. It looks to me as though you scientists have made the world extremely insecure, and now you are coming to the politicians and asking us to go about and make the world secure again by some sort of a political agreement.

At the same time, you are asking that the scientists who made the world insecure be given further appropriations to discover still another and more terrible destructive element than atomic energy.

Dr. LANGMUIR. But scientists did not go out to discover atomic energy. You have absolutely no knowledge of what science may do. Science may more likely at any time develop a cure for cancer through the use of atomic energy. That is important, for it will save more lives in a couple of years than we lost during the whole World War.

Science is not destructive as a whole. Our standard of living, our whole existence of America, has been developed through science. The reason we won the war was the basis of our civilization, which has been developed through science.

Senator JOHNSON. Then, the atomic bomb was merely an accident?

Dr. LANGMUIR. An accident.

Senator JOHNSON. Purely an accident?

Dr. LANGMUIR. It was absolutely unforeseen.

The CHAIRMAN. Yes, but the scientists were put to work on it by the Government to do the job, and as good citizens they did the job. Isn't that your contention?

Dr. LANGMUIR. Yes. We cannot have a holiday in science because we don't like certain aspects of science, because science only discovers the facts of nature. The facts of nature are there to be discovered by anybody. England is not going to have a holiday in science, if we do; Russia isn't; France isn't; and if we stop progress and stagnate, we will deserve to be exterminated in 50 years. We would just be cluttering up the world uselessly.

Senator JOHNSON. Of course, I believe that with all my heart, and I am a coauthor with Senator Kilgore of the Kilgore bill. I believe our security lies in the laboratory and in scientific development; that is my religion, but I am unable to understand your two viewpoints.

Dr. LANGMUIR. I think it is one viewpoint.

Senator JOHNSON. It is my fault, Doctor. I apologize, but I am trying to get straightened out.

Dr. LANGMUIR. I think we have a situation where we are going to have future insecurity unless we do something beginning now.

Senator CONNALLY. Right on that point, we are all interested in devising some international plan, if we haven't already secured one, to preserve peace and guarantee security. A little while ago you went on to say what you would do until such time as we got that arrangement. Doesn't that always involve an uncertainty? We have to assume we have got it, but maybe we haven't; there is no perfect agency, and that would be a risk.

Dr. LANGMUIR. We haven't now, but I have a strong feeling that this situation is going to get more and more critical, and if we do not find some solution—

Senator CONNALLY. The point I make is that you think you have got one, and maybe you haven't. That is a risk we have got to take.

Dr. LANGMUIR. But it is not as big as the risk we are now taking if we do not do anything.

Senator CONNALLY. You have got to be practical. You are going to base it on an international agreement, and on the belief that all members will honestly and in good faith carry out their obligations.

Dr. LANGMUIR. I don't want to depend on an agreement at all. I want to depend on a working mechanism, such as inspection.

Senator CONNALLY. I don't care whether you call it agreement or mechanism, but the mechanism has got to be based on some agreement, of course.

Dr. LANGMUIR. On mutual desire for security.

Senator CONNALLY. We won't have anyone coming around inspecting us until we agree to it.

Dr. LANGMUIR. That is right.

Senator CONNALLY. I say that there is an element there which we have got to take a chance on. Some nation might agree and then not live up to it. That is true, isn't it?

Dr. LANGMUIR. Then, our Congress and our people have got to decide whether the security is worth the risk we take, and we cannot decide that now, because we do not know what those provisions will be 10 or 20 years hence.

Senator CONNALLY. It is easy to say that we will make an agreement and settle everything, but we have got a practical problem.

Dr. LANGMUIR. The alternative is a war of atomic energy, which is worse than anything else you can think of.

Senator CONNALLY. Unless we have more atomic bombs than anybody else.

Dr. LANGMUIR. That would not help much.

Senator CONNALLY. I am not advocating that, but I am looking to the future and the problems we have got to face. There are a whole lot of people that say, "Yes, we will just solve that by writing it out, and that settles it."

If you are implementing these things, like we are trying to do now before the Senate, taking a week to do something that should take a day, you will find out. You can't do it in a laboratory.

The CHAIRMAN. Doctor, I think it is rather important that you comment, if you will, on Senator Connally's statement that having more bombs than anybody else gives any security.

Senator CONNALLY. I withdraw that if it is going to disturb the chairman.

The CHAIRMAN. It doesn't disturb me, but I think it ought to be answered for the record.

Dr. LANGMUIR. As I said, in stage 3, two or more nations will have enough bombs to wipe out all of the cities of the other, and you can be sure they will have them so placed that when we do wipe out the cities of the other nation we will not destroy the site from which bombs are launched. Therefore, there will be retaliation which will result in destruction of practically all of our cities.

If we had twice as many bombs, then we could go into the open spaces outside the city.

Senator CONNALLY. Just a minute. I predicated that on your question that we would try to arrive at some arrangement and some mech-

anism to prevent it. You then volunteered the alternative would be an atomic war in which we would be destroyed. I merely volunteered the statement, "unless we had more bombs than the other fellow."

It was predicated on the fact that when and if the war occurred—I am not advocating the war.

Dr. LANGMUIR. No, but, you see, having more bombs is of little importance. If some other nation had enough to destroy all our cities in one blow and we have twice as many, it doesn't do us any good.

Senator CONNALLY. Of course not. If we have another Pearl Harbor, it won't do Pearl Harbor any good to be destroyed before we act.

Dr. LANGMUIR. But we can have no security unless we have something like 100 times the number owned by another country, and then we get to the fourth stage.

Senator VANDENBERG. But you would agree with Senator Connally that an agreement per se is not so certain?

Dr. LANGMUIR. No.

Senator VANDENBERG. We have got to have a mechanism which justifies reliance on the agreement.

Dr. LANGMUIR. The Senators know that far better than I do. I agree with them.

Senator VANDENBERG. Is it your opinion that it is possible to implement inspection and control to a conclusive degree?

Dr. LANGMUIR. I think so, if the mutual desire for security is large enough.

Senator VANDENBERG. That is a pretty big "if".

Dr. LANGMUIR. No, I think it will automatically come when several nations have atomic bombs, and because of that insecurity will arise; and I think the demand for security will be such as to make a real desire for inspection. Other nations will almost want to insist on inspection of our country, and will have to have inspection of their own. Then, we have to find effective ways of doing it.

One of the most constructive suggestions that I have heard in this inspection business is Dr. Urey's suggestions that we have no plants for peacetime applications of atomic energy or atomic power pending that time when we have really come to the agreement that we know from methods we cannot yet conceive of that there really is world security. We have no security. We don't fear any danger of New Jersey attacking New York by atomic bomb. The time may come where all over the world you have such a state of world affairs that you no longer have any insecurity. If that exists, that is the time to develop atomic power.

Senator VANDENBERG. I would like to project your prospectus just one step further, to see what your answer would be.

Suppose we have this agreement. Suppose we have the mechanism and we are all pretty well satisfied with it, and suppose the inspection discloses that country A is violating the agreement. What are we justified in doing, and what would we do?

Dr. LANGMUIR. We do what we decide to do at that time, probably go to war if we have much sense, which is what we would do if we didn't have the agreement.

Senator MULLIKIN. Did I understand, Doctor, that you couple with inspection a universal intent, having no exceptions, that there shall be no violation of the peace?

Dr. LANGMUIR. I did not get the first part of your question.

Senator MILLIKIN. I understood you to say, in reply to a question by Senator Vandenberg, that you rely on inspection plus a universal intent to preserve peace.

Dr. LANGMUIR. And desire.

Senator MILLIKIN. Would you say that that would involve a fundamental change in the human nature of the rulers of the world and of the peoples of the world?

Dr. LANGMUIR. I don't think there is any change in human nature. I think the thing would be done for purely selfish interests among the peoples of the world. If it comes about, it will be the most constructive thing that has ever happened from the atomic bomb, far more important than atomic energy. It will have brought a state of world peace.

Senator MILLIKIN. Of course, I agree, Doctor, if it comes about. I am now trying to prove whether it has a chance of coming about through the selfishness, the greed, and the ambitions of unscrupulous rulers, and sometimes, of aggressive peoples.

Dr. LANGMUIR. I don't think there is any certainty that it will come about. I think it is a very well based hope that it will come about and never could have come about except through the atomic bomb.

Senator MILLIKIN. But if it does not come about completely, then we are right where we are now. Is that not correct?

Dr. LANGMUIR. Yes; if the thing is not effective, we are as bad off as if we had not started.

Senator MILLIKIN. In the meantime, we have disposed of our bombs?

Dr. LANGMUIR. No, we will not dispose of our bombs until we have a different attitude. We cannot now decide that we are ever going to dispose of our bombs.

Senator MILLIKIN. Until we are thoroughly satisfied that there are no unscrupulous rulers in the world and there are no people who desire war?

Dr. Langmuir. I don't know what we have to decide. We simply have to be satisfied 5, 10, or 20 years hence that that is our best bet.

Senator MILLIKIN. Doctor, I suggest we will have to base ourselves more solidly than that, because we are just talking theories in that event.

Dr. LANGMUIR. No, it will not be done until we believe that things have been accomplished.

Senator MILLIKIN. That is my point. I suggest that we may have to wait eternally for that point, and in the meantime this threat you speak of is in our hands.

Dr. LANGMUIR. I don't think it is eternally. I think the thing will come to a crisis within 10 or 20 years, and it has to be decided by then or else we will have a war.

Senator CONNALLY. According to your view, the industrial use of atomic energy—according to the dangers you point out—is a secondary matter, isn't it?

Dr. LANGMUIR. Almost trivial.

Senator CONNALLY. If we didn't ever use an ounce of it for industrial purposes, it would be worth abandoning it?

Dr. LANGMUIR. For large-scale power purposes. I did mention that small-scale production, which offers no hazard, might revolutionize science and medicine and bring us some extremely important developments.

Senator CONNALLY. On the other hand, if you did permit the use for general industrial purposes, you would manifoldly increase the difficulties of inspection and holding the military aspects of it in proper control, wouldn't you?

Dr. LANGMUIR. Yes. I think it is very hazardous. I think we ought to consider that ultimate security or any world control will involve unforseeable uses, but we don't have to answer those questions.

Senator CONNALLY. But we can think about them; that is what we are trying to find out, is to get the basis of all these things.

The CHAIRMAN. Doctor, if I understand you correctly, you believe that control is scientifically feasible?

Dr. LANGMUIR. Yes.

The CHAIRMAN. Now, then, the second question arises: Is it politically feasible?

I gather that you are confident that it is, based on the fact that all people in the world want security above all else, and therefore they will be willing to forego some rights that they might otherwise have in order to attain that security.

Do you think that that desire, and in fact the compulsion of the situation could be brought home to the peoples of the world by demonstrations of the power of this monster?

Dr. LANGMUIR. I think it would be very helpful at a later stage, no doubt, after people have begun to more or less forget about Hiroshima, when I think it would be well to have through the United Organization a test or demonstration under proper conditions so that people can see just what this thing means.

The CHAIRMAN. I believe plans are going forward in the Navy Department to make a test on naval vessels. Do you think it would be desirable if representatives of other peoples could see the results of that situation?

Dr. LANGMUIR. Yes, I think full world publicity should be given to it.

Senator HART. Doctor, I gather that you do not advocate again making the attempt at disarmament by example, similar to what we did in the early 1920's?

Dr. LANGMUIR. No; I do not.

Senator HART. Doctor, referring to your testimony about secrecy during the war and the incident when your passage to Russia was somewhat interrupted and you felt somewhat resentful about it at the time—

Dr. LANGMUIR. The way that it was done.

Senator HART. Were you worried, at that time, lest Germany solve the atomic fission problem and create a weapon sooner than we did?

Dr. LANGMUIR. No.

Senator HART. You were not at all worried?

Dr. LANGMUIR. Well, not seriously. It was a possibility, but improbable, I thought.

Senator HART. Now, certain numbers of people of course, as you know, were very decidedly worried about it; and some of them were carrying the responsibility for seeing to it that Germany did not get any aid from us in that.

As you look back upon it now, can you blame their state of mind for taking overprecautions, or what looked to be overprecautions now, but which had a different aspect at that time?

Dr. LONGMUIR. I don't blame the intent of anyone who carried through these security regulations. I think it was all done with the very best intent, but I think the details of it went far afield in the methods that they used in many cases.

I think this is one of them. In the first place, the implication was that I would be drugged or tortured in Russia, which I don't think is a reasonable one for anyone to make. I was willing to risk my life. A lot of people had warned me that 16 Poles had been invited to Russia and did not come back; and that we were 16 Americans and might have better luck. I did not take that seriously.

Senator VANDENBERG. That is because you were an American and not a Pole.

Dr. LANGMUIR. As a matter of fact, the 16 Poles never were invited to Russia, you know.

Senator HART. Did you hold those same opinions then that you have been expressing this morning as to the ridiculousness of various of the security measures?

Dr. LANGMUIR. Yes.

Senator HART. You thought at the time they really were ridiculous?

Dr. LANGMUIR. Yes.

Senator HART. Another thing, Doctor: You said in your statement that the fundamental scientific information should all be disclosed now. Is it your thought that in Dr. Smyth's book that has not been done on a very considerable scale?

Dr. LANGMUIR. Oh, the Smyth report only contains a small fraction of the fundamental scientific knowledge, and it was stated at the end of the Smyth report that there would be other reports of a similar nature giving further progress; and the President's declaration says practically the same thing, that from time to time there will be other releases of scientific information. I hope that is implemented.

Senator HART. Have not some of your colleagues in the scientific field stated that 85 percent of the knowledge was disclosed in that report?

Dr. LANGMUIR. I don't know what they said, but I would not agree to that. The qualitative information was given; the more detailed information was not given, and yet that information can be obtained by anyone. They are facts of nature. As was brought out by Dr. Urey, the day and place of D-day is something you can keep secret, but you cannot keep secret the energy released by the fission of plutonium, because anybody can try that. It takes time to set up the apparatus, but the answer is in nature itself, and not in our hands.

It is absurd to try to keep fundamental knowledge away from the human race. It cannot be done.

Senator HART. You are talking now about the future, Doctor. I was trying to get the record straight as to what did happen and the statement that 85 percent of the disclosure has already been done.

Dr. LANGMUIR. I think that is largely a matter of definition as to what aspect of knowledge you are referring to.

Senator HART. In speaking of Russia you gave two estimates. You said Russia might catch up with us within a period of 3 years, and then I think you gave a somewhat larger estimate at another point. In making either of those estimates, did you take into account the devastation that has already gone on in Russia and the amount of

work they have to do to restore before they can get ahead with anything?

Dr. LANGMUIR. Yes. Remember, the 3 years I gave was the time in which Russia could get her first atomic bomb. That would not be very important. It would take longer than that before she could reach one of these other stages. It would be more nearly 10 years, where we might have a serious uncertainty or hazard in the development of the atomic race.

Senator HART. One last question, Doctor, in the political field.

You stated that you did not wish to wait for the United Nations Organization to solve this question of world security, that you preferred that it be done by Britain, the United States, and Russia. Would you care to elaborate on that?

Dr. LANGMUIR. I did not mean to imply that the thing should in any way not be done through the United Nations Organization. I think it must be, but I think we should explore the possibilities of having a receptive approach to the thing by Russia by informal discussions which I presume are taking place. I hope so, at least, because I think that to propose the thing in a formal way and to go through the regular procedures—that is, if the motion could be brought before the United Nations jointly by the United States and by Russia, it would probably be helpful. The way for that might be paved by some informal discussions, but I don't put a great deal of stress on that.

Senator HART. Thank you, Doctor.

Senator HICKENLOOPER. Having seen the proof, Doctor, that fission is possible on substantial scales, and having been admitted to this at least first dawning of this great field of energy, is there any reasonable possibility that science the world over could be prevented in any way from dabbling in this thing further and going on?

In other words, science is inevitably bound to go forward with further experimentation in this field?

Dr. LANGMUIR. It is like the Catholic Church trying to stop progress in science. It just can't be done, because the knowledge already is there to be found. It is in nature, and to prevent us discovering the facts of nature is a hopeless job.

Senator HICKENLOOPER. And science will go on exploring this field despite what politicians or anyone else attempts to do?

Dr. LANGMUIR. If you regiment them here so they can not do it, they will go elsewhere.

Senator HICKENLOOPER. Therefore, in the light of that probability and almost certainty, I take it that it is your view that agreements and commitments and arrangements, whatever they may be, are about the only hope of solution of this thing to prevent destruction?

Dr. LANGMUIR. And all we have to have is a step-by-step progression toward something. We cannot ask now for an effective method of world control, for that would make it impossible to attain, because you know you cannot get it. That is utopia.

Senator HICKENLOOPER. I get back then to bringing up a line of suggestion you made a moment ago. I think probably it was a remote suggestion that we might destroy or suppress this. I take it you think that probably would not be a very practical thing.

Dr. LANGMUIR. I think that it is rather likely that in the progress toward world control it will become a desirable step.

Senator HICKENLOOPER. That is to suppress the bomb?

Dr. LANGMUIR. If you are going to suppress the bomb, you must suppress all the materials to make the bomb, and even destroy them.

Senator HICKENLOOPER. You think that might be a likely step in the future?

Dr. LANGMUIR. Yes.

Senator HICKENLOOPER. In the face of the fact that the thirst of science for knowledge in new fields will continue?

Dr. LANGMUIR. That has nothing to do with the thirst for knowledge. The thirst for knowledge in science comes in insignificant amounts of this material. We would not destroy all of this material, only that in pound lots.

Senator HICKENLOOPER. Experimentation in fission would go on in spite of everything, wouldn't it?

Dr. LANGMUIR. Certainly.

Senator HICKENLOOPER. And if they can explore new fields in minute amounts, that is the way this bomb was started.

Dr. LANGMUIR. That takes a long time, and by that time we hope we will have such agreement or such desire for agreement that even those things will be an international cooperative effort.

Senator HICKENLOOPER. It may be an arduous job to get from the laboratory to full production, but it still is an incidental thing in connection with this whole field of exploration—that is, the mechanical and engineering end of getting from the laboratory in minute quantities to the ultimate production line in substantial quantities is only a mechanical detail?

Dr. LANGMUIR. A mechanical detail, but it is the major part of the whole problem.

Senator HICKENLOOPER. But it is arduous?

Dr. LANGMUIR. It takes a tremendous amount of time. It is the thing that took the most time in the Manhattan project.

Senator HICKENLOOPER. As the laboratories increase their knowledge and produce different types of materials, and things of that kind, isn't it reasonable to assume that the methods of producing it in quantity will become easier?

Dr. LANGMUIR. I don't think so.

The CHAIRMAN. Doctor, now that the science exists, even assuming that we adopt your proposal to do away with it in any quantity, but of course leave certain minute quantities for experimental purposes—

Dr. LANGMUIR. Oh, leave enough for one atomic bomb, if you like.

The CHAIRMAN. You still have to have, because of the existence of the knowledge of science, an international inspection force to see that it does not go past the stage Senator Hickenlooper has outlined; is that true?

Dr. LANGMUIR. Of course, the whole problem, all of these details that we are discussing, really emphasize that we have got to learn to live with our neighbors in this world. We have to, and it is a question of relations between human beings. That is the real problem and the problem that has got to be solved.

Senator HICKENLOOPER. I understand that is your premise.

Dr. LANGMUIR. The mechanism by which things are to be facilitated is what we have to discuss at present. I think the magnitude of the problem is such that it is either existence or learn to get along with other nations.

Senator JOHNSON. How are you going to get along with a Hitler, a Mussolini, or a Tojo?

Dr. LANGMUIR. We cannot, but who takes the place of Hitler now?

Senator JOHNSON. I don't know.

Dr. LANGMUIR. I don't either.

Senator JOHNSON. But I hope he is the end of that string.

Dr. LANGMUIR. As far as I can see, I think every nation—I don't mean the people of Germany want everlasting peace, for we cannot trust them; we cannot trust the people of Japan, and that will have to be handled in a separate way—but I believe all the United Nations desire security more than anything else, and that was not the state of affairs before this last war.

Senator AUSTIN. Doctor, it really narrows down to a very simple, or perhaps oversimple proposition. Your ultimate remedy for destruction involves corresponding action by all countries, doesn't it?

Dr. LANGMUIR. Yes.

Senator AUSTIN. Therefore, we are really on a spiritual basis with the thing. It is a question of self-discipline by nations, is it not?

Dr. LANGMUIR. That is right. I just cannot see how we can ever get world cooperation except on a basis of substantial equality. You cannot go to a nation and say, "We hold bombs in a sacred trust, and we want it to stay permanently that way; you have got to trust us, but we don't trust you."

That is not world cooperation.

Senator TYDINGS. Doctor, would you advocate that a solution for this problem would be attempted by the three great powers, or through the United Nations, or do you think it would be well to consider a world conference to deal only with atomic energy at this time?

Dr. LANGMUIR. I am a scientist, and I am not a statesman. I don't think scientists should be asked to be statesmen. However, they are American citizens and they can all be able to express their opinions.

Senator TYDINGS. None of us are statesmen; we only work to try to be.

Dr. LANGMUIR. I personally would like to see the development of the United Nations. It will have to go way beyond what it is now.

When I suggested an informal conference before the United Nations I did it more as a way to paving action to present the thing to the United Nations, not only from England and America, but also Russia, because those are the ones that are mostly involved in this problem, obviously. Those are the Big Four, the United States, England, Canada, and Russia; so let us be frank about it and let us therefore present this thing to the United Nations if possible as the desire of all those nations.

If it can be done that way, it will go fast. If it cannot be done that way, then let us handle it through the United Nations.

Senator TYDINGS. Maybe you missed my question. I mean to ask whether you thought through the Big Four, as you delineate them, or through the United Nations, there was the best chance of finding the solution to this problem rather than by some conference called particularly to deal with it on an international scale.

Dr. LANGMUIR. I would say through the United Nations.

Senator BYRD. Doctor, you stated in the paper you read that Russia had ample supplies of uranium. Has that been discovered?

Dr. LANGMUIR. I don't know much about it, but I have had several conferences with people who presumably know a great deal about it. It is brought out very clearly that uranium is a widely spread material. It is known that some of the biggest deposits in the world are in Czechoslovakia, and I presume Russia could get those.

Senator BYRD. Do you know of your own knowledge that there have been supplies discovered in Russia?

Dr. LANGMUIR. No; I don't know. It is an element that is widely distributed in small amounts.

Senator BYRD. I was not here when you made this statement: "Russia certainly has ample resources in uranium."

Dr. LANGMUIR. Yes; but she doesn't need much, you know.

Senator BYRD. Is there any other source of atomic energy except uranium?

Dr. LANGMUIR. Not that we know of at present, but in the future there may be.

Senator BYRD. I have often thought that the inspection and the policing of it could be done more by the materials, by inspecting the materials that are used, than perhaps by the factories. What is your opinion about that?

Dr. LANGMUIR. My idea is that the control or inspection would come first by contacts between scientists, and that through mutual desire you would then implement that by inspection of factories and possibly the elimination of large plants, and probably simultaneously with the inspection of all production of uranium. It would be very effective and relatively simple.

I think there would be politically less difficulty in that than there would in a great many other things.

After that has been done, as I go on and say in my paper—that is a thing on which public opinion can really take grasp—if you have once set up the machinery for that, it seems to me almost inevitable and automatic that you extend it to all weapons of war.

Senator BYRD. Where are the known deposits of uranium now?

Dr. LANGMUIR. I don't know much about it.

Senator BYRD. Then you are not certain they have been discovered in Russia?

Dr. LANGMUIR. Not personally, no; but I have heard through various people, from some people who I believe know, that there are known deposits in Russia.

Senator BYRD. I was told on good authority that no deposits have been discovered in Russia, but of course there have been in Czechoslovakia.

Dr. LANGMUIR. Yes; but when you think what a large fraction of the surface of the earth is covered by Russia, and how little we know about it and how much the Russians know about it, it is reasonable to assume that there are such deposits.

Uranium costs \$2 or \$3 a pound, and nobody was interested in amounts of uranium at that price; but, for the purposes of atomic energy, you could afford to pay a thousand times that much, and that entirely changes the situation. Instead of paying \$1 or \$2 to work up the ore, you could now spend a thousand times that. You could take ores that have a thousand times less uranium, and still get away with it.

No one knows how widespread these ores are which have a small amount of uranium in them which might become workable.

The CHAIRMAN. You just made an interesting statement. I take it that you believe that if we get an agreement to eliminate this most horrible weapon that it necessarily follows, if the nations agree to give it up, that they would be willing to give up other forms of armaments?

Dr. LANGMUIR. I think so. I think the whole machinery could be carried through, and it would be desirable. After all, if you have no atomic bombs and no weapons, you still have poison gases and you may have perhaps biological warfare and what not that might be almost as bad. You will want a good solution for the thing. The same kind of mechanism, the same desire, the same motivation would lie behind the complete renunciation of war.

The CHAIRMAN. In other words, you regard this as a catalytic agent that would bring to people of the world the determination to disarm?

Dr. LANGMUIR. I don't think personally we need to worry about those things. We must not make them issues at present, because we now know that the most important thing is the atomic bomb. If that were solved, we then would come back to these other problems which would be almost as bad. The difference is that atomic bombs could destroy a nation in 24 hours, and the others might do it in a year or so.

What we have done in this war, doing nothing in the way of preparation until the war came and then building up our defenses, is out with the atomic bomb.

The CHAIRMAN. We foresaw quick death; but you fellows think slow death might still be more attractive.

Dr. LANGMUIR. I think most people feel that slow death can possibly be averted; but if quick death comes, then you need not worry.

Senator TYDINGS. Doctor, as to your idea of disarmament, if we have civil wars such as happened in China, or unrest such as has happened in India for a long while, you would have dictators springing up pretty much if you had no armaments.

On the other hand, we all meet ourselves coming back sometimes, don't we?

Dr. LANGMUIR. We have a police force that carries guns or clubs, and I suppose you will always need something like that.

Senator TYDINGS. It seems to me that in big countries like India, China, Russia, the United States, or parts of the British Empire, that if you had no armies at all you would simply give hostage to new dictators who might decide not to stay in the United Nations, and it might be hard to track them down.

Dr. LANGMUIR. I hope the United Nations will have an organization that can handle the policing of the world; but it does not need atomic weapons for that purpose. You can not use an atomic bomb on India; you cannot use it on Java, for instance, or the civil war in China. That cannot be settled by atomic bombs. It isn't a suitable weapon at all, any more than it could be used against a city in Louisiana which decides to do something illegal.

Senator TYDINGS. Suppose some man, though, wants to call a mob to his colors and start marking on the capital; what would you do about it under the United Nations? What is your conception of it even without the atomic bomb?

Dr. LANGMUIR. Well, haven't we a police force?

Senator TYDINGS. Suppose some leader arises in one of these countries and surrounds himself with a lot of reckless spirits and starts to march on the capital. That would be civil war. Would we have a right to interfere in the internal affairs of another country?

Dr. LANGMUIR. I think that has got to evolve. The United Nations, I think, is going to evolve faster than anybody had any idea of.

Senator TYDINGS. I hope you are right.

Dr. LANGMUIR. What form it will take, or the possibility that it may not take a desired form, cannot now be considered as a reason for not making progress. We cannot predict the future.

Senator CONNALLY. Doctor, as I get your testimony, you think that ultimately the abolition of the bomb would result in probable disarmament in other respects; but I don't understand you to mean that before we do anything about the bomb we have got to agree on all these other weapons.

Dr. LANGMUIR. I say the opposite.

Senator CONNALLY. If we could deal with the bomb and make a success of that, then you think that would give cause for spreading it still further?

Dr. LANGMUIR. The machinery set up for handling the atomic-bomb security could be such, if it worked over a period of years, that there would be an inevitable desire to have that apply to all other forms of war.

Senator CONNALLY. I am trying to get the point that you would not do all that with one stroke, because if you did you could not do any of it.

Dr. LANGMUIR. I think even the first thing is a matter that no final decision can be reached on in the next 10 years. It may take 10 years to get to that stage by constant effort.

The other thing may take another 5 or 10 years, but to put those in as prerequisites will kill the whole program.

Senator CONNALLY. Now, you went on to say that there will be development of science, with which I thoroughly agree. You don't know and nobody else knows but what science in the years to come may discover other materials out of which this atomic energy can be developed.

Dr. LANGMUIR. I said I think it is probable.

Senator CONNALLY. Just the fact that you found one method and one group of elements does not shut the door on future developments?

Dr. LANGMUIR. Of course, the field has been pretty well explored and we have made really great progress; but, nevertheless, I believe it is probable that other forms of atomic energy will become available before the next war.

Senator CONNALLY. Thank you.

Senator JOHNSON. Dr. Langmuir, how long were you in Russia?

Dr. LANGMUIR. Eighteen days. The whole trip was 30 days from New York back to New York.

Senator JOHNSON. Did you see anyone there, or did you have conferences with anyone, or did you meet anyone outside of scientists in Russia?

Dr. LANGMUIR. Practically not.

Senator JOHNSON. Is it fair to base a conclusion on Russia and Russia's political intentions by these few scientists that you met?

Dr. LANGMUIR. No; certainly not. In 18 days you cannot get a very deep view of a country. Nevertheless, the things I did find were in so many cases so different from what I have been led to expect that it is rather interesting, I think.

What I meant to say is that the Russian scientists are people you can cooperate with; that I know, and that is a step. That is why I like to see in the President's declaration a statement that they are planning to exchange scientists with other nations. That would be a useful step.

Senator JOHNSON. All scientists, whether Russian, German, or American, from whatever source they may come, are internationalists in viewpoint; are they not?

Dr. LANGMUIR. A great many of the Germans were not.

Senator JOHNSON. The very nature of their science causes them to be.

Dr. LANGMUIR. A great many Germans were originally, but under Hitler ceased to be.

Senator JOHNSON. Of course they were regimented under Hitler.

Do you have any knowledge of the secrecy imposed by the Russian Army? I have been told on pretty good authority that the Russian Army did not permit any observers, even of their allies, to come within many miles of their battlefield to see their weapons or to see their military techniques at all.

Dr. LANGMUIR. And they did not come anywhere near our Manhattan project, so there was no cooperation in fundamental technique.

Senator JOHNSON. And you said, "because no one outside of the American Army could be so stupid."

Dr. LANGMUIR. These were British people saying that, not Russians. I am repeating something the British said.

Senator JOHNSON. And given it considerable emphasis?

Dr. LANGMUIR. Yes. They had had contact with the American Army; they had been here and they knew.

Senator JOHNSON. Do you agree with that statement, that conclusion of the British?

Dr. LANGMUIR. I think there is a certain amount of justification for it.

Senator JOHNSON. You don't think the Russian Army gives the American Army any competition along that line?

Dr. LANGMUIR. I don't know anything about the Russian Army, but I agree that the Russian Army did not disclose anything about their weapons.

Senator JOHNSON. That is your criticism of the American Army, because they were too secret?

Dr. LANGMUIR. No, not at all, but the way they did it. The way they did this was the thing that was so stupid, not the fact that these men were not allowed to come, but the whole way the thing was carried on was such as to disclose the very thing they wanted to keep secret. It was a blundering process, but it is the kind of blundering process that takes place when military people try to control secrecy in fields in which they are not adequately trained. They have done a wonderful job as to keeping secret D-day, but when they come to try to control scientists, they don't know how to do it and they make a mistake in thinking they can.

Senator JOHNSON. Does anyone else know how to do it?

Dr. LANGMUIR. I hope not.

The CHAIRMAN. Doctor, you know Mr. Kettering of General Motors?

Dr. LANGMUIR. Yes.

The CHAIRMAN. Did you see his observation that, "If you lock the doors of a laboratory, you lock out more than you lock in"?

Dr. LANGMUIR. I didn't see it, but it is good.

The CHAIRMAN. Looking to the international science and the freedom of exchange, we owe a good deal to the development in some very important fields to scientists in England, Germany, and other countries of the world, do we not?

Dr. LANGMUIR. Yes.

The CHAIRMAN. Do you know where DDT originated?

Dr. LANGMUIR. I think it first was discovered by a German scientist a long time ago, and then its insecticidal properties were discovered by someone in Switzerland.

The CHAIRMAN. How about uranium fission?

Dr. LANGMUIR. That was done, I think, by Fermi—no, it was done in Germany.

The CHAIRMAN. How about synthetic rubber from alcohol?

Dr. LANGMUIR. I don't remember, but the Russians certainly have done a great work in synthetic rubber.

The CHAIRMAN. Penicillin?

Dr. LANGMUIR. England.

The CHAIRMAN. And jet propulsion?

Dr. LANGMUIR. Also England.

The CHAIRMAN. Radar?

Dr. LANGMUIR. England, and it was at least going on independently in the United States, but the English were the first ones to reduce it to practice and use it on a large scale.

The CHAIRMAN. Did you hear General Groves' testimony?

Dr. LANGMUIR. I only heard yesterday's questioning and replies to the questions asked.

The CHAIRMAN. He testified that in his opinion there wasn't any nation that would, unaided, arrive at the production of atomic weapons within 20 years. I take it you don't agree with that.

Dr. LANGMUIR. I don't agree at all with it.

The CHAIRMAN. Doctor, have you any recommendations to make as to ways in which the research on cancer with radioactive materials, and other diseases, could be immediately stimulated?

Dr. LANGMUIR. Apparently the difficulty in cancer is that we don't understand it. We don't know what cancer is. We know that growth processes go in wrong directions, but we don't understand those growth processes.

By the use of radioactive substances, radioactive carbon, for example, and other radioactive elements that are now available relatively cheaply as byproducts of the production of plutonium, we get an understanding of chemical processes. The method is just being worked out, but it is sure to be amazingly successful in studying the complicated processes that take place in biology.

I believe that in a few years when a large number of physicists have these tools available and get to use them in routine work in the studying of fundamental problems, the rate of progress will be speeded up

manyfold over what it otherwise would have been. Although we might ultimately have reached a solution of the cancer problem in a certain number of years, now I think the chances are it will be reached in perhaps a third or a quarter of that time.

The CHAIRMAN. Common decency would require us, pending any arrangement for international control, to make some kind of interim arrangement to get small amounts of this material into the hands of men who can proceed experiment with it for the alleviation of these diseases?

Dr. LANGMUIR. I should like to see these materials given out, since we are the only ones that can produce them in reasonable quantity, not only to American scientists, biologists, chemists, and physicists, but also to those all over the world.

The CHAIRMAN. Doctor, you mentioned a project for cheap oxygen for blast furnaces being developed in Russia. Have we a comparable program in this country?

Dr. LANGMUIR. No, but I think the Russians have shown great vision in undertaking a program of that magnitude, and apparently with great success.

The CHAIRMAN. How did you find out about that?

Dr. LANGMUIR. It was told me voluntarily by Mr. Kapitza in Moscow.

The CHAIRMAN. Did he outline the program?

Dr. LANGMUIR. He told me a great deal about it.

The CHAIRMAN. Did he discuss the scientific details with you?

Dr. LANGMUIR. A great many of them. I talked to him altogether 2 or 3 hours on the thing, and he gave me practically all the information he could have given me in that time. He answered all my questions very frankly.

Since then, when I came back, we have been trying to get in touch with them to get more information on five or six things I saw in Russia away ahead of the rest of the world, and we have been trying, through the State Department, to get in touch with the Russians to get additional information and have had no success whatever.

Senator TYDINGS. How do you rate the Russian scientists as a body in comparison with the scientists of France, Sweden, England, and the United States? Are they about as good, generally inferior, a little better, or what—taking them as a whole?

Dr. LANGMUIR. Well, it is hard to put any definition on that thing.

Senator TYDINGS. The reason I asked you the question is that I have a hunch, without any knowledge of it, for I have no Gallup poll at my disposal, that the American generally thinks of the Russian scientist as being much inferior to the leading scientists of other countries. Is that true, or is it false?

Dr. LANGMUIR. There are some excellent Russian scientists doing very fine work, but the number of scientists doing such excellent work as compared to those in America or England—United States and England are certainly leading the world.

Senator TYDINGS. You would not say they are top-flight scientists?

Dr. LANGMUIR. I don't know just what you mean by that.

Senator TYDINGS. You mean some of the better ones in the world?

Dr. LANGMUIR. A few of them are right up among the best in the world; but on the whole the Russian scientists have suffered from lack

of good equipment, I should say, largely. Their laboratories, outside of Kapitza's laboratory, and some others who are building new laboratories, are equipped with the kind of equipment that would have been used in the United States 20 years ago.

Senator TYDINGS. Could Russia make those instruments, or would they have to buy them abroad?

Dr. LANGMUIR. Russia makes their own.

Senator TYDINGS. They have the precision tools, and so on?

Dr. LANGMUIR. Yes. In this oxygen development, for instance, that is really precision work, they have turbines and a lot of equipment there which represent a very high degree of mechanical perfection.

Senator TYDINGS. Let me ask you this question, which you have already covered, but pointedly: In your opinion, given a free hand under what you conceive to be the conditions and circumstances, how long will it be before it will be possible for Russia to turn out atomic bombs?

Dr. LANGMUIR. Well, I think I gave that.

Senator TYDINGS. Five years?

Dr. LANGMUIR. I put 3 years as about a minimum. That is, I put 3 years down, if Russia really seriously devotes her attention to it and starts on a big-scale production.

Senator TYDINGS. And they say publicly they are going to do that.

Dr. LANGMUIR. I haven't heard that statement.

Senator TYDINGS. Molotov made the statement that Russia would have the atomic bomb and more before long.

Dr. LANGMUIR. I think he said, "and other things."

Senator TYDINGS. That is right.

Dr. LANGMUIR. But he didn't say how big the project is.

Let me tell you about the project they already have.

The Academy of Sciences has six or seven institutes, and those are just for the rather pure scientific work, the basic science that underlies other things. We did not go to the industrial laboratories, of which there are a large number.

They have a new building for the Academy of Sciences, which has just fairly recently been completed, and they showed us pictures which looked to be about 10 times the size of that building which they are planning.

The whole emphasis that they place on it, the awards they give, the incentive system in pay and so on, all show that they place almost the highest priority on science.

In these meetings, they said that the whole future development of Russia depends upon application of science. They believe that the scientist should receive the highest possible facilities for his work, and they give the scientists the greatest freedom.

Senator TYDINGS. What countries do you envisage in the world that eventually would be capable of supporting a program for the manufacture of atomic bombs? The United States, Canada, or Britain, or Russia?

Dr. LANGMUIR. Of course, the United States already has the equipment and we know how to do it. We could extend that as far as we want. England, I think, has said she is planning to build them. Canada already has some plants for making some parts.

Senator TYDINGS. Russia would be fourth eventually?

Dr. LANGMUIR. Russia will be fourth at first. Russia, however, would far outrun England in the long run.

Senator TYDINGS. I am looking ahead 10 years or 15 years. What countries?

Dr. LANGMUIR. In 10 years, to my mind, it is very uncertain whether the United States or Russia will lead.

Senator TYDINGS. I am not asking who will lead, but what nations will be capable of producing atomic bombs if they make up their minds to produce them within 15 years?

Dr. LANGMUIR. Oh, many of them.

Senator TYDINGS. Well, name some of them.

Dr. LANGMUIR. France, Sweden:

Senator JOHNSON. Spain?

Dr. LANGMUIR. I don't know about Spain.

Senator TYDINGS. Czechoslovakia?

Dr. LANGMUIR. Undoubtedly.

Senator BYRD. Switzerland?

Dr. LANGMUIR. Switzerland would probably do it on a small scale. She would not have the necessary financial resources.

Senator TYDINGS. Germany, of course.

Dr. LANGMUIR. Of course.

Senator TYDINGS. Japan, when the military controls are withdrawn?

Dr. LANGMUIR. No, Japan, even if all controls are withdrawn, I think is going to be pretty weak.

Senator TYDINGS. But there would be some 8 to 10 of the leading nations within 15 years?

Dr. LANGMUIR. I would say in 10 or 15 years there is a possibility of German influence in Argentina, which might be very serious.

Senator TYDINGS. Suppose that eventually happens, and there are 8 or 10 nations that have these bombs, and nothing has been done—for the sake of illustration—to curb them or control them. In the next war, what happens?

Dr. LANGMUIR. I don't like predicting the future.

Senator TYDINGS. I would like to have it. I think we ought to have your views on this.

Dr. LANGMUIR. I think it is up to the United Nations to evolve the mechanism.

Senator TYDINGS. Some nation might violate its agreement.

Dr. LANGMUIR. As Dr. Urey said yesterday, the bombs may drop on Washington which will destroy the whole city, and simultaneously on Chicago, New York, and maybe some others, and everybody says, "Who done it?" Nobody knows, and never can find out.

The CHAIRMAN. There is no possibility of retaliation, because you don't know who to go after.

Dr. LANGMUIR. You don't know who to attack.

Senator TYDINGS. That is what I am trying to bring out. If 8 or 10 nations have these bombs and there is a formal declaration of war, not delivered in the Pearl Harbor style, what happens in the course of that war with the atomic bomb in the possession of 6 or 8 of the warring nations on the earth? What is your opinion?

Dr. LANGMUIR. Well, the warfare would continue one way and another until one nation came out on top. If it cannot get along with other people, it exterminates them and then goes ahead with a unified

population of all one race or one group doing whatever is necessary to see that nobody else ever builds an atomic bomb.

Senator TYDINGS. Which would bring us right back to where we are today to start over again with the remnants of civilization.

Dr. LANGMUIR. It isn't a pretty picture to look at, and there is no nation in the world today that ever desires to be a victor in a warfare of that kind.

Senator JOHNSON. Doctor, do you know of any other nation on this earth, including Russia, which would have published the Smyth Report?

Dr. LANGMUIR. England probably would have.

Senator JOHNSON. Any others?

Dr. LANGMUIR. England almost did, you know. They have a report almost as good as the Smyth Report, which is a wonderful report. It is shorter and different from the Smyth Report, but it is excellent in the way of presentation of the basic facts, and a little more popular than the Smyth Report.

Senator JOHNSON. It followed though; it did not lead?

Dr. LANGMUIR. Simultaneously, I think, it was issued.

Senator TYDINGS. Doctor, in your opinion, in a country that contains one-sixth or one-seventh of the world's earth surface, how much actual acreage would be necessary for the construction of a complete plant for the manufacture of atomic energy?

Dr. LANGMUIR. Well, I would rather leave that question. I never visited these plants, and some of the Senators here have.

Senator TYDINGS. Assuming, for the sake of argument, that it would take 200 acres, or let us say a square mile, or let us even say 10 square miles. Many parts of the earth are very thinly populated and very seldom visited. Wouldn't it be possible, even after the international agreement with the best intentions of well-meaning people to work out control, for some nation to decide to build such a plant in secrecy and to produce the bombs under present conditions of government?

Dr. LANGMUIR. That is a scientific question which, with proper data, could be answered. I think a great many scientists have gone into that kind of question and think it would be possible to expect under those conditions. Of course, in Siberia you have enormous wastes. In fair weather we can see 100 miles either way, which is 200 miles wide. A dozen or two dozen planes across Siberia with photographic equipment could show up every building in the thing. It would take only a reasonable number of flights to get a map of the whole of Siberia, which could be done every year.

Senator TYDINGS. The reason I ask you these questions is that if all the nations in the world had free press and free speech, and you could go in and out, our problem would be a simple one. But all the nations don't have that, and unless all the nations do have that, can any sort of inspection ever be efficient?

Dr. LANGMUIR. I would like to see, in the United Nations, some discussion to get those points on which the nations can agree, and then take the points of disagreement and try to analyze to what extent they hamper progress toward world government, and bring these matters up. Nothing can be done about it for 2 or 3 years, but one of the things that impresses me in Russia is the rate at which things are changing, and in every case I think changes for the better.

Senator TYDINGS. I think that is true.

Dr. LANGMUIR. Now, what may that mean in 5 years?

I don't know, but I am hopeful. I am hopeful that Russia will have a free press and will allow interchange of knowledge, because it will become her need to do so.

Senator TYDINGS. Until we do get that sort of climate in which to live, we cannot accomplish the inspection, and the whole thing would then be hopeless, wouldn't it?

Dr. LANGMUIR. Absolutely, but I think that we have something like 10 years in which we can accomplish these things, so let us not be discouraged by the fact that we cannot do them in two, or three, or five.

The CHAIRMAN. Doctor, the statement has been made that in the building of an atomic bomb, it is necessary for us to keep our lead over other nations which may develop the bomb.

What is meant by and what would be the purpose of this so-called lead? In other words, we would be better off, if other nations had bombs as good as the ones we dropped in Hiroshima, if we had developed bombs 10 or 50 times better.

Dr. LANGMUIR. You see, in dropping bombs, you first want to pick out the most important target. The enemy would attack Washington first, Pittsburgh, and several industrial centers, and the destruction by those bombs would be terrifically high. Then they would have to attack smaller cities of less importance, and then they would attack the more unimportant towns, and finally they would be able to attack all the cities and all smaller towns; and still they have only covered perhaps one-thirtieth of the United States.

If they had still more bombs, they could drop them in open farmland; but what good is that? Not much unless you have 30 times as many so that you can cover all the farmlands and wipe out all the people, or probably 100 times as many. In other words, if you take the total number you need to completely wipe out a country, 1 percent of that is very effective. The next 1 percent, 10 percent, and so on, are almost useless. It does very little good to be able to produce enough to wipe out the cities, and then produce ten times that much, which is trivial in importance.

Being able to outproduce some other nation is of no importance if we can produce enough to destroy their cities. Beyond that, we do not need them unless we go to a different order of magnitude.

The CHAIRMAN. Does our set-up in the United States make us peculiarly vulnerable to atomic bomb attack?

Dr. LANGMUIR. We are particularly vulnerable. Our cities are badly distributed. We have great concentrations of cities.

We have certain areas in the East where industries are very much gathered together, and other nations—at least, a country like Russia, of course, is already far better dispersed and much less vulnerable to attack.

The CHAIRMAN. Doctor, do you believe that the Government should have an absolute monopoly on the production of fissionable materials?

Dr. LANGMUIR. Yes.

The CHAIRMAN. And the processing of them?

Dr. LANGMUIR. Yes.

The CHAIRMAN. Do you feel it is too important and too dangerous to have it in private hands?

Dr. LANGMUIR. Except it may be desirable to get cooperation through private hands, but the title and ownership should reside with the Government.

The CHAIRMAN. Yesterday, Senator Byrd asked as to what we ought to do with the bombs we have if an international agreement for control is reached. Would you care to comment on that?

Dr. LANGMUIR. I think I already have. I would go so far as to not only destroy the bomb, but destroy, if need be, all the materials from which the bombs are made.

Senator BYRD. What about the factories?

Dr. LANGMUIR. Destroy the factories, too, if need be.

If that is a critical point, let's yield on that point. That would put us in an equitable position with other nations we are trying to agree with, and how else can we do that except by putting ourselves on an equal basis?

Senator BYRD. You are talking about reaching these agreements 10 years from now. Every nation will have bombs 10 years from now.

Dr. LANGMUIR. I think the number that will have them 10 years from now—

Senator BYRD. I mean the nations which we have reason to fear would have them. Maybe the small nations would not, but certainly there will be five or six of the large nations that will have bombs.

Dr. LANGMUIR. The more nations there are, I think the easier it is to get an agreement. I think the United Nations is likely to be far more effective.

Senator BYRD. What assurance has anybody got with a bomb that you can practically put in your pocket that all of them would be destroyed?

Dr. LANGMUIR. You cannot put them in your pocket.

Senator JOHNSON. You could put them in a suitcase.

Senator BYRD. What assurance have we got?

Dr. LANGMUIR. I don't see any possibility of that. If a gangster in his attic or cellar can go out and make bombs and destroy anybody, I think the world is about out.

Senator BYRD. We had gangsters at the beginning of the war and will as long as the world lasts.

Dr. LANGMUIR. These have got to be very big gangsters.

Senator BYRD. Human nature doesn't change. You will have totalitarian dictators as long as you have a world. We have had them before, we have got them now, and will go on having them.

Dr. LANGMUIR. I don't know what human nature is, and in the second place, I don't know that it won't change.

Senator BYRD. It has not changed for the better in my lifetime. I think human nature in the last war was at the lowest level ever known. If there has been any improvement in it, I have not been able to judge it.

Dr. LANGMUIR. Let's hope for something better.

Senator BYRD. We cannot base our future on hopes alone.

Dr. LANGMUIR. The alternative of not doing something is absolute destruction. The risk in whatever you do is better than total destruction. Don't think there is a risk in undertaking these things; it is the only possible salvation. That is the thing we have to make clear. The worst thing that could possibly happen is to do nothing, so, therefore, let us do something and let us make it good.

Senator BYRD. I believe in doing whatever we can do, but when it comes to destroying the factories and all the materials to make the

bombs, I think we ought to know exactly where we stand before we do it.

Dr. LANGMUIR. How can you cooperate with anybody except as an equal? It is all right to hold bombs in sacred trust. I agree fully, but if, 10 years from now, we come to an agreement and say we are holding our bombs as a sacred trust, but we don't trust you, there can never be world agreement.

Senator BYRD. I can see a great deal of merit in your position, if what you mention could be done immediately; in other words, if what bombs we have on hand now—and I understand we have some—were destroyed before other countries had started to make bombs. But you intend to take action 10 years from now. Am I correct about that?

Dr. LANGMUIR. I think other nations will have them long before 10 years. I don't want to wait at all. I want to go ahead as fast as anybody goes ahead.

Senator BYRD. But you say repeatedly that you would not destroy the bombs in this country unless you were satisfied the other country would be in agreement with us. That cannot be done overnight.

Dr. LANGMUIR. No.

Senator BYRD. It has got to be done over a period of years, and in that time these other nations are going to have bombs.

Dr. LANGMUIR. We are not going to destroy our bombs unless they destroy theirs.

Senator BYRD. What assurance or guarantee can you get that they will destroy theirs? The bomb is not a large one, we will have to agree on that.

Dr. LANGMUIR. We will have to guarantee a time to destroy the bombs.

Senator BYRD. Would you take their word?

Dr. LANGMUIR. No, certainly not; and they would not take ours.

Senator BYRD. Here is a bomb that you can put in a satchel and carry around.

Dr. LANGMUIR. But the bombs can only be produced in plants employing hundreds of thousand of people, enormous plants. They have books and equipment which must all be inspected. Their records must all be gone over, like anything else in international affairs, and all cards must be put on the table before you could prove that you were really destroying all your bombs, and we would have to have similar assurances from other nations.

I cannot decide those things; I cannot even discuss them. It is a matter for the United Nations to work out, and it cannot be done next year.

Senator JOHNSON. I have one further observation to make, and that is that you scientists have gotten a long way ahead of human conduct, and until human conduct catches up with you, we are in a precarious condition unless you scientists slow up a little and let us catch up.

Dr. LANGMUIR. Scientists are not going to slow up; they are going faster.

Senator JOHNSON. Then, we will have to speed up.

Dr. LANGMUIR. You will have to speed up.

Senator JOHNSON. I am in favor of it.

Senator HICKENLOOPER. Mr. Chairman, I might suggest to Senator Byrd that we had one experience along the line he was discussing.

We sank a lot of battleships and other things, and the other nations didn't.

Dr. LANGMUIR. I don't recommend that.

The CHAIRMAN. Doctor, don't you think it would be more politically feasible to accomplish international agreement as to the setting of an inspection if this program was undertaken before other nations had atomic bombs?

Dr. LANGMUIR. Oh, yes. It must all be started, the sooner the better. The President's declaration of November 15 is excellent.

The CHAIRMAN. You will agree that if under the United Nations organization a commission could be set up and come back on the 1st of October of next year, we will say, with an agreed-on program that all nations are going into for the setting up of an inspection force, that is something you would like to see happen, isn't it?

Dr. LANGMUIR. Yes, but I do not believe the first time it is proposed that it is going to work. I think if nations could agree on inspection, fine. Then, it will have to be implemented; we will have to have teeth in it; we will have to have safeguards and all kinds of things which may take a few years to work out. If the intent could be expressed, and that may be done within a year, that would clarify the atmosphere tremendously.

The CHAIRMAN. I think it is dangerous, in view of your assertion that they could be produced by many countries within a period of 5 to 10 years, to give any impression to the American people that this is something that can be sort of taken easy in separate steps; but rather the desire should be to accomplish this just as quickly as possible in a working program.

Dr. LANGMUIR. Yes, but not to the extent of making an ultimatum that it has to be done next year or else.

The CHAIRMAN. I realize that.

Dr. LANGMUIR. That must not be done and we must not be disturbed or discouraged if it takes a little longer than we hope, because we must allow reasonable time in which these things can be done.

The thing that impresses itself on me is this: If you let things slide, as we did for 3 or 4 months after August, conditions get worse and worse and worse. They rapidly diverge and get into a more dangerous state of security.

If, on the other hand, you take constructive steps, get general points of agreement, when they first agree to inspect, that won't mean that inspection goes into effect right then and there. It means they begin to pave the way for mechanisms, and it may be 2 or 3 years before the thing comes to a point where there is inspection.

The CHAIRMAN. Winston Churchill gave as his estimate that unless we, so to speak—I don't suppose he would use this expression—but toned it up within 3 years, that the prospects for any kind of world security and peace would go.

Do you remember reading that statement?

Dr. LANGMUIR. Something like that; yes. I think I would agree that what is done in the next 3 years is perhaps the most important of all; but if at the end of 3 years we have not got our world security, that would not worry me much. If we have made progress toward it, and if we have an increasing desire to see the thing through on the part of several nations, then I say we have made great progress and there is great hope.

The CHAIRMAN. Do you think, if an invitation were issued by this Government to scientists from other countries, that they would be universally permitted and allowed to come here?

Dr. LANGMUIR. I think so; yes, within a reasonable time.

The CHAIRMAN. One further matter, Doctor. General Groves stated yesterday that many of the good men were leaving these projects because of uncertainties, which I believe is the way he phrased it.

Do you concede that that is the reason why these fellows are leaving these projects, these scientists, or do you believe that the fact is that they don't want to work on bombs?

Dr. LANGMUIR. Well, I don't think I am particularly qualified, for I don't know a great many of these men, but those I have talked to have expressed the opinion that the thing they like least of all are the security regulations and also they don't like to work on bombs. They are really scientists, and would rather work on nuclear physics. That is the thing that seems to them their life work. They have become engineers, and they don't like it; they would rather be scientists.

The CHAIRMAN. I might state, Doctor, for your information and for the record, that we have called for a report from the National Academy of Sciences. We have asked Dr. Jewett for a comprehensive report about the known sources of uranium and thorium. We will have that in a short time.

I want to thank you very much indeed, Doctor; you have been very helpful, and I want to thank you for coming down to talk to us.

The committee will meet on Monday at 10 o'clock.

(Whereupon, at 12:15 p. m., the committee recessed until 10 a. m., Monday, December 3, 1945.)

ATOMIC ENERGY

MONDAY, DECEMBER 3, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding:

Present: Senators McMahon (chairman), Russell, Johnson, Connally, Byrd, Tydings, Vandenberg, Austin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The committee will be in session.

Dr. Bush, will you proceed?

STATEMENT OF DR. VANNEVAR BUSH, PRESIDENT, CARNEGIE
INSTITUTION OF WASHINGTON, AND DIRECTOR, OFFICE OF
SCIENTIFIC RESEARCH AND DEVELOPMENT

Dr. BUSH. I have a brief statement, Mr. Chairman.

First, to identify myself, I am president of the Carnegie Institution of Washington and director of the Office of Scientific Research and Development.

I have had official connection with the development of atomic energy since June 1940. At that time, the National Defense Research Committee was established by President Roosevelt under my chairmanship, and the Advisory Committee on Uranium, headed by Dr. Lyman J. Briggs, which had been functioning since the fall of 1939, was reconstituted as a subdivision thereof. It was reorganized at this time, its work was somewhat expanded, and it proceeded with investigation of the possibilities of fission. In June 1941, I became director of the newly formed Office of Scientific Research and Development, of which NDRC became one major part. Under this arrangement, work on the uranium project was expanded, and over-all responsibility for it continued to be a part of my assignment.

It became apparent during that time that there was a strong possibility that a bomb would be developed during the war. The recommendations I made at that time for an all-out effort were based on the recommendations of two committees, two strong scientific and technical committees set up by the National Academy of Sciences at my request, which reported unanimously and which gave strong recommendations.

By the summer of 1942, the point of large construction had been reached, and the project was thereupon turned over to the Manhattan

145

Engineer District, Army Service Forces. On certain auxiliary research, and in other ways in aid of the War Department's program, OSRD remained active. My own connection with the development work took the further form of chairmanship of the Military Policy Committee, with Dr. James B. Conant as my alternate. This committee was dissolved this fall. As a member of the Interim Committee also, I have had a continuing share in responsibility for the program.

Development of systems for the control and utilization of atomic energy is the most important task ever faced by the governments of the world.

The CHAIRMAN. Doctor, do you mind being interrupted?

Dr. BUSH. Not a bit.

The CHAIRMAN. This Military Policy Committee was dissolved this fall. Why was it?

Dr. BUSH. It had completed its work, Mr. Chairman. I will enlarge upon that somewhat.

In the summer of 1941, when an extensive program was recommended, the President instructed me to report to an over-all policy committee which consisted of the Vice President, Mr. Wallace, and the Secretary of War, General Marshall, Dr. Conant, and myself. I took up with that group all matters of major policy from there on. When the program was turned over to the Army, to the Manhattan Engineer District, there was formed at the instance of that committee a Military Policy Committee, of which I was chairman, with Dr. Conant as my alternate, and on that committee were General Styer, then Chief of Staff of the Army Service Forces, and Admiral Purnell for the Navy. General Groves was made executive officer and had complete management of the program. He reported to the Chief of Staff, but he was instructed to review all of the major programs and policies with the Military Policy Committee in regard to the construction of plants and the like, so that his reports and recommendations received the endorsement of that committee before they went to the Chief of Staff.

That committee had entirely a wartime function and assignment to develop a bomb for use; having completed its assignment, it was dissolved at the time that the parent committee was dissolved, the major policy committee, at the end of the war.

For the continued progress of civilization, it is imperative that people be safeguarded against sudden destruction by atomic bombs. It is highly to be desired, for the betterment of living for mankind everywhere, that the great resources of useful power offered by further development of atomic science become generally available.

No more intricate and exacting problem was ever posed to governments than this one. It is inherently complex because the science of the atom is complex. The fact that the deadly military potentialities of the atomic bomb and the beneficent industrial applications of atomic power are almost inextricably intermixed complicates it further. The urge to prevent wars is very strong in all minds, for we have just emerged from a terrible war. The desire to enjoy the better life promised by applications of atomic power is strong also. Because the means of producing this peaceful power can readily be converted into an atomic bomb for destruction, the mechanism for world peace and the mechanism for world control of atomic energy are profoundly

interrelated. Preventing war is a long task, which must be done bit by bit, step by step; so also is the development of peaceful atomic power. The two must be related in our thinking, and what we do toward achievement of the one must be weighed in the balance of its effect on the other.

In a nationalistic world, all peoples will seek to attain an equal footing with respect to anything so powerful as atomic energy. If the mechanism of world peace is available and is strong enough, peoples may be expected to relinquish something of their traditional nationalism to attain that equal footing through international organization.

The CHAIRMAN. Wait a minute. You say, "In a nationalistic world, all peoples will seek to attain an equal footing with respect to anything so powerful as atomic energy," which means that all powers who are competent to do so are striving for it now; isn't that right?

Dr. BUSH. They either are now, or they will be in a nationalistic world, certainly.

The CHAIRMAN. If they relinquish nationalism to an international organization, they wouldn't try to stop getting atomic energy, would they?

Dr. BUSH. I think not, but my point is that if there is a strong enough international organization, instead of doing it independently, they may be expected to relinquish some of the nationalistic viewpoint in favor of attaining an equal footing through an international organization.

If no dependable mechanism is available, a secret arms race in the surreptitious development of atomic bombs may be foreseen. Any well thought out plan for orderly progress toward the banishment of war will start here, with the prevention of such secret preparations. The end of open preparations may then follow, to be followed in turn by the end to war itself. The start of the journey toward this great goal is in such a seemingly simple thing as the establishment of the complete flow of information—particularly of basic scientific information—across national boundaries.

The three governments which shared knowledge and skill to enable scientists to achieve the chain reaction and industry to create the materials for the bombs that ended the war have fittingly made the first move toward the establishment of mechanisms for the control of atomic energy and for the development of peace for which that control is an essential requirement. The declaration which grew out of the recent conference of President Truman, Prime Minister Attlee, and Prime Minister King is a very important document. It would have been important simply as a declaration for a peaceful world. It is of the very greatest importance because it chose the right path to that goal, blocked out the journey into practical, sensible stages, and clearly mapped the crucial first marches. The declaration is notable, moreover, because it entrusts to the United Nations Organization this momentous international responsibility. It is of the utmost importance that the member states, especially the great powers, upon whose cooperative effort success depends, do all within their capacity to assure that success. The way to international collaboration and control has been opened. But it will be a long way. As we progress along it, the separate national states must set their own houses in

order, establish their own internal systems of control, and thus bring into being agencies which can support the international agency.

Eagerness to assure world peace is laudable enough. The great hazard is the kind of over-eagerness which cannot endure the long patient work which will be needed, and which therefore argues for quick answers, such as "outlawing" the atomic bomb. Premature outlawry could well be disastrous, for it is impossible to outlaw when there is no effectively supported law. The first task is to create this. A good start has been made. The best possible support which our Government can bring to that good start is the expeditious passage of sound legislation for domestic regulation and development of atomic energy. During the lengthy period necessary for creation of an international system, it will be possible for this Government not only to enact the needed legislation but also to operate, test, and if necessary revise the domestic control system which that legislation establishes. By the experience of so doing, we may well secure experimental evidence that will be helpful in the performance of the international task.

Moreover, the passage of suitable domestic control legislation is urgently needed for purely domestic reasons. The present state of world affairs demands a strong United States. This is no time to let delay dissipate our strength, to let doubt and indecision hamper the great program of atomic science on which we are well embarked. People are getting tired of hearing about the atom, and when people get tired, they tend to turn away from issues. This is an issue which cannot in conscience be so ignored. Between the First and Second World Wars, the United States experimented with disarmament in an unorganized world—to sad result. The sort of thinking which that involved should long ago have been discredited. If we are to do our fair share in the exacting, patient work of international regulation, we must vigorously get at the domestic task now. Though the problem itself is great and new, it is susceptible of solution by the same means which have brought governments into being, gradually rendered them more efficient as agencies for the general betterment of man's lot, and reached a high point in the United Nations Charter. Those means are hardheaded analysis and honest good will. The first, used to the full in determining our internal control system, will clear the way for the second in international affairs.

From this point of view, then, let us consider general principles which legislation for internal control and development of atomic energy should embody.

The vast physical plants, the stock piles of materials, the varied applications of knowledge which taken together constitute the Manhattan Engineer District belong not to any men or group of men, nor to any corporation or group of corporations. They are the property of the people of the United States through their Government, in which are vested title to the physical properties and patent rights covering the engineering processes. This is as it should be, for the power of this development, for good or for ill, is too great to be otherwise held. Legislation for the further control and the further extension of this development should fortify this condition. At the same time, it should make proper provision for the active participation of private individuals and private corporations in the further utilization of atomic energy, under sound regulatory procedures embodied in a sensible licensing system.

For the years immediately before us, the deadly rather than the beneficial power of atomic energy will continue to hold first place in men's minds. Until suitable and effectual means for international control of military applications of atomic energy have been established and proved, the atomic bomb will continue to be a menace. Rigorous provisions for security concerning military exploitation of atomic energy, therefore, will continue to be essential. Our experience here will be of double value in the international effort, for it can become the basis for provisions to eliminate from the war machinery of nations not only atomic weapons but also other weapons nearly as deadly, by which we should be seriously imperiled in another war if atomic bombs had never existed. To solve the problem of the bomb is important in itself and of greater importance still as a contribution toward solving the entire international problem of war.

The manufacture of fissionable materials is by long odds the most dangerous manufacturing process in which men have ever engaged. The process is accompanied by the production of radioactive by-products as poisonous as the basic material itself; should the process used in producing power be ill-managed and get out of hand it would produce a great and deadly volume of such poisons. Improper or incautious manipulating of substantial amounts of fissionable materials by inadequately trained or irresponsible investigators is a danger to the public safety which Government must avert. Legislation for the internal control of atomic energy would be short-sighted, indeed, if it did not make thorough provision in this regard.

No better illustration of the complexity of the atomic energy problem can be had than the dilemma posed by this need for security and public-safety provisions as against the need for scientific freedom in the further study and investigation of atomic science. Atomic energy as we now know it and as we have employed it in the making of atomic bombs came about as a result of long and patient experimental investigation. If we are to press forward with the further development of atomic science for employment in peaceful power installations, if we are to explore to the full the beneficial possibilities in medical use of the radioactive byproducts of the fission process, if we are to go ahead with the search for pure knowledge in the field of which our present atomic knowledge is but a small part, we must so arrange controls that the research worker will possess the right and the freedom to carry on his studies.

A nice line of distinction hence must be drawn in security and safety provisions, in order to make possible not only untrammelled investigation but also the publication and sharing of results through which alone can we be sure of the fully productive thought on which scientific advances are based. The best way of determining this line is to define the critical situation that trenches on safety or security and provide for regulation up to that point only.

The United States is on record in favor of open doors in laboratories throughout the world and has declared its readiness to open its own doors if others will do likewise. Our legislation must be so drawn as to give substance to this declaration. Study of safety and security provisions must in addition take into consideration such questions as whether we should go beyond the declaration and open our laboratories before we are sure that this is world policy, and

whether we should specifically provide for the dissemination of our findings regardless of reciprocation.

The CHAIRMAN. I notice that you do not come to any conclusion in that paragraph, which interests me very much and raises the question: Are you studying further the question of opening the laboratories?

Dr. BUSH. As matters now stand, I think that question is not too pertinent at the moment. It is clear it will be some time before our internal legislation is enacted.

We know now that the United Nation's movement for some form of commission is likely to start as early as January. Certainly what we do in our domestic legislation depends upon the progress being made internationally. I think it might be much easier to approach that question specifically when the legislation is more nearly ready to issue.

Extreme care in the formulation of the legislation, extreme judiciousness in the selection of men to administer the legislation once drawn, are essential if we are to insure against freezing the science at its present stage, hamstringing further study, and repelling able minds from this field.

Not at once, but surely in a reasonable time, it will be practicable for man to use the controlled energy of the atom for direct peaceful purposes. Atomic energy as a source of steam power and of electric power will in due course—and not necessarily a long course—become available. If only because the best way to insure against the existence of atomic bombs is to separate and distribute their components in industrial installations, we should seek to bring about the industrial use of atomic power at the earliest moment. There are many regions of the earth where a supply of cheap power would be the greatest of boons. Wise legislation will therefore encourage to the full this undertaking.

The foregoing five principles, it seems to me, must be properly recognized in legislation for the domestic control and development of atomic science. Such legislation should insure to the American people their control of plant and process, should safeguard knowledge of the military applications of atomic energy, should properly guard the physical well-being of the people against the many hazards to life and health which the investigation and production of atomic energy involve, should provide for free and full research and interchange of knowledge in this new and promising field, and should reckon with the future task of putting fissionable materials to useful work. The five parts of the problem are of unparalleled difficulty; to meet them successfully will demand unprecedented authority and responsibility on the part of those whom the Government calls to carry out the provisions of its laws in this respect.

I hope to see the Congress enact legislation which will provide for all five of these issues and which will bring into the public service to effectuate it a group of men selected for their competence, disinterestedness, and judgment. Under the leadership of two farseeing Chief Executives and with the guidance of two farseeing Secretaries of War, the Manhattan Engineer District under General Groves has enabled American science, engineering, management, and labor to bring about an achievement of profound significance in the history of the human race.

It is imperative that as we move ahead into a world rendered more promising and more difficult by this achievement, and as others take up the burdens that have been thus ably carried during the emergency, we have leadership and wisdom of equal stature.

To this end, I hope that through its atomic energy legislation the Congress will make the grant of authority fully as broad as the task demands, and that it will so constitute the resulting agency that the most qualified and public spirited of our citizens will be proud to serve thereon. This is imperative both to insure the effective internal control of this vast new wealth and to give firm basis for the United State's effective international collaboration in dealing with a problem of vital concern to every living human being.

The CHAIRMAN. Senator Tydings.

Senator TYDINGS. Dr. Bush. I take it from your testimony that the hope of the world in the field of the atomic bomb is by international agreement.

First, your premise seems to indicate that they will promise not to manufacture the atomic bomb. Is that correct?

Dr. BUSH. I would put that rather late in the stages.

Senator TYDINGS. I mean eventually, not tomorrow.

Dr. BUSH. Eventually, most certainly.

Dr. TYDINGS. They will agree, by treaty through the United Nations or through some international medium, never to manufacture the atomic bomb.

I think that it will be necessary, under the premise you lay down, to have very rigid inspection all over the world on the theory that nations will not keep their word, and we cannot afford to take a chance.

Dr. BUSH. Quite right.

Senator TYDINGS. That will entail a great change in the internal policies of some of the governments of the world, access in and out, more freedom of speech, more freedom of the press and the right to publish what you want, and so forth and so on. Do you agree to that?

Dr. BUSH. Yes, sir.

Senator TYDINGS. It will also entail some sort of transportation system because many areas of the earth are not settled, and therefore we will have to have international airplanes that will have the right to fly over without interruption, and to survey, just as we would plot topographically the area of any other country.

Dr. BUSH. Yes, sir.

Senator TYDINGS. I take it that that international force would have the right to go into any plant where suspicion seems to indicate that atomic energy or atomic bombs might be in the course of manufacture.

Dr. BUSH. I think ultimately that would certainly be the case.

Senator TYDINGS. And without all those things—and they are not all, but some of them are preliminary things—there is no hope of an international agreement worthy of the name that would be effective.

Now, therefore, our task seems to be not only to get this international agreement which might come quickly, but to get the implementation of that international agreement so that it would be worth something.

Dr. BUSH. Quite right.

Senator TYDINGS. So, in order to get that, we would have to ask nations to alter their present governmental systems to the extent that they would fit into the premise.

Dr. BUSH. Let's say their practice under the system, and not necessarily the system.

Senator TYDINGS. Their system of ingress and egress, and so on.

Dr. BUSH. Yes, sir.

Senator TYDINGS. How do you suppose we could best bring that about?

Dr. BUSH. I think we would bring that about, sir, to best advantage if we realize at the outset that it will take time, and if we have plenty of patience. I believe also that it will come about to best advantage if we utilize the mechanism already set up under the United Nations Organization for that purpose; but in so doing we ought to use care on one point particularly. We should not overload the United Nations Organization with tasks that it cannot perform at the outset.

Certainly everyone wishes the United Nations Organization to be a success, and in order to be a success it must particularly be successful in the first tasks that it undertakes. Hence, I urge that our recommendations to the United Nations Organization involve at first only the parts of this long program which can be accomplished within a reasonable time and with almost certain prospect of success in their fulfillment, and to step on from there to the point where we arrive at the situation you describe.

Senator TYDINGS. There must be a certain amount of candor in these discussions, and no idea of hostility toward any nation if we are to achieve progress.

Have you given thought to the matter that the delegates to the United Nations from any country will probably have to telephone back to their own governments each time they commit their nation to any international program? That applies in varying degree, according to the country affected. Have you therefore given thought to the question, if an international plan is to be set up, considering all the difficulties which need not be mentioned of a change in the outlook of some governments toward inspection, and so on, as to whether or not that task could be best performed through the United Nations Organization or by a meeting of the heads of the three or four or five big powers of the world so as to prepare the groundwork and make these long interchanges of communications between the governments and the UNO workable?

Dr. BUSH. I think we all know, Senator, that any such large body as will be the United Nations Organization works to best advantage with some of the principal participants having preliminary interchanges and preliminary discussions on every work that is contemplated.

Senator TYDINGS. You have answered my question. I take it you think that the degree of success would be greatly heightened if, preliminary to turning this over to the UNO to implement the basic plan and the basic conditions, not all of them, not the mechanics in detail, but the basic plan and the basic implementation be first agreed to between the leading nations of the world.

Dr. BUSH. I think that would be excellent. I would go so far, Senator, as to say that the objectives and the general plan should be discussed, and then the first steps discussed in great detail, because no one, I think, can lay out the entire plan at the present time.

Senator TYDINGS. That was not my plan. First of all, there must be a meeting of the minds of the nations affected that they want to

outlaw the atomic bomb, and then there must be a discussion of the ways, and there are three or four principal things without which you cannot make any progress unless those three or four things receive some degree of settlement.

Now, therefore, my question after this preliminary discussion is this: Do you favor now a meeting of the leading powers of the earth, apart from the UNO, through their chief representatives, whether they be presidents or marshals or prime ministers or what not, to explore and prepare the preliminary ground before this is turned over to the UNO?

Dr. BUSH. We have already had one such set of discussions, and I think successfully, and quite properly that first discussion occurred between the three countries that have principally participated in this affair during the war. I think, as far as time allows, the more such discussions there are the better.

Senator TYDINGS. Then, you would favor, I take it, now that the three have agreed on their plan—that is, Canada, Great Britain and the United States—and have presented it to the world, that before the UNO deals with it that those three invite three or four more of the leading nations of the world to see if they accept the proposition we offer, and under what conditions, and to see if a preliminary arrangement can be agreed to?

Dr. BUSH. Apart from the exact mechanism, Senator, as to how it is done, I certainly favor such discussions as are possible in the interval before the United Nations meet, realizing there is not now very much time.

Senator TYDINGS. When do you favor this meeting between the leaders of the nations in the future for this purpose?

Dr. BUSH. I think, Senator, that I could not prescribe that. It depends upon a great many things about which I know very little.

Senator TYDINGS. Do you favor it as soon as it can be held, or can we put it off?

Dr. BUSH. I don't think we could go into the details of specifying how or when. I simply say that personally I am in favor of all such discussions as can be arranged before we get into the large meetings.

Senator TYDINGS. I think, too, from our answers, the obvious idea involved is that to turn this over to the UNO without this preliminary spadework between the heads of the great nations is to turn it over to a society that will debate it to death, and that one will have to turn it back to his or her government over and over again before any action can resolve.

Dr. BUSH. We have no United Nations Organization at the present time. An organization consists of people, and consists, also, of people that have learned to work together. It will be some time before we have an effective working United Nations Organization.

To turn over to the United Nations Organization the entire problem at this time would, in my opinion, be absurd—

Senator TYDINGS. Thank you for that specific answer.

Dr. BUSH. As absurd as to talk today about outlawing the bomb before we have talked about the means by which outlawry of this bomb and other weapons of mass destruction can be made in force.

If I may add one other word, I think it is entirely proper to turn to the United Nations Organization the beginnings of the matter and to hope that they will take some initial steps fairly soon.

Senator TYDINGS. I think I follow you, but I would like to make it a little more specific, and with no idea of being captious with it at all.

I take it you say now that, if we turn this whole problem over to the United Nations Organization for settlement, the prospect of success, which is so essential to this first undertaking, is not too bright; and that therefore the great governments of the world should make sure, through preliminary exploration and conference, that when it is turned over to the UNO there is that promise of success which we all hope for.

Dr. BUSH. I think that they ought to make plans so that the United Nations Organization will have something specific to work on, with the definite assurance that the great powers are anxious to see the thing move along that path and will cooperate.

Senator BYRD. What plans can we make? What should be done prior to the meeting of the United Nations Organization to consider this matter? What do you have in mind that can be done?

Dr. BUSH. I think one very great step was taken when the two Prime Ministers and the President joined, studied the entire matter, and made a specific proposal and plan.

Senator TYDINGS. But there was nobody present at that conference to accept it or reject it or to say, "That is all right, but how about doing it this way, or how about leaving that out and putting this in?"

Dr. BUSH. That was one suggestion; there may be others. There may be better ones, but there can be other conferences.

Senator TYDINGS. How can you get action if just three men give out a statement when the recipients to whom that statement is directed are not present? Do you see what I mean?

Dr. BUSH. I don't quite follow you, Senator.

Senator TYDINGS. I mean to say this: Do you think that you can achieve the preliminary success in this undertaking without a further conference of the leaders of the great nations of the world and particularly those that were not present when the three men gave out their original statement?

Dr. BUSH. But note, Senator, that the declaration itself indicated the desirability of further conferences among the great powers on this same matter prior to the United Nations operations.

Senator TYDINGS. Do you advocate that they have that further conference now?

Dr. BUSH. I was entirely in agreement with that conference, with that declaration throughout and that is one of the points in it.

Senator TYDINGS. I understand that, but we cannot let it hang right up there on the limb. Where do we go from here?

Dr. BUSH. Senator, that is someone else's guess, and not mine.

Senator TYDINGS. What do you mean?

Dr. BUSH. Well, that the President and the State Department proceed with the matter, as I judge they are doing at the present time.

Senator TYDINGS. And try to bring others in this field to see if they are in accord with this offer that has been made?

Dr. BUSH. Either formally or informally, I think there should be further conversation, and I judge such will occur, although I know nothing about it.

Senator TYDINGS. Until that is done, the hope for handling this successfully by the UNO is not too promising?

Dr. BUSH. I think that the UNO will undoubtedly have discussion of this matter just as soon as it starts. I hope it will proceed toward the formation of a commission on this subject, because I believe in that commission, internationally, discussions in regard to details of the plan can prove to best advantage.

I think that that will go on from step to step, and I hope that through the next several years, when that is occurring, that there will be not only that procedure in the United Nations Organization, but also continued conferences among the principal members.

Senator TYDINGS. Dr. Bush, you and the other men who have preceded you have all indicated the same general approach to it.

As a legislator that may have to take a stand on this sometime, I believe the theory is pretty clear, but I think where we are weak is that nobody is presenting to us possible steps that should be taken. They say eventually it should be decided by the UNO, but the UNO may fall to pieces. It may be a great success. We may be a long time in meeting. There may be obvious difficulties, and they may take up other matters.

Now, in the meantime, isn't it important that what preliminary work has been done be immediately followed up?

Dr. BUSH. Yes; I think it is important that all of this be followed up.

Senator TYDINGS. Where will we follow it up?

Dr. BUSH. Let me point out that the declaration to which I referred did not talk in generalities. It made two very specific suggestions of immediate and rather simple steps that would go, in my opinion, a considerable distance along the path that you outlined a moment ago; and that path is exceedingly important as you outlined it, because I believe fully that even in the absence of international agreements to that effect, if there was free interchange throughout this world, a free flow of information that there is in this country among the States and which did not always exist, then we would have removed three-quarters or nine-tenths of the danger of great wars by that mechanism alone.

Senator TYDINGS. That goes back to my question that in some countries perhaps that free flow will not be permitted, and therefore how can you achieve what you think is so desirable—and I agree with you if it can be worked out—without having this meeting to prepare the ground so that we can make progress along these lines?

Dr. BUSH. It seems to me, Senator, that the trend in this world is all in the direction of the free flow of information, the free flow of knowledge that we have talked about.

Now, it is not true today that it flows unimpeded everywhere, not by any manner of means; but the trend is in that direction, and I believe if we encourage it sympathetically, patiently, and in a realistic manner, that that can be brought about in time.

Senator TYDINGS. But how should we encourage it?

Dr. BUSH. I think the first step should be by the interchange of scientific information of a fundamental and basic character.

Senator TYDINGS. Can that be done until the other governments of the world agree to meet us on that same basis?

Dr. BUSH. I think the governments of the world will be anxious to meet us on that basis.

Senator TYDINGS. How can you achieve that without bringing the heads of these governments together?

Dr. BUSH. I think that will be almost, but not quite, automatic. Before the war we had full and free interchange in the scientific fields to an extraordinary extent. There may have been impediments here and there, but there were certainly no more impediments internationally to the flow of fundamental scientific information than there are internally in the flow of applied science in industry.

Senator TYDINGS. Hasn't that been changed somewhat recently?

Dr. BUSH. During the war every nation, of course, placed restrictions; but the point is that we do not need to create a wholly new situation. We simply wish to return to the situation that occurred previous to the war in regard to the flow of fundamental science and to improve upon that. We have had some indications in that regard already, and in this very field.

We had the courage, and I think the wisdom, to publish the Smyth report with a great deal of the fundamental information in it, which was certainly a gesture, it was certainly an indication that we wished to proceed down the path of free interchange of basic scientific information.

We have not yet gotten back to the point where scientists flow across boundaries easily, because of transportation difficulties; yet, a while ago, Russia invited a group of American scientists to visit them, and that was done quite successfully.

I believe that by encouraging that procedure, by making it clear that we as a country wish to encourage it, that we can bring that very simple point about without very much difficulty.

Senator TYDINGS. Assuming that that simple point, which is a good point, is of such transcendental importance, and that this whole problem is like Damocles' sword hanging over all of civilization, it seems to me that the natural result that would flow from what you have said is that there must be a meeting of the leaders of the great nations at some place to arrive at an understanding of the fundamentals that must be present before any of these things can take place.

Dr. BUSH. When it comes to the particular mechanism by which governments and peoples get together, Senator, I think you are in a better position to judge what will work effectively than I am.

Senator TYDINGS. The reason I ask you this in such detail is that I share your belief, as you imply, that this is a pretty big task to hand over to the UNO as one of their first problems, and that if it fails, civilization will be consumed with fear, and the one instrumentality set up for the keeping of the peace of the world will be given an awfully fatal blow.

Therefore it seems to me that as we are in this stage where we don't want that to happen, and we are confronted with that problem, that it is a natural conclusion that the heads of our great governments—and I am a Democrat, understand me.

Dr. BUSH. I thought you were, Senator.

Senator TYDINGS. The heads of our great governments, some five or six of them in particular that I won't name, have got to get down to the table and see whether or not they can eliminate the fears that attend the interchange of information and the outlawing of the bomb, and all of that sort of thing, before you can proceed anywhere.

The United Nations cannot bind any government internally.

Dr. BUSH. We can remove the fear only as we make progress, and it will take us years to make progress to the point where the peoples of the world can have the fear removed from their minds on the atomic bomb.

But we can't get there in a moment by wishful thinking. It is going to take patience and hard work. Hence, the things that I urge are, as far as our influence extends, as far as the United Nations operates on this matter, that we urge that they go step by step and deal only with such steps as can be carried into effect effectively, and do not try to take the whole problem at once and jump to a quick solution which does not exist.

Senator TYDINGS. One of your first steps is that we must have this interchange of scientific information to eliminate fear and to free genius, so to speak. How can you do that unless the leading nations of the world agree on the fundamentals that must be present when that solution is arrived at?

Dr. BUSH. I think there will be no difficulty whatever in getting the nations of the world to agree on the ultimate objective. The ultimate objective is to abolish war. Short of that objective, there are other objectives that are more easily attained, and those can be placed in steps.

I would point out this: First, it will be possible when there is an adequate system for obtaining full knowledge—and I don't call it an inspection system; it is not necessarily in that explicit form—to remove from the world at that time the fear of the use of atomic energy in bombs, and also of other weapons capable of mass destruction, for there are others that are just about as bad and might be worse.

Short of that, even, it may be possible by international agreement and with full knowledge to remove the threat of sudden surprise attack. If we could remove from this world the fear of sudden attack by atomic bombs, or otherwise, we would have gone some distance. Now there is a long path to proceed.

Senator TYDINGS. But before you can eliminate one single "if" with which your whole premise is studded, how can you remove one of them until the leading representatives of these great nations, in many but not in all cases the only men who can speak for their nations, eliminate the weeds and the undergrowth so that you can get a foundation in which you can plant this seed?

Dr. BUSH. I have already said that I hope they will do just that.

Senator TYDINGS. And you would advocate it in general terms?

Dr. BUSH. Yes.

Senator TYDINGS. Then I think I have the answer to my question, which I will summarize as follows: That this is too big a task for the UNO to take in its present form and under present circumstances with a reasonable hope of success.

Dr. BUSH. Without all the help that can be given by prior conferences.

Senator TYDINGS. And that nations, through such intermediaries as they may set up, either through direct dealings with governments—which is preferable—or something similar, must prepare a vast field of small but important details before any of these things that you desire or think are wholesome for ourselves in the world can follow.

Dr. BUSH. That is right.

May I go back to one point that you raised previously which comes right in on that.

You spoke about an inspection system that would go into every factory, that would go into great detail in every country.

Senator TYDINGS. Not necessarily go, but have the right to go.

Dr. BUSH. That is a very great difference. That is an ultimate situation. There are much simpler situations before that is necessary.

For example, for an early step I think that the nations of the world might readily agree that they would disclose to one another and make available completely through the United Nations Organization full information in regards to the sources of ore of the principal fissionable materials, that they would make known the movements of those ores, the extent to which they are prepared and shipped.

Senator TYDINGS. All the raw materials?

Dr. BUSH. All the raw materials. Now, we know what those are. We know just about where they are in the world in general, and it would not take a great inspection system to determine whether such facts as were supplied by every nation were correct or not. In fact, it would take very little beyond the visit of a few geologists to the principal sites of the world, mining engineers, to know what the facts are in regard to that.

Yet that very simple thing, if the nations of the world all knew what every other nation was doing in regard to the preparation of the raw materials, would be a significant step on the path that I have outlined, and a step that could be taken with assurance.

Senator TYDINGS. Obviously that would help, but let us suppose that in Canada—with no reflection on Canada, which I pick out because I am sure it would not happen in Canada—there were charted all the places where uranium exists that are known at present, and let us suppose that some place up in the Hudson Bay country that is not very accessible to the outside world a new deposit of pitch-blend or uranium was discovered; and let us suppose that a group of men who discovered it did not communicate that, for patriotic or other reasons, to the Canadian Government or to the world organization. What would you say to that?

Dr. BUSH. I think they would have a very difficult time, indeed, even if there were no international inspection system, because they would need to consult geologists and mining engineers. They would need to purchase mining equipment.

Senator TYDINGS. I don't mean to manufacture it; I mean to let it lie there. They would just discover that it was there, and would not do anything about it, but would not report it.

Dr. BUSH. Well, why worry?

Senator TYDINGS. Why worry? Well, I would want to know where the raw material is; it is essential that we know where all the raw material is.

Dr. BUSH. But it is far more important to know whether the raw material is being mined and processed.

Senator TYDINGS. You are starting out by saying, "If we know where the raw material is." What I am getting at is that then we might work on the supposition that there is raw material which we do not know about.

There wouldn't be any bank robbers if everybody would abide by the laws of the State.

Dr. BUSH. My policy is a small step, but I think a significant one and relatively easily enforced, because I think a relatively simple system of gathering of information would disclose the salient and principal facts. There might be some that would escape, but I don't think they would be significant.

Senator TYDINGS. Having in mind Pearl Harbor, and other instances which I won't delineate, as one who has some little responsibility I would be pretty reluctant to exchange information with the world unless I knew that the preliminary steps had all been taken first so as to make certain that exchange did not impair our own safety.

Dr. BUSH. Certainly; so would I.

Senator TYDINGS. Therefore I want to know before we exchange that information, if that were deemed wise on thorough thought, whether or not the other nations were really going to permit this exchange and have an open and aboveboard transaction, or whether we were going to be in somewhat the situation we are in today.

Dr. BUSH. That is why, Senator, I would proceed by stages, step by step, on a system, if you wish to call it so, of partial payments, so that the accomplishment of each step successfully will, in the eyes of the world, prepare the way for the next one, so that confidence in an international organization will be gradually developed over the years, and so that—incidentally, and a very important point—there will be developed within the United Nations Organization an inspection system under a commission which has great pride in its accomplishment and great esprit de corps. That is possible, and when that occurs we may gradually come to have confidence in its pronouncements and to feel that it knows the facts on which it makes those pronouncements.

When that day arrives, we will have come to the point where we can make enforceable national agreements for the purpose of removing from the scene the principal methods of mass destruction, whatever they may be, but not before that; and I believe that our steps at the present time should be planned to develop that situation gradually and definitely, and we should have all the patience in the world in so doing.

Senator TYDINGS. I have just one more question. There is nothing more difficult to outlaw than the atomic bomb, is there?

Dr. BUSH. Oh, I think it is equally difficult to outlaw any other mass weapon.

Senator TYDINGS. Why shouldn't we outlaw everything, while we are outlawing the atomic bomb—the battleship, the artillery, and the whole business? Why stop at the atomic bomb?

Dr. BUSH. The idea, Senator, is to stop wars. I am against wars of every kind carried on by every means.

Senator TYDINGS. I agree with you; but why do we limit this to the atomic bomb? Why don't we go at the whole thing at one time?

Dr. BUSH. I would not limit it to the atomic bomb. I would say, "Let's remove from the world the fear of every other weapon of mass destruction and let's remove from the world finally a fear of war itself."

Senator TYDINGS. How?

Dr. BUSH. By the path that you and I have discussed, and over a period of many years in which we will have to have patience and perseverance to work through the United Nations Organization and

to support it; but if that doesn't work, to try again by other means and to keep on trying until we succeed in producing an international system under which we can remove wars.

The CHAIRMAN. Dr. Bush, I am more impressed every day with what Aristotle said, that politics was the art of the impossible, and it is rarely repeated.

I am a little bit disturbed about these long periods of time that you envisage in getting control of this problem.

Now, we have a weapon that, produced in any kind of quantity and used aggressively, could wipe half the population off the earth by action of the other half. This, I presume, is known to the statesmen of the world; I don't say it is known to all the peoples of the world.

Don't you feel any sense of urgency about trying immediately to accomplish an over-all control of this thing?

Doesn't it worry you any that these steps are to be taken years apart? Don't you feel that the accomplishment of the art by other nations will make perhaps more difficult the mechanics of control? Is there not something to be said for the laying down of an over-all control plan that is fair and equitable so that the fear of the peoples of the world can be removed at the soonest possible moment, and that we won't have to go along this long series of years with that fear overriding everybody?

Dr. BUSH. Senator, there is a difference between the sense of urgency and the sense of panic. I have, indeed, a sense of urgency. The problem should be attacked at once, as you gentlemen are attacking it. It should be analyzed, and we must proceed with expedition down the path.

But that is quite a different thing from the sense of panic that wants a solution overnight. There is no solution overnight.

The danger, as I see it, is this: The American people are a great people, but they have one fault that I know full well. They like immediate, over-all solutions, and on this particular matter we are, all of us, tired of hearing about atomic bombs and atomic energy. I may be more tired than you gentlemen are, because I have been thinking about it intensely for 6 years; but you gentlemen, everyone, are tired of hearing about this thing. We, all of us, wish we could suddenly remove this threat and could forget this element. We can't.

The danger, as I see it, is that in that mood, quick——

The CHAIRMAN. I don't want to interrupt, but don't you feel, Doctor, that mankind is so constituted that it depends upon the intent of the purpose with which you approach an objective as to whether or not you are going to get that objective?

Dr. BUSH. The point of view of mankind will depend upon whether progress is being made, not upon whether a solution is brought out immediately.

The thing that I am afraid of is that in the urge to get too quick solutions, we may do things that are not wise.

Let me go back to one other point of your remarks, which I want to enlarge upon.

Senator VANDENBERG. You discriminate between hysteria and prudence?

Dr. BUSH. Quite right, sir.

The CHAIRMAN. I hope that the questions that I suggested did not denote any state of hysteria on my part, Doctor?

Dr. BUSH. No; but I think you felt as I do, that there is some hysteria as this thing is thought about.

But I want to make two points: First, you spoke of a situation where there are enough atomic bombs in the world to destroy a large part of civilization. That situation does not exist today. Now, of course, I don't want an open session to go into the question of how many bombs are available, or any such thing; but every country, every people in the world, knows that today we have not got such great quantities that that statement would be true in its generality.

The CHAIRMAN. We would have to make that knowledge available, though, before we got any other country to agree to turn up the uranium sources they have, wouldn't we?

Dr. BUSH. We would; and under proper circumstances and proper controls I would be entirely in favor of making it known.

Senator HICKENLOOPER. I get the impression from your statement, Doctor, that there are two things involved here: One is the physical and mechanical development of this monster we have created, that that is our responsibility, that we have it along with England and Canada, but that we cannot hope to arrive at any point of mutual confidence in the world until the moral questions are settled.

Those moral questions involve the moral attitude of other nations.

I would like to ask you this: Do you think there is any remote hope of any security against the use of atomic energy as a weapon until those moral problems have been substantially solved within the nations themselves?

Dr. BUSH. Well, it is all according to what you mean by "moral," Senator.

Now, I come from New England. My forebears came from Cape Cod. There are small towns on Cape Cod that live in peace, and yet I wouldn't want to say that they do so because they are highly moral in the specific sense. But they have an understanding; they have a basis of interchange. The word "moral," I think, carries too much.

Senator HICKENLOOPER. I mean in the broadest sense. Perhaps I should amplify or explain that a little.

There are certain nations in the world today that are very vitally interested in controlling atomic energy because the peoples of those nations have a fair understanding of its potential or its actual power.

There are other nations. Let's, just for the sake of our discussion here, go back to the conditions in Germany before this present war started, where the people were kept completely in ignorance of many of the things that went on in the world and were fed a propaganda that only suited the needs of the leaders.

In that case, if there should have been, or if there were, any moral weight to be exercised by the people of Germany, it did not have a chance to be exerted or exercised because of propaganda that directed their thinking.

Now, until the peoples of the more or less enlightened nations of the world pretty universally know what they are facing in the possibility of this atomic power, do you think we have too much chance of getting any moral support—I mean the honest, well-intentioned support—of all of these nations?

Dr. BUSH. Yes; I do. Eight years ago there were two countries in the world whose people had been trained for over a generation

to prepare for a war of aggression, Germany and Japan. The leaders of those countries had their peoples so propagandized and so under control that they did not know the world situation; and that was an enormous threat to the world, and out of it came a great war.

No such situation exists today, and those two nations are conquered and under control and should remain so. We have no nations in the world today that do not wish a long, fruitful period of peace; and in my opinion, every country is anxious to bring that about, not only the peoples of every country but the rulers of every country. We have no situation as then existed.

We will have misunderstandings; we will have friction; we will have difficulties. But I am perfectly sure, personally, that there is no danger of great wars breaking out until there has been time to work this thing out with care and deliberation, and fully; and in that sense, I am optimistic; I believe it can be done.

Senator HICKENLOOPER. Is it not possible that, either now or within some reasonable time in the future, the leadership of some nations may persuade their people that it is desirable to have space, that they may personally desire peace, and yet is it not possible that they may be willing to adopt a policy of war in order to obtain their own ends?

Isn't there a danger that the leadership of some nations might desire peace but still cling to the policy of war as national policy?

Dr. BUSH. We have got to be sure, of course, that there will be no more Hitlers or Tojos, all right. However, that is not a question merely of a rule of a country by a single person. We have got to be sure that no nation, over a long period of years, becomes oriented in the direction of conquest. That can come about if we have the right international understanding, so that the nation that became thus oriented would immediately become a pariah among nations of the earth.

Of course, we have gone through that. We have seen Hitler rise to power in Germany and, step by step, many of them rather obvious, prepare for this war. What he was doing was evident to every one, to all nations; yet the nations either did not have the courage or ability or vision to stop the march of that machinery working toward war.

But that is not the situation today, the situation I have mentioned. That situation is absent now. Then the nations of the earth did not join and make that nation, Germany, a pariah. If they had, we never would have had a war; Germany could not have started it.

Senator HICKENLOOPER. I like your statement very much, Doctor, and I think you have given us a lot of food for thought.

However, I had a rather strong feeling—I am not at all encouraged to think that we will be able to do too much, in immediate or positive agreements, until the peoples of the countries involved began to exert their moral influence. I feel that perhaps we will, whether we like it or not, face substantial delay; and I do feel that it might be in this period of delay that we perhaps might have to exert our greatest fortitude.

Dr. BUSH. This is the period, right now, when it must be done and when we must not lose time and when we should proceed with all possible diligence. Now is the time.

Senator TYDINGS. May I ask the doctor a question?

The CHAIRMAN. Certainly, Senator.

Dr. BUSH. I would be glad to have you do so.

Senator TYDINGS. Do you think it is possible to accomplish in the world a free exchange of scientific knowledge—in a world that does not permit the free exchange of religious knowledge?

Dr. BUSH. I haven't thought of that particular parallel, Senator. If you are making a premise that the world does not permit the interchange of religious knowledge and that that will continue, I would say "yes"; I think that is true.

However, I disagree with you when it comes to science, because I think that the flow of scientific knowledge can be brought about in the world largely as it was under the conditions which existed before this war.

Senator TYDINGS. Well, why can't the flow of religious knowledge, likewise, be brought about?

Dr. BUSH. Well, Senator, I am an engineer, primarily. I would not try to qualify as a man schooled in religion and its international aspects.

Senator TYDINGS. I agree with your premise that the spread of scientific knowledge all over the world would be a very desirable thing, if we could get it done, if it could be accomplished. I would like to have thought move freely and remove the barriers to thinking.

But I do feel this, that if we cannot do it in one field, what hopes may we have that we can do it in another field? If freedom of the mind is interdicted, so to speak, by the Government in one of the oldest and strongest traditions, why is it reasonable to believe that the freedom of the mind will not be interdicted in this other field of science?

Dr. BUSH. Science, Senator, has always been more or less free; it has always had a flavor of internationalism, you know.

Senator TYDINGS. So has religion.

Dr. BUSH. It has always been the practice of the scientist to publish his discoveries so that his colleagues all over the world can read them. And, as the scientists become more and more specialized, they will become more and more international.

There is a reason for that. Suppose we take the field of mathematics. The man who is in the top rank of mathematicians may publish a paper. In this paper which he may publish there may not be more than 8 or 10 men in the whole world who can read that and understand it, who can go into such an intensely specialized thinking. And those 8 or 10 will not be located in his country, they will be all over the world.

Those men will read that publication, no matter where they are located, and by reading that publication and understanding his thinking, they will be his colleagues. That is international.

Senator TYDINGS. But, suppose that man is not allowed to send out his thought?

Dr. BUSH. Well, I am simply saying that in this particular field it is easier to bring about the international pull than otherwise.

Senator TYDINGS. I think it is logical, as you say, that perhaps you can achieve more success in other parallel fields than in religion. Nevertheless, where there is a reticence on the part of the government concerned, where there is a feeling that the national safety might be endangered, there is another situation. Suppose that the government believed it imperative to suppress that knowledge;

whether or not it rightly believes so, they might hold that information back, having the preservation of the government in mind.

Dr. BUSIR. Right, and it is that hesitancy to allow free interchange of knowledge that we shall have to overcome. I think we can overcome it. I think it will be comparatively easy, in the field of science.

Senator JOHNSON. I have heard what the other Senators on this committee have said about your presentation. I want to add that I think it is very logical and comprehensive, and I enjoyed it very much. I would like to refer you to some of the conversations between you and Senator Tydings before the Senator got into the question of theology, his first line of questions.

It seems to me that international factors are something like the game of checkers. First it is your move, and then it is the other fellow's move. Now, as I see it, Britain, Canada, and the United States, the nations possessing the knowledge of the atomic bomb, have made the first move.

They met at a conference and laid down a very simple formula for the interchange of atomic knowledge, and, especially, the controls to be placed over the atomic bomb.

The other nations have not made so much progress yet in the atomic bomb, but it is their move, isn't it? There is no way in which you can compel another nation to take an interest in the control of the atomic bomb, if they don't have that information. We have the atomic bomb. We created it. We have laid down a broad basis for its interchange.

Now, if they don't come along and say, "All right, I am interested, although I do not altogether like your terms; I would like to see some amendments to your terms, but I am interested," if they don't make such a move, you are almost stymied, it seems to me, in going about settling the question in which Senator Tydings is so interested, the international control of atomic bombs and atomic energy.

I would like to go to another question that you raised in your prepared statement.

You refer to atomic energy as a source of steam power and of electrical power. You say that we will, in due course, and not necessarily a long course into the future, have that available.

As I recall it, when Dr. Langmuir was here, he touched upon this question.

He indicated that the peacetime and domestic potentialities of atomic energy are trivial, as compared to its wartime possibilities, its destructive possibilities. I think he used the word "trivial." I think he was speaking in relative terms.

If I remember his statement correctly, he emphasized that you cannot create steam or other power with uranium; that you cannot use atomic energy for such purposes without that energy having an atomic bomb—

Senator VANDENBERG. Potentiality.

Senator JOHNSON. Yes; an atomic-bomb potentiality. That is, every plant which you are using for making power would be, essentially, connected with the possible creation of atomic bombs.

I listened to a discussion, not very long ago, where they were talking about the industries of Germany. They seemed to agree that we have got to crush the industries in Germany that are making steel bridges,

that we have got to crush them, that we have got to destroy them, because an industry which can make steel bridges can make weapons of war.

The feeling was that war and industry are so closely interrelated in this machine age, in this advanced age, that every manufacturing possibility, every industrial possibility, is also a warmaking possibility.

Now, my question is this: Until the over-all international question of the development and the control of atomic power has been made, is it safe to go ahead and be thinking of the domestic and industrial applications of uranium energy?

Dr. BUSH. Well, Senator, there seems to be nothing safe in this world. Let me, however, expand on this point of yours a moment before I answer.

I think that before this committee finishes these hearings it ought to bring before it one or two engineers that can answer the questions you want answered better than I can, in regard to the industrial possibilities in this field. I am an engineer, it is true, but I think I am a bit rusty as an engineer.

I can suggest a number of people whose names come immediately to mind who know the power-plant situation. I think you should have those people to testify as to those matters.

As I understand it, I think that the situation is this:

The power applications of atomic energy are not trivial in any absolute sense. Water power—

Senator JOHNSON. I am talking about in a relative sense.

Dr. BUSH. Well, if you want me to go on to that point, I would say that it is very difficult to compare atomic energy in industry as opposed to its destructive power in war. They are not quite comparable. I would not want to try to give you a relative figure on that aspect.

But, speaking about the industrial power application of atomic energy, I say that I think it is not trivial. Water power is certainly not trivial. It is an important source of power, in spite of the fact that we have coal and oil.

Now, as I see it, the distinction is, with respect to the utilization of atomic energy, largely the same as with respect to water power, about the same kind of distinction. In order to develop power by atomic energy, you have to have an expensive plant. This is also true with a hydroelectric plant.

You have to consider the total cost that is involved in the price of the power. There is the cost of operation, including the cost of fuel and the cost of the plant, the amortization and the interest on it, and the other costs.

A hydroelectric plant has a high cost, yet hydroelectric energy competes with coal and oil and hydroelectric energy has been very important in the economic development of certain nations.

Now, in this field of atomic energy, looking ahead, there are certainly certain possibilities of developing power in large quantities for steam and electrical purposes without any fuel costs.

We do not know what the cost of the plants will be, the atomic energy plants, but I cannot see, myself, why they should be very much greater than the cost of the steam plants.

Now, if that is the case, it can make a very considerable difference in the economy of some of the other nations of the world. It may not

make so much difference to us. We have oil, coal, hydroelectric power. We have our power sources pretty well developed. But it would certainly make a much greater difference in some of the undeveloped parts of the world, particularly where they have got natural resources and no power at the present time.

I believe, therefore, that ultimately and over a period of years we will see power come in this fashion. I think it will produce not sudden transformations but a gradual lowering of the cost of power, which will make a difference in the industrialization of the country which utilizes atomic power.

I do not think that we will see it running the family automobile; its subdivision is not easy. I do not think that we will see it immediately because there are problems concerned with safety.

Let me say another thing: I think it is fortunate that atomic energy has an application for power purposes as well as an application for explosive purposes. I use the word "fortunate" because there will be a great urge among the peoples of this earth to use such fissionable materials for power purposes where they can confer a benefit on the general national economy, rather than to leave them stored up simply in the form where they can be used for atomic bombs.

I think that will be one of the factors which we will face as we work toward a solution, as we work toward a general understanding, where the use will be for power purposes and not otherwise.

Senator JOHNSON. But, Doctor, in your comparison of electric power with atomic power, it seems to be that you overlook the fact that in the use of atomic power, uranium power, that that is just one step, one very important step, toward the creation of atomic bombs.

That is, it seems to me, that there must be two steps. First, you have to collect large amounts of uranium. That is the first and most important step. Then, the second important step is the process of creating explosives. It is a step in the creation of an atomic bomb.

Now, you do not have those two steps in hydroelectric power or in the creation of electric power, and I think that was the point that Dr. Langmuir was referring to.

Dr. BUSH. Now, if you are raising the question, Senator, of whether we should start making fissionable materials, at the present time, internationally—

Senator JOHNSON. No.

Dr. BUSH. I would say we are not ready to do that in any case, so we might as well forget that part of it. But fissionable materials are going to be made.

The CHAIRMAN. They are going to be made?

Dr. BUSH. They are going to be made, of course.

Senator JOHNSON. That is not my point. My point is simply that, until we have an international control set up over atomic bombs, is it safe to go ahead with the use of uranium in the creation of power?

I have in mind the fact that we have been talking here about inspection and espionage and all those things, of discovering the amount of uranium that is available and whether anyone else has atomic bombs stored back some place in their safety vaults. We have all those questions involved.

Now, is it safe to go ahead and use uranium in the creation of power until these international questions are settled?

Dr. BUSH. My point, Senator, is this: Whether it is safe or not is beside the point. We do not have any means, effectively, to prevent it from being done, at the present time, and we won't have for some years.

"Is it safe?" you ask. It seems to me a question we cannot answer until the time when we have come to have effective enforcement of international control.

Now, at this time, I make this point: Since fissionable materials can be used in power plants, where they will confer a great industrial benefit, there will be an inclination on the part of nations, generally, to use that power, rather than to hold it in an inactive, nonproductive form, simply as material for bombs.

As I see it, if the nations of the world feel sufficiently secure in their international relationships, they will do that very thing and use fissionable materials to generate power.

Now, you say and it has been said by others that it can be taken out and made into bombs. Certainly it can.

You can do it. But when you do that, you shut the power plants down. It can be taken out as bombs but it takes a considerable time to do it. Certainly, if it is being used in the power plants, the danger of its sudden, surprise use is remote.

Moreover, if it is in use in the power plants, it would be very difficult indeed to take it out of there and make it into bombs without its being internationally known, because you could hardly do it without disrupting the entire power situation in the country where it is being used for important industrial purposes.

Hence, I say by all means let us bring the time up when this material can be used for industrial purposes to such great advantage. That is the way it should be used, for the good of the world, and that is the natural way that people will use it, for industrial purposes.

Senator AUSTIN. May I ask a question?

The CHAIRMAN. Certainly.

Senator AUSTIN. In your statement you speak of the five points that you think the legislature ought to consider in determining the policy or declaring the policy of the country with respect to this matter.

You speak of, first, this vast machine, the physical plant, the stock pile of materials and the varied applications that have been made or can be made of the scientific aspects of the matter, the special knowledge.

You say that we should consolidate our position rather than retreat from that and that we should maintain what we have gained thus far.

The question arises in connection with your last remark, concerning the cost, the money cost to the taxpayer of performing that first function to be carried on. My question is, can that first function be carried on and continued in our economy unless we do utilize these things in an industrial way?

Can we continue, in other words, to maintain a city of 75,000 people on our pay roll, operating a huge plant such as we have at Oak Ridge and as we have at other places, though not so large; can we continue that in our economy unless we do progress to the point where the thing begins to pay for itself?

Dr. BUSH. Until we arrive at the time where we can disarm internationally, with assurance and with the guaranty and the knowledge that it is going to be done by all peoples in the world, until we arrive at that time and until we arrive at the point where we have international, enforceable understandings generally, this Nation has got to retain its strength.

There is no question about that. The cost of remaining strong is going to be large. There is no question about that, either. How should that cost be distributed among the various elements?

That should be determined by the people who study that and have great, detailed knowledge of it, who can say what size Army we need, what size and nature Navy we need, and what amount of money we need to produce atomic bombs, and so on.

I cannot tell you offhand what fraction of our effort should be thus distributed on the atomic-energy angle, but I do feel sure that the plants we have at the present time should be kept operating.

Senator AUSTIN. You do feel sure, then, that we should keep organized this very technical group of scientists, who are, at the present time, gradually separating from the organization?

Dr. BUSH. Yes. That group is rather disintegrating at the present time, naturally.

I feel that we should, at the earliest possible moment, complete a proper and deliberate study of what the legislation should be.

I think we should quickly decide whether it should be in the hands of a commission, the control over this matter, rather than in the War Department, as at the present time. The War Department itself has suggested that transfer to a civilian commission and I think it is a wise step.

The CHAIRMAN. Do you feel that some of the scientists have left these projects because of "uncertainty," whatever that may mean, or because they have been working on making bombs and they are not particularly interested in that?

Dr. BUSH. Why, Senator, let me answer that rather generally, because that brings up an odd situation.

I was put in a position, during the war, by the action of President Roosevelt, where I had a great deal of responsibility for keeping the scientists in the plants, enforcing the security regulations and the like.

Now, no scientist likes to be regulated in any way whatever. However, it is necessary, we all know, in time of war, to have enforceable security regulations, which do not fit well with a group of scientists.

The CHAIRMAN. But which they obey under the compulsion of war?

Dr. BUSH. But which they obey under the patriotic impulse, their patriotism in time of war, and which they accepted very well indeed in this country. I am proud of them, I am proud of what they did, these scientists connected with my organization.

I think we have a right to be proud. In regard to security during this war, they did a grand job, holding things secret that should be held secret.

Nevertheless, no scientist likes to be subject to control, that is inherent in a scientist and I would not expect him to like it and he would not be a good scientist if he did.

Now, we have had a very long period of time during which the scientists in this country have voluntarily submitted to arbitrary con-

trol. The question is not whether it was too rigid at one point or another or not rigid enough. Those are details. Those controls had to be there and they were there; but they did not like them.

When the war was over, I fully expected that the scientists in this country would begin to break loose of such controls and would make a great deal of the point that they have been kept under rigid control. I have been surprised that there has been as little said on that subject as there has been. I have been surprised that the scientists not only during war patriotically submitted themselves to an organization in which they did not feel natural, but I was also surprised that, at the end of the war, so little outcry has been made about it. The scientists have done very well indeed and I am proud of them.

The CHAIRMAN. But that is one of the reasons, this release from patriotic compulsion, war compulsion. Don't you think that that is the reason why a good many of them have left?

Dr. BUSH. Yes, for that reason, of course, with the war being over. Most scientific men, engineers, and so forth, felt a great inclination to leave the development of weapons, and so forth, and get back to their normal pursuits. That is only an inclination which is natural, not only natural, but a wise one.

It is wise, because we need in this country plenty of scientists in industry to aid in reconversion. We need, also, men in the colleges to train returning veterans. Due to our manpower policies during the war, we have a decided deficit in scientists and technical manpower. The effects of this deficit in this country we will feel for many years.

There has been a natural inclination for scientists and technical men to leave war work and get back into industry and universities and that is where they should be. That disintegration, as you called it, that has extended throughout the entire range of war research and development is going on in my own organization. We are down to about 5 percent of our maximum operation.

We are carrying on a certain amount of work, primarily on medical research, on new instructions from the President, rather than having an abrupt termination. However, practically all of our work on weapons has been stopped since the war has been over.

So, of course, the men want to go back and they are correct. They should go back.

Now, in this particular field, these scientific men have done a very difficult job; it has been a hard work and they are all tired out, they want to get away from the war.

Senator RUSSELL. The scientists and the soldiers are GI Joes under the skin.

Dr. BUSH. That is right, they have the same feeling about it. The scientist, due to the nature of his training, had to serve in the laboratory rather than in the field, but they both think the same way about it.

Senator VANDENBERG. I imagine you could not compete with industry, in the scientific field, when it comes to pay?

Mr. BUSH. In the Manhattan project, under contract with some of the companies we had competition. I think there is no reason why we shouldn't be able to compete in a reasonable way.

However, I do not think that that is quite the point. I do not think that the matter of salary usually enters into it.

The CHAIRMAN. I have some more questions, but I do not want to monopolize this hearing. Do any other Senators have questions?

Senator HICKENLOOPER. I have just one question here.

The CHAIRMAN. Certainly, Senator.

Senator HICKENLOOPER. And I just wanted to ask you this, Doctor. Assume that a nation of the size and resources that we have will make promises not to use atomic power for bombs. Assume that secretly, in the minds of its leaders it intends to go right ahead and pursue a policy of making bombs.

In your mind is there, at this time, any effective control against such deception?

Dr. BUSH. At this time?

Senator HICKENLOOPER. Yes.

Dr. BUSH. At this time—

Senator HICKENLOOPER. At this time or within the reasonably near future. I mean, is there any effective control except in the sense that we might be prepared to use immediate force when we find out about it? In other words, other than force, the use of force at the present time, do you think that we can defend ourselves against a nation which might be following what might be called a dishonorable attitude, giving lip service toward peace and seemingly in conformance but secretly not?

Dr. BUSH. Well, there is nothing improper about any nation arming itself in order to maintain its security to a reasonable extent. We are doing so, other nations are doing so, and it is quite appropriate. I feel that the way in which they do it is up to the nation, that it is not our affair at the present time and should not be until they have arrived at international cleavage. There is no violation of an agreement, because none exists.

Now, if you are looking toward the future where there may be such an agreement, I would say let us approach this problem in such a way that when those agreements have been made they will be kept and not avoided.

In order to do so, let us go forward, let us make those agreements in such steps that each step will be one which the nations can and will wish to carry out.

Senator HICKENLOOPER. And that is the reason for your strong recommendation that we take this matter progressively by stages?

Dr. BUSH. Yes, sir.

Senator HICKENLOOPER. And not attempt to rush full-blown into it in the very immediate future?

Dr. BUSH. Yes, sir.

Senator HICKENLOOPER. Thank you.

Senator RUSSELL. I have just one question. It is not really a question, I will ask it merely for the purpose of my own information.

My attitude toward scientists, to use an illustration, is pretty much like the attitude of the boy living in the country going to the country doctor. He thinks the doctor can do anything.

Dr. BUSH. Some of the scientists do, too, Senator.

Senator RUSSELL. I am glad to hear that.

Now, I would like to know what are the possibilities of generating atomic energy from other elements, other than uranium.

Dr. BUSH. Well, I am not a nuclear physicist, of course, and I think that you might get better testimony on that from some other men.

My understanding on the matter is this, that the utilization of atomic energy at present can be found only among the elements at the

extreme of the periodic table, primarily in the very heavy elements, such as uranium and polonium. Hence, if other elements are brought in, I think that they will also be the very rare, unusual elements that are beyond uranium in the periodic table.

Personally, from what I have learned and from what I know about it, and I have associated with these men for many years, I think it is highly improbable that atomic energy will be produced out of any such things as common materials.

Senator RUSSELL. Lead, for example.

Dr. BUSH. Lead, for example.

Senator CONNALLY. Well, they will keep on trying, will they not, scientists will keep on experimenting, will they not?

Dr. BUSH. Well, even scientists do the things that they think can probably be done.

Senator CONNALLY. That is true, but they will be trying other things, they will be working in other fields and among the other elements. Maybe they think that they will fail, but they will keep on trying.

Dr. BUSH. I think the better answer will be that I am quite sure that the efforts of scientists will be devoted to those elements that are at the extreme of the periodic table, because that is where progress can be made and where they will feel that there is a probability of success.

The CHAIRMAN. Dr. Bush, you stated in answer to Senator Johnson's question that fissionable materials are going to be made. You mean by several countries or continued in this country?

Dr. BUSH. Russia, I believe, has already stated that they will. I believe Molotov made the statement to the effect that they propose to develop atomic energy. From Great Britain there have been statements in the Commons, I believe, to the effect that the Government is developing a plan for making atomic energy available. I think, as any other country becomes economically in the position where it can undertake such a project, it will.

The CHAIRMAN. Now, Doctor, you spoke about our economic resources with reference to power in this country and how well developed they are as compared with some of the other areas of the world.

I take it that you feel—if I misunderstood you, I wish you would correct me—that it would be an unfair requirement, or shall I say an unlikely requirement, unlikely in the sense that they would not agree to it, to specify, in some kind of an international agreement which we might go into, that the peacetime use of atomic energy not be permitted?

Dr. BUSH. No. Think what you would be asking the world, Senator. In the first place, it is not the atomic bomb alone that threatens the world. Let me make that clear.

I will make it clear this way. By the use of incendiaries we wiped out great areas of the Japanese cities. The most effective of those incendiaries was developed in my organization. I knew what it could do, I knew from the studies which had been made what it could do to the Japanese cities.

The decision to use them was made by President Roosevelt, after due consideration of what it meant. It was a difficult thing to answer: Would we wreak devastation on Japan's cities, realizing that in order

to wipe out the industries within those cities we were bound to kill innocent people?

We did, because only in that way could we shorten the war and save lives. At the time that that decision was made, I had a serious problem in my mind as to whether that was justified, but fortunately I did not have to make the decision myself.

I had the same question when the atomic bomb came along but to me it was not much of a question in my mind because I knew that it would end the war and save many lives.

The point I make is that it is not the atomic bomb alone that this world needs to fear. If there had not been atomic bombs, the application of science and technology had reached such a point that another great weapon—

The CHAIRMAN. For instance, bacteriological war.

Dr. BUSH. Yes. Science could produce devastation beyond thinking. We must avoid war, not just control an atomic bomb.

Now, other methods of warfare, involving incendiaries, rockets, aircraft, guided missiles, or what have you, came out. These weapons involved the entire industrialization of the Nation.

Are you going to say that no nation shall have any industrial capacity of building war materials? That, certainly, is impossible. In the same way, we are not going to say that no nation shall be industrially dependent on atomic energy.

We are going to say, rather, that all industries shall be for peaceable purposes and we will make international agreements to be sure that they do not get diverted to making war materials. I would say that would apply to atomic energy plants, as well as to any other kind of manufacturing plant or power.

The CHAIRMAN. Isn't much of what you have said based upon the feeling that it is impossible to suppress anything that is good for the health, comfort, and wealth of nations, because it goes against the very essence of human nature?

Dr. BUSH. We don't want to suppress this, gentlemen, if we could.

The science of atomic energy is in its infancy. It is probably in the stage where electricity was at the time of Faraday. Let us go back to an earlier time than that. Let us go back to when gunpowder first appeared.

When gunpowder came out, there was an attempt to outlaw it internationally. When the crossbow first appeared there was an edict of the Pope against its use in war.

Gunpowder, nevertheless, came in as an explosive. Certainly it might have been outlawed as an explosive. If that had been the case, it would have been of no good to man. Its utilization as an explosive material was merely the entering affair; it led to a vast chemical development, out of which have come all sorts of chemical industries, out of which have come a contribution to the rise of our standard of living.

In the same way, electricity came in. We can use electricity for guiding a missile from a launching platform to hit a target. But we can also use it and we do use it for communication and light; electricity has created a rise in the standard of living of the world.

In the same way, atomic energy comes in, first as an explosive. Any new thing is likely to come in the simplest, easiest way. Uncontrolled

explosion is, on the whole, much easier than the controlled use for development of power.

But no man can say today where this new path may lead. If we believe that the path of expansion of knowledge, expansion of man's control over his environment, that long path—if we believe that that path is, on the whole, upward, then we must believe that this new knowledge will also take its ultimate place where it will be useful for man's purposes for good and to where we will learn to control it, for the purposes of good.

The CHAIRMAN. Doctor, to reach the objection proposed by Senator Johnson and also advanced by some of our other witnesses, that peacetime use of atomic energy in power plants complicates the problem of control, would it be possible or feasible, do you think, to have any such peacetime power plants, controlled under the United Nations Organization, to be internationally maintained with, perhaps, a stock to be owned on a basis of contributions, such as the UNRRA organization. That is, each country putting in that portion which their national income will justify for international control of these power plants, internationally inspected and internationally operated?

Dr. BUSH. It certainly would be possible, whether it would be desirable or not.

I think, myself, upon that question that, in certain places, owing to certain considerations, such as territories under trusteeship, that such an arrangement could be used to bring atomic power to remote districts, that it might be advisable.

However, I have no idea that nations that do not have power plants owned by the nations themselves would like it. I think it is necessary to avoid that. I think that that is just one feature of the whole international economy which needs a better understanding if we are to eliminate war from the world.

The CHAIRMAN. Doctor, it has been testified, or I believe there has been published, information that we are continuing to manufacture bombs. Have you any comment on that policy?

Dr. BUSH. I would make simply the comment that we are also continuing to maintain an Army, although it is rapidly becoming very small. We are continuing to maintain a Navy. We are continuing to maintain the varied elements of our armed forces for our own defense which we think necessary.

So long as we proceed down that path, to the point where we have a reasonable strength, I do not think that any nation in the world will think that we are building that strength for aggression.

I do not think, therefore, that it will interfere in any way with the procedure of coming to international understanding with other nations which are doing the same thing.

The CHAIRMAN. Doctor, this fissionable material that we are making to fabricate into bombs could be used right now, some of it, for peacetime purposes—in medicine, for example?

Dr. BUSH. No, not quite, Senator. Some of the byproducts would be useful for medicine. Just as soon as the commission is set up, I hope that it will make arrangements as rapidly as possible for getting those byproducts disseminated for medical experimentation and other scientific experimentation, but that is a byproduct.

Now, as far as the fissionable material itself that is useful for bombs, it will also ultimately be useful for power purposes, but not immediately. We need a period of time, a period for development.

Senator VANDENBURG. What do you think it is, a year, or 2 years, or what?

Dr. BUSH. The first step could be taken almost at once, and that is the development of heat for industrial purposes. I could see its being used right now for heating. For instance, it could be used for heating the buildings in Washington. We could today, I believe, let a contract to a company to change the installation we now have over to atomic energy, if we wanted to. That is a very simple step, the only problems would be problems of safety, of taking care of the radioactive materials in such a manner as to be sure that there was no danger of poisoning the population.

Senator BYRD. What about the comparable cost?

Dr. BUSH. Within a few years—

Senator BYRD. What about the comparable cost?

Dr. BUSH. I think probably today, Senator, the comparative cost, if we did it immediately, would probably be more than it would be if we waited. I don't think we would want to plunge into that tomorrow. While we could place such a contract, I think we would not. But I do think that within, oh, 3 or 4 years, as industrial companies study and work on this matter, the application of atomic energy for heating purposes will be made economically feasible in many parts of this country.

Senator JOHNSON. The water would be radioactive?

Dr. BUSH. No, not with proper precautions. That is the point I have brought in, that there has got to be ample precaution taken to control the radioactive products.

I feel quite sure that can be done and done with reasonable cost.

Now, suppose we go beyond that, suppose we go to the use of atomic energy for developing power. That is somewhat further out. How long it will take I don't know. It depends on how hard we are going to work on it. Until that time comes, of course, we have no use for fissionable material except for storage. It does not deteriorate and we can store it and, when the time comes when it can be used for generating power, it will be available for that purpose.

The CHAIRMAN. Doctor, most men in the field have had some estimate as to how long it would take other nations to get into production of fissionable materials. I suppose that estimate would have some bearing upon our sense of urgency in arriving at a system of control.

Now, what, if you would care to give it, is your best estimate? I realize it would be an estimate. What time will it take for any other nation to get into operation?

Dr. BUSH. Well, I would like to qualify my answer, in order to be clear, because conditions determine the answer to such an extent.

To take an example, Great Britain could, if it wished to throw its industrial effort into it, if they went into the thing on an all-out basis, there is no doubt that they could build and put a plant into operation in, say, 3 years.

On the other hand, I think it is highly questionable that Great Britain would wish to do it on such an accelerated basis. They might be able to do it in a year if they put wartime efforts into it—priorities and all sorts of measures taken in wartime.

I think, rather, that they would wish and choose to do it on a longer time scale, and hence more economically.

The CHAIRMAN. Of course, Great Britain would have no fear of any stock pile of atomic bombs which we might have.

Dr. BUSH. I agree with you, I do not think they would have any fear, any more than they would be afraid of our Navy and Army.

The CHAIRMAN. How about other nations?

Dr. BUSH. Well, take a nation like Russia. I think she, if she threw her full weight into it and if she imported freely those things which she does not herself manufacture adequately at the present time, then I think in 4 or 5 years she could have a plant in operation. On the other hand, if she did it relying entirely on her own resources and building those up as she proceeded, meaning by that that she would have to build plants to make the parts before she could use those parts, I think it would take them somewhat longer, it might take as long as 20 years, if she did the entire process that way.

Now again, if she wishes to accelerate the process by making it very important, all-important, in her economy and if she makes the sacrifices in her standards of living in order to accomplish it at a maximum rate, it might shorten the time somewhat. I do not think she would choose to do it that way because it would be uneconomic.

Senator TYDINGS. May I ask a question?

The CHAIRMAN. Yes.

Senator TYDINGS. Dr. Bush, have you any doubt—first, preliminary to my question, let me say this: I don't believe that it has been shown that this new government which has come into being in Russia has ever been guilty of bluffing. It has had the merit of saying it would do something and then doing it, and it has taken a very realistic approach to things. It was realistic with respect to Hitler and the German crisis.

You will remember that they did reduce the standard of living of the Russian people so far as was possible to prepare for this war, over a long period of years. It was their own program.

Now, keeping that in mind, and in view of a statement of Mr. Molotov that they would have atomic bombs "and more," is there any room for doubt that the Russians are now proceeding with all their might and main, so far as they know how? Can there be any doubt of that?

Dr. BUSH. I think it would be very doubtful, sir.

Senator TYDINGS. Why?

Dr. BUSH. At the time when Russia had her 5-year plan and when she made her sacrifices which you mentioned, she was threatened by Hitler and by the military development of Germany and she knew that she would have war.

But now, it is different. I do not believe that they feel that way now.

Senator TYDINGS. But how do you know that the Russians do not still consider themselves threatened?

Dr. BUSH. I am quite sure that the Russians do not feel that we are a threat. We do not have interests which conflict seriously. They know that we are not warlike; they know that for a fact.

If I believed that Russia feels threatened by the United States, I would despair of their realism. I think they are very realistic.

Senator TYDINGS. Do you think Molotov was just simply making conversation?

Dr. BUSH. All he said was that they were going to have atomic energy.

Senator TYDINGS. He said they would have the atomic bomb "and more."

Dr. BUSH. What are, do you think, "and more"?

Senator TYDINGS. The discovery of new weapons.

Dr. BUSH. All he said, as I got it, was, "We are going into the development of this field." That is what Russia is going to do, and I feel quite sure that they will do it well. He did not say that they were going to develop it at the maximum possible speed. I would be quite surprised if it was made a matter of such urgency, under the present circumstances.

Senator TYDINGS. You don't think it will be made a matter of urgency under the present circumstances?

Dr. BUSH. I say there is no reason whatever why they should make it such a matter of urgency, why they should sacrifice all of their other interests.

They have a great interest in restoring their economy after this war; they will be busy.

Senator TYDINGS. That is true. They also have an interest in survival, as we have.

Dr. BUSH. Let me say once more that there is a great difference between Hitler and the Germans and this country, and the Russians know it.

Senator TYDINGS. Well, if I were a Russian, I would want to proceed with all possible speed right now. I don't mean what I am saying as criticism, but I do say that if they had a bomb I would want my government to proceed.

I think they are just as human in their feeling toward their own country. They love their country, and they want to protect it.

Furthermore, I think it would be contrary to all recent Russian history if they did not try to keep abreast with all the others.

Dr. BUSH. We have to think of it as a whole. If we limit it to one factor alone, we might distort the whole picture.

For instance, there is the matter of delivery of the bomb, whether it be by airplane, guided missile, rocket, or other means, we have the problem of delivery of—

Senator TYDINGS. And the suitcase.

Dr. BUSH. Yes, although when you mention that, that brings up something I would like to comment upon.

You have the elements of war. You have the Army, the Navy, submarines—the whole power of war. The atomic bomb is one element only, a very important element and the deciding element at the end of this war, and in the future, when bombs are plentiful, if they ever are, I think it will be controlling.

Today, however, in thinking of our national defense, we don't think of atomic bombs alone, and we should not think of them alone. We think of a great many elements.

So does Russia. I believe that Russia, like ourselves, will maintain such armed forces as she will determine will be needed for her national security in a reasonable manner as to—

Senator TYDINGS. And also maintain its plant?

Dr. BUSH. Yes, as a part of that system, that is quite right.

Senator TYDINGS. And, therefore, you think that they are approaching this in a rather leisurely way?

Dr. BUSH. Not leisurely, but in the same way we are, with a determination of reasonableness.

Senator TYDINGS. I cannot imagine anything more important in the national defense, so far as Russia would be concerned, right now, than the production of atomic bombs in Russia. I say that in no spirit of criticism. If I were running Russia, knowing that one nation had this great weapon and that we did not have it, it seems to me that I would be getting on the job right away to get it. I would get it so that I could be in as strong a position as any other nation for the business of war.

To show you what I mean, I would not want to sit down in a poker game where one fellow had a royal flush and I had two deuces, three treys and a five spot—

Senator BYRD. I would ask for another deal. You would be holding six cards.

The CHAIRMAN. Do you want to amend your hand, Senator?

Senator TYDINGS. Well, let it go.

Dr. BUSH. My point is that I don't think they will sacrifice their national economy.

Senator TYDINGS. You don't?

The CHAIRMAN. Dr. Bush, you spoke of atomic bombs as being capable of control, that they could be controlled when they came into existence and after they came into existence.

Now, we had here last week some testimony, and I believe it was Senator Tydings who brought up the example of 40 of these bombs being planted in 40 of our major cities and activated at the same time, and there was discussion of the consequent tremendous loss of lives, maybe 40,000,000 people.

Do you believe that the country could wage any war after such an event?

Dr. BUSH. I don't believe the event would occur.

The CHAIRMAN. Well, I don't think so either.

I didn't think Pearl Harbor was going to occur, but it did.

Dr. BUSH. Yes, but we don't have to believe in miracles. I can say this, that this situation is serious enough without going back into Jules Verne and Buck Rogers. I have been annoyed in recent weeks in reading some of the discussion about these possibilities. We have realistic things enough to think about, without going into the realm of fantasy.

The CHAIRMAN. I am interested in the realistic, too. What is unrealistic about carrying in an atomic bomb in sections and planting it in one city, if not in 40 cities?

Dr. BUSH. Well, thinking realistically about it, I would say that at the present time there are no atomic bombs in the world except the ones we have got, and we certainly don't intend to do it.

Now, what are you asking?

Are you asking about now or 10 years from now? I will have to know that. I want to know the conditions, the conditions of international understanding, and approach the question from that standpoint.

I think the question is without meaning at the present time because it is in regard to the future. We do not know the nature of war as

it might be then, and until we do know I don't have any answer to the question, I can make no comment as to such a fantastic way of using bombs, whether it would be feasible or not.

Senator AUSTIN. But you have heard about that, about suitcases?

Dr. BUSH. I have heard about suitcases until I am tired of hearing about them.

Senator TYDINGS. Doctor, you do know that there were plenty of plans for sabotage during the war—of course, with such things as dynamite, and so on, not atomic bombs. Most of the plans were frustrated during the war because we captured the saboteurs when they landed from a submarine.

We also know about Pearl Harbor; we also know about Poland, and we also know about many similar cases throughout history.

We have got to prepare not only for this hour and this minute and the next 6 months, we have got to enlarge, imagine, and comprehend this thing not only as to what it is but as to what it will be 5, 10, or 20 years from now. We have got to lay a foundation.

Dr. BUSH. That is quite right, Senator.

Senator TYDINGS. The only thing I am interested in is this: Is it possible, in your opinion, in 5, 10, 15, or 20 years from now, assuming that a foreign nation or a group of nations intended to make war, that foreign agents, undetected, could come into this city with atomic bombs and plant those bombs and explode them simultaneously?

Dr. BUSH. You mean simply from the standpoint of not being interfered with?

Senator TYDINGS. Yes.

Dr. BUSH. Such as driving a truck across the border?

Senator TYDINGS. Yes.

Dr. BUSH. The answer is "Yes," of course.

Senator TYDINGS. Also, for instance, they could drive a submarine up the river here and carry it in on a truck into Washington?

Dr. BUSH. I think that is a little complicated; it sounds that way to me. Without going into details, however, the answer is "Yes, from a technical standpoint."

Senator TYDINGS. The point is that it could be done?

Dr. BUSH. Yes. But by the same token, it is technically possible to drive 10,000 trucks across the border, each with 10-ton bombs, and do in the same way. That is a technological thing only. It is an entirely different question, whether any nation would do such a thing—quite different.

Senator TYDINGS. Well, as the world is constituted today, perhaps it wouldn't be. I saw Germany rise again after the last war, and I am not certain that she will not rise again after this war, in spite of its disasters, and I am not certain that, in another 20 years, there will not be another Hitler to bring the world into war again.

We don't know what will happen. Maybe the stock market will be as high as it was in the 1920's and people will be more interested in gambling than in national defense.

We have to look into the future, 10, 15, or 20 years ahead. I see no reason in the world to assume that we might not have another Hitler and that he might not send his agents over here to blow us up.

Dr. BUSH. Senator, I would not want you not to look into the future, and I would not urge you not to use your imagination.

My point is simply that we have plenty enough to think about that is very definite and very realistic—enough so that we don't need to step out into some of these borderlines which seem to be, to me, more or less fantastic.

Let me say this: There has been a great deal said about a 3,000-mile high-angle rocket. In my opinion, such a thing is impossible today and will be impossible for many years.

Senator TYDINGS. But not ultimately impossible?

Dr. BUSH. I say nothing is ultimately impossible, because I do not know. But I can say with confidence that I would not know how to do it today, and I do not think that any man in the world, today, would. I am speaking about a 3,000-mile rocket.

Senator TYDINGS. What would you have said, 10 years ago, about the 100-mile buzz-bomb?

Dr. BUSH. I would have said, 10 years ago, if anybody wanted me to design a 100-mile buzz-bomb, that I could readily get people to do it.

Senator TYDINGS. What do you think will be the limit, 10 years from today, as to range?

Dr. BUSH. Buzz-bomb?

Senator TYDINGS. Yes.

Dr. BUSH. 2,000 miles.

Senator TYDINGS. 2,000. Then, what is there to stop you from putting on that rocket or buzz-bomb with a 2,000-mile range an atomic bomb?

Dr. BUSH. A buzz-bomb flies in the air; an airplane flies in the air. You can leave the crew out and you can control it by remote control. The buzz bomb can fly just as far as an airplane and carry the same load, and it is subject to all the antiaircraft interception that an airplane is subject to.

Senator TYDINGS. But there is no reason why the atomic bomb could not be put in that device?

Dr. BUSH. No, there is no reason why you could not put an atomic bomb in such a device. It could be delivered in an airplane, say, over Japan, without a crew, if somebody wanted to do that.

But the people who have been writing these things that annoy me haven't been talking about that. They have been talking about a 3,000-mile high-angle rocket, shot from one continent to another, carrying an atomic bomb and so directed as to be a precise weapon which would land exactly on a certain target, such as a city.

I say, technically, I don't think anybody in the world knows how to do such a thing, and I feel confident it will not be done for a very long period of time to come.

Senator TYDINGS. Of course, it would not take much brain power to use an aircraft carrier or some modification of an aircraft carrier and equip it with rocket-firing guns and get within 100 miles of the shore and use the atomic bomb from there, from 100 miles?

Dr. BUSH. That is what I mean when I say that we have got enough troubles, enough serious practical problems to deal with now, without letting our imagination roam.

The CHAIRMAN. Well, Dr. Bush, I read in this week's Collier's magazine an article by General Carl Spaatz of the Air Forces. I would like to have you read that article.

Dr. BUSH. That would not worry me in the slightest degree. I have just been criticizing the report of General Arnold of the Army Air Forces.

The CHAIRMAN. I wish that you would, sometime later on, comment on that article.

Senator TYDINGS. What does it say, Mr. Chairman?

The CHAIRMAN. What it says, Senator, is that the Germans, the year preceding the end of the war, were designing a rocket, and were pretty well along on it, that could carry from that continent to this continent and that would contain a warhead. They did not, of course, at that time have in mind an atomic warhead. That is my understanding of the article, at least.

Of course, I do not qualify General Spaatz as an engineer, but he has written this article in Collier's.

Dr. BUSH. If you were talking about 400 miles or 500 miles, I would say by all means. That is what the Germans did with their V-2. I would say yes, even with 2,500 miles.

But 3,000 miles? That is not just a little step beyond, it is a vastly different thing, gentlemen. I think we can leave that out of our thinking. I wish the American public would leave that out of their thinking.

Senator TYDINGS. If you were Secretary of the Navy or Chief of Staff, as Admiral King is, and had the responsibility for keeping our fleet up to par and ready for all emergencies, and you had Congress in back of you, what would there be from hindering you from taking one or more aircraft carriers and modifying them or adapting them so that they could have an equipment of guns that would fire an atomic bomb 200 or 150 or 100 miles?

Dr. BUSH. I would like to say not a gun, a rocket.

Senator TYDINGS. Whatever it might be. You could then stand off the coast out of sight and level the cities along the coast, could you not?

Dr. BUSH. Provided the country you are trying to level doesn't do anything about it.

Senator TYDINGS. But they would not know about it. We did not know about Pearl Harbor until too late.

Dr. BUSH. If I were the Secretary of the Navy, I would be sure to see that the best possible group of people, both Congress, military men, scientists, engineers, industrialists, study every angle of the armament of the Navy to see what the relative emphasis ought to be on the developments of today.

More than that, I wish that that could be done effectively and rationally and not merely service by service, because we need a national program of research and development on weapons and we have not got it at the present time.

However, whether your particular scheme would fit in that, Senator, I do not want to say.

Senator TYDINGS. Pearl Harbor made a profound impression on me, and so did the development of the atomic bomb. I don't want to be caught napping twice at the same open switch.

Senator JOHNSON. Dr. Bush, you are just about the most reassuring witness we have had. You are different from the other scientists which the committee has had; they were all gloomy scientists, and they have made these hearings virtually a chamber of horrors.

Dr. BUSH. On the other hand, please don't misunderstand me. This is a tough problem and it is going to be a long time before we have a solution to it, but I am not pessimistic.

Gentlemen, I believe the advent of the atomic bomb means the end of great wars, world wars. I hope that I am right. But it is going to take a long time and a lot of hard work to get to that consummation.

Senator JOHNSON. I possess the same kind of optimism that you have, and I believe that this new creation will stop wars.

Dr. BUSH. As General Eisenhower said, it might blackmail the world into peace.

Senator JOHNSON. I hope you are right. But, using your illustration of a few minutes ago, you said that when gunpowder came out, and the crossbow, and other weapons of war, they tried to outlaw them. On the other hand, there was the statement made with each of those weapons, as it came out, that it would be so bad that it would stop war. Well, they did not.

Dr. BUSH. There is a lot of difference, Senator. I think this is the first time we have had a new element come into it of this type.

I cannot imagine two nations, each of which had atomic bombs in quantities and in each of which the people knew all the facts and knew the world situation and in each of which the government was responsible to the people, I cannot imagine two such nations ever going to war.

Senator TYDINGS. Your imagination outstrips mine. To me it seems as if you have laid down a premise of two great nations that have all the things that go into the making of a war.

I think that we have even a longer road before us to travel than you have indicated in the control of the atomic bomb. I hope it is not so. I am really in sympathy with your objective and my only reason for asking questions is that I want to make sure that our use and consideration of this new weapon does not tie us to a state of unpreparedness.

Dr. BUSH. Right. Right. But let me repeat, as I said before, that meanwhile this Nation has got to be strong.

Senator TYDINGS. That is right.

Dr. BUSH. We ought to be so strong as not to threaten anyone else's security but so strong that there will be no question about our own security.

Senator HART. I do not want to ask Dr. Bush a question. I want simply to say something about him.

I learned of his wartime activities some time ago. Naturally, what I learned primarily was his activities as a scientist. I followed them somewhat and I was particularly struck all the time by the doctor's balance and his innate and continuous common sense throughout this difficult time, these difficult years which we and he have been going through.

This statement which he has produced this morning is very representative of those qualities in him. It is, as we might expect, a brief statement and I sincerely hope that it will be published in full all over the country. I have not seen anything which would be so effective as this statement, in my judgment, much more effective than this article in Collier's Weekly, the article which you referred to, Mr. Chairman.

The CHAIRMAN. I hope you understand, Senator, that I do not vouch for what General Spaatz said, but since 5,000,000 or 10,000,000 people are going to read it, it probably would be well if we could have some comment on it from Dr. Bush.

Now, Dr. Bush, General Groves in his testimony before this committee mentioned a figure of \$500,000,000 a year for the operation of these plants. Have you given that matter any thought at all?

Dr. BUSH. No, sir; I haven't been into those estimates.

The CHAIRMAN. If, to take it hypothetically, if such were the figure, what part, what proportionate part do you think we should devote to further peacetime uses and what part to military uses?

Dr. BUSH. It is very hard to separate them, Senator, of course. In fact, you might say that every part of material produced would be capable ultimately of being put to commercial purposes, peaceful purposes, if the commercial development is successful, as I feel quite sure it will be.

Senator HICKENLOOPER. Mr. Chairman, may I ask a question?

The CHAIRMAN. Go ahead, Senator.

Senator HICKENLOOPER. I just want to revert to a statement you made a moment ago, I believe to Senator Johnson, in which you said you could not imagine two nations where the people of the countries knew, that you could not imagine those nations going to war with each other.

With regard to your approach there, the point he was trying to raise a while ago, I think, that ultimately we would reach our final production of this bomb and there would be a time when we could relax.

Do you feel that there might come a time when the people of the country might realize the enormity of this thing and realize the potential destruction, and do you think that then, in turn, they will police their officials, if you please, to keep the heads of the governments from using this power to the destruction of people?

Dr. BUSH. Quite right.

The CHAIRMAN. Dr. Bush, do you believe that a scientifically feasible control system can be worked out?

Dr. BUSH. Scientifically, such a system could be worked out. I would go more than that. I think a practical system, a system practical and feasible, can be worked out in time, after we have gained a knowledge sufficient for the purposes of control; yes, in time.

The CHAIRMAN. In time. Well, now, if the principal nations or the United Nations were to meet in session and agree to a scientific system of control, would you not be in favor of putting it in immediately?

Dr. BUSH. I don't think I know quite what you mean.

The CHAIRMAN. Let us assume that they meet in the United Nations Organization and that they set up a commission. The commission reports with a recommendation for scientific inspection, inspection of all the countries of the world.

Dr. BUSH. For what?

The CHAIRMAN. To see whether or not there is fissionable material made and, if so, by what process and whether or not any military use was going to be made of that material. Would you not be in favor of putting it into working order immediately?

Dr. BUSH. I think that would be going rather far for a first step.

The CHAIRMAN. Well, if it could be accomplished, it would be highly desirable, would it not?

Dr. BUSH. Yes; but I imagine that there will have to be several steps. The first one might well be an agreement among the nations

through the United Nations Organization to make known all the situation in regard to resources in war materials and the extent to which they are being moved, and so on.

The CHAIRMAN. To that extent you would be in favor of an agreement?

Dr. BUSH. To that step, certainly.

The CHAIRMAN. Or to all steps to a scientifically feasible inspection system?

Dr. BUSH. But an inspection system, Senator, has got to be for a purpose. There is no use talking about an inspection system in the abstract. What is the inspection system supposed to do?

I have given you one example and in that example, that case, the inspection system would be to find out the facts in regard to the distribution of the resources and raw materials and their shipments. As I say, I believe such a system could be set up and it would work effectively.

Now, if we could find another step, the next step—

The CHAIRMAN. What would be the next step?

Dr. BUSH. Specifically, it does not need an immediate setting up under the United Nations Organization of an inspection system with vague and general commitments. Rather, it means that we set up first an agreement among the nations to make certain facts known and then an inspection system to produce explicit effects—which is a very different thing.

The CHAIRMAN. Well, do you think a demonstration of the power of this thing to statesmen of this world might hasten their agreement to a completely implemented inspection system?

Dr. BUSH. No. There has been sufficient demonstration in Japan.

Senator HICKENLOOPER. In other words, the statesmen of the world know what this thing can do now.

Dr. BUSH. Of course, and so does everybody.

Senator HICKENLOOPER. We have got to the point where we have rubbed the lamp and the genie has come out and we cannot get him back into the lamp.

Dr. BUSH. That is right.

The CHAIRMAN. My point is, Doctor, whether or not you agree that we should take a lot of steps, fast, Doctor, which might be for the betterment of the future health and safety and security of the world.

Dr. BUSH. Right, but not too fast, Senator. We must adjust the burden to the means that can be employed and we should proceed with such deliberation that we can be assured that the agency we set up is successful from the outset and will continue to be successful and shall not be overburdened.

The CHAIRMAN. Dr. Bush, I want to thank you on behalf of the committee for your statement. It may be that we might ask you to come back here later.

Dr. BUSH. I would be very glad to come back any time.

The CHAIRMAN. Thank you.

There will be no session of the committee tomorrow. We will resume on Wednesday at 10 o'clock.

The hearing for today is adjourned.

(Whereupon, at 12:30 p. m., the committee adjourned until Wednesday, December 5, 1945, at 10 a. m.)

ATOMIC ENERGY

WEDNESDAY, DECEMBER 5, 1945

UNITED STATES SENATE, SPECIAL COMMITTEE ON ATOMIC ENERGY, *Washington, D. C.*

The special committee met, pursuant to adjournment, at 10 a m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Byrd, Austin, Millikin, Hickenlooper, Hart.

Also present: Representative John R. Murdock; Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. We have with us this morning Dr. Oppenheimer, a most distinguished nuclear physicist, who was in charge of the Los Alamos laboratory, which was one of the most important parts of this project.

The doctor has flown across the country to meet with us. I am glad to see you, Doctor, and if you have a prepared statement, go ahead and make it; and at the end of that we will ask you some questions.

STATEMENT OF DR. J. R. OPPENHEIMER, PROFESSOR OF PHYSICS, CALIFORNIA INSTITUTE OF TECHNOLOGY

Dr. OPPENHEIMER. I think you may wish to know my qualifications. I am a physicist and teacher of physics at the California Institute of Technology in Pasadena and at the University of California in Berkeley.

During the war I was in charge of that part of the work which had to do with the use of the special materials, Uranium-235 and plutonium, for the actual design and making of atomic bombs.

There are one or two important respects in which I am not a qualified witness, and I think I should point these out to the committee. The operations in Tennessee and in the State of Washington took very great advantage of American industrial organization, and, once the basic principles and designs of the process were elaborated, enormous demands were made on some of the greatest corporations for the actual construction and operation of these plants.

In the work which we did in New Mexico, we were neither able to take advantage of industrial experience, nor did we in fact do so, and therefore there is a very important part of the job which I am not competent to testify about, namely, the part that was played by

185

American industry in creating these atomic weapons. I think it essential to emphasize this, because I deplore the tendency of myself and my colleagues to pretend that with our own hands we actually did this job. We had something to do with it. If it had not been for scientists, there would have been no atomic bomb; but if there had been only scientists, there also would be no atomic bomb.

I have an extremely brief prepared statement. May I read it, sir?

The CHAIRMAN. Certainly.

Dr. OPPENHEIMER. This committee has been created to deal with problems of more than ordinary gravity. It is proper that those of us who have had technical knowledge and responsibility in the work on atomic energy should attempt, in every way we appropriately can, to be helpful. Perhaps I can do that most effectively by answering your questions. I should be reluctant to take your time with a long statement of facts and arguments with which you are well acquainted. It may be that you will wish to ask me of things that cannot be adequately discussed at this hearing, because they are secret. I shall be glad, insofar as I am competent, to go into these matters with you at another time.

I may interpolate here and say that it is my view that this committee should have any information which in its opinion is required for the carrying out of its grave responsibilities, and if I can help get that information to you I should be glad to do so.

In the all-important problems that are not primarily technical it is my conviction, as it is of the great majority of my colleagues, that we must speak, if at all, not as scientists but as American citizens. For in these questions the welfare of science is inseparable from the welfare of the American people, whom you represent.

Let me explain this as I see it. Science has flourished because, in the long term, its works were good for mankind. It has often happened in the past that the progress of science has turned up some development that was hard for society to digest; at such times we have learned not to repudiate science but to accept it and to use it to reshape our ways of life. Last summer the progress of science turned up something very indigestible: the atomic bomb. As a culmination and a complement to a long series of technical advances in the arts of war, atomic weapons have made it necessary to examine with a new earnestness and a new courage the steps by which peace could be established, maintained, and made permanent. Only insofar as this is successful will science itself survive and flourish. In the world of atomic war it will not be true that the works of science are good for mankind. A world fearful of cyclotrons is a world fearful of knowledge. It is not a world in which science can survive. In this issue of peace our interest is the interest of America, the interest, I think, of all the people of the world.

Scientists have spoken very much of atomic energy. Undoubtedly this will have been construed as expressing a desire on their part to assume the responsibilities of statesmen. I do not believe this. I believe that the solution of the problem created by the development of the atomic bomb does not lie within the field of science—that this is a political problem, a deep problem of human values, and a problem of statesmanship. It is to this end that we have testified, that I

should be glad to add my testimony. Let me restate a few of the points that you may wish to ask me about:

There follows a summary of some of the things which have been testified to by scientists and others.

There are, and there will be, no specific countermeasures to atomic weapons.

The prospects seem poor for any adequately effective military defense.

There can be no long-term security, either in the scientific novelty or in the vast technical complexity, of the project.

There are no ingenious devices whereby one nation could detect or control atomic armament in another nation committed to sovereignty and secrecy in this field.

Atomic weapons can now be, and could increasingly be, cheap instruments of devastation—cheap compared to the costs of war as we have known them.

Atomic weapons are now, and could increasingly be, effective instruments of devastation, so effective that they are unlikely, in a world at war, to be renounced for humane or for tactical reasons.

Scientists may be helpful, in a world desiring fraternity, because there is a sense of fraternity among them in all lands, but in a world of admittedly secret armament, they will not even make good spies.

There are high hopes that atomic reactors can contribute to knowledge, to technology, and to the eventual enrichment of our civilization, but these developments will not avert atomic warfare, nor prosper under the threat of atomic warfare.

We have tried to say these things lest the one great hope, that there be peace on earth, and fraternity among peoples, be subverted by lesser ones, which cannot be realized in fact.

There is one thing that I should add, not as a technical witness, but as a citizen. Today all nations, all peoples, have an overriding community of interest in the prevention of atomic warfare. There would thus seem to be good reason for attempting to establish in the international control of atomic armament those patterns of confidence, collaboration, and good faith which in a wider application must form the basis of peace. There would seem to be some practical reason for undertaking such control, not only as a necessary step, but as the decisive step, on this road, that we, as a nation, have determined to follow. There may not be a comparable opportunity again.

That is my prepared statement, Senator.

Senator HART. Doctor, in your first point you say there are "no specific countermeasures to atomic weapons."

I assume you mean by that that there is no countermeasure which would operate solely by reason of the fact that the explosive in the missile is one of atomic fission?

Dr. OPPENHEIMER. That is precisely what I meant. The problem of countermeasures against an atomic bomb is technically the same problem as that of countermeasures against any other type of bomb. It differs from it only in that the numbers of such missiles may be smaller, and their effect very much greater, and that the requirements of interception may correspondingly be very much higher.

Senator HART. Would you extend that opinion to the detection of the missile in flight also?

Dr. OPPENHEIMER. I would, yes. It seems to me—and on this I will not make quite as categorical a statement, because the future may have something in store—I can see no way by which a bomb can be detected to be an atomic bomb, or detected because it is an atomic bomb, which would not apply equally well to a block buster.

You can learn to recognize its color or its shape, but it will be that kind of thing.

Senator HART. A little further down you say “there can be no long-term security.”

Dr. OPPENHEIMER. Right.

Senator HART. Do you wish to give an estimate as to how long it would take any particular nation—Russia appears very much in the press—starting today with what they now know, to be ready to deliver atomic bombs?

Dr. OPPENHEIMER. Such an estimate would be of no use to the committee. A sound estimate would have to be based on a knowledge of the economy and on the social and military philosophy of the nation, and at least I know nothing about this in the case of any other country.

I would say that I believe I know a little bit about Britain, and if Britain went into it, I think they could be quite far along within 2 years. I do not know anything about the other lands.

I think it is not a predetermined question. What this committee decides, what the Government of this country does, will have more bearing on it than anything else; because if we make it clear that no power can be a first-class power that does not have atomic weapons, we will invite the investment of an enormous effort in other lands.

Senator HART. Do you estimate that the state of industry in Britain right now is such that by going full out they really could accomplish that in 2 years?

Dr. OPPENHEIMER. I would think so. I would think it would be unlikely that they would do that, because they have problems, like building houses, which seem to me more urgent for the welfare of the British people, and which I think will be so judged in Britain.

Senator HART. Another point, Doctor, a technical one in your field: Assuming that the whole world or any nation of the world is entirely open to our inspection, are there ingenious devices, which you mention in your statement, which would be very useful in detecting the up-growth of any industry which might eventually produce atomic bombs?

Dr. OPPENHEIMER. Yes, if everything were wide open, then I think actually the problem would be solved. But if you wish to make doubly sure that the problem is solved, there is equipment with which you would get some idea of what the nature of the water coming out of a plant was, what the nature of the product was, which would supplement the ordinary visual inspection that you might expect to use.

I would put it this way: If this committee wanted to go to Hanford and to Oak Ridge and to Los Alamos, I think we could rig up some gadgets which would start ringing bells at certain points in those plants, and with which you could confirm what you already know; namely, that they were working on atomic energy.

Senator HART. In a system of inspection which would extend over an industrial nation of considerable size, it would be necessary to have a rather large force of men trained in that kind of science to operate those devices, would it not?

Dr. OPPENHEIMER. My view on that is that if you have to inspect every house and every plant as a regular thing, that you have not solved the problem.

If the inspection is used as a complement to the reports which that government will make, and to the facts which will be the common gossip of scientists and common knowledge, if you use it as a spot check to find out whether there is any two-timing by any group within that nation, it is only if you do it that way that it seems to me to have any practical elements.

A thoroughgoing inspection of everything all over the world is such a full-time job that I am afraid we would have very little time left to do any of the useful work of life.

The CHAIRMAN. I don't know; we are talking about taking a million or so boys and putting them in uniform for a year.

Dr. OPPENHEIMER. I do not mean to argue, and should not—

The CHAIRMAN. That is purported to be a protection against war,

Dr. OPPENHEIMER. I don't mean to argue that it is not worth putting a lot of effort into inspection. On the contrary, I believe it is; but I believe that that inspection must be based on a formal and open recognition on the part of the governments that they are not interested in making atomic weapons, that they are not interested in doing any of this work secretly. It will be easy to detect the secrecy, but what will be hard to detect is what is the secret.

If you take our place at Los Alamos, a year ago I think there were no physicists in this country that did not know what we were doing there. They did not talk about it, because it was contrary to the national interest. But this peculiar conglomeration of scientific talent in a very remote place aroused that suspicion, and they made quite a good guess as to what we were actually about.

Now, the fact that there is a secret laboratory there is recognized, but I think you could ask any physicist now what is going on at Los Alamos, and unless he is actually there he would not know. He would not be able to tell you whether we are or are not making bombs. I speak of "we" generically, since I am not there.

This is a good example of the fact that, once secrecy is adopted as a national policy, the problem of finding out what is secret is very tough. When it is not adopted, finding out that something is going on is very easy.

Senator HART. In a country with vast spaces geographically, so great as to make it difficult even to cover it, do you visualize the practicality of such inspection in that type of country?

Dr. OPPENHEIMER. I visualize it with some concern. It seems to me that the way it probably would work is this: At the present time the problem of inspection is rendered almost hopeless by the fact that outside of the United States there just isn't anything to inspect. That is, there is nothing going on, and it is a very abstract problem.

As work on atomic energy starts up in other places, I would think that it would be desirable that these be completely wide open, and that conversations about what was going on and participation in the work be a very public matter.

I think that when a new mining operation is started, it would be reasonable to investigate the nature of that mining operation, the probable output, and to keep books on it, to ask the operators to keep

books and to make audits of these books, and physical audits of the situation from time to time.

I think that inspection should supplement the assumption that we are dealing with honest people whose desire is to prevent atomic armament, and that we should be in a position to detect a change in spirit, if that should ever arise.

It is very much like the laws against murder. Everyone accepts these because he does not expect to be the murderer. I think everyone must accept, and I think with skill everyone can be persuaded to accept, the undesirability of atomic armament.

Then if a situation arises where in some place this decision is reversed, I think it will not be hard to find it out.

Senator MILLIKIN. Doctor, does it follow from what you say that if there is a single nation that does not permit inspection, or does not permit effective inspection, that inspection is useless?

Dr. OPPENHEIMER. I would be singularly unperturbed if Guatemala failed to permit inspection.

Senator MILLIKIN. If Guatemala failed to permit inspection, that might indicate that Guatemala was being used as a stooge by someone that did permit inspection.

Dr. OPPENHEIMER. It might, but they would have to import more than uranium to make atomic bombs.

Senator MILLIKIN. If any important nation refused full and free inspection, then all inspection would be useless, would it not?

Dr. OPPENHEIMER. I think that if one important nation refused, it would be a source of great concern about that nation. I think one would still wish to know and be glad to know what was going on in the rest of the world.

My view of it is this: One of the things which we now realize is that in the 1930's there was a growing and very visible threat of world war in the policies of the Axis nations, and that we in America were both inadequately informed and inadequately convinced by such information as was available that this threat was real.

I think there is no doubt that in the early thirties the military problem presented by the strength of the Axis was not a serious problem. It got to be serious only after many years of armament.

What I think we need is an indication that a threat of war begins to exist, and if you had a group of nations agreeing to atomic inspection and cooperation, of which one or two suddenly started to make barriers or started to two-time so that you were convinced that the information you were getting was unsound, this I believe would be a danger signal and would call for the declaration of an actual emergency.

Senator MILLIKIN. Let me put it to you this way, then: If one important nation refused the right of complete inspection, then the other nations would not be warranted in demobilizing, so far as atomic bombs are concerned?

Dr. OPPENHEIMER. I would think it would be a very serious mistake to allow any nation to fail to cooperate in this point, if we had the power to prevent that.

Senator MILLIKIN. Your first proposition was that there are and will be no specific countermeasures to atomic weapons. Would there be any way of detecting the presence of a planted bomb?

Dr. OPPENHEIMER. It would be most difficult, as I think Admiral Purnell testified before another committee. The design of such a thing is not frozen. The shape is not frozen. The active material which makes it an atomic bomb is usually not near the surface, and I think that just by walking along past a crate you would not be able to tell that in that crate there was an atomic bomb. It wouldn't tick.

Senator MILLIKIN. Would there not be detection devices, the same as the devices that you have in these plants, to indicate radioactivity? Do you not have a detection instrument?

Dr. OPPENHEIMER. The nature of the radioactivity is such that it is not very penetrating, and in many of the designs that I think reasonable the active material would be so thoroughly buried inside a mass of other junk that the evidence coming out of that that there was radioactivity might be very slight.

Senator MILLIKIN. Could that kind of bomb in fact be covered with an insulating material?

Dr. OPPENHEIMER. Well, it generally is covered. I am not supposed to reveal how bombs are designed, but I think I can say this much: The active material in any designs we have been concerned with is like a small diamond in an enormous wad of cotton wool. There is an awful lot of junk outside which is not active, not radioactive, and I believe it would be unsafe to rely on it picking up any activity.

Senator MILLIKIN. I am talking, of course, of the theory we hear expressed frequently that mines could be planted all over the world, and at the crucial moment touched off in one way or another. I am trying to satisfy my own mind as to whether we could set up mine-detecting devices that would give us some measure of protection against buried mines.

Dr. OPPENHEIMER. I understand that. I would recommend that you ask this question of others. I don't want to give categorical answers, but I would not know how to do this.

Senator MILLIKIN. I mean that we in normal warfare, as it is now carried on, have mine-detecting devices which are rather effective if used thoroughly. I was wondering if anything of that kind might be available to use as a defense against that particular type of use of atomic bombs?

Dr. OPPENHEIMER. If you hired me to walk through the cellars of Washington to see whether there were atomic bombs, I think my most important tool would be a screwdriver to open the crates and look. I think that just walking by, swinging a little gadget, would not give me the information.

Senator MILLIKIN. Generally, as science has progressed, at the present time you do not have much confidence in that sort of a defense. Is that correct?

Dr. OPPENHEIMER. That is true of me; I may be wrong in this, but it is true of me.

Senator MILLIKIN. What have been the military defenses proposed aside from shooting V-bombs out of the air?

Dr. OPPENHEIMER. The only defenses I have heard are focused either on preventing anyone from making them, or on intercepting them in flight. I have not heard, and I believe that there are no advanced plans for the interception of the V-2 type rocket. The V-1 turned out to be a soluble problem after a lot of anguish. The V-2 I think

should be worked on. I don't know what the results will be. It is extremely difficult, and as you know it is made particularly difficult by the fact that no defense in fact, whatever we may hope, is ever properly alerted over the years. That is, you do not retain your defense equipment and your personnel at an adequate pitch except when there is a known emergency.

Senator MILLIKIN. May I ask you whether this would be correct—that in your opinion the maintenance of military forces for the purpose of sending them to destroy the possible launching sites of bombs, and to destroy the installations that make them after the use of them had begun, would be far from a complete defense?

Dr. OPPENHEIMER. It looks that way to me. That is, of course, the way in which the V-bombing of England was stopped, but it cost the lives of many men, and it took many, many months, and if those V-bombs had had atomic war heads, it would not have saved England.

Senator MILLIKIN. I am not suggesting by my question that that should not be attempted if we were the victim of an aggression of that weapon.

Dr. OPPENHEIMER. The time scale is wrong. You just do not have the chance.

Senator MILLIKIN. When you speak about effective military defense, I assume you are speaking in the passive sense. Military defense often consists of aggression, of moving first, and I assume that you preclude moving first—that you exclude moving fast—from that proposition?

Dr. OPPENHEIMER. The history of the American people shows that we do not do that, and I am very proud that this is the case; but I think it is one of the facts of life which must be taken into account in planning our future.

Senator HART. That is what is meant by "preventive war," in which America has never participated?

Dr. OPPENHEIMER. Well, we have after considerable persuasion.

Senator HART. Doctor, may I ask you one thing along another line?

All of our talking and thinking thus far has been based on uranium or some other very heavy material as a fissionable material.

Do you visualize science progressing to the point that much more plentiful and more widely distributed materials may become fissionable and not constitute a danger?

Dr. OPPENHEIMER. No; with the exception of the very heavy elements, it will take some very new idea and some new discovery to extract energy from them. My frank opinion is that for all but the very light and the heavy elements, the project will not be successful; that is, I do not think that iron will ever be a source of energy. I say that with the full confidence that I may read in tomorrow morning's paper that somebody has found a way to do something, but I myself will look many times at that note before I believe.

The phenomenon of fission is a very specific phenomenon. It is an accident which this committee has every reason to regret—that uranium and thorium exists in the world at all and that these things can be realized.

As you know, the energy we always use comes from the sun, and solar energy, according to a theory of Dr. Bethe—whom I believe you are to hear later—derives not from a fission process but a series of

reactions upon very light nuclei, primarily involving the conversion of hydrogen to helium in quite a tricky way, which he might describe to you.

In the sun and in other stars, the enormous mass of the star and the effect of gravity play an absolutely decisive part in making this reaction occur, and I will explain that. The reaction generates energy and maintains the material at a high temperature. The reason it doesn't expand and cool off and stop the reactions is that it is held together by gravitational attraction.

It is conceivable that development of this kind might be carried out terrestrially, but I am sure I don't know how, and I do not think it is an immediate prospect nor a very likely one. So my answer—a rather long answer—is, to the best of my knowledge, “No.”

Senator MILLIKIN. May I ask you this, Doctor: Roughly speaking, does it come down to this—that unless we can reach a state of complete and honest world cooperation, at least among the powers that are capable of making or causing to be made a bomb, that we should continue to have our fears on the subject and continue to keep our bombs dry.

Dr. OPPENHEIMER. I would like to turn it around and say it comes down to this: that we have got to find a way in which to have a state of honest cooperation. I am afraid of the word “complete,” because I am sure that even this country will impose some obstacles to such a complete cooperation, and that it is natural we will; but fundamentally honest cooperation.

Senator MILLIKIN. Unless we have as close an approximation to that type of cooperation as is possible among erring humans, until we do have that type of cooperation among the important nations and the nations that are capable of making bombs or having them made, we have got to have our bombs “dry.” Wouldn't you say that is correct?

Dr. OPPENHEIMER. Well, I don't know what we will do with them.

Let us take a concrete example, and suppose we have the very greatest difficulties in negotiations with Power A and that Power A wishes to circumscribe any proposal they can think of, or we can think of, in such a way that we have the most profound doubt that we really will know what is going on. Then, it seems to me, the problem is to question whether we cannot get around this situation.

Let us try to find a minimum basis of agreement, because the building of a stock pile of bombs, when we don't intend to use them, when we certainly would not use them unless we were attacked, would be done with a half-hearted feeling—namely, the feeling that it neither deserves the full support that we would give such a program in an emergency, nor an abandonment of it—and would be one of those half measures which would give us an absolutely illusory security. An atomic bomb which you do not use is of no use to you.

Senator MILLIKIN. To put it another way, you would not advocate that we destroy our stock pile of bombs prior to that state of cooperation which you have described?

Dr. OPPENHEIMER. I think that I would put it this way: This is certainly a problem which goes far beyond what I know about, but my feeling is that our objective is to get started on the control of atomic energy. If we get started, the negotiators who represent this

country must certainly be prepared to make very big concessions about the inspection of our facilities, about the declaration of our stock pile and, if necessary, about the destruction of our stock pile.

I believe that such problems will arise. They should not, in my opinion, be discussed by us alone. They are part of the job of achieving a collective security.

Senator MILLIKIN. I would agree completely with you that we have got to get started, but let us put our minds now solely on the question the inspection of our facilities, about the declaration of our stock pile, of bombs. Let me have your observation on that.

Dr. OPPENHEIMER. I would say that as soon as we have a reasonable degree of conviction that it is not the intention—not the avowed intention—of any nation to manufacture atomic weapons, and as soon as we are convinced that it is the avowed intention of nations to make available to us the evidence that they are not in fact arming atomically, then we should no longer arm atomically ourselves.

Senator MILLIKIN. Don't you think we would have to go further than a reasonable degree of conviction? I think you could take out the "reasonable" angle in connection with the other things that you have said. Should we not have complete conviction?

Dr. OPPENHEIMER. I would like to think that, but I doubt whether it is reasonable to ask it.

The point that I would make is this: The safety which the cooperation of various nations in preventing war can give this country, and the advantages that they can give it in our not having to maintain a military establishment of overwhelming proportions, and the confidence with which we can go ahead with the work of peace are things worth aiming for. The possession of 300 bombs in some vaults around the country is something that I, myself, don't see any good in.

Senator MILLIKIN. You believe that we can take some risk, then, in connection with destroying our stock pile. That is all I am talking about—destroying our stock pile.

Dr. OPPENHEIMER. I believe that we can take great risks if the purpose is the achievement of peace.

Senator MILLIKIN. If there is a doubt or a reasonable doubt that we might not achieve peace by destroying our stock pile, I take it that of course you would not favor destroying our stock pile?

Dr. OPPENHEIMER. I think that this committee should not assume that the stock pile, as at present constituted, is one which would be of any assistance to us in fighting a major war.

Senator MILLIKIN. I wish, as far as you can, or feel that you should, you would elaborate on that a little.

Dr. OPPENHEIMER. This would have to be done under more private circumstances. I would be very glad to.

Senator HART. Doctor, I think perhaps you may be misunderstood at one point on account of brevity. You said that atomic weapons can be cheap instruments of devastation and then explained it briefly. I think it would be better for purposes of the record if you expanded that.

Dr. OPPENHEIMER. Well, I have seen a figure—I don't know whether it is a reliable figure, but it is surely not a crazy one—that it has cost us in this war \$10 a pound to deliver explosive on the enemy. I am unable to give an accurate cost figure on atomic weapons—partly

because I don't know and partly because if I did know it I would be prevented by that knowledge from saying it—but I think that I can say that, even taking account of the in-some-ways diminished effectiveness of concentrated bombing; it is somewhere between 10 and 100 times cheaper to deliver atomic weapons, which is simply in terms of the area destroyed—it is 10 or 100 times cheaper. I don't know if it is 10 times or 30 times, and this will depend on policy, but it is an enormous factor. It is not a trivial change.

Senator HART. Cheaper, for instance, than TNT?

Dr. OPPENHEIMER. That is right; and I am using a figure which may well be criticized, but which is, I believe, the figure used by Army Ordnance for over-all cost of delivering a pound. You can see what that means if you take a round figure of 10,000 tons as a possible effective equivalent for an atomic bomb. That is 20,000,000 pounds, which is \$200,000,000. Now, without revealing any secrets, I can say that an atomic bomb, and the equipment for delivering it, is not going to cost that by an enormous factor.

Senator HART. But those large TNT bombs, which are the usual comparative figure—though the destruction in any one point, any one small area, is by no means as great, it is sufficient and is spread over a wider area, is it not?

Dr. OPPENHEIMER. I used a somewhat conservative figure of the 10,000 tons rather than the actual equivalent in part to take this into account. The actual atomic bomb releases more energy than this.

Senator HART. But it is true that the comparison, as is usually made, is a little faulty because of the respective areas involved?

Dr. OPPENHEIMER. What I would say is this—and I will be somewhat sharper about it, if you wish: For the equivalent tonnage, the factor of cost will be more than 100. For equivalent area, it will be somewhere between 10 and 100, and that is to try to take account of this effect which you mentioned.

Of course, if you want to knock out three houses somewhere, you will not use an atomic bomb.

Senator BYRD. Doctor, when you spoke of destroying the stock pile of bombs, would that mean, too, destroying the organization and the factories that made the bomb?

Dr. OPPENHEIMER. In the first place, I did not speak of destroying it; I was asked about it.

Senator BYRD. I understood you to say that if you had faith in other nations you would then favor the destruction of the bombs we accumulate during this period before we can ascertain what other nations are going to do.

Dr. OPPENHEIMER. I would say this country should do, for the problem of atomic armament, what we expect other nations to do. If we expect them, and are convinced that they wish not to arm atomically, then I think that we should not arm atomically; and if we want to keep the plant some place, I think we should have that plant completely open and should allow the representatives of the powers with whom we are dealing to know as much about what we are doing as we would want to know about their plants.

I do not think that when we get to that point—I don't know that we will but hope that we will—we will treat atomic weapons as an entirely separate problem, because the problem with which we are faced is

not to have wars. It is not to make them pleasanter wars, like this last one; and I think that other weapons will come in for the same kind of discussion as the atomic weapons. We are a long way from that today.

Senator BYRD. Under what situation which you visualize may occur would you keep this present organization for the peacetime development of atomic energy?

Dr. OPPENHEIMER. Some parts of it I think should not only be kept but expanded. My own feeling is that the possibility of maintaining even an effective bomb factory, such as we are supposed to have at Los Alamos, depends on operating there so that there are some peaceful uses of the work, because it is very hard for a group of men to be making bombs which they think (a) will never be used and (b) should never be used. It is very hard for them to do this as their only lifework. Therefore, I have recommended and continue to recommend that as long as that place must be kept in operation, it consider problems of a nonmilitary character as well.

Senator BYRD. Isn't there a very thin line in the manufacture of this atomic energy for peacetime purposes and for the making of bombs?

Dr. OPPENHEIMER. The line is thick with some types of plants and thin with others, and it is perhaps one fortunate thing that for the type of installation which has the greatest use as a research tool and the greatest promise of power development, the line is a little bit thicker. That means it is something of an effort to convert from one to the other; it is not a matter of many years.

Senator BYRD. The material that would be useful for peacetime purposes being available, how long would it then take to use that and convert it into a bomb?

Dr. OPPENHEIMER. If one were completely set up for it—and this Nation now is, on a small scale—it would take a matter of 2 or 3 months to start the various things going that need to be done and to start production; maybe 4 months if one had trouble.

If it were a nation or a group of people that had never had any experience with the job and had to find out how to do it and had to build the installations, I would think 15 or 18 months might be a more reasonable guess.

Senator BYRD. Then, if you permit the use of this material for peacetime purposes, you are just 2 or 3 months behind?

Dr. OPPENHEIMER. For a group of people who know how.

Senator BYRD. We are assuming that sooner or later all the scientists of the world will know the formula and process we have here. You concur with the other scientists who have testified, do you not?

Dr. OPPENHEIMER. I think they would find out quite a lot about it; yes.

Senator BYRD. Let us assume they know as much as we do about 25 years from now, and that then the world organization permits the manufacture of these materials for peacetime purposes. Then, it will only take 3 months to convert that material into bombs for war purposes.

Dr. OPPENHEIMER. I think if you did not have the establishment, if you had to build the place to make this conversion, it would take that much longer; but it is still not a very long time.

Senator BYRD. If we have such a world agreement, the other nations of the world will then permit us, even if we have destroyed the bombs we actually made—are they going to permit us to keep this tremendous plant and organization without having themselves an equivalent plant and organization?

Dr. OPPENHEIMER. I hope that the problem will not appear in this light.

Senator BYRD. Why won't they appear in that light? Every nation is going to say this: "All right, we won't make bombs if America destroys her bombs; and America, then, will also have to destroy the machinery she has established for making the bombs, because that gives her a year or 2 or 3 years advantage over us."

What would be your answer to that situation? Shall we just destroy the organization completely?

I think Dr. Urey, as I recall it, advocated that if such an agreement be reached, we not only destroy the bombs but destroy the machinery and the organization we have set up to make atomic energy.

Dr. OPPENHEIMER. No.

Senator BYRD. Except in very small quantities.

Dr. OPPENHEIMER. I don't know. You see, I don't think you can stop things like this. If atomic energy is good for anything, I think the answer is probably that not only this country but other countries will be using it for anything it is good for.

Senator BYRD. Isn't that a great weakness, though, in the suggestion which has been made that this can be controlled by agreement among nations and by inspection?

Dr. OPPENHEIMER. It is a very great difficulty. It is the reason why everyone is so worried about it.

Senator BYRD. To me it is pretty nearly an insurmountable weakness.

The CHAIRMAN. Do you mind an interruption on that point?

Have you considered the possibility of a United Nations Organization ownership of such power plants as might be developed?

Dr. OPPENHEIMER. I think it would be a very good thing. I think that, for instance, if in China, where I understand we are prepared to help with the generation of power in the Yangtze Valley, it were possible and economically sound to establish atomic power, it would be a very good thing to do that through the United Nations Commission.

Let me answer your question in the following way: We have great factories in Detroit whose purpose is to make automobiles. Everybody knows that within a relatively brief time they can be converted into making tanks. No one argues that for that reason we should stop making automobiles.

Senator BYRD. I don't think that is comparable at all to the situation we have in hand, because nobody wants to stop making automobiles, and the one reason we want to stop making this is because of the terrific destructiveness of its use in a sudden attack.

Dr. OPPENHEIMER. That is right; but as I say, I don't know what the policy of the United States Government is going to be in the conquered nations, but certainly we are going to allow them some industry in spite of the fact that we know that any industry can be converted

in wartime to war making. We are going to do this, taking such other safeguards as we can to be sure that they are not going to make war.

I think that no nation now in the world as it actually is, no major nation, has any interest in making war.

Senator BYRD. That is true. It is just like a man that has been on a drunk and doesn't want to get drunk, maybe, the following day. We don't know that that is going to happen 25 years from now.

Dr. OPPENHEIMER. But that is what the next 25 years must be used for. It must be used to establish such machinery and such human relations between the different nations that this temptation to go on the next binge will be resisted and can be controlled.

Senator BYRD. I have been trying to clear my mind as to this so-called control, to be exercised by the international agreements, of the atomic bomb.

It seems to me that if you have any control that is effective you have simply got to banish the atomic bomb or atomic energy, which I frankly don't think can be done. You cannot do it half way because if you use the same materials for peacetime purposes, the same materials will be used at the beginning for wartime purposes.

Dr. OPPENHEIMER. Right.

Senator BYRD. You have got a time there which you have got down to 3 months. That is, a nation that has the facilities that America now has above every nation in the world, unless we dismantle those facilities, even if we destroy our present stock pile, can make atomic bombs in 3 months.

Dr. OPPENHEIMER. You can start making them. It is a thing that takes time to accumulate.

I would put it this way: If I saw in the abandonment of atomic power as a commercial source of power any real insurance that the world would remain at peace, it would be a very cheap price. You could mine a lot of coal for \$200,000,000.

Senator BYRD. But you are asking something that has never occurred in the history of the world.

Dr. OPPENHEIMER. But I don't think it will occur.

Senator BYRD. It isn't likely that the entire experience of the world for 2,000 years or more is going to be changed.

Dr. OPPENHEIMER. I agree with you.

Senator BYRD. Sooner or later there may be some great dictator of some nation in the world that would take it into his head to conquer the world. That has happened time and again in the history of the world. You cannot depend upon Christianizing and humanizing all the rest of the world within this limited time we have to make a decision as to what to do with the atomic bomb.

Dr. OPPENHEIMER. I think I would put it this way: At the present time the problem does not appear as a problem of preventing the use of atomic power for an energy source, because this is not an existing development and no one knows whether it would or would not be an economical one.

I believe we would have to face that problem later.

I hope when we come to it the situation will have been altered by a history of collaboration.

Senator BYRD. You speak of the inspection. Suppose that government A had an agreement they would not make any atomic bombs.

Suppose we discovered government A was breaking that agreement. What would you do? Would you use bombs we had here to destroy the other nation by bombs, or what will you do about it?

Dr. OPPENHEIMER. I don't know what the word "sanctions" means, but I believe there is such a word and that it means any measures which are necessary in order to cause that power to desist.

Senator BYRD. How would you do it? Suppose within 3 months this nation, which was using atomic energy for peacetime purposes, having the equipment and the plant, had manufactured a bomb and we discovered they were making that bomb.

Dr. OPPENHEIMER. One bomb will not do any harm. I would say that is a case for whatever sanctions were required.

Senator BYRD. What do you mean? If we had no bombs on hand, what could we do? We couldn't invade that country perhaps in 3 months or 6 months or longer.

Dr. OPPENHEIMER. I think if there is such a thing as the United Nations, certainly before atomic bombs were stock-piled to the number of 500, or something like that, they could do an awful lot.

Senator BYRD. But I understood you to say you wanted to destroy the stock pile.

Dr. OPPENHEIMER. I say, before they were stock-piled. It seems to me that the decision to go into this thing may start having some effect within a period of 3 to 6 months. There may be some military weapons made in that time, but it will take a long time to be a real menace, to be a decisive thing, and it seems to me that it is a case where one just must not allow this critical period of armament to occur.

Senator BYRD. If you could explain to me, I would be very much interested to know how you are going to prevent that. If some nation desires to break secretly and surreptitiously the agreement that is made, what are you going to do about it?

We know, and everybody knows, that we talk about a league of 51 nations. We know that the military power rests in three great nations. The others just are not important.

In a warfare which may come as suddenly as the atomic warfare, what are you going to do? Are you going to use the bombs to bomb that nation out of existence, if we have any on hand, because they have broken the agreement and used the materials which they were allowed to use for the making of peacetime energy by converting that into a bomb? What would you do about it?

Dr. OPPENHEIMER. If this situation arose, and it is clear from what I have said that I don't think it needs to arise, I would use military measures of all kinds against the offending country.

Senator BYRD. Then you would want a stock pile of bombs? That is the only effective military measure you could use.

Dr. OPPENHEIMER. I think there you make the thing a little bit too abstract.

Let us put it this way: The United States—and this is a reasonable assumption—starts two-timing on its engagements and starts manufacturing atomic bombs contrary to convention. All right, we start in and we drag off some of the scientists who were down there, and some of the machinists, and we get some new people in and start to get this rusty machinery working, and it is found out by people who are in this country that something odd is going on and an investigation reveals that something odd is going on.

Well, I don't think it is true that this country would have to be bombed atomically, for it would be ganged up on by the whole rest of the world. We would not have any atomic bombs.

If your argument is that any security council, or any United Nations Organization should have available some atomic weapons for reprisal, I will not argue with that. I don't know the answer; that may be a possible answer.

Senator BYRD. It comes down to this, does it not, that if other nations get hold of atomic bombs and these bombs are supposedly under the control of an international organization working through international cooperation, we have got to assume that every nation, not a single nation, is going to abide by the agreement? I mean, that not a single nation is going to take advantage of another one?

Dr. OPPENHEIMER. That is right.

Senator BYRD. The physical means whereby you can prevent that taking advantage seems to be inspection and so forth. That would seem to me to be rather negligible in its efficacy; I do not think that it is going to amount to much.

Take, for example, in regard to this matter of inspection: There are great nations in this world with vast areas. It will be very difficult to find out, unless you can trace the source of the material, that uranium, from which atomic bombs or atomic energy can be manufactured—do you think that would be practical?

Dr. OPPENHEIMER. It is, I believe, a fairly practical thing to do.

You must keep in mind that there are several ingredients going into the production of atomic weapons—at least, there has been in the past.

One ingredient is raw material; one is a whole lot of industrial effort; one is a bunch of technical men who are not, instantly, abundant.

My own feeling is that one of the best leads is to keep some account of what these men are doing, to have some idea of what physicists and engineers are doing. If you see them vanishing into thin air, then you can have reason for becoming worried.

Senator BYRD. This one question has bothered me a great deal. If you permit the use of uranium or any other materials to make atomic energy, allow that material to be put into peacetime uses, the material now in existence, it seems to me to be a most serious barrier if you try to keep that material from a military use.

Dr. OPPENHEIMER. I agree with you entirely, Senator. It bothers us too. That is the reason why we think that, at a time when no other place in the world exists today where atomic energy is being used—although you are speaking of peacetime purposes—we have got to start worrying now about these problems.

Senator HICKENLOOPER. Mr. Chairman, I would like to ask a question.

The CHAIRMAN. Yes, Senator.

Senator HICKENLOOPER. Doctor, does the history of scientific development in the world, at any time, show that the scientists have ever discarded something that opens new ground for scientific investigation?

In other words, can you, by legislation or even by intent of government, stop scientists from investigating or exploring new fields, especially when they have had success in a field, as is the case, the proven case, with atomic energy?

Dr. OPPENHEIMER. Well, enormous discouragements can be proposed and scientific advances can certainly be opposed.

It was not easy, in the days of the Renaissance, for a man to investigate the laws of nature, because he was likely to get himself into extreme personal trouble.

Senator HICKENLOOPER. But scientific development did go on.

Dr. OPPENHEIMER. Yes; but official disapproval is a thing which can discourage it enormously. There are countries in which science at one time flourished and in which the lack of recognition and approval has caused it to languish.

I don't believe that it is going to happen in a permanent way, but I do feel that if the opinion of the American people and of the people of the world is that science is an enormity, that it is synonymous with devastation, then I do feel that the scientists are going to find that they are not going to get support and encouragement and that the next generation of scientists is going to be taught by teachers who have doubts and those scientists are not going to come to it with a deep passion for finding out, which has been one of the qualities characteristic of scientists in the past.

Senator HICKENLOOPER. Well, is it possible or reasonable to think that continued investigation may enable scientists to produce this fissionable material at a far less cost and with a far less or smaller physical development than that with which we have produced it? In other words, we have built great plants to do it.

Dr. OPPENHEIMER. Yes.

Senator HICKENLOOPER. We found it necessary to build great plants to produce this stuff and we had to concentrate scientists in great numbers, spend lots of money and effort.

Is it not possible that, with future experimentation, the size of those plants can be reduced and the amount of effort?

Dr. OPPENHEIMER. I think, in the light of hindsight, all of us would say that some of the plants which we built, although they worked fine, need not have been built. In other words, you don't have to put three bridges or four bridges across a river; one is enough.

Senator HICKENLOOPER. That is right.

Dr. OPPENHEIMER. We only did that so that this program would be insured. Even today we could do it—I won't say at how much less cost—but at a fairly small fraction.

Now, new developments may occur. They have been occurring, and these developments have been watched very carefully by us. We feel that there will be developments in the production of these fissionable materials, that the methods will be improved, but we do not think that it will be possible to install a process, say, in a bathtub. We do not think that you could use a bathtub in a, say, garage, or some place like that.

Senator HICKENLOOPER. Well, let us get a little bigger place than a bathtub. With regard to this question of the size of the plant, we have an installation that required, say, 70,000 or 80,000 people in one area.

Dr. OPPENHEIMER. Yes.

Senator HICKENLOOPER. And we have another installation that requires thousands of people and a tremendous physical plant. The only point I am trying to develop or trying to get information on, your opinion, is this.

Is it reasonable to assume that if experimentation were pursued vigorously, we could very materially reduce the size of the physical plant in order to produce that material and also reduce the number of personnel very materially?

Dr. OPPENHEIMER. Well, let us take, say, one of the plants we have; for instance, the one at Hanford. It certainly is possible to build that today, with less than was put into it and one could change the plans somewhat and make a smaller physical installation.

However, I do think that an enormous production is not feasible. To me it is not. I would not know how to do it and I can only say this, that science always turns up odd things and what they might do in this matter I don't know, but I do not think what you have in mind is very likely.

Senator HICKENLOOPER. I realize that. I am merely wondering if, with vigorous research in the future—it is my opinion, completely unschooled, but it is my opinion that it is reasonable to assume that we may develop less arduous methods of making this.

Dr. OPPENHEIMER. Right.

Senator HICKENLOOPER. And, therefore, that if science continues to investigate a field that they know is successful now and in a field of such magnitude, a field which offers such tremendous scientific possibilities, do you not think that those developments may increase ability to produce these materials, and also increase the difficulty of detection?

Dr. OPPENHEIMER. Absolutely.

Senator HICKENLOOPER. In your prepared statement, in the last paragraph, you say: "Today all nations, all peoples have an overriding community of interest in the prevention of atomic warfare."

It occurs to me that that statement would certainly be true, as far as it concerns people who have any reasonable knowledge of atomic warfare. But I would not assume that it would be true among peoples who have not been privileged to know what atomic warfare is. I have the feeling that it will be only the moral pressure of the people themselves that will give us any hope of control over this thing, and not the opinion or desires of governmental heads, because they are subject to immediate emotions.

Dr. OPPENHEIMER. I quite agree with you, sir.

Senator HICKENLOOPER. If they have a full realization of the powers of this thing and the potentialities of it can be given to all people, the people of all countries, including the powerful countries, it seems to me we might have a better basis upon which to build, perhaps, than in concealment and lack of information.

Dr. OPPENHEIMER. I agree with you entirely. It would seem to me that one of the things that might be useful in this connection is to repeat the sort of demonstration which was made in New Mexico last summer.

That demonstration was performed there really to check up. We were by no means certain that the thing would work as we hoped it would; that was the purpose of it. However, I do think that the explosion of the atomic bombs was partly for the purpose, anyway, of keeping them in the minds of the people of the world, and enabling them to find out what it was really like.

I think that is a very sound thing; and I support you.

Senator HICKENLOOPER. These explosions in New Mexico—the people were told that a munitions plant blew up.

Dr. OPPENHEIMER. Yes; but that did not mean that the people of this country believed that.

Senator HICKENLOOPER. The general proposition I had in mind was that people had knowledge of this power which had been turned loose down there.

I am not criticizing that method of publicity, saying that it was a munitions explosion. At that time it was essential to keep this matter quiet.

I do say, however, that if people of the United States had no other publicity than that a munitions plant blew up, rumors might arise, but the facts would not have been believed by the people.

We would have no appreciation of the power of this thing and its potential dangers.

Therefore, I think one of the first things in attempting to arrive at any control of this is the matter of educating and informing the masses of the people of these other countries.

Dr. OPPENHEIMER. I agree with that. My own impression, and I am not qualified to guarantee this, is that the thing is a fairly spectacular thing, and it has taken great hold of the imagination of the people, even where there has been no systematic effort to publicize it.

The CHAIRMAN. "Fairly spectacular." I think that is a masterpiece of understatement.

Senator HICKENLOOPER. The point that I wanted to try to develop here was I think the suggestion of demonstrations is a good suggestion; it gives a lot of food for thought.

But what good will demonstration be in some area or in some country or some nation where only certain public officials will see it and then retire into a great silence, and the public knows nothing about it?

Dr. OPPENHEIMER. This was not what I had in mind. I was not proposing to convince the Senate of the United States, but to demonstrate it before a somewhat wider audience.

Senator HICKENLOOPER. I am still talking about publicity on a larger scale to a wider audience. Are you in favor of that?

Dr. OPPENHEIMER. Absolutely; I do think that the manner in which my colleagues have handled this—I would not want it indicated that the manner in which the publicity angle of it was handled was due to any lack of zeal.

Senator HICKENLOOPER. Well, I am certainly not criticizing you for lack of zeal. I think their zeal has been proved.

Let me ask you this: Suppose we take an atomic bomb over the ocean and use it to bomb ships. Through publicity and education we could show what the effects would be. Of course, the American people, in my opinion, would not need any further demonstration.

Dr. OPPENHEIMER. Of course.

The CHAIRMAN. Senator, I am not so sure that that is true. I have talked with some people lately. Yesterday I talked with a gentleman who comes in contact with many people in Connecticut. The day before yesterday he spent some time listening to some testimony here and he went back to my office and saw me and he said that people do

not understand what is involved in this thing. I might say that he is a very level-headed observer, by the way.

Senator HICKENLOOPER. I think that is true. I think that probably members of this committee and people who have sat in these hearings know about it.

However, I think that we could go on for literally months and none of us, except the scientists and the engineers who had been present and actually physically examined these things, could fully appreciate it.

But I do believe that the American people are really convinced, the overwhelming bulk of the people, that this is the most ominous and powerful thing ever released and so many more times more powerful than other things when it comes to destruction, that they are fully convinced something has to be done to attempt to put it under control.

I only hope that the rest of the peoples of the world could be informed, at least as much as we have been informed at this point, so that their realization could bring pressure to bear.

Dr. OPPENHEIMER. I agree. However, isn't one reason why the people in this country know something about it is that perhaps there is a certain national pride arising from the fact that it was developed in this country. That works against us everywhere else, but we know we have developed it.

I think that only in the measure in which the people of other nations feel it will be necessary to have power to control the troubles that are in the world—I feel that first they must be aware really of what those troubles are.

Senator HICKENLOOPER. Yes.

Dr. OPPENHEIMER. And the very fact that there are discussions going on about this problem, how it may be met, will enable people to face the fact that it is a tough problem.

Senator HICKENLOOPER. We have quite a free press and quite a free radio in this country; these mediums are free to give the information to the people. If we didn't have them, I doubt whether 1 person out of 10,000 could have any proper conception of this.

The CHAIRMAN. Senator Johnson.

Senator JOHNSON. Dr. Oppenheimer, you inferred in your testimony that there was such a thing as compelling cooperation. Is that not a rather strange conception of cooperation—compulsory cooperation?

Dr. OPPENHEIMER. If I so implied, I erred. I did not mean to so imply.

I think that the facts of the world compel us to cooperate.

What I think I said—what I meant to say—was that if there were violations of agreements which would endanger the peace of the world, then it seems to me that one had no other choice but to treat it as a state of war.

Senator JOHNSON. My understanding was that your position is that we should compel nations to cooperate. I gathered, by inference, that you wanted to declare sanctions if the atomic bomb were used, and that you really believe we would be justified in declaring war on a nation that did not cooperate but did go ahead and presumably construct atomic bombs. That is what I understood from your testimony.

Dr. OPPENHEIMER. I thought I said that the necessity has arisen for an overriding community of interest in preventing the atomic war.

Senator JOHNSON. Oh, yes, that is what you said, but I got your position as being that now is the time to bring about cooperation of all nations, the time when we have the atomic bomb and no one else has it.

Certainly, other nations will be very foolish, it would seem to me, if they would not agree at this moment to say, "All right, let us ban the atomic bomb."

Whether they would live up to that agreement or not is another thing; I recognize that. I recall that after the Disarmament Conference we destroyed our battleships and the other nations destroyed their blueprints. The same thing might very well occur again.

It would be very easy to get assurances now, provided we made all the disclosures. That would be simple, because we are the only ones who have any disclosures to make. They will say, "All right, we agree," but tomorrow they might change their minds.

If they change their minds, is it your position that we are justified in immediately declaring war on them? Your testimony would seem to indicate that to me.

Dr. OPPENHEIMER. It is an abstract question and it is certainly a question to which a scientist can give no especially informed answer.

But I think that when Japan started her aggressions in 1931, or when the Germans declared their intention to rearm and started to rearm in the early years of the thirties, if the other countries of the world had said to them that it had to stop, we would have had very much less of a war and very much less misery than in fact we had.

Now, if a situation like that arises in the future—I hope not, I hope we have learned in the last fifteen years that it is better not to let those things get under way—

Senator JOHNSON. Yes, but my understanding of your position is that if a nation denied inspection and if we suspected any nation of accumulating atomic bombs, that we would be justified in doing something about it. Would you deem that a cause of war?

Dr. OPPENHEIMER. I think it probably would be.

Senator JOHNSON. A cause of war?

Dr. OPPENHEIMER. I think it probably would be.

Let me state more clearly what I have in mind.

Let us assume that, taking advantage of the present situation, agreements are entered into in good faith and maintained in good faith for, let us say, 15 years.

Let us further assume that we find out—I don't mean, particularly, this Nation, but whatever agency exists, perhaps a commission of United Nations, as recommended—find out that there is an attempt to get around the agreements by a country, to get around them for the purpose of making atomic weapons.

Atomic weapons are only useful in war. If that were going on in the world, under the circumstances I have stated, it would mean that somebody is planning a war.

I think and I believe that it would be desirable that the rest of the world recognize it and try to keep that war from being fought as this last one has been fought.

The CHAIRMAN. In other words, Doctor, into the agreement you would write a new definition of aggression, based upon the power of the atomic bomb?

Dr. OPPENHEIMER. It seems to me—I don't know that that condition will come about or whether it will exist in the future—but it seems to me that that was the intention disclosed in the Three Power Declaration of Principles, to set up a commission which will, in time, say what is safe to have going on in the world and what is not safe.

I believe that if things which are recognized as not safe do go on, that it is in the intention of the administration that this commission point this out and raise the problem of what steps must be taken. I don't know what those steps will be.

Senator BYRD. Pardon me for interrupting. I believe what you are talking about now would mean a session of the United Nations Organization. As you know, if any one of the United Nations wants to, it can veto any questions relating to matters discussed there.

We tried to change that; we couldn't get it amended to make unanimous consent unnecessary.

Dr. OPPENHEIMER. Certainly. Wiser people than I have pointed out that this veto provision may not be too practical.

Senator BYRD. Well, it is in there and it cannot be gotten out except by unanimous vote of the Big Five.

Dr. OPPENHEIMER. Nevertheless, it is—

Senator JOHNSON. Pardon me for interrupting. I would like to go on.

If I had the planning of that, if I were a world conqueror and had any plans for taking over the world, the first thing I would do would be to build a great power plant, plutonium power plant, and then I would secretly develop atomic energy for atomic bombs from that power plant.

I am quite surprised in your statement here this morning advocating the building of a uranium power plant in China.

It seems to me that that is the most reckless proposal I have ever heard made by anyone, scientist or politician or anyone else, because all of us know that there is only a thin line, as the Senator from Virginia stated, between the development of atomic power, through uranium, and the development of atomic bombs.

Dr. OPPENHEIMER. First I would like to say that I did not advocate that we do it today. I advocated it very conditionally. I mean, only insofar as it would be really useful, a power plant in China.

I don't think we can stop this kind of thing. I don't think we can stop the advance of technology, and I hope by the time these advancements are made and by the time power plants are built in China, or wherever else, wherever it might be, that we will have a machinery for assuring ourselves that they will not be converted into instruments of war.

Senator JOHNSON. Yes, but right in your statement you say that there is no defense against atomic bombs, absolutely no defense.

I agree that it is going to be hard to stop industrial development, and I doubt very much that it can be done.

Dr. OPPENHEIMER. It can't be.

Senator JOHNSON. Or that it should be; I will even go that far.

But, since it is hard to stop it, then I think that our scientists, instead of entering into the political arena and deciding what should be done on this question, as a political gesture, should be devoting their energies to finding out what we should do scientifically. If there is no defense,

they should be developing one, some counteraction against it; that is their job.

I think they ought to keep on trying, or, at least, not advise the political agencies of this Government to scatter plants all over the world, especially in a country as unstable as China is at present.

Dr. OPPENHEIMER. I would like to take that up. I said that I thought that there would be good reasons for putting in a power plant in the Yangtze Valley; that we were thinking of the development of a power project in that valley. I said that that might be a good place, where the economics involved in the use of atomic power for energy would be sound.

I made it very clear that I was not trying to advise political agencies on political matters. I was very clear that my position on that is this: My purpose in coming here was to make available such technical information as I have.

Senator JOHNSON. I appreciate that, but you did advocate—or, at least, I understood you to advocate—that we build a uranium power plant in China instead of a hydroelectric power plant, which has been proposed.

Dr. OPPENHEIMER. I said it might be a better type of plant.

Senator JOHNSON. Well, it might be a better type of plant, but I have this other question that I want to get some information from you about.

You had considerable experience of course, with the bomb and its explosive effectiveness in New Mexico.

What is your opinion of the effectiveness of an atomic bomb exploding in a building in a city, for instance; not in the air, but perhaps in a basement or maybe in the top story of a building.

Dr. OPPENHEIMER. As far as the blast goes, the effectiveness increases as the height of the detonation is increased, up to a certain point. The building wouldn't make any difference.

Senator JOHNSON. The building would not make any difference. You mean that if it were inside a building it would be no more destructive, say, in the city of Washington, if it were exploded in a basement downtown?

Dr. OPPENHEIMER. If it were well underground; but a basement usually is not. It is only 10 feet or so. But if it were well underground, then we would begin to get new effects—earth shocks, and so on. But if it were on the surface or 10 feet under, the 10 feet under is just about the same as being on the surface and you could not note the difference.

The radioactivity would be, if it were well underground, very much decreased; the blast effects would be very much decreased.

Senator JOHNSON. What about the expansion, the radioactive expansion covering the city?

Dr. OPPENHEIMER. I think it would be a very bad mess.

Senator JOHNSON. What about using it as a depth bomb? What are your ideas on that, in the sea?

Dr. OPPENHEIMER. In the sea? I can't tell you quantitatively, because that is one of the things that is secret, but it certainly is effective.

Senator JOHNSON. As effective, you think, as discharged in the air?

Dr. OPPENHEIMER. More so.

Senator JOHNSON. More so.

Senator TYDINGS. Mr. Chairman, may I ask—

The CHAIRMAN. I have been trying to get at him myself, but I will yield to you. Go right ahead.

Senator TYDINGS. Doctor, how large a plant would be the minimum-sized plant, in area, that would be necessary to produce atomic energy?

Dr. OPPENHEIMER. Well, I think the main structure—

Senator TYDINGS. I will qualify that. Looking ahead 10 years, from what you can conceive of the development of atomic energy in the future, what is, in your opinion, the smallest plant of which you can conceive that can efficiently manufacture it?

Dr. OPPENHEIMER. Of course, you are using the word "efficiently."

Senator TYDINGS. Reasonably efficient.

Dr. OPPENHEIMER. Are you talking about large power production?

Senator TYDINGS. My question is directed to this point: Assuming that there is a system of inspection—

Dr. OPPENHEIMER. Yes.

Senator TYDINGS. I want to know, if one nation attempted to cheat inspection, how small a plant could be erected to avoid detection and produce bombs?

Dr. OPPENHEIMER. Oh. I think that the main building, the main reactor, if it were 100 feet square, you would get an awful lot out of it. The building itself would not have to be large; but there would be a lot of auxiliary works.

In other words, atomic bombs could be manufactured in a building or a series of buildings of not more than 100 feet, of which the largest building was perhaps 100 feet.

Senator TYDINGS. 100 feet long and 100 feet wide. And how high?

Dr. OPPENHEIMER. 80 feet high.

Senator TYDINGS. 80 feet high. That would be pretty hard to detect, would it not?

Dr. OPPENHEIMER. Yes.

Senator TYDINGS. Now then, the next question is: Could plants be so diversified in the manufacture of atomic bombs that each of them would be smaller than the ones you have just described, if that was the desire of the country erecting the plants?

Dr. OPPENHEIMER. I think there will be a few buildings—I mean, if they are going into the thing in a practical way and want to make a sizable number of bombs, I think that there will be quite a few buildings not smaller in linear dimensions than 100 feet.

Senator TYDINGS. Now, if they were using a building, if they had a manufacturing process housed in a building which would be limited to not more than 100 feet long to not more than 100 feet wide and 80 feet high, how many bombs do you think it would be possible to make a month?

Dr. OPPENHEIMER. Per building?

Senator TYDINGS. Per building or per combination of buildings scattered in different cities.

Dr. OPPENHEIMER. Well, let me put it in the form of per building.

I don't think that you could make the material for probably more than about five bombs in one such building, maybe as low as one.

Senator TYDINGS. The reason I am asking these questions, Doctor, is that every witness who has appeared before this committee has

stressed the fact that detection is necessary and that that is the only and final hope we have of control.

That being so, I am interested in knowing whether a nation that desires to frustrate inspection might conceivably arrange their atomic machinery and plants so as to avoid detection. Therefore, I have asked you, could plants be so diversified so as not to attract attention?

Dr. OPPENHEIMER. I think it is possible. I certainly do not wish to argue that inspection is easy.

Senator TYDINGS. Well, the reason I asked you is that one of the preceding witnesses on the stand here, in talking about the large and undeveloped areas said it would be necessary, to inspect, to fly back and forth in a plane. He was quite an eminent man and he said that he thought you could detect such a plant.

As a layman I do not believe that that is true. I think that covers a lot of ground, because I think ingenuity would be used. The plants would be either underground or they would be diversified, and would carry the diversification to such an extent as to avoid detection, that kind of detection, from a plane.

Do you agree with that thought or not?

Dr. OPPENHEIMER. I agree that it would be very, very, very tough. I should think that before the process of building the plants is begun would probably be the time when inspection should come in. Inspection would reveal the most about it then.

Senator TYDINGS. But suppose they built a plant 50 miles from any other place in the country?

Dr. OPPENHEIMER. Well, it would need power, it would need water, it would need a lot of stuff.

Let me put it this way: With what we know today, I think atomically to arm a country would involve a general effort and commotion, and if you tride to add, in addition, the fact that you wanted the installations to be invisible, the effort would be very much greater. I think you will notice the size of the strain, even if you did not notice the building itself.

Senator TYDINGS. I admit that there is a good possibility of detection.

But suppose the President of the United States said to you: "We are not permitted to use atomic bombs. However, I have reason to believe, although we haven't been able to detect it, that nation X, nation Y, and nation Z are working on these bombs."

Dr. OPPENHEIMER. Yes.

Senator TYDINGS. Then the President says, "I want you to conceive of a plant where we can manufacture atomic bombs, utilizing diversified operations already in existence in such fashion that nobody making any part of the bomb will realize that the whole thing is to be assembled for that purpose."

What prospect of success could you offer to the President if such a proposition were put to you and supposing you were given a free hand?

Dr. OPPENHEIMER. I would say, "Better ask General Groves to do it." [Laughter].

Senator TYDINGS. Do you think General Groves would have a fair chance of success?

Dr. OPPENHEIMER. No.

Senator TYDINGS. Now, suppose that same proposition were put up to you in one of three, four, or five countries, other than the United States of which you might conceive under existing circumstances, what prospect of success would there be then for this undertaking?

Dr. OPPENHEIMER. When I was running Los Alamos, I had sometimes great difficulties, but I always consoled myself with the thought that any other country would not have done it so well, that it would have been worse.

Senator TYDINGS. I know, but I don't think that answers my question.

Dr. OPPENHEIMER. No? I believe that the more highly industrialized the country is, and the more different are the things going on, and the more complex its organization is, the better chance you would have of doing something, of accomplishing atomic bomb manufacture, and I think that all of these things with reference to complexity, high industrialization, apply to this country, at the present time, more appropriately than to any other country.

Senator TYDINGS. Then, too, General Groves testified that the value of inspection would not be 100 percent, that it would not be naught, that it would be naught plus.

From what you have told me of the difficulties of concealing this operation, I would assume that inspection, in your mind, would be much more successful than was the conception of General Groves. Am I wrong?

Dr. OPPENHEIMER. I think there is a little difference of philosophy. If you are dealing with part of the world, a nation or a group of nations which says, "It is none of your business what we are doing," and if the country or group of countries is full of secret arms plants and you cannot get into it, if they will not let you go into the country but say, "We will let you follow our work on uranium," and do not let you see what is going on—when you come to a country like that you are going to have a terrible time finding out what the plants may or may not be working on.

But if the obstacles are not presented to you in this form and you have people already in the country in the normal way and the government has said, "We are not making or going to make any secret in this field," and does not make a habit of secrecy, then I think you have a chance.

Senator TYDINGS. Don't let us take such an optimistic view. Let us take the world as it is, not the world as it ought to be.

In the case of the world as it is, do you believe it would be possible, assuming that the plant would not have to be more than 100 feet wide and 100 feet long and 80 feet high, do you assume that it would be possible, considering the wide areas that many nations have control over, like Britain as an empire, or like Russia which has one-fifth of the world's land area, or France as an empire, do you believe it would be possible, in any of these countries to make atomic bombs that would have a 50-50 chance of avoiding detection?

Dr. OPPENHEIMER. I don't think it would be possible to get started and make atomic bombs and have a 50-50 chance of avoiding detection.

Senator TYDINGS. Why?

Dr. OPPENHEIMER. Because I think that the effort necessary to do to the job would show up. It would show up.

Senator TYDINGS. To whom?

Dr. OPPENHEIMER. To anyone who lived in those countries.

Senator TYDINGS. Well, suppose they couldn't get out.

Dr. OPPENHEIMER. In that case, it might show up, it might be detected, but the detection would not be valuable; that is, if you don't have freedom of travel, I think the problem is impossible.

Senator TYDINGS. In other words, inspection is not worthy of the name unless it is unimpeded and free?

Dr. OPPENHEIMER. Absolutely.

Senator TYDINGS. And if the country refused to cooperate with inspectors?

Dr. OPPENHEIMER. Absolutely.

Senator MILLIKIN. Mr. Chairman.

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. I was very much interested in a part of the discussion between you, Dr. Oppenheimer, and Senator Byrd a while ago.

Let us assume that, instead of the United Nations, that the five or six principal powers of the world should sit down and make an agreement that they will not use atomic energy for warfare.

Let us suppose that this agreement is filled up with all sorts of pious declarations on the subject. Let us suppose that, as time goes on, it is discovered that one of these nations has violated the agreement and has a store of atomic bombs.

I gathered from what you said in answer to one of Senator Byrd's questions, that we then would have to take protective measures, and that we would have to move in on that country.

Would that carry the thought in your mind that we could move in effectively?

Dr. OPPENHEIMER. Well, I don't think that I should be asked, on the one hand, not to discuss political questions, and, on the other hand, approached to answer them.

The CHAIRMAN. Doctor, I want to say this to you: If the political scientists had kept up with the other scientists, there might be some question of complaint or cause for complaint about receiving advice on the subject of political questions.

However, as far as I am concerned personally, the political scientists have made such a mess that I think we would do well to hear such advice. After all, you people have been thinking about this thing for 4 or 5 years, and I, for one, am very glad to hear your advice.

Senator MILLIKIN. What I wanted to find out, Mr. Chairman, was whether the witness' answer carried the implication that, without bombs, one nation could move in and protect itself against a nation with bombs. I think that is a very significant and important question.

Dr. OPPENHEIMER. I will tell you what I thought I said. It is my conviction that the easiest time, and, in fact, the only time when one might hope to discover that there were violations of the convention would be the time when it is started, when you are pulling in your technical people, when you are having the equipment manufactured, when you are building the plants.

During that time, the nation that is doing this is not going to have any atomic bombs.

Senator MILLIKIN. For my purpose, let us assume that that is absolutely correct. Let us take the next step.

Let us envision that situation I portrayed, where one of the principal powers, also having other military resources, confronted us suddenly with the fact that she had a store of atomic bombs.

Could the other four or five principal nations protect themselves against that situation?

Dr. OPPENHEIMER. They could not protect themselves adequately against the atomic bomb, sir.

Senator MILLIKIN. Thank you.

The CHAIRMAN. Doctor, we have spent, and rightly so, I think, a considerable time examining the difficulties of control, international control, the difficulties of having any peacetime development of atomic energy even if we do have control.

Have you thought about the alternative of unlimited atomic armament races between six or seven countries of the world and the possible outcome of that, considering history, if you are to look at history?

Dr. OPPENHEIMER. Yes, of course. That is a problem which I can easily answer.

I believe that if there is atomic armament there will be atomic war. I believe if there is atomic war that the damage which has been pictured to you by many witnesses before me will, in fact, occur.

The CHAIRMAN. Let us assume that all nations—all nations making atomic bombs—have, in a period of time to be denoted as "X," an equal number of bombs. General Groves' estimation of "X" is 20 years, which he admits is a guess; in Dr. Langmuir's mind it could be 3 years or in the case of Russia possibly 5; Winston Churchill's estimate, given, I presume, after talking to English scientists, is 3 years. Now, assuming they all have an equal number of bombs—

The military thinking on it, as I get it, as evidenced by General Groves, is that if you have a great big stock and everybody has a great big stock, no one will use atomic bombs because of the fear of retaliation, and that is that upon which we have got to rely for our defense.

Do you wish to comment on that mental state of mind of the 130,000,000 or 140,000,000 people of this country, as well as the 2,000,000,000 or so of this world, living in an atmosphere where there is the possibility of destruction to come anywhere from the four corners of the globe?

Dr. OPPENHEIMER. You have been so eloquent that I don't need to comment.

The CHAIRMAN. Thank you.

Dr. OPPENHEIMER. I think that that would not be the whole thing. Although the fear of retaliation is a very serious one, the advantages of attack are enormous, the advantages of initiative are enormous.

I believe, when the thing goes far enough and the stock piles get bigger and bigger, that, at least, the advantages, the seeming advantages of the initiative will outweigh any possible disadvantages of having other powers gang up on them.

The CHAIRMAN. Have you thought about the possibility of a nation getting this advantage without even suffering retaliation because the attacked nation would not know where the bombs came from?

Dr. OPPENHEIMER. It is possible. That is not one of the things that keep me awake nights, as the first point you mentioned is. The idea of three or four or five arsenals, each containing 5,000 atomic bombs, that is something to lie awake nights about.

The fact that the weapons might have traveled so many times around the world to their target that you couldn't identify their origin is, I think, a minor worry. I think, as a matter of fact, that technical equipment could be set up so that you would know where they came from, if you were there to read the meters. [Laughter.]

The CHAIRMAN. Well, assuming that you wouldn't be there to read the meters and assuming furthermore that the attack might come from a small country, a nation which might be taken over by fifth column methods, what then?

Dr. OPPENHEIMER. There is certainly danger, there is unquestionably danger. That is why it seems to me worth while to face the terrible problems of inspection and the terrible problems of the situation, because the alternative seems a lot worse.

The CHAIRMAN. Doctor, you made a statement about the effect of the bomb as a depth bomb. I assume that you are able to compute pretty accurately, particularly after these three tests—two of them, of course, were not tests, but use—as to the physical effect.

Assume that there was a fleet of ships in a harbor and that an atomic bomb was dropped in the center; or, perhaps, to put it more realistically, assume that a fleet has been discovered at sea, operating as, say, Admiral Halsey's fleet would be operating.

Dr. OPPENHEIMER. Yes.

The CHAIRMAN. Assume that a bomb such as you know is now capable of being manufactured, be dropped upon such a fleet. What would be the effect of it?

Dr. OPPENHEIMER. Am I allowed to answer that in open session? I think I am not.

Senator TYDINGS. I think you ought to answer that.

The CHAIRMAN. I think that is answerable, Doctor.

Senator TYDINGS. In general terms.

The CHAIRMAN. Yes.

Dr. OPPENHEIMER. I am afraid about that. There is a specific Presidential prohibition on saying anything about the military or naval uses of atomic weapons and saying anything in public.

Senator TYDINGS. I think there is a good point there that should be brought out.

The CHAIRMAN. Frankly, Doctor, it never occurred to me that that could be regarded as a secret.

Dr. OPPENHEIMER. Well, if it does not have to be answered quantitatively, if it can be answered generally—you see, it is obvious, I could say, "It would do great damage." I am willing to say, I am willing to go on the record as saying that it will do great damage. [Laughter.]

But I would like to point out one thing. It is sometimes asked whether a single weapon can destroy this or that by the use of such a weapon.

I would say that that depends upon the details and a lot of things. For example, in the example you cite, it would depend upon how the fleet was disposed of, where the bomb was set off, and so on. That would determine how much of the fleet would be destroyed.

As I see it, the cost of an atomic weapon is going to be so small, compared to the cost of a capital ship, that the problem of the usefulness of capital ships, which is a very serious one in any case—that is, even if you only hit one ship—there you have a big target, you have an expensive target.

Senator TYDINGS. I have one more question.

The CHAIRMAN. All right, Senator.

Senator TYDINGS. I would like to have you give me a comprehensive answer to this if you feel that you can and circumstances will permit you.

Can there be a reasonable separation of the manufacture of atomic energy for peace, as differentiated from its manufacture for war?

Dr. OPPENHEIMER. The manufacture of atomic energy for peace, in any plants that I have heard discussed, would make material latently which could be used for war.

Senator TYDINGS. May I interrupt? Up to that point, the line between the manufacture of atomic energy for peace and using the materials so manufactured for war is a very thin and difficult line to draw?

Dr. OPPENHEIMER. I would put it this way.

If you did this, if you made atomic energy and sold it in kilowatts and so on and definitely made no provision for military inspection of the products which you were making at the same time and did this on a large scale, you would have perhaps solved, let us say, more than 60 percent and less than 90 percent of the problem of making atomic weapons.

Senator TYDINGS. So, by the manufacture of atomic energy for purely peaceful purposes, we have by so doing considerably lightened the manufacture of atomic energy for war purposes from between 60 percent and 90 percent, somewhere around there, of its potential?

Dr. OPPENHEIMER. That is right, and it is a very serious problem and if we do it we would want to have the most rigorous inspection of such a plant.

Senator TYDINGS. Do you believe it is humanly possible to manufacture atomic energy for peacetime purposes in a country that desires to use it for wartime purposes eventually without having to reach, preliminarily, the 90 percent potential to which you have alluded?

Dr. OPPENHEIMER. I don't know.

Senator TYDINGS. I mean if they have the will to do it, you understand.

Dr. OPPENHEIMER. I think—my guess would be that, let us say, if a plant is erected in—if you don't like China, let us say France—

Senator TYDINGS. Or in the United States.

Dr. OPPENHEIMER. Or in the United States. If there is such a power plant and we have any inspectors in this plant, I would say that the part of the job which needs to be done, circumventing these inspectors—and I think that would be very hard to do—is about one-third or one-fourth of the total.

I could also say that you can make power plants, make plants for the creation of atomic power for peaceful uses which do not make materials for military uses; but you can only do this if you have other plants which are making the ingredients of atomic bombs.

Senator TYDINGS. So, you think, with respect to inspection and this question of other countries being permitted the making of atomic power for peacetime purposes, that then we would be, approximately, at that point, within 25 percent of the ultimate goal of starting from scratch and manufacturing atomic power for the atomic bomb?

Dr. OPPENHEIMER. That is my understanding.

Senator TYDINGS. I think that is a fair statement.

Dr. OPPENHEIMER. And I would go further and say that this problem, obviously, is a tough one.

The heads of three states, who have very good advice on it, were not only worried about it but, in their official statement said they were worried about it; namely, they felt that the time was not yet here when it was possible to cultivate the application of atomic energy to peaceful purposes on an international scale. By implication, they said that they thought the time would be here.

Senator TYDINGS. Assuming that 10 years from now atomic energy in many countries has been licensed by the government for peacetime manufacture and uses and that our country was one of them.

What do you think would be the necessary time to construct the remaining 25 percent of the process, for war purposes, of producing atomic bombs?

Dr. OPPENHEIMER. It depends on the scale. If we wanted to have, I will say, 1,000 bombs, 2 years would be a lot of work and the whole country would feel it.

Senator TYDINGS. In other words, it would take 2 years?

Dr. OPPENHEIMER. Yes, to accumulate 1,000 bombs.

Senator TYDINGS. If it were decided to make military bombs from our peacetime atomic energy, how long would it take us to complete 200?

Dr. OPPENHEIMER. Maybe a little over a year.

Senator TYDINGS. How long would it take us to make 50?

Dr. OPPENHEIMER. Maybe a year.

Senator TYDINGS. So that we are faced with the prospect—

Dr. OPPENHEIMER. I think a year is too long; maybe 9 months.

Senator TYDINGS. So, then, we are faced with the prospect, if countries were permitted to manufacture atomic energy for peacetime purposes and 10 years after, if they got the all-out and oriented themselves into production, you say that within 9 months they can make 25 or 50 or 60 bombs thereafter for military purposes, utilizing that peacetime machinery?

Dr. OPPENHEIMER. Not without, I would say, its being known; but it could do it.

Senator TYDINGS. As I say, if they were given a free hand.

Dr. OPPENHEIMER. Yes.

The CHAIRMAN. Doctor, of course any peacetime use of atomic energy presupposes widespread distribution of the power generated by the fissionable materials.

Let us say we have a central heating plant in Chicago that is so devised that it could furnish heat to every house and apartment house in Chicago cheaper than it could be done in any other way.

Now, if it is decided that that fissionable material was going to be used for bombs, somebody would get his heat cut off in Chicago; would he not?

Dr. OPPENHEIMER. It wouldn't have to work that way.

The CHAIRMAN. It wouldn't have to work that way?

Dr. OPPENHEIMER. No. You would need new stocks of uranium, but the normal way you would do the job, you would not have to cut off the power. I think not.

But, that is one of the few problems that I don't see as a serious one.

The CHAIRMAN. I see.

Dr. OPPENHEIMER. It is clear, of course, if you have a lot of power plants and you suddenly change their use, their use for power generation may be impeded, but it would not have to be if you had an adequate supply of materials.

The CHAIRMAN. Senator Johnson.

Senator JOHNSON. Would the water used for heating purposes be radioactively dangerous?

Dr. OPPENHEIMER. The plant could be designed so that that would not be the case.

Senator JOHNSON. It could be so designed?

Dr. OPPENHEIMER. Yes. I ought to say quite clearly that although the generation of power at high temperatures looks to me like a solvable problem, it might be a matter of a couple of years or more than that before a working solution could be arrived at, even if it were decided to be the right thing to do.

Senator JOHNSON. Would the steam coming from such a plant be radioactive?

Dr. OPPENHEIMER. It shouldn't be. It should be done by means of heat exchanges, so that there is no direct contact between the hot fluid going to heat the homes and the radioactive materials.

The CHAIRMAN. Doctor, assuming that you believe that inspection was scientifically feasible—and not injecting into it the political feasibility of control—you have, it seems to me, this result: That nations willing to forego the control of a weapon of warfare such as the atomic bomb would also be willing—if this is a logical situation and it seems to me it might be—would they also be willing to forego other weapons of warfare?

Dr. OPPENHEIMER. That is my hope. You see, I think that the whole situation is completely turned around.

Here is a development which makes it clear that the dangers of warfare are enormously greater than in the past—and they have been terribly great in the past—and I think our thinking and that of every one else has got to be in the direction and will be in the direction not only in this country but everywhere, that no one will be interested in making war.

I think that those steps which you have got to take that may involve the giving up for the time being of a certain technological development in order to control atomic weapons—I think that these are the steps that tie the people of the world together in their determination not to have a major war.

That is my view, but it is a political view and I am quite willing to admit that it might not be well informed.

The CHAIRMAN. It seems to me that if I can induce my neighbor to put away a pistol with which he could blow my brains out, I should also be able to prevail upon him to put away a stick with which he can rap my knuckles or shin.

Dr. OPPENHEIMER. It would be completely logical. I don't think that it will happen in the real world that the major weapon is abandoned and that people will still plan wars.

Senator HICKENLOOPER. May I ask a question?

The CHAIRMAN. Yes.

Senator HICKENLOOPER. Doctor, am I correct in assuming that you believe, assuming freedom of inspection, whether we get the help of other governments or not, that our inspectors have freedom to go into a country if they want to and examine—with that freedom of inspection assumed, do you believe that we can detect the beginning of the manufacture of fissionable material. Is that correct?

Dr. OPPENHEIMER. With the freedom of inspection and with effort.

Senator HICKENLOOPER. Well, that is part of my assumption. I am assuming all of the efforts that are necessary for the inspection and I am also assuming the freedom to do it.

Dr. OPPENHEIMER. That is right.

Senator HICKENLOOPER. Now, if we have that freedom of inspection, including definite agreements, we could, in your opinion, be reasonably sure that we could detect the beginnings of the manufacture of these materials; is that right? And, that later, if we did detect it being manufactured in violation of an agreement, that it would be up to us to determine what to do about it?

Dr. OPPENHEIMER. That is right.

Senator HICKENLOOPER. That would be another problem, what to do about it, political or otherwise.

Now, let us assume that, with that freedom of inspection we, by license or treaty or agreement, or any other means, permit countries to make this material for power and for scientific experiments and for public health and all the rest of the things, the beneficial use of it, with their agreement not to make the material for a bomb or to attempt to make it, at what point, assuming the situation that there were factories making this material and putting it into heating plants, for example, and using it for that purpose—from that point on, at what point or how soon do you think free inspection could detect that they were changing that production or using a part of that production for the manufacture of fissionable materials?

In other words, do you think it would be when they begin to do it or when they had part of the bombs made or in the midst of the process, or when?

Dr. OPPENHEIMER. I think that you would detect it as soon as any material was diverted if you had a good inspection system. My view is that you may or you may not go into every house in the country, but if they really have got a plant that is making these different things you would have a pretty active group of inspectors and I think they could detect that right away.

Senator HICKENLOOPER. In other words, it would be possible to detect any substantial diversion of the original material in the process of manufacture for peacetime purposes?

Dr. OPPENHEIMER. That is right.

Senator HICKENLOOPER. From the beneficial, peaceful use to the manufacture of weapons, this other 25 percent of the process that you are talking about?

Dr. OPPENHEIMER. That is right.

Senator HICKENLOOPER. And that would depend entirely upon adequate and efficient inspection?

Dr. OPPENHEIMER. Yes, sir.

Senator HICKENLOOPER. I presume that there would be some disagreement as to what is adequate and efficient inspection, but assuming that it is, it can be done?

Dr. OPPENHEIMER. I say if you are dealing with open plants, the problem of inspection is not so tough. If there is a power plant some place and we are allowed—we, or the United Nations, or what have you—are allowed to maintain inspectors there, this problem does not look hopeless.

The problem starts looking hopeless if you have a country where you do not know what is going on, a country where there are limitations of freedom and movement.

Senator HICKENLOOPER. Just one more question.

May I ask your opinion on this?

You have been in the scientific end of this and you have been in it, of course, as deeply as anyone and you have had a tremendous responsibility, both as a scientist and as a citizen. At this moment I would like to have your opinion although I realize that at this moment you may not be able to give it.

Would you care to answer this, as to whether or not you believe we should point our efforts towards a suppression of atomic energy and the scientific development or should we point at efforts towards the continuance of atomic investigation and center on the attempted control by inspection and other allied means.

Dr. OPPENHEIMER. That is the easiest question I have been asked this morning.

I believe we must continue with the work and attempt to solve the problems created in the political sphere.

Senator JOHNSON. That is the same question I was trying to get at a while ago. The Senator from Iowa has couched it in much more courteous terms. He is less blunt about it.

What I was trying to say was this: That the scientists have created an instrument, a terrible instrument. Now, they are coming to the politicians to control it. They say that is the only way it can be controlled, that the only answer is political control. They say we must have a political solution and that there is no scientific solution whatsoever.

As I understand your testimony, that is your position.

Dr. OPPENHEIMER. At the moment, as you surely know, every imaginable effort is engaged in the problem of intercepting airplanes, rockets, guided missiles, and I know what is going on. I am sure that progress will be made along these lines. I think the people working on it are doing the best they can do. It may be that such progress will be made that this problem may be solved.

Senator JOHNSON. My question was whether the scientists have given up in their efforts to find a countermeasure or whether they are relying entirely upon the politicians to find the answer to the problem which they have created through their energies.

Dr. OPPENHEIMER. That is really beating your wife. The idea of a specific countermeasure has never had—I myself wrote a memorandum on it, some 5 years ago, which gave a completely impracticable

solution. It could work against some other weapons, that scheme I had, but I would say that it would not work against this weapon.

Senator JOHNSON. But don't you think the scientists ought to continue along the line of discovering physical means of combating atomic bombs, rather than to come in and say that it is just one of those things that cannot be done and we must have a political solution?

Dr. OPPENHEIMER. I honestly believe it can't be done. I realize, in saying that it must have a political answer, we are passing the buck.

Senator JOHNSON. No, it is not a question of passing the buck.

Dr. OPPENHEIMER. I am very much afraid that the buck really is passed; but it is one of those things where we will, 10 or 15 years from now, have reasonable interception methods, but the military people working with them will report back that they are not satisfactory.

Senator JOHNSON. It is not a matter of passing the buck. It is a matter of being very frank with us, because we are trying to find the answer, and if the only answer is political you are rendering a great contribution to the world in positively stating that.

Dr. OPPENHEIMER. That is my conviction. I think you should ask other people who may be better informed on some parts of it than I am. I say not only do we not have now but I don't believe we ever will have anything that will prevent the atomic bomb from working unless you hit the carrier and physically demolish it. It is the same problem that you have with any other bomb.

I might be wrong; but I know of nothing that I could say more confidently than this, that I believe it is a political problem and I believe it is about the toughest one that has been handed to any group to struggle with.

Senator HART. Doctor, we have profited greatly by your observations in the international field concerning Dr. Smyth's report. As I understand it, after that, they issued the Truman, Attlee, and King statement.

Dr. OPPENHEIMER. Right.

Senator HART. As a citizen with a splendid background, what do you think should be the next step?

Dr. OPPENHEIMER. Well, I would answer it this way, that certainly the step proposed in the Truman-Attlee-King memorandum is sound. If there were, on the part of those competent, real doubts as to the willingness of any important group of nations or a nation to participate in the steps that are there proposed, I think this problem should be attacked by direct conversations with such groups of nations, or such nation.

If there are no such doubts, then I think the steps proposed in the memorandum are right and, particularly, the emphasis on the fact that this problem is going to be solved inch by inch, that they should start with a very modest program and would have to take advantage of the war weariness and the absence of atomic bombs to get into a frame of mind in which the major problems might be properly presented.

Senator HART. Specifically, whose move is it next?

Dr. OPPENHEIMER. It is always the move of the United States, because the United States is committed to peace.

The CHAIRMAN. Doctor, there are 2,000,000,000 people on the face of the earth. If they were to be given a chance to vote on the control of this thing, what do you think the results would be?

Dr. OPPENHEIMER. I have no doubt that they would say, "Let us have no wars."

The CHAIRMAN. Doctor, Senator Hart has brought up the declaration made by President Truman and Mr. Atlee and Mr. King. In the eighth paragraph of that declaration there is a statement that we should proceed by steps and stages.

I noticed that the first stage suggested was the exchange of information on scientific data. Does this mean, according to your interpretation, the exchange of information on nuclear energy?

Dr. OPPENHEIMER. I think it mentions the exchange of a good deal of the basic scientific findings of our laboratories and our experience, calculational experience, which are not specific to the making of atomic energy or atomic bombs.

I am sure that those who wrote the statement are better qualified in saying what it means than I am. I think it is purposely vague because it is not clear just to what extent this will proceed.

I think it is the intention of the Government of the United States to release noncritical technical information which has been gathered in the work on this.

The CHAIRMAN. The purpose being, I presume, that that information will have a peacetime value?

Dr. OPPENHEIMER. That it will develop science and industry and technology.

The CHAIRMAN. That is, peacetime use.

Dr. OPPENHEIMER. But not necessarily atomic energy. A lot was discovered that will be useful in other endeavors.

The CHAIRMAN. Have you any comment to make as to proceeding by stages which, I take it, contemplates a period of considerable length of time for the solving of this problem?

Dr. OPPENHEIMER. Well, certainly, no one would argue that it was not desirable to solve the whole problem at once; but I believe that the men who issued this statement must have been aware of the impossibility of so doing and the dangers involved in the setting up of full interchange and full construction programs of atomic reactors all over the world. I think they must be aware of those dangers. I know of nothing which causes me to doubt the soundness of their views. I think it might be dangerous if the steps were too small.

The CHAIRMAN. Doctor, I think there are some more questions that some members of the committee would like to address to you which you can only answer in executive session.

We are going to meet again this afternoon at 2:30, but we have some other witnesses, and I will try to arrange that with you later.

Thank you very much, Doctor.

We will recess now until 2:30.

(Whereupon, at 12:25 p. m., a recess was taken until 2:30 p. m., of the same day.)

AFTERNOON SESSION

The CHAIRMAN. Dr. Bethe, I believe you have a prepared statement. Will you proceed to give it to us, please?

STATEMENT OF DR. HANS A. BETHE, PROFESSOR OF THEORETICAL
PHYSICS, CORNELL UNIVERSITY

Dr. BETHE. I am normally a professor of theoretical physics at Cornell University. During this war, during the last 3 years, I have been working on the atomic bomb project at the Los Alamos Laboratory, the director of which you heard this morning. I was the leader of the theoretical physics division in that laboratory.

I have been asked to testify on the problem of obtaining energy from atomic nuclei other than uranium and plutonium.

The CHAIRMAN. Doctor, for purposes of the record, where were you born?

Dr. BETHE. Strasbourg, Alsace-Lorraine.

The CHAIRMAN. When did you come to this country?

Dr. BETHE. 1935.

The CHAIRMAN. Had you worked in this science in Germany?

Dr. BETHE. Yes.

The CHAIRMAN. When did you begin working on it here?

Dr. BETHE. You mean on nuclear physics?

The CHAIRMAN. Yes.

Dr. BETHE. All the time I have been here.

The CHAIRMAN. Will you go ahead, Doctor?

Dr. BETHE. This is a very difficult subject to discuss because practically all of it is still in the realm of speculation.

It is necessary to make a clear distinction between the theoretical possibility of releasing atomic energy, and the practical feasibility of doing so. Theoretically, on the basis of the energy stored in the atomic nucleus according to Einstein's theory, energy could be obtained from most atomic nuclei. For instance, the splitting of any of the heavy nuclei into two or more parts, such as takes place in the fission process, will release large amounts of energy if the splitting can be accomplished. Likewise, the combination of two or more light nuclei, such as hydrogen into one, will also release considerable energy—in this case the energy release is connected with a building up of nuclei, not with a splitting. Only some medium-weight nuclei such as iron are exceptions—no energy can be obtained from them either by splitting or by building up.

The problem then does not lie in finding great stores of energy in atomic nuclei, but in finding a way to release it. It is common practice in nuclear physics laboratories to produce transformations of atomic nuclei, either splitting them or building them up. In many of these transformations, energy is released. However, these transformations can be induced in only relatively few atoms at one time. The transformations are generally produced by particles accelerated in a cyclotron or similar device; some of these particles hit atomic nuclei and cause them to transform into other species—but this is where the process stops. There is no further transformation after the particles accelerated in the cyclotron are on their course. No amount of atomic energy of any practical importance is released. It is the same situation as when you hold a burning match to a large piece of wood: some of the wood will be charred but the wood does not catch fire; therefore you do not get any appreciable heat out of the wood.

How, then, can we ignite atomic nuclei? In other words, how can we start a nuclear reaction which continues on its own power and which releases energy from the atomic nucleus in practical amounts? There are only two known methods to obtain such a so-called nuclear chain reaction: one of these is the nuclear fission on which the atomic bomb is based. The other involves the nuclear reactions which we believe take place in the interior of stars, and which involve light nuclei.

The chain reaction based on nuclear fission is well known. The principal agent in this chain reaction is the neutron. The neutron, having no electric charge, can approach an atomic nucleus without being repelled from it and can therefore enter the nucleus and cause transformations in it without difficulty. The principal reason for the working of the fission-chain reaction is that in the fission process neutrons are emitted which in turn can cause fission in other nuclei.

The process of atomic fission has so far been observed only with the very heaviest atomic nuclei, plutonium, uranium, thorium, and one or two others of less practical importance. There are good theoretical reasons why the fission process should become less and less likely, the lower the atomic weight. The most important practical question is whether fission could occur in any element which is abundant on the earth. The heaviest abundant element is lead and, somewhat less abundant, bismuth. But these elements are much lighter than uranium, and it is therefore theoretically quite unlikely that they could be made to undergo fission to any useful extent. In fact, up to the present no fission has been observed with either lead or bismuth. From general principles, it is then most improbable that elements still lighter than lead would show this phenomenon. This leaves us with thorium and uranium as the most important raw materials and, of course, with the elements which can be produced from these by nuclear reactions, such as plutonium.

As we go to elements of smaller atomic weight we come into the region where nuclei are even theoretically incapable of releasing energy. If we go to still lighter nuclei, we can get an energy release by building nuclei up rather than by splitting them. It is such a building up of light atomic nuclei which is believed to be the source of the energy in the sun and in the stars.

More precisely, the sun's energy is believed to be due to reactions between hydrogen nuclei on one side and carbon and nitrogen nuclei on the other. Each atomic nucleus has a positive electric charge, therefore they repel each other. It is therefore difficult for two nuclei to get into contact and undergo a nuclear reaction. They can do this only if they move at each other with very high velocity. Then the velocity carries them together in spite of the repulsive forces.

The high velocity is provided in the interior of stars by the very high temperatures existing there. For instance, at the center of the sun the temperature is about $20,000,000^{\circ}$. In our laboratories, the high velocity is given to the nuclei by accelerating devices such as the cyclotron. The velocities involved are about the same in both cases; actually they are somewhat higher in the cyclotron. But the main difference is that in the stars all atoms have the high velocities, in the laboratory only a few do. Also in the laboratory, these few atoms lose their velocity quickly when they traverse matter.

The matter, of course, is at a low temperature, has not high energy, and if you hit an atom which is at rest with an atom which is in motion, then the atom which is in motion will lose most of its velocity and give some of it to the atom at rest. That doesn't do the atom at rest any good, but it does some harm to the power of the atom which used to be in motion.

In the stars, they keep their high velocities forever; therefore the nuclear reaction can go on indefinitely and we have again a self-sustaining reaction: The energy released from the nuclei produces the high temperatures in the stars, and the high temperature in turn enables the nuclei to get together and to release their energy.

You will see that this mechanism of the sustained nuclear reactions in stars is quite different from that in the atomic bomb. In the bomb, neutrons are causing the reactions; they are not repelled by the electric charge of the atomic nuclei, because they are electrically neutral and therefore the reaction can take place irrespective of the temperature of the bomb and of the velocity of the neutron. In the stars, on the other hand, the reaction takes place between two atomic nuclei which repel each other; a sustained reaction is therefore only possible at the high temperatures in the stars.

There are some stars, the red giants, which have lower temperatures in their interior than the sun, namely only about $1,000,000^{\circ}$. They are supposed to derive their energy from a reaction between two nuclei of heavy hydrogen.

It is not impossible that some day in the future we shall be able to release nuclear energy by reactions similar to those taking place in the stars. The difficulty is to obtain a high enough temperature to start such a reaction, and to obtain this temperature in a sufficiently large volume.

This latter is a particularly great difficulty which has already been mentioned by Dr. Oppenheimer this morning, that in the stars you have an enormous region, an enormous mass which is at high temperature, and on earth it is very difficult to imitate these conditions.

In the stars, the temperature of the interior is kept up by the fact that there is almost equally hot material around it which shields the interior from losing too much of its heat, and the fact that there is so much material around is made possible by the gravitational forces in the star which keep the star together and enable the star to have such large amounts of high temperature material.

Senator AUSTIN. Do you consider the star as gaseous, entirely?

Dr. BETHE. Yes. It seems almost impossible to imitate these conditions on earth. Moreover, the reactions taking place in the sun are exceedingly slow; it takes several billions of years to consume the hydrogen nuclei in the interior of the sun. There would be no practical value in producing nuclear reactions at such a slow rate on earth, but we should be interested only in reactions which would take place in a matter of at most a few years or, for bombs, even in a fraction of a second. In order to get the reactions accelerated to this extent, it would be necessary to have even higher temperatures than even in the center of the sun.

At this point I should like to discuss the question of setting the atmosphere or the ocean on fire by atomic bombs. This question has been very much talked about recently, and I think there was very

much loose talk about it. In the atmosphere the only abundant elements are nitrogen and oxygen, in the ocean oxygen and hydrogen. Nuclear reactions between these nuclei are very unlikely and require enormously high temperatures, much higher than the reaction which takes place in the sun. It can be stated with complete assurance that atomic bombs of the present type or of any type that is now in sight will not produce high enough temperatures to cause nuclear chain reactions in either the atmosphere or the ocean. Theoretical arguments which are probably reliable would even indicate that no temperature, however high, would permit the "ignition" of the atmosphere. Only if one had an enormous amount of water or air, about the size of the sun, and if one then raised this large amount all at the same time to a temperature of many millions of degrees, could there be a self-sustaining nuclear reaction in these substances.

The point is, of course, that in that case the temperature does not get lost by radiation, by heat exchange with the surroundings; and if the temperature can get lost by radiation, then the temperatures required are very much higher and the conditions for the nuclear reaction are much more severe. It therefore seems extremely unlikely that there will be any possibility of igniting the atmosphere or the sea by atomic bombs.

To sum up, the reactions between light nuclei are of possible interest for the future development of atomic power, although the difficulties are undoubtedly very great. To produce such reactions the primary problem will be that of obtaining the extremely high temperatures necessary. In addition, of course, the nuclear reactions themselves will have to be studied.

There is, however, another and much more profound reason for studying the reactions between light nuclei. It is hoped that from such reactions, physicists will be able to learn about the nature of the mysterious forces which hold atomic nuclei together. The light nuclei are the only ones from which such information can be expected, because the heavier ones have such a complicated structure that it will be nearly impossible to analyze any experimental information that might be obtained.

The study of nuclear forces is a problem in pure research. It is not possible to predict whether any practical results will be obtained. I can only say that, in the past, progress in pure research in physics has led to practical applications sooner or later. It is in the nature of pure research that it is impossible to say beforehand where it will lead.

It is my belief that everything should be done to encourage and support pure research on light nuclei. The reasons are both the attempt to understand nuclear forces and the possibility of imitating the nuclear reactions of the stars. Like any kind of pure research, the research in this field can only be done successfully if it is free from restrictions on subjects to be investigated and on publication of the results. Because of the possible practical applications, it may be desirable to require that all results obtained must be communicated to the Atomic Energy Commission whether they are otherwise published or not. Apart from this, the research in this field will flourish most if it is unrestricted in any way, but encouraged in every way.

Research in fundamental fields has in the past benefited very greatly from international collaboration between scientists. This will, no doubt, continue to be the case and such collaboration should be encouraged as much as possible. Arranging for the exchange of scientists and for international conferences are some of the best methods for this purpose. The international collaboration of scientists in the field of pure research in nuclear physics may also be one contributing factor to improve collaboration between the nations in the field of atomic energy which is so necessary for the survival of all nations and which has been initiated by the joint statement of President Truman, Prime Minister Atlee, and Prime Minister Mackenzie King.

I have mentioned in this testimony two ways of releasing atomic energy which are known at present. It is always possible that other mechanisms may be found even though at present there is no indication of the possibility of such mechanisms. Only pure research without any definite aims can lead to the discovery of such alternative methods.

I should like to add one point: There is somewhat more to this story which I think I could only mention in an executive session, and which would make the picture more complete.

The CHAIRMAN. Thank you, Doctor.

Are there any questions?

Senator HART. Doctor, may I ask if this is correct? That the reason that these extremely high temperatures in the middle of the sun are effective is because the atoms under those conditions are always moving at such an extremely rapid rate?

Dr. BETHE. Yes; in fact, from the standpoint of physics, the two statements are identical.

Senator HART. One other question, Doctor. You were very encouraging to all of us in the assurance that there is no danger of burning ourselves up by burning the atmosphere or the water, which you mention has been spread around.

It has not been said in here, but a certain number of men of supposedly very good scientific training have given those statements. Have you any idea how they came to do that?

Dr. BETHE. I am afraid I don't know. They were not men who have worked specifically on this problem, and I can only explain it as ignorance.

Senator HART. They are, however, men who have standings before the country by virtue of their educational attainments.

Dr. BETHE. That is true.

Senator HART. Possibly their attainment or production lies elsewhere.

Dr. BETHE. That is quite true. It is a rather complicated problem, and it took us the work of several years to find out about this subject and about the other subjects mentioned in this report.

I think I should say that before we made our first test of the atomic bomb, we were sure on theoretical grounds that we would not set the atmosphere on fire.

Senator MILLIKIN. Mr. Chairman.

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. If you wished to render the atmosphere inflammable, what would you do?

Dr. BETHE. I don't think you could do very much. If you had enormous amounts of energy available and could heat, let us say, all the atmosphere covering the city of Washington all at once—

Senator MILLIKIN. I was thinking of in the laboratory, if you wished to make atmosphere rare or inflammable, what would you do?

Dr. BETHE. You cannot do anything. The only thing you can do is char it. That is to disintegrate some of the nuclei. You cannot get a self-sustaining reaction in the atmosphere.

Senator MILLIKIN. I am not speaking of that. What does atmosphere consist of?

Dr. BETHE. Nitrogen and oxygen.

Senator MILLIKIN. If you withdrew one or the other, what would happen?

Dr. BETHE. Nothing. If you added heavy hydrogen, then there would be a slightly better possibility; but still I think it would be very unlikely that you would succeed.

Senator MILLIKIN. I am not thinking in terms of nuclear physics at all.

Dr. BETHE. You mean just chemistry?

Senator MILLIKIN. I am thinking of how to make the atmosphere inflammable. I have a vague idea that if you subtract one or the other of the components of the atmosphere, it becomes highly inflammable.

Dr. BETHE. If there are other substances around. If you have a piece of iron, for instance, it will burn in pure oxygen but it will not burn in ordinary air. That is, if you withdraw the nitrogen, then certain chemical substances such as iron can become inflammable in pure oxygen.

Senator MILLIKIN. That is what I was referring to.

Dr. BETHE. But this, of course, is not nuclear.

Senator MILLIKIN. I understand. Would there be any way of preparing the atmosphere to any large extent by the method you have described, and then subjecting it to nuclear energy?

Dr. BETHE. Yes, but it would still be extremely unlikely that you would succeed in setting it on fire. Also, it would certainly be noticed.

The CHAIRMAN. Dr. Bethe, if you had an air-tight chamber over Washington, you would have to draw it out in order to make it inflammable, wouldn't you?

Dr. BETHE. Just about.

Senator MILLIKIN. What started the stars off on this rampage?

Dr. BETHE. I don't know; I wasn't present.

Senator MILLIKIN. That is one of those "egg or the chicken first" things. Have you any theory on that?

Dr. BETHE. Some theories have been made; none of them are very satisfactory, and all of them are rather complicated.

Senator MILLIKIN. There is no simple explanation?

Dr. BETHE. No simple explanation, as far as I know.

Senator MILLIKIN. No explanation that withstands scientific measurement.

Senator JOHNSON. What is the temperature at the center of the earth?

Dr. BETHE. Probably only about 10,000°, so it is very low.

Senator JOHNSON. Comparatively cold?

Dr. BETHE. Yes; compared with the center of the sun.

Senator JOHNSON. Have the scientists succeeded in controlling the splitting of any atoms other than elements that naturally split themselves, like uranium and plutonium?

Dr. BETHE. Yes, definitely. I think I should mention two different types of splitting. Uranium and plutonium, naturally, that is, if you leave them to themselves, split themselves by emitting so-called alpha particles, which are small particles taking away only 4 units of 200 units of atomic weight.

Distinct from that is the splitting which takes place in the atomic bomb, which is a splitting into two almost equal parts, and which is induced by shooting a neutron at the nucleus of uranium or plutonium. If you shoot a particle, either a neutron or a hydrogen nucleus, or some other nuclear particle, at any nucleus, you will very frequently succeed in causing a nuclear transformation, that is causing the nucleus to transform into a new element.

Now, this has been done with practically all nuclei which exist; that is, with practically all elements that exist. For most of these elements, all you can do is shoot your projectiles in, and let us say 1 in 10,000 will make a lucky hit and will transform one of the nuclei. But this will not start a reaction which then goes on by itself, and if you want to get atomic power you cannot depend on sending a few projectiles in and getting a few lucky hits; you must get the whole piece to ignite. That is, you must get a nuclear reaction which goes on in the substance by itself.

Senator HICKENLOOPER. Doctor, is it the theory of the physicists and scientists that the earth at one time was a tremendous mass of heat with this fission going on, and that our present earth crust is the residue of that or the remainder of the stabilization of those things?

Dr. BETHE. We have no reason to believe that fission was a very important source of energy in any star or in the earth. It is not quite certain in what state the earth was when it first separated from the sun. I think the general belief is that it was hot—perhaps it came from some part of the sun, but that is not certain—and then cooled down very rapidly, because it was a smaller mass and a small mass loses energy or heat very rapidly to the universe which a large mass, like the sun does not.

Senator HICKENLOOPER. Perhaps I did not make my question quite clear. Is it the theory that the solids that we know, the various elements that we see—wood, metal, and so on—represent the results of nuclear transformation until it more or less wears out and stabilizes into these various forms?

Dr. BETHE. That is a fond belief of physicists. However, there is no established theory which permits us to explain that. We just don't know. We know that at present, in most stars, it is only the very lightest nuclei which transform; so the stars must have been in an entirely different condition if they had to produce such elements as iron, let us say.

Senator HICKENLOOPER. Now, is it the theory that the sun is a mass of reacting atoms, or is the sun in theory composed partly of a solid, as we know it?

Dr. BETHE. No; it is supposed to be closest to a gas; but it is a gas at very high density.

Now, by that I mean the following: In a solid, the atoms are carefully arranged to certain patterns, and that is not the case in the sun. In this sense it is a gas. On the other hand, the material is very dense at the center of the sun. It is 10 times denser than iron, which is a fairly heavy stuff.

Senator HICKENLOOPER. Getting back to the theory, whether it is reasonable or not, that the earth may have broken away from the sun, then apparently at the time the earth broke away from the sun it was this dense gaseous formation?

Dr. BETHE. That would be correct.

Senator HICKENLOOPER. Then what would be the generally accepted theory, under that theory, as to how the earth developed its solidification, or produced the solids which we now know, the various elements we find here?

Dr. BETHE. Well, the elements would be the same from the start. The elements in the gases are the same as the elements in the solid. The sun, for instance, contains a very large amount of iron, but this iron is in the gaseous state; and you can heat iron in the laboratory sufficiently high so that it does become gaseous. There is no particular difficulty in that.

Senator HICKENLOOPER. In other words, in cooling it solidifies?

Dr. BETHE. When it cools, it solidifies, and that is the theory.

The CHAIRMAN. Doctor, I take it, to sum up your testimony, that we do not have to anticipate that there will be use in the foreseeable future of any other basic materials than uranium and thorium to make atomic energy?

Dr. BETHE. Certainly not by the fission process. If somebody finds a way how to imitate the reactions in the stars—and that may not take a tremendously long time—then other materials will come into play.

The CHAIRMAN. You mean creating this intense heat?

Dr. BETHE. Creating this intense heat, and thereby igniting substances, igniting nuclear reactions in light nuclei.

The CHAIRMAN. The other day in the paper it was announced that Kapitza, the Russian, had done certain work. Will you fit that, as you read it, into this projection of what might be possible?

Dr. BETHE. I have heard of this, but unfortunately from the newspaper reports it is impossible for me to form a clear picture of what he has done.

It is claimed that he has discovered a negative proton, which is a particle which is similar to the nucleus of hydrogen but has a negative charge instead of a positive charge, and the claim would then be that such a particle will not be repelled by the positive electric charges on nuclei, but will be attracted by them and therefore it will be easy to make such a particle combine with nuclei, with atomic nuclei, and power might be liberated by such a combination.

Senator HICKENLOOPER. That would be the combination of combining rather than fission?

Dr. BETHE. Yes; that is right. Now, I don't know what is behind this story. It seems that the particles which we normally find on earth are all of the opposite nature—namely, of positive particles; so there seem to be two possibilities.

The most likely is that these negative protons come into the atmosphere from other stars, from other galaxies, maybe, with the cos-

mic radiation, and in very small quantities. In this case they will obviously not be of practical importance for making atomic energy.

The other possibility would be that some mechanism could be found by which such particles could be produced in the laboratory. If that is the case, it is likely that you use up as much energy in producing them as you afterward get out in making them combine with other nuclei; so again it is not likely that it will be a practical scheme.

The CHAIRMAN. You would say it was theoretically very interesting, but as far as you can project it, you would not look for any positive results from it?

Dr. BEHE. That is correct.

The CHAIRMAN. In the way of making, we will say, an explosive?

Dr. BETHE. Yes.

Senator HICKENLOOPER. In that connection, does science, so far as you know, know any method now by which either a positive charge can be altered in a nucleus to a negative charge—that is, that the charge can be altered—or that a neutral body, such as a neutron, can acquire either a positive or a negative charge?

Can we put any kind of a charge by any known method of science into a neutron?

Dr. BETHE. Not to my knowledge. There is one process which can go on and which is fairly well known; namely, a neutron in the nucleus can split into a proton, which has a positive charge, and an electron, which is a light particle which has a negative charge. The total charge in this process is always conserved, but you can have a neutral particle split up into a positive and a negative particle.

Senator HICKENLOOPER. Would it be possible that this so-called discovery of a negative proton is merely one of these that is split into the positive and negative?

Dr. BETHE. That is perfectly possible. It is quite possible and has in fact been theoretically predicted that there might exist the possibility for the neutron to also split the other way; namely, into a negative proton and a positive electron. The positive electron has been known for quite a long time. No one has ever seen a neutron split into a negative proton and a positive electron—at least not in this country; but there is nothing in theory which makes that impossible.

Senator HICKENLOOPER. I presume that if a method were discovered to alter these charges, that that would then open up an almost unheard of field of experimentation and activity, would it not?

Dr. BETHE. That is certainly true. The question, however, is whether it would be of any practical importance. It would probably be of this kind: That you can produce some negative protons in the laboratory and they might live for a short time, but you can probably not put them into a bottle. You cannot fill a bottle with hydrogen particles with negative charge, because presumably they would in a short time transform back into a neutron and the negative electron, and therefore I don't think it would have much practical importance.

But as I said, it is very difficult for me to say because I have not read the scientific paper about Kapitza's discovery, but only the newspaper accounts, which are always very uncertain about scientific facts.

The CHAIRMAN. Doctor, we have done a good deal of talking here back and forth about the scientific feasibility of an inspection system world-wide in scope.

Is it your belief, and do I gather correctly from your testimony, that if we were to be able to control uranium and thorium from its source to see that it did not go into bombs, that for the foreseeable future we would be protected?

Dr. BETHE. That is probably true, if we could really control and inspect all the supplies of uranium and thorium.

The CHAIRMAN. I had that as a predicate to my question.

Dr. BETHE. But these are very abundant elements, especially thorium which is found in very many places, and also uranium is found in quite a few places in lower-grade ores than are usually exploited.

If we could control all the supplies of uranium and thorium, then I would say "Yes" to your question.

Senator HICKENLOOPER. Doctor, I assume that you have had some acquaintance with the extent of scientific development and of scientific engineering in foreign countries, in Europe, and areas of that sort.

Considering the condition of the other nations of the world today—that is, their physical devastation or whatever their condition may be—do you believe that any other nation in the world today has the extent of scientific personnel available, plus the scientific engineering, plus the necessary finances, and plus the necessary determination, to start on their own basis, knowing that a bomb can be produced, and produce it within any short number of years?

Dr. BETHE. Yes; I believe so, very definitely. It does not take an enormous number of scientists. Many countries have quite a number of good scientists; Russia has, and France has; and while no other country has industrial facilities comparable with this country, the production of plutonium or uranium-235 is not a very expensive venture.

It cost us \$2,000,000,000, but we used three different methods because we wanted to be sure that one of these methods would be successful.

Now, other countries know that all three have been successful, so they can start on one of them and can choose the cheapest. Probably for half a billion dollars they can produce atomic bombs. Half a billion dollars is a very small amount for a country like Russia or France.

Senator JOHNSON. Doctor, do you think that the Smyth report gave any information to European scientists that they did not already know? How much information did it give?

Dr. BETHE. It is hard to tell, because we don't know how much the Intelligence Service of these countries knew. It gave more information than was known to us in the beginning of 1939.

The three processes which were used and are described in the Smyth report are probably the processes which any nuclear physicist would first investigate before anything else; and these three processes would occur, I think, to all the nuclear physicists in European countries. In that respect, it did not give away anything. It did say something in stating that every one of these three processes was successful. However this would have been very easy to find out even with a minimum of Intelligence Service, because it could not have been concealed that there were three separate industrial plants engaged in the manufacture of materials for this process; and if you know that there are three separate plants looking very differently, so obviously using differ-

ent processes, then it would have been probably the first guess of any scientist in Europe that these three processes are the three that we actually used.

Senator JOHNSON. Would you care to discuss briefly your career as a physicist in this country as compared with your experiences in Europe, as to your liberties and your accomplishments, your assistance or general appreciation by the Government through regimentation, or anything of that kind?

Dr. BETHE. I am very glad to do so.

I was very young when I left Germany, and I left Germany immediately after Hitler came to power, so I did not have much experience with the regimentation of science there. I knew enough in a couple of months so that I knew that I did not want to stay.

I can say that in this country working conditions have been extremely good, and I have liked working here much better than I liked working in Germany, even before Hitler. I think that the spirit of the scientific work here is very excellent, and the collaboration of the scientists in the war effort, which was completely voluntary, at least to start with, and which started sufficiently far ahead of the actual war to do some good, was something which would not have been possible in Germany even before Hitler.

I think this democratic spirit of collaboration is something which I greatly admire, and which I think is an enormous strength of this country.

All the same, I think things can be done in different ways. They can be done by collaboration, or, if one knows the aims, if one has a definite directive, I am sure that research can also be done by directive in a dictatorial country. I would rather work in a democratic country where I can determine myself what I want to work on, and I think in the long run this is somewhat more successful.

Senator JOHNSON. Do you believe that any other country on the face of the earth would have printed the Smyth report, other than the United States?

Dr. BETHE. I don't know. In the old spirit of scientific research, it would certainly have been printed; in fact, more than that would have been printed.

The Smyth report, as you probably know, contained no detailed data. It does not contain any numbers. This is very regrettable for scientists, because numbers is what science consists of.

I think the most relevant information which came out was the fact that the bomb itself was successful. The Smyth report added something to that.

I think that in some European countries, perhaps in Russia, it would not have been published. I think in France it probably would have been.

Senator AUSTIN. There is a report in process now in Great Britain, isn't there?

Dr. BETHE. Yes; some report has come out actually from Great Britain.

Senator HICKENLOOPER. But the point you just mentioned there is one I was going to ask you about when Senator Johnson finished.

One of the greatest aids to other people about this whole situation is the fact that we proved the bomb could be made?

Dr. BETHE. That is exactly so.

Senator HICKENLOOPER. And that is beyond any question of experimentation or research now?

Dr. BETHE. Quite.

Senator HICKENLOOPER. We have proved the fact that fission is possible and the bomb can be made.

Dr. BETHE. Exactly.

Senator HICKENLOOPER. And therefore it only remains for them to work toward the accomplishment of something somebody has already done?

Dr. BETHE. Yes, and they would presumably, if the Smyth Report had not come out; the fact that the bomb could be made would have proved an enormous incentive to them, and they would have started on it just the same, Smyth Report or not, and would probably have used one of the three methods.

Senator HICKENLOOPER. They were almost bound to know it was made by one of these three major methods?

Dr. BETHE. Yes.

Senator HICKENLOOPER. And by the three major methods, you mean the methods of separating U-235?

Dr. BETHE. Separating uranium-235 by the electromagnetic method, or by the diffusion method, and the third is the manufacture of plutonium.

Senator HICKENLOOPER. Isn't there a thermal diffusion method?

Dr. BETHE. The thermal diffusion method could also be mentioned, and then it would be four.

Senator HICKENLOOPER. I didn't know whether you meant those three methods, and then the plutonium as a fourth, or included that among the three you mentioned.

Senator MILLIKIN. Doctor, was the Smyth Report published through the pressure of the scientists or did it come out through the initiative of the Army exclusively?

Dr. BETHE. I don't know. The scientists, I know, would have recommended it. The release, I think, was made by the Army after, I think, the President was consulted.

Senator MILLIKIN. If there was an error in this publication, it would be attributable to the Army, then?

Dr. BETHE. I should think so.

The CHAIRMAN. Any further questions, gentlemen? [No response.] Thank you very much, Doctor.

Do we have any other witness? Apparently there is none.

Senator AUSTIN. Why not have an executive session now?

The CHAIRMAN. I think that is a good idea. The committee will now go into executive session. Dr. Bethe, don't leave.

(Whereupon, at 3:35 p. m. the special committee retired into executive session.)

ATOMIC ENERGY

THURSDAY, DECEMBER 6, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Millikin, Hickenlooper, and Hart.

Also present: Representative John R. Murdock; Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The hearing will come to order. We will hear Dr. Morrison.

STATEMENT OF DR. PHILIP MORRISON, PHYSICIST, LOS ALAMOS LABORATORY

Dr. MORRISON. I have a prepared statement. I believe it is appropriate to indicate my qualifications before I begin.

After the completion of my graduate work at the University of California in Berkeley in 1940, I was for a short time instructor in physics at San Francisco State College and later at the University of Illinois. In December 1942 I began work at the metallurgical laboratory of the University of Chicago. In October 1944 I came to the Los Alamos laboratory. At Chicago, my work consisted of theoretical, experimental, and design work in connection with the plutonium-producing chain reactors. At Los Alamos, it was concerned with the active components of the bomb itself. Following the Trinity test in New Mexico, I went to the Marianas to assist in the final assembly work on the bomb. On September 6, I came to Japan to join General Farrell's party there. I returned to Los Alamos in October.

Senator MILLIKIN. Mr. Chairman, who is General Farrell?

Dr. MORRISON. General Farrell was General Groves' deputy; he was sent overseas to head the military party.

Many Americans have visited the cities, or the ruins, of Japan since the end of war in the Pacific. The reporters and the photographers have made clear for us all the appearance of the war-damaged towns, especially of the cities destroyed by the first atomic bombs, Hiroshima and Nagasaki. But there is more to be learned from those scenes than the newspapers have yet been able to tell. It was my job to visit the damaged cities of Japan, to speak with the people there, and to assist in the carrying out of certain technical studies. You have heard and

233

you will hear more expert testimony on the kinds and extent of the damage done by the atomic bomb. I am a nuclear physicist, not a specialist on this or that kind of damage; I wish I knew even less about damage than I do. It is my purpose to tell the committee as clearly as I can what the impressions of an American physicist are when he views the ruins and talks to the survivors of the bombing he and his coworkers spent so much time to make possible.

The atomic bomb is not merely a new weapon: it is a revolution in war. I saw the blackened ruins of Tokyo and Osaka, of Kobe and of Nagoya, and I know that a city cannot live under the fire raids of a thousand B-29's. The destruction of a great city in itself is not the new feature of the atomic bomb. To make clear why the atomic bomb is different one must talk first of the B-29.

We of the Los Alamos project who went overseas in July to prepare the bombs for delivery over the target were stationed on the small island of Tinian, near Saipan in the Marianas chain. Tinian is a miracle. Here, 6,000 miles from San Francisco, the United States armed forces have built the largest airport in the world. A great coral ridge was half-leveled to fill a rough plain, and to build 6 runways, each an excellent 10-lane highway, each almost 2 miles long. Beside these runways stood in long rows the great silvery airplanes. They were there not by the dozen but by the hundred. From the air this island, smaller than Manhattan, looked like a giant aircraft carrier, its deck loaded with bombers. I have flown many times in a B-29, and I doubt that there is a more complex and wonderful machine of any kind. And here, far from the factories in Seattle or Wichita, were several hundred of these million-dollar craft. Here were collected tens of thousands of specialists, trained in the operation and repair of the delicate mechanisms which cram the body of the plane. In the harbor every day rode tankers, laden with thousands of tons of aviation gasoline. A net of pipe lines supplied the airfields with fuel. The radio dial was busy with signals of every kind. And all these gigantic preparations had a grand and terrible outcome. At sunset some day the field would be loud with the roar of the motors. Down the great runways would roll the huge planes, seeming to move slowly because of their size, but far outspeeding the occasional racing jeep. One after another each runway would launch its planes. Once every 15 seconds another B-29 would become air-borne. For an hour and a half this would continue with precision and order. The sun would go below the sea, and the last planes could still be seen in the distance, with running lights still on. Often a plane would fail to make the takeoff, and go skimming horribly into the sea, or into the beach to burn like a huge torch. We came often to sit on the top of the coral ridge and watch the combat strike of the 313th wing in real awe. Most of the planes would return the next morning, standing in a long single line, like beads on a chain, from just overhead to the horizon. You could see 10 or 12 planes at a time, spaced a couple of miles apart. As fast as the near plane would land, another would appear at the edge of the sky. There were always the same number of planes in sight. The empty field would fill up, and in an hour or two all the planes would have come in.

Next day the reconnaissance photographs would come in. They showed a Japanese city, with whole square miles of it wrecked and torn by flame. The fire bombs dropped on wood and paper houses by the thousands of tons had done their work. A thousand B-29's, time and again, burned many square miles of a city in a single raid.

The atomic bomb was something else. There were no shiploads of incendiaries. Instead of all the ordnance men and their bomb dumps, there were about 25 people from Los Alamos, a few Quonset huts transformed into testing laboratories, and a barricaded building. The strike took off after midnight. The field was deserted. Only two or three planes were warming up. A few lights burned around a single hard-stand.

Senator MILLIKIN. What is a hard-stand?

Dr. MORRISON. It is a path on the airfield on which the airplane sits before taking off.

And one plane roared down the runway, took off, and set course for the cities of the enemy. The reconnaissance photos next told the same story. One plane, with one bomb, had destroyed many square miles of a city, destroyed them even more thoroughly and with even less chance for resistance or escape than the 1,000-plane strike.

I can imagine a thousand atomic bombs and an airport like Tinian's to send them off. But not even the United States could prepare a thousand Tinians with ordinary bombs. There are simply not enough people. Destruction has changed qualitatively with this new energy. War can now destroy not cities, but nations.

There is even more to be said. I remember vividly the lunch we had at the prefectural building in Hiroshima. The Japanese officials came there to talk to us and to describe their experiences. I sat at lunch next to and spoke to the chief medical officer of the district. He had been pinned in the wreckage of his house for several days after the explosion. He lived a little more than a mile from the point of impact, and was still wearing splints. His assistant had been killed, and his assistant's assistant. Of 300 registered physicians, more than 260 were unable to aid the injured. Of 2,400 nurses, orderlies, and trained first aid workers, more than 1,800 were made casualties in a single instant. It was the same everywhere. There were about 33 modern fire stations in Hiroshima. Twenty-six were useless after the blast, and three-quarters of the firemen killed or missing. The military organization was destroyed; the commanding general and all his staff were killed, with some 5,000 soldiers of the garrison of 8,000. Not one hospital in the city was left in condition to shelter patients from the rain. The power and the telephone service were both out over the whole central region of the city. Debris filled the streets, and hundreds, even thousands of fires burned unchecked among the injured and the dead. No one was able to fight them.

Senator MILLIKIN. What was the population of Hiroshima?

Dr. MORRISON. About 300,000.

There is a word for this kind of attack; it is described as an attack of saturation. If you strike at a man or a city, your adversary protects himself. If you attack a man, he runs or strikes back at you; if you attack a city, it throws up flak, it musters its firemen, it treats the wounded. But if you strike all at once with overwhelming force, your enemy cannot protect himself. He is stunned. The flak bat-

teries are all shooting as fast as they can; the firemen are all busy throwing water at the flames. Then your strike may grow larger without increased resistance. The defenses are said to be saturated. The atomic bomb is a weapon of saturation. It destroys so quickly and so completely such a large area that defense is hopeless. Leadership and organization are gone. Key personnel are killed. With the fire stations wrecked and firemen burned, how control a thousand fires? With the doctors dead and the hospitals smashed, how treat a quarter of a million injured?

There is one more novelty. A Japanese official stood in the rubble and said to us: "All this from one bomb; it is unendurable." We learned what he meant. The cities of all Japan had been put to flame by the great flights of B-29's from the Marianas. But at least there was warning, and a sense of temporary safety. If the people in Kobe went through a night of inferno, you, living in Nagoya, were going to be all right that night. The thousand-bomber raids were not concealed; they even formed a pattern of action which the war-wise Japanese could count on. But every hour of every day above any Japanese city there might be one American plane. And one bomber could now destroy a city. The alert would be sounded day and night. Even if the raiders were over Fukuoka, you, in Sendai, a thousand miles north, must still fear death from a single plane. This is unendurable.

I should like to interpolate a few remarks on the kind of damage that the bomb does. I think I can describe to you very simply what happens and that will make clearer to you what we saw there.

When the bomb is detonated in the middle of a city, it is as though a small piece of the sun has been instantly created. There is formed what we have called the ball of fire, which is a hot, glowing mass something about one-third of a mile across, with a temperature of about a hundred million degrees Fahrenheit in the center of it.

The effects from this small sun are as you would expect. In the first place, there is a sudden creation and expansion which pushes away, with terrible violence, the air that once occupied this region.

This air, shocked into motion, as we say, moves just like a blast wave from a great explosion of TNT. We often measure the effectiveness of a bomb in tons of TNT equivalent.

This pushing air creates an enormous pressure, even a great distance away. Behind the wave of pressure, which travels rapidly through the air, there come great winds, 500 to 1,000 miles per hour, winds which damage and destroy all structures.

If you stand near this piece of the sun—

Senator MILLIKIN. Those are the winds rushing to fill the vacuum; is that right?

Dr. MORRISON. They are winds which occur partly from that, sir, and also partly because the wave starts in the air. It runs too fast—the air cannot move fast enough to keep up with the wave, so it follows somewhat like a breakwater wave, and this is the great wind.

Senator MILLIKIN. I see.

Dr. MORRISON. If you are near the sun, you must expect to get burned. The people near it are burned on the body; the people and the structures underwent terrific radiant heat.

In New Mexico, where we were 10 miles away, on a cold desert, I felt as though the hot sun had been out for an hour when the explosion occurred. My face was warmed up.

There, in Japan, the same effect happened. Since they were closer there, instantly all organic material was burned up. For some distance it burned up the flesh.

As I shall show later in my prepared statement, for a considerable distance it set fire to piece of wood, curtains, textiles, to anything inflammable in the neighborhood.

There are two more effects. At the instant of the explosion there is emitted from this small sun not only the great push through the air, the violent blast, which is the violent explosion—there is not only the concentrated heat which you would expect from being close to the sun, there was also a great amount of radiation, like the radiation used by doctors, like the X-ray radiation used for the treatment of cancer.

This radiation is very penetrating. There is no protection behind a foot of concrete, for example.

Senator MILLIKIN. How about lead?

Dr. MORRISON. It is possible to have protection. It depends on where you are. You will have no protection unless the material is thick enough. If you have 20 feet of concrete or 5 feet of lead, you are safe enough if it is in front of you.

This radiation produces special physiological effects which I would like to describe.

There is one more effect which may or may not be effective in a military sense, besides the instantaneous burst of these ray-like emanations.

There is left on the ground an enormous amount of radioactivity, corresponding, in the maximum case, to thousands of tons of radium. If this is the case, if this is deposited on the ground, it will be difficult to approach that area, that region, for a long time.

Senator MILLIKIN. Mr. Chairman, I have a question.

Would it disturb your sequence of thought if I would go into the lead matter now?

Dr. MORRISON. No, sir.

Senator MILLIKIN. Are there any other readily available metals that could be used to shield things, that could be used as a defense against the atomic bomb?

Dr. MORRISON. The only point is getting enough material. It doesn't matter what it is if you have enough of it. It may be concrete, dirt, or lead; whichever it is is not very important. Lead, of course, is very heavy and to get a mass of material is convenient with lead.

Senator MILLIKIN. In other words, a thin sheet of lead may be equivalent to 2 or 3 feet of some other material?

Dr. MORRISON. I am afraid not. An inch of lead is equivalent to 10 inches of concrete. The factor of lead to concrete is about 1 to 10. Gold would be twice as good.

Senator MILLIKIN. What does the person wear if he goes into one of these infected areas?

Dr. MORRISON. I don't know. I don't quite understand. There is nothing you wear for protection.

Senator MILLIKIN. I saw a picture in a paper of a tank that moved in there, in New Mexico, and it said that the tank was coated with lead, or something of that kind.

Dr. MORRISON. Yes.

Senator MILLIKIN. Now, when the men get out of that tank, what do they wear?

Dr. MORRISON. They didn't get out. They would have been fried if they had gotten out at that time. They stayed in.

Senator MILLIKIN. Do you see a field of considerable usefulness, where defensive measures are concerned, in lead or any other metals?

Dr. MORRISON. Well, going underground would be helpful. I think that lead is especially valuable, lead is useful, if you have a small room and you want to keep it small. Otherwise, you might as well make it with concrete. We have a similar problem when it comes to sealing in all plutonium reactors. As far as I know, except for instruments, there lead is not employed. These other materials are cheaper. You see, it is much cheaper to use 10 feet of concrete than its equivalent in lead.

Senator MILLIKIN. Thank you.

Dr. MORRISON. As I was saying, there is left on the ground, under some circumstances, this large radioactivity.

In New Mexico, where the explosion was on the surface, this activity was sizable. In both cities of Japan, this activity was negligible, simply because of the tactical choice of the method of employing the bomb.

It has been described in the press. In New Mexico, the bomb was detonated close to the surface; in Japan, a considerable distance above the ground.

In one case the radioactivity was concentrated on the ground; in the other case, in Japan, it was spread over a great area, and so there was not enough of it; it was negligible.

Senator HICKENLOOPER. May I ask a question?

The CHAIRMAN. Yes, Senator.

Senator HICKENLOOPER. How far away did the heat generated from the bomb kill individuals? At say the 100-foot level in New Mexico, as compared to the 1,500- or 1,800-foot level over these Japanese cities, what would be the comparison?

Dr. MORRISON. Would you please wait? I think I have that question covered in my statement.

Senator HICKENLOOPER. Yes. I don't want to disturb your train of thought.

Dr. MORRISON. Yes, sir. I answer that question directly in the statement.

I simply want to give a picture of what the physical effects were and then I have this prepared statement from observations in the area of damage.

Senator JOHNSON. You left out one step.

Could you tell us something about the reaction? I suppose that the air rushes back into the vacuum. That is, you describe the air as being pushed out at the time of the explosion.

Now, there must be the secondary reaction, of air rushing back in and causing damage through that suction that would follow naturally.

Dr. MORRISON. Mostly there is nothing left by that time to damage. If you built one in between the two, it might suffer some damage.

Senator JOHNSON. The buildings are all torn down but that suction is, relatively, something that will not amount to very much because the damage is all done. Is that the theory?

Dr. MORRISON. That is right.

Senator JOHNSON. But is there not a tremendous suction?

Dr. MORRISON. There is; but not too much effect where individual buildings were concerned. We could sometimes see buildings where, at the edge, the air blast had struck from behind, not in the front. That effect would depend upon the shape of the building and such freak effects might happen.

Mostly, the impact, like a hammer, causes the damage, and following this hammer blow is the rapid wind; after that, the suction phase is not very important.

Senator JOHNSON. We have had described to us here cases involving concrete buildings reinforced by steel. We have been told that the interiors of the buildings and the partitions had all been torn out. It just occurred to me that that reaction, perhaps, did that.

Dr. MORRISON. That is quite likely. I was just going to say that in the next sentence.

Senator MILLIKIN. Mr. Chairman, pursuing that same subject a little further, I have seen many pictures of damage over in London during the bombing, which showed that the buildings collapsed towards the location of the bomb. The explanation was that it was caused by the suction rather than by the hammer effect of the blast. Does that prevail also as far as this particular bomb is concerned?

Dr. MORRISON. No, I don't believe it does. It is rather less important in this case than in small explosions.

Senator MILLIKIN. I was curious about that.

Dr. MORRISON. I think that the effect has been exaggerated even in the smaller explosions. If I might put it this way, the bigger the explosion, the more negative the effect of the suction phase, the less important it is.

Senator MILLIKIN. You get the first hammer effect, which does the job, and the second effect has nothing to pull down.

Dr. MORRISON. Yes.

The damage done in the cities struck by the atomic bomb is not easy to realize. Houses and buildings for a mile in all directions are totally destroyed. A good deal of comment has been attracted by the ferro-concrete structures whose walls still stand. These are very strong buildings. But they too are useless. I have been in these buildings. The window casements are gone, the interior walls are down, the roofs are collapsed, the furniture battered, plumbing fixtures and heavy machinery overturned. A great blast wind followed the shock and ripped through the buildings, destroying their interiors. Most of them burned. Brick buildings, and even steel-frame buildings with brick walls, are extremely vulnerable.

Senator MILLIKIN. Did I understand you to say a while ago that this wind you have described reaches a velocity of 500 or 600 miles?

Dr. MORRISON. That is a very conservative figure. A 1,000-miles wind is common.

Senator MILLIKIN. What is a hurricane wind?

Dr. MORRISON. About 120 miles an hour.

Senator MILLIKIN. I wanted that just for a comparison.

Dr. MORRISON. At Nagasaki, the Roman Catholic church was an old and heavy brick-walled building nearly a mile and a half away, and it suffered total destruction. It is likely that an American city would be as badly damaged as a Japanese city, though it would look less wrecked from the air. In Japan the wreckage burned clean; in a

western city, the rubble would still stand in piles in streets. But the city would be just as ruined, and the people of the city as dead.

The action of the blast on steel-frame factory structures is known from the wreckage of the Mitsubishi Torpedo Works in Nagasaki. Japanese homes are lightly built, but their factories are about like ours. And the torpedo works buildings collapsed in a twisted jumble of steel onto the heads of the workmen and the still-turning machines. For a good mile and a half all factory structures were totally destroyed.

For 3 or 4 miles from the point of impact there is heavy damage, making half the buildings unusable. In Hiroshima the fires which began after the blast, some set by overturned stoves and chimneys, some by the heat from the bomb itself, burned for 10 hours. The flames stopped at the edge of the river. Many places were completely destroyed by fire which had only been partly smashed by the blast. It is not hard to understand that fire-fighting was impossible.

Senator MILLIKIN. Mr. Chairman, I hate to interrupt so often.

Dr. MORRISON. That is all right.

Senator MILLIKIN. Yesterday we were questioning a witness as to whether these same effects would occur in a heavily constructed area, like lower Manhattan, for example.

I think I asked the question whether the great bulk of the heavy construction, the buildings, would serve to insulate and confine the effects of the blast. Would you mind giving us your impression on that?

Dr. MORRISON. As the blast wave moves over the face of the city it loses energy by the knocking over of structures, it carries debris around; therefore, I think the more densely the city was built up, the more the number of buildings that would be caught in a given area. Therefore, the extent of the damage would be, or might be, somewhat smaller because there were more buildings.

Senator MILLIKIN. But the effect, in a quantitative way, would be the same?

Dr. MORRISON. Yes, sir.

Senator JOHNSON. What is the direction of this blast? Is it straight down?

Dr. MORRISON. It depends on where you are and where the bomb is set for. I am not sure that I can go into the details, but if it is close, it is straight down; if it is some distance away, it is horizontal.

Senator JOHNSON. Of course, this straight-down blast might raise havoc with the roofs, but it might not raise havoc with the walls of the buildings.

Dr. MORRISON. That is true. For example, in Hiroshima, the walls directly under the impact were intact while the roofs had been driven straight down. The heat and the radiation had killed the people; but the walls and even the telephone poles were still standing up.

The effect, of course, depends very much on how far away it is. At some distances, you have one effect and at some other distances you have another.

Senator MILLIKIN. Is it true that, so far as the bomb is concerned, passing what is below it, as far as the bomb itself, does it throw out energy in equal directions or does it have that energy thrown out directionally?

Dr. MORRISON. If the bomb is released very far above the earth, it would throw out the same energy in all directions. It is not, as a matter of fact, done this way; but I would not like to go into that question.

Even more striking than the damage to buildings is the great number of casualties. Very few people were in shelters, because there was evidently no large bomber raid. Virtually all the people in the streets within almost a mile were instantly and seriously burned by the great heat of the bomb. These burns covered all the exposed flesh, sometimes even clothing caught fire and burned the wearer fatally.

I remember seeing one man, a patient, who had worn a railway worker's uniform. This uniform, in Japan, is a dark serge with an insigne to designate his grade. This man wore, as insigne, a kind of a cross-shaped emblem over the left breast.

His whole body was burned very badly and blackened, with the exception of the region under this cross. That was because the white clothing passed the heat somewhat less than the dark clothing did. The dark clothing absorbed the heat and caught fire and burned him. Of course, the white clothing would ordinarily not do this.

There were reported to me some people who had even been wearing striped clothing upon whom they found the body had been burned in stripes. I did not see that.

People inside buildings were not burned by the flash, but were for the most part killed or seriously injured by falling walls and beams. Caught in the wreckage of their homes, many were burned to death by the secondary fires. Those fires resulted from combustion material set ablaze after hundreds of stoves had been overturned; this was in addition to the fires started by the bomb itself.

Of these people within a thousand yards of the blast, about one in every house or two—perhaps 5 or 10 percent—escaped death from blast or from burn. By chance these people were screened from the heat of the bomb by some object too light or too strong to kill them by falling upon them. Many literally crawled out of the wreck of their homes relatively uninjured. But they died anyway. They died from a further effect, the effects of radiumlike rays emitted in great number from the bomb at the instant of the explosion. This radiation affects the blood-forming tissues in the bone marrow, and the whole function of the blood is impaired. The blood does not coagulate, but oozes in many spots through the unbroken skin, and internally seeps into the cavities of the body.

The CHAIRMAN. Would there be a third-degree burn?

Dr. MORRISON. No; not from radiation; no burns at all. There were some dramatic cases of people who were protected from the burns—

The CHAIRMAN. You mean the skin would be absolutely normal and yet the blood would be coming through?

Dr. MORRISON. Yes. There might be a slight burn on the skin, but it was not essential.

The white corpuscles which fight infection disappear. Infection prospers and the patient dies, usually 2 or 3 weeks after the exposure. I am not a medical man, but like all nuclear physicists I have studied this disease a little. It is a hazard of our profession. With the atomic bomb, it became epidemic.

The facts and figures of this and other related effects of the atomic bomb are still under study, and remain for the time being classified information. I am not a medical expert in these matters, and I have tried to tell you only the things I have seen.

It goes without saying that, like most of the scientists of the project, I am completely convinced that another war cannot be allowed. A working and realistic domestic policy ought to be determined on the premise that some measure of international control of atomic energy will come and come immediately, based on functioning, material agreements among the great and the smaller powers. We have a chance to build a working peace on the novelty and the terror of the atomic bomb.

But I should not be a physicist if I left you with the impression that only in war a revolution has been made by the large-scale release of atomic energy. Man will not live the same again for this advance. I do not think you will soon see atomic automobiles, though you may soon see atomic rockets and atomic power plants. But the changes which will come are sure, and great, and beyond prediction. When science learned to control mechanical and thermal energy, we had the early nineteenth century maturing of the industrial way of life. When science learned control over electrical energy, we had the manifold changes which electricity has brought to daily life and to the structure of nations. When the chemists understood the nature of chemical energy, there was opened the way to new materials, to freedom from the restrictions of mine and farm, to the changes which chemistry is even today still bringing us. Now we have nuclear energy, based on a more profound insight into and control over the fundamental nature of matter itself. We have seen war change only 6 years after the key laboratory discovery in this realm. We physicists are professionals in change and in novelty. That new times will come is our firmest conclusion.

Senator HART. Mr. Chairman.

The CHAIRMAN. Senator Hart.

Senator HART. Doctor, when you compared in your statement an attack by 1,000 B-29's and one B-29, you said there was a great qualitative change in the destruction. Then you followed with your observations on Hiroshima, and about the only thing you said to support that statement was about the damage done by the gamma rays.

We had been led to believe from other testimony that when the bomb explodes well off the earth, as was the case there, that the gamma rays' damage is a very small proportion of the total damage.

Dr. MORRISON. I think I detected two questions in your question. Would you mind if I separated them and tried to answer as I see them, separately?

Senator HART. Yes, sir.

Dr. MORRISON. When you gradually increase something by simply piling on, by quantitative implementation, you come to a point where something new has occurred, and we have a qualitative change.

For instance, if you heat water, you heat it 1° at a time until it boils and there is still a quantitative change going on. But if you keep on heating, you get a qualitative change; it is no longer water, you have something new.

The reason I say that the bomb has made a qualitative change is the manner in which the atomic bomb works. Take the destruction of cities. When you use ordinary bombs to destroy a city, you do it with a great effort, all the resources of a nation.

With the atomic bomb, it is done, more or less, with the left hand. I mean, one bomb, one city.

The whole attitude has been changed. They are not talking about the destruction of one city at a time any more; the new strategy will have to deal with weapons of destruction which will make one city too small a target.

In the future, it will not be the case of a raid against Berlin or against Hiroshima or Nagasaki on separate days, but it will be against all of them on the same day.

Senator HART. It seems to me still that you are terming as qualitative a change which I consider a quantitative change.

Dr. MORRISON. Well, this is a question of philosophy. What I am implying is that, by the piling on quantitatively you have produced a new mode of action which is in nature qualitative.

As you know, you might say an army is a collection of, say, 1,000,000 men. But if you have a collection of 1,000,000 men into an army, you have something different from just a collection of 1,000,000 men. In the same way, when you have a collection of atomic bombs, you have something different, then, which becomes a qualitative difference, because there you have a chance to destroy whole nations.

Senator HART. Well, I will drop that, Doctor, although I still think you mean quantitative rather than qualitative.

Do I understand you to say that the gamma factor in your explosion is not a material part, that mostly it is blast and heat?

Dr. MORRISON. This is correct.

Senator HART. Is that correct?

Dr. MORRISON. This is correct. The gamma radiation is a part of it, or could be; it all depends upon how the bomb is used, as I said. The way the bomb would be normally used, I do not think that the gamma rays would be material.

Of course, I do not know what the statistics are. In the case of Japan, under the conditions that existed there, there are simply no records, no officials, men familiar with the town who could tell us exactly what happened.

It is known that in Hiroshima 40,000 people came into the town the day before the bomb was dropped, to help evacuate it, because the town was on the list, and they felt it would be attacked and they wanted to evacuate it.

They had started work at 7 o'clock in the morning, they were still moving shops and furniture and the contents of warehouses, and so forth, and they were killed by the bomb.

However, no census taker, no statistician, is able to say how many people were killed in that explosion. It is my impression, gained as I walked through the city and the hospitals and talked to the men, that there was one man who escaped immediate death out of every one or two houses that were destroyed. There was always someone who, by chance, escaped the building falling on him and killing him, who, by chance, escaped the burns, even from the direct heat or through the fires that raged throughout the district. There were people who

walked away more or less unharmed, by chance—and even these did not escape death in the end.

Senator HART. Doctor, in the latter part of your statement, when you went into the political field, I believe you used the words that something must immediately be accomplished in our international relations so that atomic bombs would not be used.

What is your thinking around that word “immediately”? Is that altogether a theoretical idea, or have you some practical ideas about that?

Dr. MORRISON. I think, for example, that the implementation of the Three-Power Declaration, if it comes in the near future and if it is extended, will be an immediate step in the right direction.

I did not mean that the problem would be solved immediately; I mean that we should act at once. The reason I think that is this: that one of the great advantages that we have with regard to the control of this decisive weapon which does not adhere to any other weapon is that it is something new.

It is something which is not all over the world. There are no great industries connected with it, it is not filled with a tradition of continuity, it does not have a tradition of money or economics—those interests do not enter into it. There is none of this.

I think that if we catch hold of this opportunity and soon begin control, you will find it to be a much easier situation to handle than if we sit around 1 year, 3 years, 7 years, 10 years, making no progress. Then, when it has come to a full-fledged realization, by that time there will be greater difficulty. It will be widespread; there will be money in it; there will be great industries, and the economy of great regions may be dependent on it. It will be sizable, and it will be great, and it will be difficult to make such changes as should be made, because then, at that time, people will say that it is not practical.

Senator HART. I take it that you did not think that there was an immediate and complete solution practical. Let me ask you one thing.

Your statement has been about the power, the destructive power of the atomic bomb alone. In your thinking, do you place that in a different category than, for instance, an entirely merciless bacteriological form of warfare?

Dr. MORRISON. Yes, sir; I do.

Senator HART. Why?

Dr. MORRISON. I am not a bacteriologist, and perhaps I am wrong, but I have been in Washington on military affairs and on these matters I have spoken to people that know—

The CHAIRMAN. I defer to your greater knowledge, Senator, about the propriety of an open session to a discussion of bacteriological warfare.

Senator HART. I am merely asking a general question. If he is going into anything that he ought not to go into, I will withdraw the question.

The CHAIRMAN. You are acquainted with that?

Dr. MORRISON. Yes, sir; I will not discuss it.

The CHAIRMAN. I just wanted to caution you.

Dr. MORRISON. Yes, sir; thank you very much. I simply wanted to say that the absence of successful bacteriological warfare is not a statement that people do not think about it.

Senator HARR. Well, you do; and you do not put it in a different category, as a political matter looking forward to the protection of the world?

Dr. MORRISON. I do put it in a very different category, because it does not exist.

Senator HICKENLOOPER. Would you care to answer my question of a little while ago now, of a bomb set off 100 feet in the air? Will it burn better than a bomb set off 1,500 feet in the air?

Dr. MORRISON. A little further away, because, at a given distance, you are a little closer to the bomb. In other words, if you are right below the bomb and it is 1,000 feet above, you are 1,000 feet away.

Senator HICKENLOOPER. I understand that, but I wondered if the radiation would be conducted along the air or whether it might be dissipated in the air.

Dr. MORRISON. I don't think so; it might be. The reflected heat from the ground might have a small initial effect, but not serious.

Senator HICKENLOOPER. It is all hot enough?

Dr. MORRISON. Yes, sir. In New Mexico, where it did touch the ground, the ground is covered with glass for about 1,000 feet.

Senator MILLIKIN. Mr. Chairman.

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. What would be the effect if the bomb exploded in the ground, in terms of radiation, blast, and heat?

Dr. MORRISON. If it exploded at or near the surface of the ground it would be very much the same as high in the air, with the difference that the people would be closer to it and the difference that the radioactive material would then probably be left on the ground in large amounts; and, perhaps, with the other difference that the ground, perhaps, would be glazed and might be untenable for a very long time to come.

If you also wanted to include a situation where it was very far below the earth, 50 or 100 or 500 feet below, then it is clear that the situation would be very much changed here. I don't like to go into detail, but I would say this. It would simply produce not an air blast but an earth blast, a ground shake. There is no doubt but that it would have great military importance. I would rather not discuss it.

Senator MILLIKIN. How would you protect rescue workers and other relief forces that necessarily would have to operate in an area where the bomb had exploded in the ground?

Dr. MORRISON. I would keep them out.

Senator MILLIKIN. Well, there are essential functions, in any large city especially, that have to keep going—rescue functions and utilities and things of that kind—that, unless there was complete destruction, unless there was a determination that this area be forever abandoned, you have got to keep going.

I am curious as to how you would protect people that would have to work in the area as best they could.

Dr. MORRISON. I hope we don't have to face these problems. I would say simply that I imagine they should run in and out quickly, there would be a fringe where they could do that. There would be another fringe where they might send volunteers to do dangerous things, using tanks, and there would be a central region which they could just abandon.

Senator MILLIKIN. Suppose they had to go in, what sort of protective material would you clothe those people with?

Dr. MORRISON. Oh, you would need 50 tons of lead.

Senator MILLIKIN. Lead. I don't want you to think I am fanatic on the subject of lead.

Senator HART. Where is lead mined?

[Laughter.]

Senator MILLIKIN. Coming from the West, we are interested in those things. I want to know about what might be used in a defensive way. I quite agree with you that in most instances, for these stationary objects, for instance, it would be cheaper to get insulation from other materials. Then, you could close in the work with thicknesses of concrete or other materials, but if you have moving objects, people or appliances, perhaps, I take it that you will agree with me that lead and possibly other metals would make a good insulating material.

Dr. MORRISON. I do not want to give you the impression—it is quite wrong, but it is very easy to do it—that it depends on the material. There is really no specific material. It depends on the weight of the material you use.

If you could dress a man in a suit weighing 50 tons of lead or any other material, I don't care what the material might be, you could do that.

Senator MILLIKIN. You can't practically do that. You stated that you could surround it or him with a wall of concrete.

Dr. MORRISON. Yes; or lead.

Senator MILLIKIN. And, of course, there are many places where you could not surround even a stationary object that way. You could not put a wall of concrete around it, due to its placement. From what I have read it seems to me that you do have protection already for the articles of clothing, like shoes and personal equipment of people who have to approach these radiation places, that they may be clothed with protective material.

Dr. MORRISON. No; that is really a misapprehension, Senator, if I may say so. It is not possible to gain any worth-while protection by the amount of material that a man can carry on his own body. It is not possible; you just can't do it.

Senator HICKENLOOPER. That would depend on the degree of contamination.

Dr. MORRISON. But the point is that a man cannot carry enough protection, he cannot increase his weight that much. Also, the time element enters into it; how soon it is after the explosion.

Senator HICKENLOOPER. It depends on whether you want to go into that area in 20 minutes or 2 days.

Dr. MORRISON. It depends on whether you want to go into it in 20 minutes or in 20 minutes and 10 seconds; and most people would rather wait 10 seconds rather than carry the tons of lead they would need for protection.

Senator MILLIKIN. It comes from the degree of harmful radiation that remains, does it not. It loses its strength as time passes, does it not?

Dr. MORRISON. Yes; it does.

Senator MILLIKIN. Therefore, you have a decrease there in terms of time of radiation and, perhaps, some sort of protective material which

might be utterly useless at the moment might be useful a week or two or 10 days from the explosion.

Dr. MORRISON. That is true; but it is not true that anything that a man can carry around will give protection worthy of being called protection.

Senator MILLIKIN. That depends entirely upon the problem of when you have to go into the area. Sometimes you, of necessity, have to go into an area. You are postulating that it would be better to stay out. I suggest it might not be better to stay out. I suggest that it might be essential to get in there. Neither you nor I can sit here now and imagine the particular circumstance that will call for the decision, but I do suggest that there might be a circumstance which will call for a decision.

Dr. MORRISON. This is quite true. I am simply saying that if he must get in there, he will not get the protection with, say, 100 pounds of lead; he can with 10 tons. The additional amount, say about 100 pounds, that he can carry will not protect him sufficiently.

Senator MILLIKIN. That, again, follows that you can theoretically coat a tank with lead.

Dr. MORRISON. Exactly.

Senator MILLIKIN. And so there are circumstances, and one of them was demonstrated by coating the tank with lead. I am not mentioning lead, except that I have heard it mentioned in the press; but it could be coated with some sort of a protective material?

Dr. MORRISON. Yes, but the protective material which is worn on the body of a man is not adequate against radiation.

The only reason that existed for coating the shoes of these men who walked in later and for their wearing special clothing was this: It was simply clothing in the nature of overalls, so that they would not carry away on their person any of the contaminating material. It was not to give protection.

You can get protection from walls. You must use walls, and these walls will be much heavier than anything a man can carry. He could not carry enough to get a worth-while increase in protection.

Senator MILLIKIN. Then, you have a double problem. You have the problem of protecting the man himself against radiation, and you also have the problem of keeping him from carrying out the radiation; is that right?

Dr. MORRISON. That is right.

Senator MILLIKIN. And in the latter instance, there is a definite need for some sort of protective material to cover that man.

Dr. MORRISON. That simply calls for clothing that he can wear and then throw away.

Senator MILLIKIN. Yes.

Dr. MORRISON. That is all the protection you provide there.

The CHAIRMAN. Doctor, the bomb was dropped over Hiroshima at something of a height. That height, I presume, was chosen to get the greatest blast effect that could be gotten. You have testified that many, many people there were killed by the gamma rays. Would that result in a large deposit on the ground?

Dr. MORRISON. It did not.

The CHAIRMAN. It did not?

Dr. MORRISON. It did not. There was no physiological injury to any person in Hiroshima from material deposited on the ground. We did not find any indication of that.

The CHAIRMAN. In other words, the gamma rays went through the body and then were exhausted before they touched the ground; is that the idea?

Dr. MORRISON. Well, the idea is this: the gamma radiation is a ray. Once it is emitted, it is absorbed; that is the end of it. It is energy which turns into heat or chemical energy, or something of that sort.

Therefore, it will not last. It is emitted, and that is the end; it is absorbed.

The things that last are the atoms of new elements which have the property of destroying themselves, giving out radiations, rays, in the process.

Now, this is not true when the bomb is exploded on ground. But these bombs were exploded in the air and the radiation disappeared, the gamma radiation moved through the area and was absorbed.

Senator HICKENLOOPER. I have another question.

Doctor, I would like to have your opinion on this question: Do you think it reasonably possible—we know that it would be theoretically possible—do you think that it is reasonably possible that science will abandon the field of investigation into nuclear research?

Do you think that there can be any law or any other force in the world that can prevent the investigations of science to the fullest possible extent in this new field?

Dr. MORRISON. I do not think that it is in the tradition of science that this has ever been done. Therefore, to secure such a result is evidently a problem of extreme difficulty.

Senator HICKENLOOPER. Science has never abandoned a field of investigation once it has been opened up?

Dr. MORRISON. I think in recent years it is quite right; in the last few hundred years, it has never been done.

Senator MILLIKIN. I mean in a field as successful as has been indicated here.

Dr. MORRISON. I don't know about the future. I hope it will not. I hope in the future they will bring forth new things, in peace as they have done in war.

Senator MILLIKIN. Won't science and education keep searching for more and more light on this subject, and more and more knowledge?

Dr. MORRISON. I believe that will be the case.

Senator MILLIKIN. Isn't that almost inevitable; I mean, isn't that the human inevitability?

Dr. MORRISON. I think on this question you probably have more experience than I.

Senator MILLIKIN. No, I am not a scientist.

Dr. MORRISON. No, but you are a man who knows how people act and organize themselves into states.

Senator MILLIKIN. It seems apparent to me that once there is an area where scientists have discovered something profitable and opened up a further field of investigation, that they will pursue that, the investigation, into natural laws. It never has been abandoned; that is, no major field of investigation of that kind has ever been abandoned because of the ultimate purpose or the ultimate results.

Dr. MORRISON. I believe that is true. I am not saying that you cannot destroy investigation, that it cannot be abandoned, if you insist upon it. I am saying simply that it has never been done.

Senator JOHNSON. Mr. Chairman.

The CHAIRMAN. Senator Johnson.

Senator JOHNSON. I should like to say to the witness, to Mr. Morrison, that he is the most eloquent witness that I have ever heard since I have been around Congress. I am sure that his power of description must be the envy of all reporters here present. I know it is the envy of all the Senators here.

I deem this paper that he has submitted to us a classic in direct statement, and I shall preserve it and I shall use it.

He has made an almost unanswerable argument against TNT, for one thing, and I think he has made some arguments that no military man can escape—much as our military high command are trying to escape, I don't see how they are going to escape the argument he is making.

In listing the choices of death, he tells us that the victims of the bomb had a good many choices. They might be killed by falling brick, or they might be burned to death by the direct blast, or they might be burned to death by secondary fires, and if they escaped all of them, the death ray would probably get them.

I want to ask him about the absence of oxygen caused by this tremendous blast and the wind that he has described, the vacuums, and all. Was it possible for persons to have suffocated for lack of oxygen, and were secondary fires handicapped by a lack of oxygen in the immediate region?

Dr. MORRISON. I do not believe so.

Senator JOHNSON. There is plenty of oxygen left after the wind has sucked them out?

Dr. MORRISON. You see, after the blast has passed you for 10 seconds, then everything is back to normal again. Presumably, if you are still in one piece under all these other conditions, you can presumably do without oxygen for 10 seconds. You cannot do without your head for 10 seconds; that is the trouble.

Senator JOHNSON. You cannot do without that at all, but the interval of the absence of oxygen would be very small?

Dr. MORRISON. Very small.

Senator JOHNSON. Ten seconds?

Dr. MORRISON. Much less, but I said 10 seconds is evidently not serious. I said that because I am sure of that figure. I know it is much less by a factor of a hundred or more.

Senator JOHNSON. So suffocation was not one of the choices?

Dr. MORRISON. Except by having things fall on you and bury you, which was not a very common cause.

The CHAIRMAN. Doctor, have you read General Arnold's report?

Dr. MORRISON. I have.

The CHAIRMAN. Did you by any chance read General Spaatz' story?

Dr. MORRISON. I read that in the train coming to Washington, sir, and was greatly impressed by it.

The CHAIRMAN. Do you think that that portrays what a future war would be?

Dr. MORRISON. I hope that it does not portray what the future circumstances of the world will be. I believe it portrays correctly, perhaps with a natural conservatism on the part of a general, what a future war would be if engaged in by the powers.

Senator JOHNSON. I have one more question, Mr. Chairman.

The CHAIRMAN. Senator Johnson.

Senator JOHNSON. I was intrigued by this statement: "I do not think you will soon see atomic automobiles, though you may see atomic rockets and atomic power plants."

Now, the atomic rocket is the thing I wanted to ask you about. My understanding is that up to the present time this atomic energy that we have is either a tremendous explosion, or else it exists in a minute sort of way. In other words, we either have a terrific explosion, or the atoms split very casually, one at a time, and nothing happens.

Is there any way of controlling that explosion so that you can use it for a continuous flight of a rocket?

Dr. MORRISON. I should like to answer that question, but not in the most direct way you asked it.

I would not like to say you could control the explosion, because that is contradictory. Before we could make a bomb, we had to learn to produce a controlled nuclear reaction. It was not a controlled explosion. I don't know what a controlled explosion means, but it was the release of energy at a uniform rate under conditions where it could be turned on and off. In fact, the great plant at Hanford is exactly this sort of thing.

Senator JOHNSON. But you cannot use the great pile at Hanford in a rocket bomb.

Dr. MORRISON. That is quite right, but you can make smaller piles.

Senator JOHNSON. Small enough to drive a rocket and still small enough to be carried by a rocket?

Dr. MORRISON. I believe so, but I don't think I can go into any more detail.

Senator JOHNSON. It looks to me as if it is the same question of lead pants you were discussing with Senator Milliken a while ago; that your pile would be so heavy that the rocket couldn't travel, that the energy it produced would be less than its weight.

Dr. MORRISON. But who is riding on the rockets, Senator? If there are no people nearby, no crew, you do not need a very heavy shield.

The CHAIRMAN. Senator, isn't that perhaps getting into classified information?

Senator JOHNSON. I think that is as fantastic as Buck Rogers, and I just wanted to challenge the witness on his statement here that we may see atomic rockets. I think that is a statement that ought to be challenged, and I challenge it.

Dr. MORRISON. I certainly will not engage in the manufacture of atomic rockets, because I see no use for them except in war; but I think it is a natural development of the thing we have been working on, and that such a thing could be produced.

Senator MILLIKIN. Mr. Chairman, I would like to ask the witness what he has done in the laboratory to prepare atmosphere so that it may become highly inflammable.

The CHAIRMAN. Isn't that classified?

It looks as though the chairman is getting security conscious.

Dr. MORRISON. These matters were discussed by Dr. Bethe yesterday, I believe.

The CHAIRMAN. Doctor, you have thought a great deal about the future of our defense, I presume?

Dr. MORRISON. Yes.

The CHAIRMAN. What relation has a 10,000,000-man army, every one of them able to shoot the eye out of a squirrel at a thousand yards, every one of them able to salute and come to attention and say, "Yes, sir" and "No, sir"—what relation has that in your mind to the ability or the power compressed in these bombs as a matter of defense?

Dr. MORRISON. Do you really want me to answer that question?

The CHAIRMAN. Yes; I don't know why it shouldn't be answered. It is something that I have thought about a good deal.

Dr. MORRISON. Well, I can say these things.

The CHAIRMAN. Unless you think it is classified information.

Dr. MORRISON. No; I think it is controversial discussion on a subject on which I have no special competence.

The CHAIRMAN. I ask it of you on the theory that has been so often quoted by Clemenceau, who said that war was too important to leave to the generals, with which I am in thorough accord.

Now, on that basis, as one amateur talking to another, tell me what the relation is as you have thought about it.

Dr. MORRISON. I am still working for the War Department. [Laughter.]

The CHAIRMAN. Let the responsibility be mine.

Dr. MORRISON. Let me say that if you have, as you will have in a future war, 1,000 or 5,000 long-range rockets striking our industrial areas, each one loaded with enough atomic explosive to destroy any city district, that is, the central part of Washington, lower Manhattan, or any small city of three or four hundred thousand, you will have an enormous installation which will perhaps intercept half of these, or seven-tenths of them, or something of that sort; but you will lose, as I think has been said before, something like one-third of your population in the first day of the war.

I do not know; I do not like to think about prosecuting a war under these circumstances, and that is why I want to stop there.

How the war would progress after that is a question I hope we will never have to answer. It is clear to me that against such an attack a conventional army is of no value; whether it is of no value in the further prosecution of the war is something I do not know about.

The CHAIRMAN. I assume we have a navy in order to defend the country. I was questioning myself last night and asked, "What good is a navy if you haven't got a country to defend?"

Dr. MORRISON. You are going to always have a navy to defend, Senator. [Laughter.]

The CHAIRMAN. I think I will let that one lie right where it is.

Has anyone else any questions?

Senator HICKENLOOPER. Not unless you want to explore that field a little more. It is a rather interesting field.

The CHAIRMAN. It is; I will let you go forward with it. That last one stopped me, Senator, and in fact I think the whole argument was made in the one sentence.

Senator HICKENLOOPER. I am sorry, Mr. Chairman, but I was engrossed in a maze of figures here so I missed the doctor's argument on this number of men, and so on.

I realize that you are a physicist and not a professional soldier—

Dr. MORRISON. Thank God.

Senator HICKENLOOPER. But let us assume that the United States, or any country, elected to use the atomic bomb, having a sufficient stock of them for either offense or defense.

Roughly, if you have any opinion, about how many people do you think we would need efficiently trained to use that weapon successfully, either in offense or defense?

Dr. MORRISON. I am not quite sure how you successfully use it in defense.

Senator HICKENLOOPER. I realize that the fellow who hits first has a tremendous advantage in this thing.

Let us suppose that we are going to use the bomb and want to use it efficiently, that is, to kill the most people and do the most damage to our enemy.

Dr. MORRISON. Well, let me try to make a guess. I have not thought about this question, and it is useful to think about only to show how expensive the whole proposition will be, I hope.

These bombs will cost, as Dr. Oppenheimer said a couple of times—and I may quote him without any violation of security—in the order of \$1,000,000 apiece.

I think to launch them in some fancy and complicated missile, like a super V-2, would probably not be practical unless the V-2 itself cost only 10 times as much as the bomb, as in the case of the airplane in relation to its bomb load.

Let us say it cost \$10,000,000 to launch an atomic missile. Now, if you have to do this in the number of thousands, and were spending around 10 or 20 billion dollars, you probably have an equal sum for all the administrative and communication problems, so that you will spend in the order of \$50,000,000,000. You can transfer that into the number of people who have to be employed in the enterprise as well as I.

Senator HICKENLOOPER. Could you give an opinion on this? Could we successfully conduct an atomic war, just using some very rough figures now, with, say, a well-trained military land force—let's leave the Navy out of it—of a million men as easily as we could with a trained force of 10 million men on land?

Dr. MORRISON. I really do not know. I would prefer not to discuss those questions.

Senator HICKENLOOPER. Well, my point is as to whether or not 10,000,000 foot soldiers would contribute anything more to the launching of an atomic attack than 1,000,000 foot soldiers, for instance, or whether the 9,000,000 would be surplus?

Dr. MORRISON. I think not one foot soldier will contribute to the launching of an attack, but there are other things to do. I do not want to discuss what other things may be done.

I think that you can see what our point of view is, namely, that to launch an atomic attack you need people to press buttons and make instruments. What else you need is not my province to discuss.

Senator HICKENLOOPER. In other words, I was trying to develop the point whether you believe marching armies would contribute very

much to the effectiveness of the atomic bomb from our standpoint, or whether it is purely or almost exclusively a scientific and engineering problem confining itself to the construction of the materials and the launching of the ships—with the trained personnel, of course.

Dr. MORRISON. I think that the impact of war will be so great in the first day that I do not know what will happen thereafter.

Senator RUSSELL. Mr. Chairman, I regret I was a bit late. I wonder if the doctor has discussed the range of these rockets and these missiles, and whether he thinks there is any limitation on the distances that they can traverse with accuracy.

Dr. MORRISON. I know nothing about rockets or missiles from my own experience. If the Germans were able to make a rocket under their conditions that will travel 300 miles and hit within a couple of miles, if they were able to do that under circumstances in which they could not develop weapons like we were able to develop, such as the atomic bomb, I do not doubt that 10 times this range and equal accuracy is attainable.

I do not know of my own experience, but it seems to me common sense that progress in this range will be made. There is certainly no new physical fact involved, but detailed engineering study.

General Spaatz and General Arnold have spoken about these things and must have received information that these things are practical. I myself see nothing against them.

The CHAIRMAN. Are there any further questions?

Thank you very much, Dr. Morrison.

Senator MILLIKIN. I would like to add my appreciation to that of Senator Johnson of the very graphic and informative descriptions you gave us of the conditions at Hiroshima.

The CHAIRMAN. Dr. Goudsmit.

**STATEMENT OF DR. S. A. GOUDSMIT, PROFESSOR OF PHYSICS,
UNIVERSITY OF MICHIGAN**

The CHAIRMAN. Dr. Goudsmit, have you a prepared statement?

Dr. GOUDSMIT. I have no prepared statement with me, but I may have one later.

I wish to point out first of all that my connection with the atomic bomb is quite different from that of the previous witnesses. I have not worked on the project at all, except in intelligence functions.

I was connected with the War Department mission which was sent overseas in order to find out what the German progress was along the project of the atomic bomb, and that was what we have done, and that is the information which I can give you.

Also, because of that function, I may have a few suggestions which might be useful, even though they are one-sided suggestions, as to control and supervision.

In spite of certain preliminary newspaper reports, we can say that the Germans did not have anything at all. They were way behind. They just did not have the vision which the Allied scientists had, I believe.

I have put down a few points about the German progress.

The German scientists had abandoned the hope of making a bomb during this war, entirely. They used the idea of the bomb to sell it to the Government and to the military officials.

Another point is that as a result they concentrated their efforts on the production of atomic energy, and all the work done was nothing else but trying to build what is called over here a pile, a uranium machine. That is all they worked on, and they had not even succeeded in constructing a pile. They had not a working uranium machine.

At the end of the war they had done just enough experimentation so that they were certain that it could be done, but they had not done it. They had not produced a chain reaction. They had not a uranium machine which they had hoped for.

The total effort expended by the Germans on the project was rather small, but it was among the scientific projects the one of the highest priority; still it was very small compared to our effort.

Senator JOHNSON. In your investigation of the German effort, did you have access to all of the efforts of Germany? Press reports have inferred, or at least I have understood from them, that certain German efforts had been taken over by the Russians, and that such plants as they took over were not open to inspection.

Now, did you have access to all the plants in Germany, and when you speak of what the Germans did, are you speaking of everything that the Germans did in the Russian-occupied zone as well as in the American-occupied zone?

Dr. GOUDSMIT. I speak with confidence of everything the Germans did on the atomic bomb project. I am certain that I have inspected all the papers and have talked to all the key men on the project, and have seen all the documents and most of the laboratories have been visited by me or by men who worked in connection with me.

Senator JOHNSON. In the Russian-occupied as well as in the American- and British-occupied zones? Have you visited any Russian-occupied laboratories?

Dr. GOUDSMIT. I think that is classified information.

Senator JOHNSON. You cannot testify on that?

Dr. GOUDSMIT. I cannot testify in open session as to that.

The remarkable thing about the Germans is that all the time they believed that they were ahead of our effort along those lines. Not until the news broke that the atomic bomb had been dropped did they realize that they were not ahead, but that they were behind. They were absolutely convinced that their work was ahead of ours.

They had no knowledge of our project, none whatsoever, except a few incorrect statements from their intelligence department, and some rumors which they did not take seriously. There was, in 1943, a rumor that in America scientists were working on an atomic bomb, but all details were lacking, and so it was not taken seriously. It was merely used as a means to have the authorities give more help, more men, more space for the laboratories. That was all they used it for.

Senator RUSSELL. You state that their work was very narrow in scope. Do you gather from this that it had not gotten beyond the laboratory stage?

Dr. GOUDSMIT. It had not gotten beyond the laboratory stage.

Senator MILLIKIN. They did not even have a pilot plant?

Dr. GOUDSMIT. They did not have even a pilot plant. The reason for the lack of progress in Germany, as I see it, can be again put down in a number of points.

For instance, as I mentioned before, the German scientists seem to have lacked the vision. They did not believe in its success from the very beginning. They knew its importance, and were convinced that the project was important; but they did not believe that it could be done within a reasonable time, 50 to 100 years.

The CHAIRMAN. Goebbels was talking all the time about a secret weapon. Do you think he had in mind, when he said that, the possibility of the development in German laboratories of this thing?

Dr. Goudsmit. He had knowledge of that, and some of the higher officials in Germany, who were utterly incompetent, may have believed that an atomic bomb was possible within a short time.

Senator JOHNSON. Hitler made many statements that he was going to bring the whole world down with him if he fell; in the light of the atomic bomb, it might seem that he had that in mind. Do you think he had that in mind, or was that pure bluff?

Dr. Goudsmit. It was pure bluff. They had it in mind, however. For instance, near the end of the war, when the Germans had made a preliminary success, they had really discovered by their experimentation that it might be possible to make a uranium machine.

Himmler's SS men went around and spread the rumor that very soon the Germans were going to use a uranium bomb, scaring the scientists who knew they were 50 or a hundred years away from such a goal.

Other reasons why the Germans did not make any real progress were probably, as I mentioned before, that the key men in administrative positions were utterly incompetent. For instance, Army Ordnance had as its chief adviser on military matters a second-rate physicist named Schumann, like the musician Schumann. In fact, his main interest was the physics of piano strings. He even rose to be the chief adviser of all the German armed forces after a while. That man was the first one who started the project for the German Army. He was the first one who went to France and tried to get the French development out of the hands of the French, and tried to move the French cyclotron, later deciding not to destroy it but to make it work, and sent some Germans down to put it in order and make it work.

That man had a small project going on in one of the Army proving grounds near Berlin, and the scientists he had working with him were definitely inferior compared with the scientists which were available in Germany for such a project; so there was one group working.

There was another group working in the so-called Kaiser-Wilhelm Institute for Physics, where a group of competent scientists by themselves had been working on this project trying to make a pile. Those two groups were always in competition with each other, instead of trying to cooperate with each other.

There were other men who had heard that nuclear physics was important. They tried to convince some other branch of the Government to give them money. They preferred the Air Forces, because in Germany the Air Forces had a lot of money. It was the only organization which was able to support research on a large and lavish scale, so some of them succeeded in talking the Air Forces into the fact that nuclear physics is important, that they should be given money for high tension apparatus, for laboratory equipment, and so on.

Again another man, a great technician and a good businessman, talked the Minister of Post and Telegraph into supporting him. He

had discovered that the Research Department of the Post and Telegraph Services in Germany had a lot of money which was not being used, and that they had research facilities; so he talked him into supporting a project along those lines.

It is clearly understandable that in such a way they could not go very far. It was only later in the history, after the war went badly, that the thing was better coordinated and that one man was put at the head of the whole organization, a competent scientist. He tried to bring some sense into the organization and diminish the competition and make it into cooperation, but that was too late. That was around 1943. I don't know exactly which month it was, but it is in the record somewhere.

Senator RUSSELL. Doctor Goudsmit, you of course are familiar with the Smyth report?

Dr. GOUDSMIT. Yes, sir.

Senator RUSSELL. From your investigations in Germany, do you think that they had knowledge of practically all or all of the facts that are set forth in that report?

Dr. GOUDSMIT. No; definitely not.

Senator RUSSELL. You don't think they knew as much as was contained in the Smyth report?

Dr. GOUDSMIT. They did not know as much as was contained in the Smyth report.

I must modify that statement a little bit. They might have known it, but they did not give the proper importance to the various pieces of knowledge they had. They could have known certain things, and could have thought of the use of plutonium, but it simply did not enter their minds.

One man mentioned it at one time in a short report of his, but it was not taken seriously. I should say the knowledge was there, they could have known it, but they did not grasp the right points in order to further the development.

Senator RUSSELL. Other witnesses have indicated that scientists in Germany, as well in other countries, have for some time had knowledge of the matters and statements in the Smyth report.

Dr. GOUDSMIT. There is indeed, as I say, the possibility that the facts were known; but knowing the facts is not sufficient, definitely not. Knowing that one can make plutonium, which is obvious to any scientist and was in 1939, would not be important; but the German scientists did not go further than that and see in it a realizable possibility of making an atomic bomb, which is something quite different.

Senator MILLIKIN. Did you find any evidence that the Germans had coordinated their individual knowledge and their group knowledge of the subject?

Dr. GOUDSMIT. Yes. They had free exchange of information in the form of reports among the various groups which worked on it. There was no compartmentalization.

Senator MILLIKIN. Then did any group or any top coordinating agency pull this altogether into some sort of definitive statement?

Dr. GOUDSMIT. No.

Senator MILLIKIN. That was not done?

Dr. GOUDSMIT. No; it was simply done in the form of secret publications.

Senator MILLIKIN. In other words, a number of groups of scientists were sort of going along, each one on its own route?

Dr. GOUDSMIT. Yes, sir.

Senator MILLIKIN. They were not working under over-all direction?

Dr. GOUDSMIT. Not until the very end, which was much too late, was there a little bit of coordination, and only a very little.

The CHAIRMAN. Doctor, you tell us that work had not gotten along very far. Now, we didn't know that until after the war, until you could get in there and make an evaluation.

You say that the Germans didn't know much about our situation, and had not learned it. Our information about them was just as poor as theirs about us?

Dr. GOUDSMIT. Yes.

The CHAIRMAN. I can recollect that General Marshall stated that they were in a race with us. That must have been based upon the G-2 reports before the end of the war.

General Eisenhower said, I believe in April, as I recollect it, that barring the bringing into effect of a new weapon, he felt that the war would be over in the spring.

I don't know whether you remember that declaration or not. The fact of the matter is that our intelligence overestimated what they were doing entirely, didn't they?

Dr. GOUDSMIT. It was known. This mission did not wait until the war was over. We have been overseas for quite awhile, and followed the armies.

The first concrete information which was turned over to the War Department, and which definitely indicated that there was no German effort along those lines, complete proof, in fact, occurred in the late winter of '44, around December of '44.

We were absolutely certain that the Germans did not have anything like an atomic bomb.

The CHAIRMAN. So when General Marshall talked about a race, it was the turtle and the hare.

Senator JOHNSON. Were the German scientists and the German efforts handicapped by Hitler's policy of persecution, which included top-notch physicists and scientists as well as other persons?

Dr. GOUDSMIT. They were seriously handicapped by the lack of prestige which science has in Germany. The scientists themselves had gotten together in an informal society, the Uranium Society, just before the war. They had taken it seriously, and had even sent over two of the top scientists to this country to find out what we were doing just before the war started in the summer of 1939.

When the war broke out, all German scientists were drafted. One of the top scientists was a corporal for a while, and stated that his Army experience was like the usual mountaineering, only made difficult by the presence of sergeants. That was the only thing, but the rest was just a mountaineering trip in the Alps.

But pretty soon the key scientists were taken out of the Army and put back in the laboratories; but the bulk of the German scientists remained in the Army for several years, 2 to 3 years. Several were killed in action as soldiers.

Only when the war went bad, especially after the U-boat war went bad, were scientists released from the armed forces and put back

on war work, which on the whole was not very successful, as I said, except for the Air Force.

Senator MILLIKIN. Prior to the war, were the German scientists regimented or were they free to pursue their own work in their own way?

Dr. GOUDSMIT. Also then did they suffer from the lack of prestige, and it was pointed out during the war by one of the key German scientists how German science had declined compared with science in America. He went around the country lecturing for various officials for the Air Forces, using statistics—some of the statistics he had obtained from American journals—to point out that Germany was rapidly declining in the fundamental sciences.

Senator MILLIKIN. What reasons did he attribute to that?

Dr. GOUDSMIT. He attributed it primarily to lack of support for science, to some extent to the loss of scientists because of persecution, and to a greater extent to the replacement of those scientists by incompetent party members instead of good scientists.

Senator JOHNSON. Did Hitler's policy of persecution reach into the scientific groups?

Dr. GOUDSMIT. Not directly, except insofar as several scientists had to leave the country, of course long before the war was started; but the replacement of those men by incompetent scientists was the greatest handicap.

Senator RUSSELL. Doctor Goudsmit, did your investigation indicate whether the rocket bombs or buzz bombs were developed by the Ordnance Corps of the German Army or by civilian scientists, or scientists who were not inducted into the Army?

Dr. GOUDSMIT. The rockets were mainly developed by excellent aeronautical engineers, who worked primarily for Army Ordnance.

Senator MILLIKIN. I thought you made a very interesting statement in recapitulating the reasons for the decline in German science when you said, in effect, that one of the reasons was that they were putting party hacks into positions of authority in science.

Is that not a danger that we must avoid as far as we can avoid it in any governmental agencies of that kind that we may set up in this country?

Dr. GOUDSMIT. Definitely.

Senator MILLIKIN. I will put it this way, that danger cannot be entirely avoided in any kind of a governmental set-up having to do with science. Would you go along with me on that?

Dr. GOUDSMIT. Certainly. We have, for instance, noticed that on this intelligence work, the reason it succeeded at all was I think due to the perfect cooperation between the Army organization and the scientists on these teams. It was really an ideal example of how such a thing can be set up.

The chief of the mission was Col. B. T. Pash, and he understood completely his responsibilities. He never questioned, for instance, the judgment of the scientists about any scientific matter. It was up to the scientists to decide which village in Germany was important; it was up to the scientists to investigate the papers to get all that information; it was up to the scientists to decide who was really an important scientist and who was just a man who had gotten his name in the newspapers.

The military never failed to get us to the places we wanted to go to, to find the man we wanted to find, to get the papers we wanted to read. They never questioned the judgment of the scientists on scientific matters, and that was an ideal cooperation. I think it should be made an example for cooperation not only in wartime, but also in peacetime.

I have been connected with other organizations where civilians and Army people have worked together, and I have been very fortunate that in all cases there was such ideal cooperation.

I was previously overseas for radar work, and there the mingling of the civilians with the Air Forces officials on radar was also really an ideal example of perfect cooperation. That should continue in peacetime.

Senator JOHNSON. I would like to ask Doctor Goudsmit to put something in the record of his personal and professional background.

I understand you are a native of Holland.

Dr. GOUDSMIT. Yes; I am.

Senator JOHNSON. And you are now a professor of physics at the University of Michigan.

Dr. GOUDSMIT. I have been there since 1927.

Senator JOHNSON. Are you a citizen of the United States?

Dr. GOUDSMIT. Yes, I am.

Senator JOHNSON. How long have you been in the United States?

Dr. GOUDSMIT. Since 1927, and I have been at the University of Michigan all that time, except that since the beginning of 1941 I have been on leave for war work.

Senator JOHNSON. How much experience in your profession did you have prior to coming to the United States?

Dr. GOUDSMIT. I had done research work in Holland and Germany and other countries of Europe, and when I came to the United States I was appointed on the faculty of the University of Michigan in 1927.

Senator JOHNSON. How much experience had you had in Europe prior to coming to the United States?

Dr. GOUDSMIT. I don't know how to measure it. - I had already published several papers in physics.

Senator JOHNSON. Had you taught in any university?

Dr. GOUDSMIT. Only as an assistant at the University of Amsterdam, and I had a Rockefeller fellowship in Germany and Denmark. I had mainly done research work, and very little teaching.

Senator MILLIKIN. What schools did you graduate from?

Dr. GOUDSMIT. I got my Ph. D. from the University of Leiden in Holland.

I would like to add a few words about the possibilities of control.

The experience we had in Germany shows clearly that some type of supervision or control is possible. I mentioned before that no knowledge of German development was available here. I can add to that by saying that the security of the Germans was inadequate. They used letterheads and envelopes which clearly stated "Nuclear Physics" on the outside. Nevertheless, we had no knowledge of the work at all over there. The allies did not know what was going on.

As soon as our mission got in touch with the first physicists, the first physics laboratory, the first correspondence and documents on physics which were available on the Continent, we obtained the com-

plete story. From that you see that if there could be free interchange of ideas among the scientists, if they could travel freely, if they were allowed to visit each other's laboratories, if that were possible, then as long as scientists are working or have to be used in work on an atomic bomb or anything of that nature, I don't believe that it can be kept secret. It would be known immediately to their colleagues all over the world without any doubt.

If, however, the art of making atomic bombs will progress so far that they do not need scientists any more, and it can be done by slave labor or prisoners, then of course control will be more difficult. But as long as scientists are needed in the building, construction, or research work on atomic bombs, it cannot be kept a secret from other scientists if they have free access to each other's papers, can talk with each other, can travel and go to meetings together.

Senator RUSSELL. I would like to ask one or two questions, Mr. Chairman.

Dr. Goudsmit, from your investigations in Germany as to the progress which has been made in their research, would you care to venture any opinion as to how long it would take any other country of the world to complete an atomic bomb or to advance to the stake where we are today?

Dr. GOUDSMIT. I can say that the Germans, at the rate at which they were going before they knew about the atomic bomb—

Senator RUSSELL. Of course that made a difference.

Dr. GOUDSMIT. That made an enormous difference, and it makes my estimate valueless. At that time it would have taken them a hundred years, they were going so slowly. You can see the progress in the research reports.

Senator RUSSELL. But you stated they didn't have any faith,

Dr. GOUDSMIT. Now they have.

Senator RUSSELL. But it is an entirely different situation today. The whole world knows the bomb can and has been created and used.

Dr. GOUDSMIT. Yes. Then my estimate must be the same as that of other scientists, and it just depends on getting the men together, getting the industry developed and organized, and I do not see why it should take them any longer than it took us.

Senator RUSSELL. We talked a great deal about rockets during the course of these hearings. Did you make any investigation into the development of the rocket in Germany?

Dr. GOUDSMIT. I did not make any investigation.

Senator RUSSELL. You dealt entirely with atomic energy?

Dr. GOUDSMIT. No; we had some other responsibilities on that mission.

Senator RUSSELL. In other words, you did not have any connection whatever with the investigation on rockets. What member of your group was dealing with the question of rockets?

Dr. GOUDSMIT. We left that entirely to the technical teams of the Army and Navy. There were so many teams over there picking up V-1's and V-2's that we thought our small group could safely stay away from it and leave it to technical teams.

Senator RUSSELL. I gather from that that you would prefer not to express any opinion as to the relative progress which has been made by the Germans and by this country in the development of the rocket as a weapon of war?

Dr. Goudsmit. As far as the large rockets are concerned, I do not think that our development went very far because we were not interested in those. As far as the smaller rockets are concerned, I was told by experts that we could not learn much from the German developments.

Senator Russell. I happened to be in the Hague this summer where the Germans launched a great many of these rockets against England, and if they didn't have better luck with them with atomic war-heads than with the bombs they used, it would be bad, because about every other one flew back. They had absolutely no sure sense of direction. About half of them landed in the surrounding countryside, and half over in England.

Unless progress is made in the rocket, it will be some time before any one tries to use rockets extensively with atomic war heads.

Senator Johnson. There is room for only one mistake with an atomic bomb.

The Chairman. Doctor, there has been some comment in the press about the fact that German scientists are finding employment in Russia. Would you care to comment on that?

Dr. Goudsmit. I think it is well known that certain German scientists are finding employment in Russia.

The Chairman. The obvious conclusion is that it will enhance their available resources of scientific development.

Dr. Goudsmit. Yes. I think similar German scientists in the French zone are working for the benefit of France, and in the British zone certain factories and laboratories may have been put back to work for British interests.

Senator Johnson. Is that true of America also?

Dr. Goudsmit. When I left, it was not well coordinated; but let us hope that it will be better coordinated by now.

The Chairman. Who is Dr. Otto Hahn?

Dr. Goudsmit. He is a German chemist who discovered fission, which is the basic process.

The Chairman. He has just been awarded the Nobel prize.

Dr. Goudsmit. Yes.

The Chairman. Where is he?

Dr. Goudsmit. I don't know where he is at the moment.

The Chairman. You don't think he will be at the Astor Hotel on Monday night when the Nobel prize dinner is held?

Dr. Goudsmit. No; I don't think so.

The Chairman. I am interested, for I am speaking there Monday night.

Are there any further questions?

Thank you very much indeed, Doctor. We appreciate your statement.

(The prepared statement submitted by Dr. Goudsmit reads as follows:)

FOREWORD

The opinions expressed in the following are entirely my own. These opinions represent my subjective reaction to information obtained abroad.

The facts quoted in the following account are derived from evidence collected in the European theater of operations in my function as scientific chief of the Alsos mission. This evidence consists primarily of documents, such as captured

79879-46-pt. 2-6

German secret research reports and administrative scientific correspondence. In addition, laboratories were inspected and several scientists interviewed.

State of atomic bomb research in Germany

The progress made by German scientists towards the construction of an atomic bomb was negligibly small. The state of affairs near the end of the war can be summarized as follows:

1. German scientists had abandoned hope of making a bomb for this war.
2. They concentrated their efforts on atomic energy production rather than on an explosive.
3. They had no yet succeeded in constructing a "pile" or self-supporting chain reaction.
4. The total effort expended on the atomic energy project was small, even though it had the highest priority.
5. German scientists had no knowledge of our work.
6. They believed that they were ahead of our developments in atomic energy.

REASONS FOR FAILURE

A careful study of the documents may reveal the causes of the complete German failure in this field. My opinion in this connection can be summarized in the following statements:

1. German scientists lacked the vision which the Allied scientists possess.
2. The Nazi Party and the German military placed incompetent scientists in key administrative positions.
3. Lack of coordination caused competition instead of cooperation among the various groups.
4. German scientists put into this field scarcely more effort than they would have into a peacetime research project, because they felt certain of their superiority.
5. German pure science had no support from nor contact with the military.
6. Allied bombing interfered with German progress.

HISTORY OF GERMAN ATOM BOMB RESEARCH

Early in 1939, as was done everywhere else, several German physicists called to the attention of the military and of other authorities the possibility of making a superexplosive as a result of the discovery of uranium fission. A group of physicists met and formed the Uranium Society (Uran Verein). This was originally an informal group, exchanging information among each other, but keeping such information from outsiders.

German nuclear physicists proceeded with their research independently. Army Ordnance had a scientific group under a second-rate physicist, Schumann, which started work on this problem. The best-qualified groups were the Kaiser-Wilhelm Institute for Physics in Berlin, under Heisenberg, and the physics section of the KWI for Medical Research in Heidelberg, under Bothe. Bothe, as well as Heisenberg, made a survey trip through the United States of America in the summer of 1939, just before the war started, obviously to find out what our plans were for the uranium bomb.

When the war broke out, scientists in Germany were immediately drafted into the Army, but a short while later the key men were deferred and returned to their laboratories. However, the bulk of the lesser academic scientists remained in the field (where several were killed in action), until about two or three years later when the military authorities finally agreed to release them for war work.

At the beginning of the war, each academic research group had to find its own sponsor. The German Air Forces had the best and most liberal set-up for research, and some nuclear physicists were fortunate enough to get support from them. A private scientist, Baron von Ardenne, a clever technician and businessman, got the Minister of Post and Telegraph, Ohnesorge, interested in his research. Ohnesorge was near to Hitler and kept the Fuehrer informed about the importance of the project. For awhile, Von Ardenne was considered by the German authorities to be the expert on the uranium problem, much to the dismay of the really competent scientists.

The various groups worked in competition with each other. The sabotage and bombing of the Norwegian heavy water plant had cut their supply so that it was barely enough for one group to make important experiments. As a result, disagreements arose concerning its use.

The bulk of German scientific research was under the Ministry of Education (Minister Rust). It was governed by a Research Council under an incompetent administrator and second-rate chemist named Rudolph Mentzel, a brigadier in Himmler's SS.

Early in 1942 the members of the Uranium Society thought it necessary to call the project to the attention of the highest members of Government and military organizations. A special secret meeting was called by Minister Rust and General Leeb, Chief of Army Ordnance, to which all top-ranking officials were invited. However, most of them declined or sent minor representatives. The program consisted of a number of talks and a scientific luncheon prepared with synthetic fats. The introductory talk was by Professor Schumann about Nuclear Physics as a Weapon. Then followed popular technical lectures by Hahn, Heisenberg, Bothe, and a few others, and finally a lecture by Professor Esau, Director of the German Bureau of Standards, on the Expansion of Nuclear Physics Research Through the Participation of Other Government and Industrial Departments. It is doubtful whether this meeting had any success.

A few months later, the Research Council was taken out of the Ministry of Education and, by "Hitler decree," placed under Goering. It was hoped that this change would bring research on other subjects up to the same high level as that of the air forces, but matters did not turn out that way. The incompetent Professor Mentzel remained the active head of the Research Council.

Professor Esau, of the Bureau of Standards, was put in charge of uranium research. Later, sometime in 1943, he was replaced by physicist Walther Gerlach, of the University of Munich, a really first-class experimental scientist and organizer. At the same time, Army Ordnance seemed to have gotten tired of this apparently hopeless research and turned the facilities and men over to the Research Council. Upon Gerlach's shoulders fell the difficult task of reconciling the two principal groups working on uranium—the Kaiser-Wilhelm Institutes and the former Ordnance Group.

In the meantime, Allied bombing had forced the scientists to evacuate their well-equipped laboratories in the cities and to seek shelter in rather primitive quarters in various small villages spread all over Germany.

In studying the Research Reports, one is, first of all, impressed with the slowness of the progress. At the beginning of 1945, most of the research was still in practically the same state as it had been in 1943. Isotope separation had been tried on a very small scale only by means of a centrifuge. It had been discovered that the Clusius method did not work. Research on several other methods had been dragging on for a few years without much progress.

Some of the key scientists worked only part time on this important research and the rest of the time did routine teaching or administrative work. The lack of proper large-scale facilities necessary for this kind of work was, of course, another reason for the lack of success.

At the slow pace at which they were progressing, it is obvious that German scientists did not believe a bomb would be constructed within the course of the war. They were confident that perhaps a uranium machine, or at least its basic principles, could be obtained within a reasonable length of time. It is remarkable, however, how incomplete their knowledge was. They were, according to their research reports, scarcely aware of some of the basic difficulties which they were likely to encounter in their efforts. Most surprising is the fact that not even their best scientists had given any thought to the use of plutonium.

Attempts were made to have German chemical industry produce heavy water because the Norwegian plant had been destroyed. However, not much progress was made with this plan either. Uranium metal was produced in quantities sufficient for small-scale experiments, and the stock of heavy water seemed to be just enough for that.

The effort was small, though it had the highest priority among all scientific research projects in Germany. The total expenditure was about 15,000,000 marks, which is perhaps equivalent to some \$10,000,000. The appropriation for 1944-45 was 3¼ million marks with a subsequent supplement of 1,000,000.

It is estimated that approximately 100 scientists were active on this project. They were divided into several rather small groups working on different phases of the problem and were spread all over Germany.

Security

Almost nothing was known about the German project before the invasion of continental Europe in spite of the fact that the security was not of a very high standard. Letterheads and envelopes were used which clearly indicated the

prominence given to nuclear physics, reading "The Marshal of the German Reich, President of the State Research Council, the Plenipotentiary for Nuclear Physics," or "The Plenipotentiary of the Reichsmarshal for Nuclear Physics," which gave Gerlach the nickname of "Reichsmarshal for Nuclear Physics." In draft deferment requests, the reason was clearly stated as "Working on Energy Production from Uranium." There were some weak protests against this lack of security but to no avail. However, this stationery was never used for correspondence with neutral countries. The locations to which the laboratories had been evacuated were kept very secret.

German scientists knew practically nothing about Allied developments, aside from what they picked up the summer of 1939. They received some utterly wrong and useless information from the German intelligence, information largely obtained from travelers or other unreliable sources. There was a rumor in 1943 that the German intelligence had information about atomic bomb-work being performed in the United States. This apparently was not taken seriously, as further details were lacking.

Results

Toward the end of the war, the German experiments had indicated that it was possible to obtain an increase in the number of neutrons, but no self-sustaining neutron source had been constructed as yet. The German scientists considered this achievement of great importance. They were convinced that they were far ahead of the Allies. They believed that this success might play an important role in the settlement of the peace terms, for they understood correctly the immense implications of the uranium-energy project. Even if the peace terms might not be influenced by them, this achievement would at least insure for German science a leading role in the world and save Germany in that way. These thoughts were, indeed, the driving force behind the German scientific efforts. Gerlach was greatly excited when he learned about the favorable result of the preliminary experiment. He immediately informed Bormann, the head of the Nazi Party, reassuring him of German supremacy in this field. Gerlach was quite upset when, shortly afterward, the S. S. spread rumors that the Germans were soon going to use a uranium bomb. The scientists knew that they were still a hundred years away from that goal.

Himmler's S. S. had begun to take an active interest in research and especially in the uranium project. This organization had threatened to evacuate key scientists and their equipment to the Bavarian redoubt where they would be forced to complete the work under pressure. To the relief of the frightened German scientists, this plan failed, probably because of the rapidity of the German collapse. Only one group was actually kidnaped by the S. S. and let loose in Bavaria.

But, the German scientists believed in their superiority. They attempted to hide their research reports and all information about their work from Allied investigators—of course, in vain.

Not until they learned about the use of the atomic bomb by the Allies did they realize how far behind they were. They had lost not only the military war, but also the war of science.

Control

In my opinion, a survey of the German work on uranium energy leads to certain recommendations for eventual control of uranium research.

It has become evident that such supervision can only be had with the help of qualified scientists. The present military methods of intelligence or of occupation are totally inadequate for the control of scientific research. These merely lead to such utterly useless extremes as the destruction of the cyclotrons in Japan.

It is not only the destruction itself which is objectionable. So much has been ruined in this war that a few expensive scientific instruments are insignificant by comparison. The destruction of the cyclotrons is bad because it indicates that those who are responsible for this deed are totally unfamiliar with the real significance of these instruments in the atomic-energy problem. Blowing up cyclotrons is almost equivalent to the attempted cutting down of the Japanese cherry trees here in Washington shortly after Pearl Harbor.

It shows that sound and competent scientific advice is essential in dealing with this matter and those related to it. In this war, there have been several examples of very close and successful cooperation in the field between the military and scientists. I am fortunate to know this from personal experience. Such coordination and supplementation should exist not merely in the laboratory but in all phases of the atomic-energy problem.

The War Department mission, which, among other functions, collected the material mentioned before, can be taken as an ideal example of such cooperation. The chief of mission, Col. B. T. Pash, never failed to execute the operations, often difficult ones, requested by the scientific chief and his staff of scientists. The military were in charge of and took full responsibility for security and for other purely military matters. The scientists were responsible for judging matters concerning enemy scientists, instruments, laboratories, and documents.

Finally, I wish to point out the scientific cooperation which exists among scientists all over the world. This cooperation overcomes the barriers of war and differences of political opinion. I feel certain that, if all countries grant complete scientific freedom to their research workers, no dangerous activity will, or can, be kept secret as long as scientists are involved. By "scientific freedom" I mean the scientists' free choice of research problems and freedom of publication.

The CHAIRMAN. The hearing is adjourned.

(Whereupon at 12:05 p. m., the committee recessed until Monday, December 10, at 10 a. m.)

ATOMIC ENERGY

MONDAY, DECEMBER 10, 1945

UNITED STATES SENATE, SPECIAL COMMITTEE ON ATOMIC ENERGY, *Washington, D. C.*

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Johnson, Tydings, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. Dr. Szilard.

We have prepared a short biographical sketch on Dr. Szilard and what he has done. He is one of the most eminent of the pioneers in the science of uranium fission.

Doctor, would you proceed, please?

STATEMENT OF DR. LEO SZILARD, STAFF MEMBER, METALLURGICAL LABORATORY, UNIVERSITY OF CHICAGO

Dr. SZILARD. I have a prepared statement in various sections. It may be too long to read all of it, and I will skip a number of paragraphs. I will skip some sections, but I will submit for the record those sections which I skip.

With your permission, I should like to begin by quoting some facts and figures and by presenting some simple considerations which may serve as a starting point. In this way it will be easier to draw a picture of the role which peacetime application of atomic energy might play in the next 10 or 15 years in our power economy.

We are at present producing in factories that were built during the war two substances which are in many respects rather similar. One of them is Uranium-235, or light uranium. This substance is not so much manufactured as it is merely extracted, by means of a rather laborious process, from natural uranium. Light uranium accounts for less than 1 percent of natural uranium and accordingly its quantity is essentially limited by the quantity of natural uranium which can be made available.

In one of the prewar years we imported, for instance, 400 tons of uranium. If we worked every year such a quantity of uranium, and if we managed to extract all the light uranium contained in it, we would obtain every year 3 tons of light uranium. We would do pretty well, however, in extracting two-thirds of this quantity and obtaining 2 tons of light uranium every year.

267

If we wanted to use up 2 tons of light uranium per year by allowing it to disintegrate, or let us simply say by "burning" it, and if we used the heat which is generated for the production of steam and steam for the production of electrical power, how much electrical power could we generate?

If we "burn" 2 tons of light uranium per year, we can produce electrical power at the rate of 1.25 million kilowatts, or about as much as the average production rate of TVA in 1944.

If this amount represented the limit of electrical power which atomic energy could be expected to provide for us, I would not take your time by discussing this question.

You obtain a very different picture, however, if you think of a fissionable substance, like, for instance, plutonium, which could be manufactured in large quantities. Plutonium can be manufactured from a component of natural uranium which accounts not for 1 percent, but for more than 99 percent, of natural uranium. If plutonium is allowed to disintegrate, or let us again say if it is "burned," heat is produced in just the same way as in the case of light uranium.

Heat is, however, also produced in the manufacture of such a fissionable substance.

Senator HICKENLOOPER. Let me ask you, Doctor, this question: Heat is produced when you produce the plutonium, and in turn the plutonium also produces heat?

Dr. SZILARD. Yes, when you burn it. You see, you first produce plutonium, and when you do that, as a byproduct you produce heat, and then you store it. If you later decide to burn it, you again produce heat.

When you make 1 pound of plutonium, you produce as much or more heat than when you "burn" 1 pound of plutonium. So you see that heat is produced twice, once as a byproduct of the manufacture of the fissionable substance and once when you "burn" the fissionable substance.

Senator HICKENLOOPER. Excuse me for interrupting you ahead of time, Doctor, as I see you answered my question later.

Dr. SZILARD. This does not hold, of course, for Uranium-235, which is not manufactured, but merely extracted.

With your permission, I will assume that the quantity of the fissionable substances which can be produced might be expected to increase from year to year in geometrical progression.

Senator HICKENLOOPER. May I interrupt you right there?

You mentioned light uranium. In the production of light uranium, you have to first produce the heat or the power that separates the light uranium, so you have to produce that in producing the light uranium; and in the production of plutonium, it creates its own heat?

Dr. SZILARD. Exactly. In the manufacture of light uranium, you use the electrical power available from existing power plants for operating your factories.

Let me now explain what I mean by geometrical progression. For instance, if you start with 1-ton production per year, say in 1946, you might produce 2 tons in 1947, 4 tons in 1948, 8 tons in 1949, and 16 tons in 1950. It might, however, be that the geometrical progression will be slower, and that the quantity which you can produce will double only every 3 years. This would mean that if you produce

1 ton in 1946, you produce 2 tons in 1949, 4 tons in 1952, 8 tons in 1955, and 16 tons in 1958.

Just how fast the geometrical progression might proceed will depend almost entirely on the inventive ingenuity of those who will collaborate in our research and development program. The time in which the production would double might be less than 1 year and might be more than 3 years. The years from 1946 to 1949 or from 1946 to 1958 ought to be considered as "the building-up period." During such a period it might not be advisable to divert any substantial quantities of the fissionable substances for the purpose of being "burned" in order to produce electrical power. After such a "building-up period," however, there is no reason why we should not "burn" up some 20 tons of fissionable material per year and produce electrical power at the rate of about 15,000,000 kilowatts.

Senator HICKENLOOPER. May I interrupt you again?

You said there is no reason to divert for a period of time this fissionable material to industrial uses, as I understand it. Now, why did you say that?

Dr. SZILARD. I said it might not be advisable to divert, and I am afraid that this leads me into a question which I would rather answer in executive session.

Senator HICKENLOOPER. All right.

Senator TYDINGS. How does that amount of power, 15,000,000 kilowatts, compare with the total amount of power generated in 1944 by TVA?

Dr. SZILARD. TVA generated $11\frac{1}{4}$ million kilowatts.

Senator TYDINGS. And you say 15,000,000 a year?

Dr. SZILARD. At the rate of 15,000,000 kilowatts.

Senator TYDINGS. A year?

Dr. SZILARD. No; kilowatts relates to rate of production. You would have to multiply this figure by the number of hours in the day and the number of days in the year.

Senator TYDINGS. As I understood your analysis of the comparison, the amount of kilowatts produced would be 10 times as great as that now produced by TVA?

Dr. SZILARD. Yes; and I could express it in a different way. This amount that would be produced by burning 20 tons per year is equal to the total electrical-power production produced by utilities in the United States before the war. Now, after the war, the value is not 15, but 25 million kilowatts. It has increased.

Senator MILLIKIN. How many tons would you burn?

Dr. SZILARD. Twenty tons. The 20 tons per year mentioned above represent by no means an upper limit and we might produce very much larger quantities if we can find customers for the electrical power produced.

Senator TYDINGS. Let me interrupt you again. At some point in your testimony are you going to bring out the relative costs of producing the 20 tons of fissionable material as compared with the relative cost of producing the electric power as it is now produced for the whole country?

Dr. SZILARD. I am afraid that in order to make substantiated statements we will have to do it in executive session.

Senator TYDINGS. You do not have to give me your answer. You can come along in executive session and answer it.

Dr. SZILARD. Clearly I would not talk about it if I did not think it possible that 10 years from now it will be much cheaper, that uranium as a fuel will be much cheaper than coal; so in a sense that must be a possibility, otherwise I wouldn't talk about it.

Senator TYDINGS. In 10 years it is possible?

Dr. SZILARD. Well, I mentioned 10 years because we have to accumulate these substances first.

Senator TYDINGS. If we could accumulate it more rapidly, the time limit would be correspondingly decreased.

Dr. SZILARD. The uranium deposits of which we know at present will not represent a limiting factor for a long time to come and the quantity of uranium contained in as-yet-undiscovered very low-grade ores might be very large. The rate of growth of the atomic energy industry will be essentially controlled by two factors: the rate at which the production of fissionable substances will increase and by the rate at which we are willing to expand our electrical power installations.

During the "building up" period, or say in the next 10 years, it might be desirable to throw away the heat which is generated as a byproduct. By doing this we would reduce the amount of the necessary investment, because the cost of a steam plant and the cost of the electrical distribution system could be saved. Moreover, the fastest ways of producing fissionable material might not necessarily be those which permit the utilization of heat for steam production.

Senator HICKENLOOPER. Mr. Chairman.

The CHAIRMAN. Senator Hickenlooper.

Senator HICKENLOOPER. Your statement there that it might be well to throw away this heat for a period of time is made, as I understand it, because you think that we might not be ready to use the electrical power during that period, and therefore the construction of the plants necessary to use the power would be, at least for a period of time, a comparative waste of money?

Dr. SZILARD. Yes. If large stocks of plutonium are to be built up, we should not be slowed down by the large investments required in the utilization of the power. Also there may be engineering reasons why production might be faster if we don't insist on making steam.

Senator MILLIKIN. There is also a political situation involved there. In the production of coal we employ vast numbers of people. We employ many people that make dynamite and make the tools of the business. Many of our railroads are heavily dependent upon transportation of coal, and so we cannot have an overnight revolution.

Dr. SZILARD. Exactly. If the output of fissionable substances will increase in a geometrical progression as I have assumed it will, atomic power will not be an important factor in our power economy for perhaps 10 years. Then, rather suddenly—that is, within a few years—it might become a very important factor affecting our economic and monetary policy.

We might then make use of the building of atomic power installations for stabilizing our system of economy. In times when a depression threatens, electrification of our railways, based on atomic power plants, may be pushed with the support of the Federal Government, whereas in boom periods an expansion of atomic energy power projects might be discouraged by the Federal Government.

Senator MILLIKIN. Do you happen to have at hand the cost per capita of electrical energy in the United States at the present time?

Dr. SZILARD. No, I do not have. I know the total power production, and you could assume a price.

Senator MILLIKIN. That would be an interesting figure in order to determine how much of an effect it would have on our whole economy.

Dr. SZILARD. This might give you perhaps an idea. About 600,000 men are employed in mining coal. Therefore you see that if we could produce a substitute for coal—and atomic energy is no full substitute, because coal is used for other purposes also—we could not save more than the labor of 600,000 miners and the cost of transportation.

Senator MILLIKIN. It has been testified that to use this energy for peacetime use takes us about three-quarters of the way along the road to its use for wartime purposes. Therefore we have a balancing problem, it seems to me, here in the committee that goes far beyond whether the production of atomic energy for peacetime purposes is desirable in and of itself, considered simply in a vacuum. We have to consider that in relation to many other things, and therefore I should like to know how much we could save through the peacetime use of this atomic energy over our present methods of producing energy, for that obviously would be one of the balancing factors that we would have to keep in mind.

Dr. SZILARD. My next paragraph makes a comment on that question to some extent.

Dr. Urey and Dr. Langmuir have pointed out to you that inspection, as it might be set up under some international arrangement, might be more difficult if atomic power plants were built on the territory of various sovereign nations. I believe it may be possible to overcome such objections. There is however, a more serious objection which will have to be scrutinized. It relates to the situation that the United States and other nations would face if, after a number of years—during which inspection may have been successfully practiced—one of the major powers suddenly abrogated the arrangement under which the inspection system had been operating.

Considerations of this sort induce me to raise the question whether we shouldn't contemplate the concentration of all manufacture of fissionable materials during the next 10 or 15 years on some internationalized territory. Since there would presumably be no market in such territory for the vast amounts of electrical power that would be generated, most of the heat that appears as a byproduct of the manufacture would have to be thrown away. I wish to point out, however, that this might not be such a very great sacrifice, and perhaps it would be no sacrifice at all, in the light of remarks made earlier in my statement.

In building such factories in an internationalized territory, we would look toward the time when the fissionable substances accumulated in the next 10 or 15 years could be made available. In 10 or 15 years, if the international situation permits, they might safely be distributed to be burned in electrical power plants located in the United States and in other countries.

This terminates the first section.

The CHAIRMAN. Dr. Szilard has said that his statement is divided into sections, and he informed me that he would like to have questions on each section as he finished it rather than go through to the end.

Senator Hart.

Senator HART. Doctor, you have given us some figures which I assume have to do with the theoretical possibility of development of power.

How far have you yourself, or those with whom you have been associated, thought through as to the practical means of using this power which you say is theoretically possible?

Dr. SZILARD. Well, this is again a question which I would much prefer to answer in executive session, because I cannot substantiate anything I say here.

There is this unfortunate situation, and I am glad to have an opportunity to say it. We have two kinds of secrecy: Information relating to technical details, engineering details—

Senator HART. That is not my question. I am asking you if you have thought it through and are ready to present something which is anywhere near as specific as the theoretical possibility you have given us?

Dr. SZILARD. I have thought it through much further than would appear from my testimony given in open hearing.

Senator TYDINGS. I would like to ask a question, either now or in executive session, as you prefer.

Are you in a position to give us your opinion, weighing the advantages of the peacetime use of atomic energy as against the disadvantages of the wartime use of atomic energy, as to whether or not it is desirable to take the risk of using it for peacetime purposes, assuming that you have—by using it in peacetime—gone 75 percent of the way toward manufacturing the atomic bomb?

Dr. SZILARD. I feel about this exactly as Dr. Urey and Dr. Langmuir feel about it. If, by giving up peacetime applications, we can appreciably facilitate the setting up of a peace system for the sake of security, I would very gladly renounce the use of that atomic power in the next 10 or 15 years.

Senator TYDINGS. In other words, I take it from your answer that, assuming that the international situation as projected in the future does not lend itself to the control of atomic energy for wartime uses on what might be called a satisfactory basis, you would prefer that the whole thing be prohibited if possible?

Dr. SZILARD. Yes.

Senator TYDINGS. To the end that the liabilities might be greater than the assets?

Dr. SZILARD. Yes.

Senator HICKENLOOPER. As a step in that direction, Doctor, as a scientist and with what knowledge you have of the history and present activities of international science, do you believe that science or even countries will stop the examination and exploration into the atomic energy field by any treaties or agreements?

In other words, will science stop investigating this great new field that has opened up here, or will they continue in spite of anything with that as a natural field of scientific investigation?

Dr. SZILARD. I believe that it would be very difficult and would be undesirable to stop scientists from further acquiring knowledge, but the direction in which science goes may be influenced by the political situation. For instance, I do not believe that good scientists in

the United States would, under favorable conditions, work on that phase of the scientific problems which relate to the making of bigger and more destructive bombs. That line would not be pursued because it is not very interesting from a scientific point of view and will be pursued only if it is necessary for political reasons.

Senator MILLIKIN. The bombs already made are big enough, aren't they?

Mr. SZILARD. They are big enough for my taste.

Senator HICKENLOOPER. The point I am trying to ask about is this: Even granted that it might eventually be desirable to try to eliminate all of this production of fissionable materials, do you think that in the face of prohibition science will stop investigating it?

Dr. SZILARD. No. I do not envisage control, which has been discussed, as control of knowledge. I envisage control as control of manufacture. I do not believe that control of knowledge is desirable.

Senator HICKENLOOPER. You get down to this point: Your answer to Senator Tydings, as I interpret it, indicates that you advocate the control of the volume production or the abandonment of volume production; but in your answer to me you state that it is your opinion that science will go on investigating the scientific possibilities of this thing; so the two answers, as I understand it, would mean that about all we could do would be to try to abolish the physical production, but the scientific investigation and enlargement of this field from the standpoint of science would go on in spite of anything we can do.

Dr. SZILARD. I think so.

Senator TYDINGS. I take it that your answer to my question comes from the knowledge that no solution is likely to be 100 percent or perfect, that no solution is likely to come for our protection from the use in war which will be watertight, which will be perfect, and your quest is to find, of the many avenues we might explore, which one seems to offer the most promise for a continuance of civilization?

Senator TYDINGS. Therefore, I take it that your answer meant that unless there was an international climate created which would make the control of the bomb or the elimination of the bomb, whichever it might be, reasonably feasible with a promise of safety that, as an alternative, it would be better if we could have an agreement that nobody would manufacture atomic energy even for peacetime purposes, because it would be so easy to slip over into the field of war purposes. Am I correct in what I have said?

Dr. SZILARD. Yes; precisely.

The CHAIRMAN. I take it that your testimony in this first section, together with a couple of other lines of testimony that you indicated you would rather give in executive session, is designed to inform the committee what we would be giving up if we made such an arrangement?

Dr. SZILARD. Yes.

The CHAIRMAN. In other words, before we can determine whether or not we are, as far as we are concerned, going to give up this use, we ought to know what we are giving up in the way of peacetime use?

Dr. SZILARD. Precisely.

The CHAIRMAN. Which will also inform us better as to the chances of other countries giving it up that might need power a great deal more than we might need it?

Dr. SZILARD. Yes.

Senator HICKENLOOPER. We learned about 3 years ago definitely that fission was possible, I believe. I think that it was somewhere in that neighborhood. In other words, as I recall it from the testimony in open hearing, it was only a step of approximately 2 years, or maybe less, from the theoretical or experimental proof that fission was possible until we began to produce the material in volume, that is, in amounts practical for war purposes.

I don't know the exact time, but I think the testimony showed that early in 1940 we confirmed the fact that it was possible, and the bomb was dropped in the summer of 1945, so that sometime between that time from experiment to production was a period of 2 or 3 years at the outside.

Therefore, if experimentation goes on, it is reasonable to assume, is it not, that we may discover ways of making this material much more quickly and much more efficiently; that is, the bomb material? Therefore, if experimentation goes on in the world and we attempt to control the physical production of it, and some nation wanted to abrogate its agreement and make the material in secret, it is entirely possible that in 10 or 15 years they could make that actual material, set up the plants and make it in a far shorter time than we did from the time we started in this war?

Dr. SZILARD. Yes; particularly if atomic power installations are in existence in that country at that time. Particularly, if there is an existing atomic energy industry utilizing uranium, then the time from abrogation to production of bombs will be even shorter.

Senator HICKENLOOPER. Let's assume that we try to outlaw, or agree among nations not to make this fissionable material in any quantity at all. If any nation wanted to abrogate that agreement, it still would only be a matter of a year or two during which they could build plants and actually make it in violation of their agreement. Wouldn't that be true?

Dr. SZILARD. If any of the major powers would abrogate an agreement, this would be true. I think a minor power would take longer.

Senator HICKENLOOPER. Therefore, as long as experimentation and scientific delving into this field goes on, we run the possible danger that some country may abrogate and in a short time actually make the fissionable material based upon their scientific advancement and investigation. I say we run that chance.

Dr. SZILARD. If the country abrogated and made these materials, of course we would know of it and make it also; and then we would be in an arms race.

Senator HICKENLOOPER. Now, then, if we permit the manufacture of this fissionable material for power purposes in the future and try to limit it to that, there still is about a 25-percent, I believe, greater step beyond the production of that until we make the bomb. I believe that has been testified to here.

Dr. SZILARD. Well, I would not call it 25 percent. I would simply say that if such power plants exist, the time lag between abrogation and production of bombs is very much shorter.

Senator HICKENLOOPER. It is very much shorter, but it couldn't in any event be much more than half; let us say we halved it, let us say a year shorter.

Dr. SZILARD. It could be even shorter than that; it might be 6 months or 9 months.

Senator HICKENLOOPER. Anyway, what we are dealing with between the end of scientific investigation and the production of material would reasonably be, say, 2 or 3 years. In other words, we did it.

Dr. SZILARD. Yes.

Senator HICKENLOOPER. The time between the production of fissionable material for power purposes and the production of a bomb would be a substantially shorter time than that?

Dr. SZILARD. Yes.

Senator HICKENLOOPER. Therefore, we are only dealing with a matter of a couple of years at the outside.

Dr. SZILARD. I would not accept that analysis for reasons which are contained in another section. I don't know whether you want me to pursue it now.

Senator HICKENLOOPER. I am not trying to get you to pursue any technical things of that kind. I am trying to get from your testimony that what we are dealing with is only a matter of 2 or 3 years in any event if any nation wants to abrogate, and a much shorter time if they have the uranium already made.

Senator TYDINGS. He said possibly 9 months.

Senator HICKENLOOPER. If they don't have the material, don't use it for power but still go into the experimental field, perhaps 2 or 3 years, somewhere along in there?

Dr. SZILARD. Precisely.

Senator HICKENLOOPER. The time from the scientific investigation on the production of a bomb either way would be a maximum, let us say, of 2 or 3 years; considering advancements, at a minimum of say 6 to 9 months.

Dr. SZILARD. I would agree.

The CHAIRMAN. Which means, in order to get $2\frac{1}{2}$ years of time in which to try to settle any international difficulty that might come up, in order to get that time you would be willing to forswear any peacetime application of it?

Dr. SZILARD. Yes. I think there is a very great difference between 6 months and $2\frac{1}{2}$ years, in case of an actual abrogation. If such a situation arose, the difference between 6 months and $2\frac{1}{2}$ years is precisely this: If we have $2\frac{1}{2}$ years, we can relocate some of our industries; we can disperse some of our population. You cannot do that in 6 months' time, and that is a very great difference.

The CHAIRMAN. Doctor, this may get you into the next part of your statement, and if so I will wait.

Assuming that an inspection system was provided and an agreement went with it that any violation of the inspection system was an act of aggression and that when that act of aggression occurs the nations of the world would have to move to protect themselves against the offender, would you not think then that 6 months or 9 months, which is the time it takes to convert from a fissionable material to a bomb, was sufficient?

Dr. SZILARD. That depends on how much stronger the nations of the world together are than the offender.

The CHAIRMAN. And also it would depend upon the nations of the world being willing to act immediately when an act of aggression, as defined under the treaty, was committed, does it not?

Dr. SZILARD. Yes, but let us assume a very unlikely case just for the sake of argument. Let's assume the United States would be the offender. I believe that the United States could be stronger than all of the nations of the world together in such a case. I am not even sure that Russia couldn't be stronger than the other nations of the world together, assuming at the time of abrogation a high standard of atomic power industry. . . Therefore that solution which you outlined is not so simply achieved.

The CHAIRMAN. You see, Doctor, I am struggling for some way out of the burying, for the first time in man's history, of something that promises an increase in the wealth and productivity of mankind. Do you see my difficulty?

Dr. SZILARD. I am aware of the difficulty.

Senator HART. Doctor, to clear up one thing for the record, in your answers to Senator Hickenlooper I think as the record now stands you are understood as saying that some other nations, some nation other than us, could, if they started now, have atomic bomb armaments within 2 or 3 years.

Other scientists in open hearings have given much greater figures. Is that the way you wish your answer to stand?

Dr. SZILARD. No, I haven't understood the Senator's question that way.

Senator HICKENLOOPER. I tried to preface my question on the advancements of science in the next 10 years in these countries so that they might get to the point where they could do it.

Dr. SZILARD. I understood him to ask what would be the situation if 6 or 10 years from now a country abrogated, assuming knowledge of this field is widespread, and started making atomic bombs, how long it would take them; and there I agreed with an estimate of 2 to 3 years.

Senator HART. But you assume no particular difficulties in their acquiring the industrial capacity to do the work which the scientists laid out?

Dr. SZILARD. No, I don't assume any such difficulty, and I am going to talk about that in another section.

Senator TYDINGS. Doctor, I hope you will do that, because a great many men, better informed in science and industry than I ever hope to be, in my humble judgment in the light of the achievement of some countries during the recent war, have woefully underestimated their potential capacity for the development of this instrument, and I don't believe any of those gentlemen who have testified are reasonably familiar with some of the conditions that exist in some of the countries. Many of them have never been there. They have certainly failed in my judgment to evaluate what has occurred in the last 20 years in some of these countries, and I am left a little cold by the fact that it is going to take as long as many of the people who have testified in open hearings think it will take to achieve a degree of efficiency which is necessary in the manufacture of this instrument.

Dr. SZILARD. If I may be allowed to read section 4 [referring to prepared statement] which relates to this question, that will contain my answer.

The CHAIRMAN. Before you go into that, Doctor, I would like to ask you one more question. You stated that one of the methods that might be suggested would be to have this manufacture of fissionable material in an international territory, in some desert part of the world, where no heat would be even useful.

Assume that that was done, and then assume an abrogation of the treaty under which it was set up. Can't you foresee the greatest Storm of Gethaim that ever was in the nations trying to get at that site first?

Dr. SZILARD. Yes, but that site might be exceedingly vulnerable to bombing attacks from the air, and could be destroyed by any one nation, by any of the major powers. It could be mined in advance and blown up.

Every power that has a veto right could have the right to blow it up at any moment after giving half an hour's notice for everyone to get out. I think it is entirely feasible to make the site so vulnerable that any of the major powers who wanted to destroy the site could destroy it.

The CHAIRMAN. You say if they gave half an hour's notice. The very giving of the notice by country A, if country B were suspected, would give country B time to marshal its forces and see that it wasn't blown up and grab control of it.

Dr. SZILARD. If every factory is mined, and if every major power has a key to the button or number of buttons to blow up those mines, it would be very difficult to save the factories.

Furthermore, you might not provide in that site for any facilities which are needed for the chemical work on uranium. You might have two sites, one in which you manufacture it and another to which you transport it, chemically work it, and transport it back again, so that the possession of that site alone would be of little value.

You see, in a sense plutonium protects itself against aggression by becoming exceedingly radioactive. No one could just go there and get it. It takes elaborate equipment, and that equipment need not necessarily be on the same site.

I have not thought through this proposal very carefully. I just wanted to indicate that we ought to think somewhat along that line, and see if that is not a possible solution in order to get a compromise between, say, Dr. Langmuir or Dr. Urey, who would be willing to give up atomic power, and those who would not like to do anything now which will deprive us from atomic power 10 years from now.

Senator TYDINGS. Let's assume that we do not give up atomic power, or that we cannot give it up, either way; and let's assume that, 10 years from now, after we have used every reasonable precaution, that the atomic bomb will neither be made nor used, but we have under certain international agreements tried to permit and control the use of atomic power for peacetime purposes; at the end of the 10-year period, some nation abrogates its agreement and decides upon war.

In your opinion, would we have not been better off to have tried to eliminate the peacetime use of atomic power as against that future contingency?

Dr. SZILARD. Yes; we would have been better off.

Senator HICKENLOOPER. Mr. Chairman, may I ask the doctor this question, which is political?

Let us assume that we have agreements not to make the fissionable material into bombs. Let's assume that has gone on for some years, and let's assume that an association of nations has a stock of these bombs, and this morning that association of nations finds out that some nation is actually in the process of making this material for bombs.

Just as an individual now, and not necessarily as a scientist, would you say we should send a cablegram to them and say, "You will either let us in there to destroy this material that you have made by noon today or by tomorrow morning, or we will drop an atomic bomb on you," or what would be your proceedings there? How fast should we act? How fast should we use the complete force of the atomic bomb to stop someone else from violating the agreement?

Dr. SZILARD. Under the assumption you made that we have a stock pile of such bombs in the hands of the international agency, there would be no sense in having the stock pile unless the intention was to use it. In that case it should be used as fast as necessary.

But I would not go so far as to say that I favor your assumption, namely to have such a stock pile.

Senator HICKENLOOPER. I wasn't asking you whether you favored it or not. I was assuming that was the condition. Then what would be our step?

Dr. SZILARD. I think that it should be used as fast as necessary because otherwise there would be just no point in having it. Certainly there would be no better case for using it than a violation of such an agreement.

Senator TYDINGS. Doctor, in the event that all the world is disarmed except the international police force, which is under the direction of the UNO, and in the event that army is equipped with such battle-ships and field pieces and airplanes and atomic bombs as evolution decides is wise, and in the event that international police force is composed of component parts of the United States, Britain, France, Russia, and so on, if you had the atomic bomb, what would stop that segment of the international police force which comes from the country to be attacked from trying to seize the atomic bombs first so that they couldn't be used by the international police force?

Dr. SZILARD. I do not know what would stop it. It depends very much on how the whole thing is set up and organized; without knowing, so to speak, the blueprint of the organization I couldn't answer that question.

Senator TYDINGS. Eliminating the atomic bomb, of course, they could not seize enough airplanes or field guns or anything else to make it decisive. The atomic bomb weapon would be the one weapon that would be more decisive, let us say, than all of the others put together if they were in quantity.

If you do have this international police force, you have almost got to have another one to watch the international police force to keep them from trying to steal these few bombs that are actually in existence in the event of any international emergency, haven't you?

Dr. SZILARD. There are difficulties of this sort. I am not sure that you cannot overcome them, but I, too, am somewhat disinclined to see a weapon, which is clearly a weapon primarily designed for the destruction of cities, used as a police weapon. It is not a police weapon.

Senator TYDINGS. I don't want to interject any political note in this, and I have no idea of doing it, because every suggested solution ought to be weighed carefully.

I understand that Captain Stassen has advocated in general terms that all atomic plants and bombs be more or less eliminated, except for five that would be stationed at five different places on the face of the earth, with supplies of bombs for use of an international force. Implied in his statement is, of course, the thought that all other nations would disarm so they would be inferior to the international force; otherwise there would be no point in having it.

Now, if disarmament is to take place all over the earth and the only real strong force is to be the international police force, why is it necessary for the international police force to have any bombs at all? Why can't they retain order with such battleships, cruisers, airplanes, and demolition bombs, and so on, as they would have without the atomic bomb?

Dr. SZILARD. Well, I believe the thought behind the Stassen plan is this: In spite of inspection, perhaps a country might be able to secure a small number of bombs. They wouldn't be able to make many bombs under inspection, but they might make 10 or perhaps 20.

If the international authority has also a small number, those 20 bombs which the aggressor has will not be of very great use.

Senator TYDINGS. So you would need a supply of atomic bombs, just in case some other nation attempted to make them, so you would be on equal or better terms with the nation who had violated the international agreement, so to speak?

Dr. SZILARD. I believe that is the thought behind the plan. My feeling is that none of these plans sound very good, but none of them ought to be discarded until we find a better one.

Senator TYDINGS. That is my attitude. I didn't say what I said in any criticism, but simply to help my own thinking.

Senator MILLIKIN. Mr. Chairman, may I ask: Have we anyone on the agenda to tell us of the possible medical contributions?

The CHAIRMAN. Yes, we do. We have Colonel Warren, who is supposed to be the outstanding authority on radioactive materials in their relation to the field of medicine.

Senator MILLIKIN. That, of course, would fit in perfectly with what I thought you were expressing very well, as to what we are giving up if we were to put a freeze on all of these operations, Mr. Chairman.

The CHAIRMAN. Exactly. That is to come later, Senator.

All right, Doctor.

Dr. SZILARD. In answer to the question of how long it would take other countries to make bombs, perhaps I can read a short section, section 4 [referring to prepared statement].

What are the essential factors which enter into the consideration of this question?

As far as the production of plutonium is concerned, which is described in the Smyth report, any competent mechanical or chemical engineer who spends some time thinking about the problem can see that no precision work is involved in the manufacture of plutonium.

The CHAIRMAN. No mechanical precision work?

Dr. SZILARD. No mechanical precision work is involved.

The design which we actually used did require rather narrow tolerances and high-class workmanship. This we could afford because we have this kind of workmanship in abundance.

Naturally, a country like Russia need not choose just this kind of design, but might prefer a design which does not require high precision work. The statement has been made before this committee by another witness that it requires high precision workmanship, such as can be provided only by a few countries, including Switzerland, to make atomic bombs. As far as the production of plutonium is concerned such a statement would have no basis in fact.

Senator TYDINGS. What do you mean by that? Do you mean that the production of plutonium in itself is not a difficult problem, and therefore the people who say that plutonium cannot be manufactured by this or that country are not guided by the facts in this case?

Dr. SZILARD. That is my view. I am not making any statement about the separation of light uranium, but only about the making of plutonium, and I am not making any statement about the construction of the bomb; but it was indicated here in earlier testimony that it was not the bomb but the production of the fissionable material which is difficult. I flatly contradict that statement as far as plutonium is concerned.

Senator TYDINGS. That is very important, that the raw material, as I shall call it, the plutonium, can be manufactured by any competent scientist and mechanical engineer working together with others without any very great or what you might call insurmountable difficulty.

The CHAIRMAN. Doctor, before you go on, the plutonium is made at Hanford, I believe.

Dr. SZILARD. That is right.

The CHAIRMAN. Under the graphite piles as described in the Smyth report?

Dr. SZILARD. That is right.

The CHAIRMAN. And that process you say is not mechanically difficult?

Dr. SZILARD. That is right.

The CHAIRMAN. Now, that is quite a different thing from the separation of 238 and 235 that goes on in the diffusion process, the thermal process, and the spectrograph process at Oak Ridge?

Dr. SZILARD. It is.

The CHAIRMAN. They are mechanically much more difficult than the pile process at Hanford?

Dr. SZILARD. Some of them are, but the others may or may not be. I do not want to make any statement about any of them, because my knowledge is not sufficient to take the responsibility for making a statement about them.

Senator TYDINGS. But you do leave your original statement stand as to plutonium?

Dr. SZILARD. Yes.

Senator MILLIKIN. Are you going to develop that theme now, Doctor?

Dr. SZILARD. Yes, a little.

As far as the production of plutonium is concerned, I see no reason why any country that is capable of industrial development should not be able to build plutonium factories. It is true, though, that a

certain amount of uranium is required for such factories, and the question therefore arises whether or not Russia has available uranium ores.

This question has been discussed at a previous hearing. The deposits in Czechoslovakia which might supply ore to Russia I would not class as important deposits, nor do I believe that any of the Russian deposits of which there is public knowledge in this country can be considered as important. However, it would be exceedingly foolhardy to assume that in the vast territory which is accessible to Russia no adequate deposits of low grade ores could be found if prospecting for such ores is carried out in earnest.

How long would it take the Russians to produce plutonium in substantial quantities?

When Germany attacked Russia I thought that Russian resistance would collapse within 3 months. With such a past record as a prophet with respect to Russia, I think I ought to disqualify myself from answering this question.

The CHAIRMAN. I might interrupt you to say that certain other people ought to disqualify themselves on the same basis.

Dr. SZILARD. If any of your other witnesses have a better record in this respect, let them disclose their record together with their forecast.

Senator TYDINGS. If you don't mind my interrupting you again, because I do think it is important, I think pretty nearly everybody is in the same class with your prophecy. When Germany attacked Russia, most everybody that I had any contact with, all of the press and all of the seers, thought that Russia would go down in about 3 months, and that is one of the reasons why I think they are still underestimating a country which has demonstrated its tremendous ability to coalesce with tenacious will, to keep on with whatever it wants to do.

I am awfully glad you brought that point out, because I do not think we have been cured of that disease yet in this country and all over the world.

Dr. SZILARD. It is a natural tendency to overestimate our own achievement, both as individuals and as a nation, but it would be very unfortunate, indeed, if by underestimating what others can do the people of this country were lulled into a false sense of security.

I may give you, perhaps, an example of the ease with which we can underestimate others.

In the production of plutonium there is another process involved beyond mere manufacture. Plutonium has to be chemically separated from the uranium in which it is produced. You might think that it is very difficult chemically to separate an element if you do not know well the chemistry of that element, and plutonium is a new element. The Manhattan district was apparently of this opinion.

Interpreting very narrowly the directive of the President, the Manhattan district gave us orders not to discuss with the joint British and Canadian project set up in Canada the chemical separation of plutonium. We had a good method, of which we were very proud, and we were not supposed to explain this method to the Canadian project.

This annoyed our British friends, because it compelled them to duplicate our work, which they thought was an unnecessary waste of their time.

The result, however, was, as I have been told by two reliable scientists, that they have worked out a method for separating plutonium which is superior to the one which we are using. It is both much simpler and more complete.

You see, there is an example of how easy it is to believe that what we have done and what seems so difficult to us is something that others cannot do or cannot improve upon.

Senator MILLIKIN. Mr. Chairman, I may say that the witness' testimony so far has reversed a number of tentative conclusions that I had reached, and I hope if there is any rebuttal to what he said it will be brought before us promptly, because it seems to me that he has struck right at the heart of a number of our problems.

The CHAIRMAN. That is right.

Senator TYDINGS. There is no doubt about it.

Senator MILLIKIN. Don't you think we ought to get somebody in here and get an answer, if there is one?

The CHAIRMAN. I suggest to the War Department representative who is present that he get a transcript of this testimony as quickly as he can and submit it to General Groves for such observations as General Groves cares to make on it.

Dr. SZILARD. I do not know how much more time I shall take. I have three more sections which I might read.

The CHAIRMAN. I think you had better go right ahead, Doctor.

Dr. SZILARD. With your permission, I would like to make a few remarks on preparedness, what this word means if we take the word seriously. Those who believe that we have practically no chance of arriving at an international solution are naturally led to think of a solution either in terms of "preparedness" or else in terms of a preventive war.

As far as "preparedness" is concerned, just what is it that we have to be prepared for? If preparedness is necessary, it is necessary because we consider Russia as a potential enemy and for no other reason.

The CHAIRMAN. We are thinking of her as potential friends, and not potential enemies.

Senator TYDINGS. You are just investigating, without throwing any reflection on any country, different contingencies that might happen in the future?

Dr. SZILARD. If we want to be prepared, we have got to know what we want to be prepared for. We want to be prepared for a potential enemy, and in our computations at least we should consider who that potential enemy might be; otherwise, we don't know what the measures are.

This does not imply on my part that Russia might attack us. I am simply analyzing what "preparedness" on our part might mean. We are afraid of Russia, not because she has atomic bombs; we are afraid of Russia because we have atomic bombs.

It is a very peculiar situation.

If we assume that Russia will be building up a stock pile of atomic bombs just as we are at present building up a stock pile of atomic bombs, we assume an arms race. It might, perhaps, be possible for us to have at any time ten times as many bombs as Russia and possibly also to have larger bombs than Russia, but in spite of this we would lose ground steadily in such an arms race on account of the

fact that we have very large concentrations of population located as easy targets for attack by atomic bombs. Moreover, Russia could, and I believe she would, if such an arms race got seriously under way, relocate within a few years the population of her large industrial centers.

Let us, therefore, be quite clear as to what the term "preparedness" means. It means a stock pile of atomic bombs. It also means a large navy and a strong army. These are important, because a war that starts with attacks on our cities by means of atomic bombs will have to be ended, assuming that we are going to win it, by invading the territory of the enemy. But if atomic bombs must be expected to be available in quantity in the hands of the enemy at the outbreak of the war—and no country is going to attack us unless she has such a stock pile of atomic bombs—getting prepared means also the relocation, in time of peace, of 30 to 60 million people, together with the industries which they serve and which serve them.

The CHAIRMAN. You are talking about digging holes now for people to go down into holes?

Dr. SZILARD. Not quite. I think I will be more specific about it, and give you some figures of cost which we have studied.

The CHAIRMAN. I hope you will leave us above ground; that is all.

Dr. SZILARD. I leave the houses above ground, but I am afraid I will have to put some factories and some railroads underground.

I, for one, do not contemplate with equanimity the death of possibly 40,000,000 people in the United States at the outbreak of war. Senator Tydings asked Dr. Bush to comment upon the possibility of such a contingency and was told that this sounded like a story by Buck Rogers or Jules Verne. Maybe this is a Jules Verne story, but by the same token you might call the story of Hiroshima an H. G. Wells story, and, as a matter of fact, Wells wrote a story about atomic bombs and their use in 1914.

There is one significant difference, however, between these two stories. It took man's ingenuity and imagination to translate the story of H. G. Wells into reality, whereas it will take only man's lack of imagination to make this Jules Verne story come true.

However distasteful it may be to us to contemplate such a large-scale relocation of population, we have to face the fact that without it there can be no policy of "preparedness" which makes any sense at all.

I quoted a figure of 30,000,000 to 60,000,000 because about 30,000,000 people live in cities of over 250,000 and because 63,000,000 people lived in metropolitan areas before the war.

If we had enough time, say 10 years, to bring about this relocation, it would be a very expensive proposition, but at least it would be a feasible one. Dr. J. Marschak, of the Cowles Commission at the University of Chicago, jointly with Dr. Klein, also of the Cowles Commission, estimates that with a yearly expenditure of \$20,000,000,000 we could relocate 60,000,000 people in 10 years and make this country considerably less vulnerable.

Senator MILLIKIN. Would that be a figure for the actual relocation, or would it also include the losses from the relocation?

Dr. SZILARD. What kind of losses, sir?

Senator MILLIKIN. Well, if I have a factory in Senator McMahon's State, it might cost me \$100,000 to move that factory out into a less

populated district. That is one feature of cost, but it also results in a capital cost, and many other factors in moving. Is this a mere moving figure, or does it include compensation for the other losses involved?

Dr. SZILARD. I would put it this way. If your old factories and houses were all dynamited, except for the equipment and the machinery, then \$20,000,000,000 per year spent for 10 years would build up all these factories and houses again in the new location.

Senator MILLIKIN. That is a moving and reconstruction cost?

Dr. SZILARD. Moving and reconstruction. They say that our economy could stand this expenditure without any appreciable reduction in the standard of living during the transition period, and they also say that the volume of the construction industry would have to be expanded only slightly above its peak volume in the year 1942, so you will see that you cannot say it is just physically not possible. Physically, it is possible.

It seems to me that those who think in terms of preparedness and talk in terms of preparedness to the American people ought to talk in terms of a peacetime expenditure for preparedness of more than \$20,000,000,000 per year. This amount may be not enough since we may not have 10 years in which to prepare.

Senator TYDINGS. Before you leave that subject, is the transmission of an atomic bomb by an individual by hand feasible?

Dr. SZILARD. You mean moving an atomic bomb from one place to another?

Senator TYDINGS. Carrying it from one place to another.

Dr. SZILARD. It would have to be dismantled if you wanted to take it in a suitcase. The amount of fissionable material could be easily transported in a suitcase.

Senator TYDINGS. How long would it take to dismantle it and re-assemble it again?

Dr. SZILARD. One could do it by making several trips.

Senator TYDINGS. Or six men in one trip?

Dr. SZILARD. Using a truck they could do it.

Senator TYDINGS. You don't rule out the possibility of surreptitiously using the atomic bomb if people have the ingredients and the "know how" to put it together?

Dr. SZILARD. Yes; if the organization of a nation is put behind it. I do not believe bootleggers could do it.

Senator TYDINGS. You don't think that is Jules Verne at all?

Dr. SZILARD. No.

Senator TYDINGS. You think that is well within the realm of possibility?

Dr. SZILARD. Yes.

The CHAIRMAN. Doctor, you made an observation about putting certain railroads underground. In view of your answer to Senator Tydings, the possibilities of sabotage below ground would be even more drastic than if the same railroad were on top of the ground, it seems to me.

Dr. SZILARD. Relocation would not help at all, as far as sabotage is concerned.

The CHAIRMAN. In fact, my point is it would be easier to sabotage underground installations than it would on top of the ground, because you would have, we will say, 500 miles of railroad underground, and

if you brought down 100,000 tons of dirt along 10 miles of it, it would be harder to repair than if you blew up the same mileage above ground where you could possibly track around it.

Dr. SZILARD. I was not thinking of putting railroads generally underground; I was thinking primarily of putting certain city railroads underground.

I think the destruction of a city or the destruction of a railroad would be equally easy if you assume sabotage.

Senator TYDINGS. Doctor, as I listen to your testimony as a layman in the field of psychology, I am impressed with the fact that what those concerned with this need more than anything else is, as you have termed it, more imagination; that the avenues of possibility of this are so numerous and the development of it is so full of potentials that one must more or less use his imagination to the *n*th degree in order to comprehend what might be involved.

Is that an erroneous statement?

Dr. SZILARD. No; I think it is correct.

Senator TYDINGS. The one thing we need to understand is the ultimate possibility of this new instrument.

Dr. SZILARD. I think so.

Since time is getting short, perhaps I may read just a part of section 5.

Senator HICKENLOOPER. I understand that your entire statement will be made a part of the record?

Dr. SZILARD. Yes, I will hand in the entire statement.

In thinking about an international solution of our problem, we may take encouragement from the fact that at least as far as the United States is concerned, this question has not become a political question in the ordinary sense of the word. It seems to me that the essential difference is not between Democrats and Republicans, or Progressives and Conservatives, but rather between two schools of thought.

According to one school of thought, two powerful countries, like, for instance, Russia and the United States, could both have a large stock pile of atomic bombs and have the means to deliver these bombs to their distant targets and yet a durable peace could exist on the basis of fear of retaliation.

According to the other school of thought, such a situation would inevitably lead to war and war would break out even if neither of the two countries wanted it, more or less automatically as a result of the arms race. I myself believe this to be true. Perhaps, if through some freak accident both countries were exactly equally strongly armed with bombs and equally vulnerable to bombs, peace could be maintained since in that case the bombs which would fall on the cities of both nations at the outbreak of the war would not materially shift the balance of power of two such countries. Conditions of this sort, however, can hardly be expected actually to arise. In most cases which we can envisage, the balance of power will be considerably shifted during the first days of the war either because one of the countries has a much larger supply of bombs or more likely because one of the two countries is much more vulnerable to attack than the other.

In the conditions which actually exist, the greatest danger which faces us is a war arising out of such a situation between the United States and Russia. What can we do to avert this danger?

It seems to me that if the United States and Russia would set up an arrangement in which there would be no stock piles of atomic bombs in either country and no manufacture of atomic bombs on the territory of either country, such an arrangement could be extended without much difficulty to all major powers, as a matter of fact to all nations whose voluntary collaboration is necessary.

Let me be quite specific in the assumption which I am going to make. I am assuming that there is no essential change in the present set-up of the United Nations Organization, that the veto right of the great powers has not been abolished, but that Russia, the United States, and other nations have concluded an arrangement of the type outlined above and that they have reserved the right to abrogate that arrangement at any time.

Under these specific assumptions, we may scrutinize the following specific question: Could Russia and the United States within the framework of such an arrangement create conditions by means of which they could convince each other, and other nations, that secret violations in their territory would be detected and would become instantly known to the world?

I am giving an affirmative answer to that, and I am not going into any detail at this time. I am saying "Yes"; with some imagination, some experimentation, we could make reasonably sure that no secret violations would remain undetected.

The CHAIRMAN. Doctor, that is a subject in which I personally am deeply interested, namely, the scientific feasibility of control. Do you have a full statement on that?

Dr. SZILARD. I have a full statement which I would prefer to put in for the record rather than read it here now.

The CHAIRMAN. I just wanted to make sure we got that, because that is a very vital part of our inquiry, it seems to me.

Dr. SZILARD. May I read to you something appraising such an arrangement, assuming that we could detect secret violations?

What would be the good of an arrangement which could be abrogated?

Senator TYDINGS. Suppose you put in a provision that you could not abrogate it except on 5 years' prior notice so to do?

Dr. SZILARD. For certain reasons, I would prefer to give the large countries who have the physical power to abrogate also the legal right to abrogate in order not to have a discrepancy between legal abrogations and de facto abrogations. I believe it would be better not to have this distinction. I think as long as we have no enforcement, we should legally permit abrogation.

But what is the use of an arrangement that can be abrogated?

Well, this is my view on it: Clearly, in the absence of machinery for enforcement, an arrangement providing for adequate inspection cannot rule out the possibility of war, and, in case of war, sooner or later atomic bombs can be expected to drop from the sky. Yet such an arrangement, assuming that the inspection system functions satisfactorily as long as it lasts, in my opinion would be a long step forward because under such an arrangement war need break only if one of the parties to the arrangement actually decided to risk a war by abrogating the arrangement.

There are two questions which have not been touched yet which will require further examination: (1) What incentives would, under such an arrangement, Russia and the United States have for abrogating the arrangement after it had been in operation for a number of years, by invoking their legal right to abrogate which we have postulated they have retained? How could we diminish those incentives, if they existed? If there is no enforcement, our aim should be to remove incentives which would lead a large power to abrogation.

Another question which must be considered, and which I would prefer to discuss in executive session, is what would be the situation facing the United States if an abrogation occurred say 5 or 7 years from now, what restrictions should be imposed on atomic power and installations in order to make the time lag between abrogation and the production of bombs a long time lag?

At the time of abrogation, always assuming that inspection was reliable as long as it lasted, there will be, of course, no bombs available, but the question is how long would it take until bombs would be manufactured, and at what rate they would come out of the factories. The answer to this question depends to a large extent on whether or not electrical power installations based on atomic energy have in the meantime been erected on the territory of the United States, and on the territory of Russia. And if they have been erected, whether or not certain specific limitations have been imposed upon them which will make their conversion more difficult.

This brings me to the last section which, with your permission, I should like to read.

Senator HART. If that is the end of a section, may I ask one question, Mr. Chairman?

The CHAIRMAN. Certainly.

Senator HART. You mentioned when you began that there were two schools of thought. I personally have not heard any expression from the one school of thought which is contemplating both nations, ourselves or any other nation, not confining it to Russia, in an armament race where both sides possessed atomic bombs.

Have you heard any expression from that school of thought, Doctor?

Dr. SZILARD. Yes. In the transcript of Dr. Bush's statement, which I have not heard but which I read, Dr. Bush expressed the view that fear of retaliation would prevent the outbreak of war if two countries were equipped with atomic bombs.

Senator HART. And that is what you were particularly referring to in that?

Dr. SZILARD. The only testimony before this committee where this school of thought found expression was Dr. Bush's testimony; but I have heard that view expressed by other distinguished men, such as Professor Viner, of the University of Chicago, who thinks that two large countries both having atomic bombs could remain at peace because the fear of retaliation would prevent the outbreak of a war. This thought is prevalent, and very distinguished men belonged to this school of thought; but only Dr. Bush expressed that view before this committee.

Senator TYDINGS. This accounts largely for the view that the nation which takes the initiative and springs the surprise would have an advantage that is almost inestimable, assuming that their surprise attack was successful.

Dr. SZILARD. I am not sure that that advantage is not somewhat overestimated. Clearly, they would have this advantage, that they would not only destroy the cities but also kill the men in the cities. But after such an attack, retaliation would come, because we would launch our atomic bombs not from the cities, but from sites which are very well protected, so the cities of the aggressor would also be destroyed.

Senator TYDINGS. I don't take issue with what you are saying, but I am just expressing the fact that if you had 6 hours' advance to do your bombing as against the enemy, as against bombing the enemy, that the side which has the initiative, which does the bombing first when they are not looking for this attack to come would have a decided advantage over the retaliation, where they would know in advance that the retaliatory attack was coming and would be presumably prepared to interdict as many planes as possible, and other conveyances of the bomb.

Dr. SZILARD. That is certainly true as long as these large concentrations of population exist. It will no longer be true if the relocation and dispersal has occurred.

The CHAIRMAN. The aggressor nation would catch twenty or thirty million people in the cities that were attacked, and they would have their population pretty well dispersed and out of their centers of population.

Dr. SZILARD. Yes, that is right, and may I have permission to withdraw the answer which I gave to Senator Tydings. I think you are right and I was wrong. I think the aggressor would still have a great advantage even if dispersal were carried out.

Senator TYDINGS. And particularly if simultaneously with that visible attack there had been a preliminary campaign to smuggle, if that is possible, other atomic bombs that would even after that attack continue to wreak devastation here, there, and wherever it was appropriate throughout the country.

Dr. SZILARD. That would make it worse, but without it it would still be very bad.

Senator TYDINGS. You are keeping in mind always that the supposition exists in this country, and I believe it is reasonably predicated on fact, that because of a borderline of 3,000 miles to our north, another borderline of large dimensions to our south, with the fact that we are completely surrounded by water in all other respects, that there always has been a great deal more illegal immigration into the United States than perhaps into all of the other countries of the world combined?

Dr. SZILARD. Yes.

Senator TYDINGS. And that therefore the avenues by which the United States can be entered are 100 times more promising than would be the case in almost any other country of which you can conceive, and therefore the means of getting the materials into the country are correspondingly improved?

Dr. SZILARD. Yes.

Senator MILLIKIN. If I may add an additional observation, Senator: you might get across some border of a foreign country, but at once your movements become regulated. Once a man gets into this country, we don't have any of the precautionary devices which foreign

countries have to observe the movements of foreigners and their own people.

Senator TYDINGS. For example, as you probably know, and as I know Senator Millikin has in mind, if you go to Britain you are immediately given a question, no matter if you are a United States Senator: Why did you come to the country? Where are you going to stay? How long do you propose to stay? Where will you go? And so on. You are given a little interview besides.

If you go to France and want to go to a hotel, you fill out a paper, and so on; and that is sent to the chief of police every night. So it is all over the other countries; but when you come over our border, there is nobody here that knows whether they are Americans or foreigners, or what they are. There is no check-up at all; so that we have a country to which more people want to come than want to come to any other country in the world, and with less precaution against their coming than to any other country in the world.

The CHAIRMAN. Go ahead, Doctor.

Dr. SZILARD. [referring to printed statement]. This is Section VI, Remarks on Secrecy.

In the past, secrecy fulfilled an exceedingly important function and we might have lost the war if it hadn't been for the secrecy which the scientists imposed upon themselves in the early stages of the war. If the Germans had known in 1940 that a chain reaction can be maintained in a mass composed of graphite and uranium and if they had known a second fact, namely, that the plutonium produced in such a chain reaction is likely to be a fissionable substance similar to light uranium, they might very well have started an atomic bomb project in 1940; and, with their eyes on the ball, they might very well have brought it to a successful conclusion by the spring of 1944. They might have won the war before we had a chance to invade Europe.

The first of these two pertinent facts which I mentioned was contained in a paper which I sent to the Physical Review in February 1940, with the request that its publication be withheld. The second fact was emphasized in a paper which Prof. L. A. Turner, of Princeton University, sent to the Physical Review a few months later, and which he decided to withhold from publication.

Neither of these facts was known to the Germans at the time when the war ended, though they are public knowledge at present through the Smyth report.

Senator MILLIKIN. Do you agree with the conclusion of a witness that was here the other day that by the end of the war the Germans had not any organized program for making an atomic bomb?

Dr. SZILARD. Yes. The witness who was here was Dr. Goudsmit; and no one is as competent as he is to state that, because he was in charge of the group which went into Germany and collected all the information on atomic energy work.

Senator MILLIKIN. From which it follows that had our intelligence been better as to what was going on in Germany, we might not have evolved an atomic bomb at least during this war. It was sponsored and pushed on the theory that we were in a race with Germany to complete an atomic bomb.

Dr. SZILARD. I agree entirely with that conclusion.

Senator TYDINGS. Doctor, if in 1939 we had been conducting a hearing like we are conducting today, and men like yourself had come before our committee and projected the possible development of the bomb up to now with reasonable accuracy, I imagine they would have been called a lot of crackpots and a lot of visionaries who were playing with theories. I certainly would have not had the receptivity that I have today, to say the least.

So using that experience of the past, I take it that many people who hear the possibilities of this bomb described for the future are just about in the same position that we were all in in 1939 if we had had hearings on it then. Is that a fair assumption?

Dr. SZILARD. Yes, they would be incredulous, but with less justification.

Senator TYDINGS. Some people have to get burned twice in order to understand they have been burned once.

Dr. SZILARD. The point I am trying to bring out is that secrecy has been maintained by the voluntary cooperation of the scientists in 1940 when it was most important that secrecy should be maintained, and that if secrecy should again become important in the future, it can again be maintained by the voluntary cooperation of the scientists. To my mind willing cooperation on the part of the scientists is the only satisfactory and really effective way of maintaining secrecy both in the field of fundamental scientific information and basic engineering principles which are involved in the manufacture of fissionable substances.

I would like to make a few remarks on the compartmentalization of information.

Compartmentalization of information to which the scientists were and are still subjected was mentioned in Dr. Urey's testimony. It is a special technique which is used in the services for keeping secret military operations, and applied in its proper sphere it is an effective method for keeping secrets. Both its meaning and its effectiveness undergo a profound change when it is attempted to apply this special technique to research and development work.

As applied to scientific work, you may justify compartmentalization of information by pointing out that if a scientist knows not only how to extract light uranium from natural uranium, but also knows how to manufacture plutonium and if such a scientist is a traitor, then he can teach the enemy how to make both kinds of bombs instead of teaching him only how to make one kind of bomb. Or even better, if he knows only part of the story of how to make light uranium and nothing about how to make plutonium, he can give the enemy information, but that information alone is not sufficient to enable the enemy to make any kind of bombs.

Compartmentalization of information was practiced in the atomic energy project from the very first day on; that is, from November 1940 on, or before the Army was in the picture. The situation was not better when we had to deal with the NDRC, which had "to play ball" with the Army and Navy, than later on, when we had to deal with the Army direct. If anything, dealing with the Army direct appears to be preferable, since the Army is afraid only of Congress, while agencies like the NDRC are afraid of both Congress and the Army.

I shall be glad to demonstrate, if required, that compartmentalization of information was the cause for our failure to realize that light uranium might be produced in quantities sufficient to make atomic bombs. We should have known that in the fall of 1940. We might have failed to realize this altogether, just as the Germans failed to realize it, if we hadn't had the good fortune that the British scientists were not compartmentalized. They were able to put two and two together and communicated their conclusions to the United States Government in the middle of 1941. Had we in the United States reached these conclusions in the fall of 1940, we most likely would have had bombs ready before the invasion of Europe.

Senator TYDINGS. Doctor, if I am not interrupting you, I would like to ask you a question right there.

Suppose Hitler had assumed that this thing might reasonably be invented. Suppose that assumption had first come to him in 1939, and that he had then assembled all the available scientists and engineers that he had and said: "I want you to do everything possible to develop an atomic bomb, or an instrument of death more deadly than any you have with atomic energy. We will put at your facility every asset of this Government, every resource of this Government."

If that had happened in 1939, with the engineers, the scientists, and the materials and the industrial plants then available in Germany, would it have been possible under reasonably human conceptions for Hitler to have had the bomb preceding our own having it?

Dr. SZILARD. I am quite convinced he would have had it about 18 months before we had it.

Senator TYDINGS. He would have had it 18 months before us?

Dr. SZILARD. We could have had it 18 months earlier, and with their chemical industry they could have moved equally fast.

Senator TYDINGS. Why do you suppose that the scientists of Germany who were then loyal to the Hitler concept failed to impress this fact on Hitler's mind, that it was a possibility and that its devastating effects might decide the war?

Dr. SZILARD. They slipped up on one point, on which we slipped up also. They did not put two and two together. We did not put two and two together because the two two's were in a different compartment; they were not together. That is, the men working on that property of uranium from which they could deduce how much was needed for the bomb had no idea that you can extract light uranium in appreciable quantities.

Senator TYDINGS. How do you account for that break-down of putting two and two together?

Dr. SZILARD. In Germany I cannot account for it. It is true that they were split up in small groups, but they were not compartmentalized.

Senator TYDINGS. Do you think the very Nazi system itself might have destroyed the free interchange of ideas?

Dr. SZILARD. It might have been, but I have no really good explanation for it. I think it was largely a matter of chance.

Senator TYDINGS. Just luck?

Dr. SZILARD. It was luck. Well, the only man who thought fairly early that plutonium might be fissionable was a man who was an immigrant in Germany. He wrote a number of memoranda, but nobody paid any attention to it. He was an Austrian who spent a great deal

of time in Russia, and finally landed in Germany. He was the only man who proposed such a plan, and we know from the record that he proposed it.

The CHAIRMAN. Who was that?

Dr. SZILARD. Houtermans.

The CHAIRMAN. Do you know his first name?

Dr. SZILARD. I do not know his first name.

The CHAIRMAN. Do you know where he is now?

Dr. SZILARD. In Germany.

Senator TYDINGS. What part of Germany?

Dr. SZILARD. In the American section.

The CHAIRMAN. Doctor, you remember one bombing raid that the American Air Force conducted which killed 400 German scientists. Do you think that had any bearing upon their lack of expedition?

Dr. SZILARD. No; and I am not sure it did kill 400 German scientists.

The CHAIRMAN. That is what I read at the time.

Dr. SZILARD. That is what I read too, but I do not believe it.

Senator TYDINGS. Furthermore, they were supposed to be working on something else than the project we are now discussing.

The CHAIRMAN. You had something to do with getting some of the scientists out of continental Europe, didn't you?

Dr. SZILARD. To England, yes.

The CHAIRMAN. When did you start?

Dr. SZILARD. In '33.

The CHAIRMAN. And you made quite a project of that of your own in inducing people to get out of there, didn't you?

Dr. SZILARD. It did not take much inducement.

The CHAIRMAN. But at any rate, whatever it took, you offered, didn't you?

Dr. SZILARD. I wouldn't say that my role was to induce them. I was in England at that time, and I tried to do my best to find temporary positions for younger men in England who wanted to leave Germany. Many of those later came to America.

The CHAIRMAN. Why did you take it upon yourself to engage in this matter at that time?

Dr. SZILARD. I had no thought of atomic bombs in 1933 in my head. I did not think of the possibility of atomic bombs until 1934 or 1935, and it was simply a matter of helping those who needed help and who wanted to leave Germany. I mean men who had been connected with various German universities.

The CHAIRMAN. It did pay dividends, though, your getting some of these men out, didn't it?

Dr. SZILARD. It did pay dividends; yes.

Senator TYDINGS. What would have happened if they had stayed behind, in your opinion?

Dr. SZILARD. I do not know. It is difficult to know what would have happened.

Senator TYDINGS. It might have conceivably, as a matter of deduction, changed the whole atomic bomb development in Germany from what it was to what it might have been.

Dr. SZILARD. I might say that the three men in England who were instrumental in reaching the conclusion that atomic bombs could be made came out of Germany in 1933. At that time in England, in 1941,

most English physicists were engaged in radar work and other types of work, and these refugees who were not taken into that work, which was considered of very great importance for the war, had more leisure than their English colleagues to think of such remote possibilities as atomic bombs.

The CHAIRMAN. Who were those three fellows you got out?

Dr. SZILARD. Peierls, Frisch, and Simon. I did not get them out; they got out on their own initiative.

Senator MILLIKIN. Who was left, Doctor, that envisaged the possibility?

Dr. SZILARD. A great many excellent people were left in Germany. Heisenberg, for instance, is one of the greatest physicists.

Senator TYDINGS. I think that ought to be left off the record unless we know where they are.

Dr. SZILARD. I can limit my statement to those who are in the American sector, if you wish.

Looking back, we now know that full secrecy would have been maintained if compartmentalization had not been imposed upon us because we know that there was not a single scientist through whom information of any kind reached the enemy. There were many compartments, but there was no traitor in any of them, and the Germans had no information whatsoever about us.

Senator TYDINGS. But on the other hand, if instead of 3 or 4 or 5 men, to take an assumption, knowing about the whole process more or less, had there been 300 or 400 men who had learned about it, from now on our secret would be less safe, wouldn't it, unless some of them directly or inadvertently released that information to sources that might find it valuable?

Dr. SZILARD. May I disagree in the following sense, that having access to all the information does not mean you are in possession of all the information. Few scientists would waste their time trying to learn all of the information.

Senator TYDINGS. The more people who know about a thing, the more difficult it is to keep a secret.

Dr. SZILARD. That is true.

Senator TYDINGS. That applies even to Senators, and it is no reflection on scientists.

Dr. SZILARD. At first, we all observed rules on compartmentalization because we did not realize ourselves how damaging it was. Later on, the rules were purposely violated, because we would rather violate rules than slow down our work. Men coming from different sites would drop into my office and they would tell me things which I was not supposed to know, but which they felt that I ought to know. They usually told me that they did not expect me to conceal the fact that I was in possession of this information. All they asked me to do was not reveal to the Army that they had given me the information.

Some of you saw at Oakridge a certain installation and were told by a representative of the Army that it shortened the war by 1 week. That installation was based on a pilot plant which was built by the Navy. The installation was erected at the recommendation of Dr. Oppenheimer after an interview he had with Dr. Bush. But if you investigated how Dr. Oppenheimer got the idea of recommending this to Dr. Bush, you would find that at least two patriotic scientists delib-

erately violated the rules and broke through compartments. Afterward, everything was covered up nicely. Dr. Oppenheimer's projects officially asked for the information which was already unofficially in their possession, and made an official study of what they already knew, and then finally Dr. Oppenheimer approached Dr. Bush and wrote to General Groves.

I am very sorry to say that I had nothing to do with this chain of events. As a matter of fact, I should have done something about it, because one of the men came to me six months earlier and complained that nothing was done along that line and asked me if I knew what could be done to get some action along that line.

Compartmentalization of information was very irritating to scientists and as a result of this many of them go much further in their opposition to all secrecy than they otherwise might do. Clearly compartmentalization is only a special technique and in my opinion an inadequate technique for maintaining secrecy. The question of secrecy is in reality an entirely different issue and ought to be judged on its merits in the light of the international situation to which we shall have to adjust ourselves.

This concludes my statement.

Senator HART. Doctor, who would you consider was the agency or the man who carried the full responsibility for our maintenance of necessary secrecy?

Dr. SZILARD. I would say after the fall of '42 it was General Groves. Up to that time, I would say it was either Dr. Conant or Dr. Bush.

Senator HART. Had you been the responsible party yourself, do you think that possibly you would view it differently now?

Dr. SZILARD. I would view it differently perhaps from the way I view it. I would also undoubtedly view it differently from General Groves or Dr. Bush.

Senator JOHNSON. Was there any delay in the creation of the atomic bombs caused by the imposition of the secrecy arrangement?

Dr. SZILARD. Very great delay, primarily due to this reason: Compartmentalization of information could be used without much delay if you had had at the center an omniscient man who could foresee everything. But the way the delay comes about is this: The most important answers are answers to unrecognized questions.

Senator JOHNSON. When would the bomb have been dropped, or when could a bomb have been dropped had the secrecy arrangements not been imposed?

Dr. SZILARD. About the spring of '44 would be my best guess, because the big delay arose from the fact that our work did not have a clear goal until the end of '41, because we did not know that amounts of fissionable material which we could produce were sufficient to make bombs.

Senator JOHNSON. That is a delay of 18 months?

Dr. SZILARD. That is a delay of 18 months, yes; and that is the 18 months that was the chief loss of time.

Senator JOHNSON. One war was finished and the other was toward its end?

Dr. SZILARD. That is so.

Senator HART. May I interject just one thing there?

I think it is in the record possibly from Dr. Bush, or it may be from Dr. Smyth's book, that there was a center for the necessary interchange

of secret information set up in the Manhattan district which was headed by one of the scientists, and I believe Dr. Tollman's name was mentioned in that respect.

Dr. SZILARD. I do not believe it would have been very difficult to get any specific information for which you asked, provided you knew that kind of information existed.

Senator HARR. I think it was represented that that was the duty of that center, to see that those who needed the information in their own work were given such as was necessary.

Dr. SZILARD. You see, it is a duty which no one can perform, because how can you tell what ideas a man would get if he had two different kinds of information? The man doesn't know he needs it.

Senator TYDINGS. Facing the contingency which the Army and the Navy always had to face, that if this were not compartmentalized, as they call it, that the information might inadvertently or directly, one of the two, leak to the enemy which it is assumed was likewise working on atomic bombs, wouldn't you say that even though the precautions taken were now in the light of subsequent knowledge unnecessary that as of the time they were taken they were at least understandable and meant to serve rather than hinder the country's ultimate welfare?

Dr. SZILARD. I am not blaming the Army for using the routine methods in the field of development and research which they used in military operations. That is what you would expect from the Army.

But from January '42 on, we did not cease to protest against it, and those in direct charge of our work knew it was damaging.

A. H. Compton was in charge of the work at the University of Chicago. In 1942, before the Army was in the picture, we received rules relating to compartmentalization. We had a meeting and all scientists protested against it and said it would slow down our work.

Senator TYDINGS. If I do not divert you and the chairman doesn't object and the committee doesn't feel I am taking you too far afield in the time that might be left, would you care to picture, from your imagination and your knowledge of the atomic bomb, what would occur in a war in which the atomic bombs were used by the nations arrayed on different sides?

Dr. SZILARD. Well, I do not know that I can give you a good picture, because I am trying to steer my imagination away from that contingency rather than to concentrate on it. But I believe—and I believe that I am quoting Dr. Oppenheimer, not from his testimony but from a statement he made elsewhere—that 40,000,000 dead during the first few hours, or, if you wish, during the first few minutes in the United States—

Senator TYDINGS. Let us say the first few months.

Dr. SZILARD. There is no reason why bombs should come staggered during a period of a few months. It is equally easy and much more profitable to deliver them within a very short period of time, so 40,000,000 dead, if the war comes without warning and if we don't relocate our population, and if there is a large stock pile of atomic bombs in enemy hands, would be a thing which we would have to count on.

Senator TYDINGS. That would likewise happen, according to the industrial density of the enemy nation.

Dr. SZILARD. It might not be determined so much by how many bombs we have or they have, as it might be determined by how concentrated their population is in cities. Our relative strength might be determined by our relative vulnerability if the war came 10 years from now.

Senator TYDINGS. I think it has been testified in open hearings that the possibility of use of the atomic bomb not only on land but on water is within the field of operations.

Do you agree with that viewpoint?

Dr. SZILARD. Certainly, the use under water may be a very important use.

Senator TYDINGS. How about surface vessels?

Dr. SZILARD. Well, still the bombs might be exploded under water in order to sink surface vessels. I do not know much about it.

Senator TYDINGS. I will not question you on that.

Dr. SZILARD. I am certainly not an expert on this question.

Senator TYDINGS. Your testimony at the conclusion of this hearing, boiled down, is simply this—as we already know, but I want it in the record: If we have a future war fought with atomic bombs, it is likely to be many, many times more devastating not only in the amount of property destroyed but in the amount of both military and civilian casualties of all kinds?

Dr. SZILARD. Well, the war against Germany caused great devastation without atomic bombs; but I think there is a qualitative difference as well as quantitative.

Senator MILLIKIN. The syllabus that we have before us, Doctor, that shows something of your record, states that you helped prepare the Smyth report. Can you tell us the reasons why the Smyth report was prepared and published?

Dr. SZILARD. I am afraid I did not help to prepare the Smyth report.

Senator MILLIKIN. It says that you assisted in the preparation of the Smyth report.

Dr. SZILARD. All I did was read the proofs of certain chapters, which I returned together with my recommendation that it should not be made public, but that was too late. It was just a proofreading, and I had no prior knowledge of the Smyth report.

Senator MILLIKIN. I should like to suggest to you, Doctor, that in the light of hindsight, I believe the Army can make a very strong case for its compartmentalizing theory for the simple reason that Germany was astonished that we had developed an atomic bomb at the end of the war, and so secrecy was preserved.

In the light of hindsight, I say that the Army can make a very good case for having done it the way it did do it.

Dr. SZILARD. Secrecy was preserved not on account of the compartmentalization, because any man from any compartment could have told the Germans what we were doing.

You see, compartmentalization was not effective in the sense that it prevented the men from knowing what was going on—that they found out; but they did not know the details. The Germans did not know even that we were working on an atomic bomb.

The CHAIRMAN. This thought occurs to me, Doctor, that if foreign agents were to kidnap, if German agents were to kidnap a scientist

who had been compartmentalized, they could torture him and get only that which he knew. He would be just as available for kidnapping if he knew it all, and he would be able to give up that much more. Have you thought of that possibility?

Dr. SZILARD. Yes; but my point is that there is a natural limitation to what a scientist knows. He knows what he is interested in, and that is usually a very small fraction of the picture. The scientists would not know everything just because they have access to all the information. General Groves has access to all of the information, but that doesn't mean he knows everything.

Senator MILLIKIN. Would you say that because of the reticence of the scientist and the security measures of the Army the enemy did not learn about our atomic bomb?

Dr. SZILARD. Our enemies did not know that Hanford existed and made fissionable materials. They did not know that in the Tennessee Valley we had plants making fissionable materials, and they did not know that work on uranium was going on at the University of Chicago. I believe that this is due to the inability of the average military intelligence man employed by Germany to grasp things which have anything to do with science. They failed as to intelligence about us just as we failed about intelligence in Germany, and that was not due to our security measures or the security measures of the Germans. It was simply due to the incompetence of military intelligence when it had to deal not with military operations but with science development and a type of industry of which they did not know the existence.

Senator JOHNSON. Doctor, Senator Millikin suggests that the Germans were astounded in August of 1945 when they heard about an atomic bomb.

Don't you think they would have been even more astounded if they had heard it early in the spring of 1944?

Dr. SZILARD. Some would be dead and not astounded, but the rest would be astounded; yes.

Senator JOHNSON. Mr. Chairman, is this witness going to come before us in executive session?

The CHAIRMAN. He has indicated in his statement that he would like to tell us some things in executive session that he has not been able to mention in public session.

Senator JOHNSON. I had two or three kindergarten questions that I would like to ask him about plutonium, because I understand he is especially expert in the manufacture of plutonium.

I don't think these kindergarten questions of mine border on secrecy at all, or would require an executive session.

If I may ask him, and if they do border on what should be confined to executive session, I hope that he won't answer them.

The first question is: As I understand it, the light uranium, the 235, comprises seven-tenths of 1 percent of uranium.

Dr. SZILARD. That is correct.

Senator JOHNSON. Now, when you put that uranium in a pile and this light uranium starts a chain reaction, you create plutonium, which is, as I understand it, 239. When you create that plutonium, do you create more than seven-tenths of 1 percent?

In other words, can you step up the production of fissionable material through the plutonium process?

Dr. SZILARD: If you do it the way it is done at Hanford, you create very much less plutonium than you use up light uranium.

The CHAIRMAN. I just want to make sure that the Doctor knows the limitations, Senator. I agree with you; I cannot see anything in it, but I just want to make sure that he understands.

Dr. SZILARD. Yes.

Senator JOHNSON. If it is anything bordering on the executive session, skip my question, please.

Dr. SZILARD. May I put it this way: As far as the Hanford process goes, we cannot make more plutonium than there is light uranium in the natural material, and we make very much less. But this answer does not do justice to your question, and anything else I would prefer not to say in open session.

Senator JOHNSON. Then, my second question is something like my first question.

In the use of plutonium or a pile process for industrial purposes, does that chain reaction continue for a long period of time? In other words, you put uranium in, and when the light uranium is used up, the U-235 is used up, you have to replace it with new plutonium. Is that a reasonably short period of time, or does that heat reaction continue for a long period of time?

Dr. SZILARD. Could I answer your question this way: I would not think of using for industrial purposes anything that would even remotely resemble that graphite-uranium pile which is described in the Smyth report for making plutonium. I think that is quite useless for any industrial purposes.

Senator JOHNSON. You think it is useless, but do you think that there is a process that is useful for industrial purposes?

Dr. SZILARD. Well, what I think I would like to defer saying.

Senator JOHNSON. All right; I won't press you; but those are two things that have been bothering me.

Senator MILLIKIN. Mr. Chairman, I should like to suggest that I do not know whether the industrial witnesses that we are going to have before us are qualified to deal with this specific matter that I should suggest, but I do believe that someone qualified to deal with it should come before us. I would like to get into the question of dispersal, the practicability of dispersal.

The CHAIRMAN. You mean the dispersal of the population?

Senator MILLIKIN. And of industry.

The CHAIRMAN. I presume, Senator, that the War Department might have some views on that. I had planned to ask the Chief of Staff, the Secretary of War, the Secretary of Navy and the Chief of Naval Operations to come either in open or closed session, at their election, to talk to us about those matters.

Senator MILLIKIN. I think it would be important that we know of that, because the boil-down of considerable testimony is that that is our best protection.

Senator JOHNSON. I would like to ask a question on that, because this witness has testified in some detail on the matter of the relocation of industry. It has occurred to me that if you should move an industry from Connecticut to Colorado—which I would think would be a very smart thing to do on general principles—you would have to take the workers along. They would have to live in a city, and you would

have to build a new city in Colorado that would compare to your dense population in Connecticut.

I noticed that when they built Oak Ridge down in Tennessee the first thing they did was build a city, and I do not know of any industry that is located out on the plains far from population.

The CHAIRMAN. Let us get away from the horrible hypothesis that you propose, Senator.

Senator JOHNSON. It is horrible, I suppose—horribly good.

The CHAIRMAN. Let us take Pittsburgh. As I interpret what the witness is saying, you have, for instance, the United States Steel; you also have Republic Steel, we will say, and Inland Steel. Let's put them at Gary, because that is where they are, and you and I have seen them many times.

The thought would be, instead of having three side by side along the waterfront there, that there would only be one, and then 50 miles away, or on the lake, that would be another; or 100 miles away there would be another. I think that is what he means by dispersal.

Senator TYDINGS. I think it has got to mean that not only would you disperse, but going with your dispersal after it is accomplished you would have to have a limitation on what other industries could come to that city.

Senator MULLIKIN. If you multiply the number of targets, it obviously multiplies the difficulty of the enemy.

Senator TYDINGS. After you have located one industry, we will say, in X, you would provide that no other industries could be located at X, but that the next industry would have to be located at Y; and you would have an over-all point that when industry grew so large that it reached 250,000 or 500,000 population, or so many acres of ground, or whatever the ingredients were, that from that point on nobody else would be allowed to live in that city or to open up any new industry. It seems to me that would follow.

Dr. SZILARD. It is not only the size of the city but the shape of the city that is important.

Senator JOHNSON. But the difficulty in locating industry is that it is not done by the eenie-meenie-minie-moe arrangement. You place industry for very definite reasons, most of them being the availability of transportation, the availability of workmen, and the cheapness and availability of energy.

Now, you just cannot go out and locate a plant where you want to. You have got to take into consideration the things that cause industrial centers to grow.

Then there is one other thing that keeps coming up in my mind, and that is that we know that following the eruption of Vesuvius and other volcanoes that destroyed human life, that the lava had hardly cooled until the people were back there building houses on top of the lava. Even though Senator Tydings says you have to burn them two or three times before they know they are burned, that is a trait in human nature that you have to contend with.

Senator MULLIKIN. I would like to suggest that China moved her entire industry inland to Chungking as a measure of military protection, and the Russians moved their whole industry to the interior of the country.

Senator JOHNSON. That is true, it transported what few machines the coolies could carry on their backs; but that is a vast difference comparing the Chinese industry with American industry.

The CHAIRMAN. Doctor, I assume that if you had a voice in the election you would view the dispersal of our cities with the consequent cost and general transferring from one part of the United States to another of thirty or forty million people to be far less preferable than some sensible international agreement, for the control of this thing, on which we can rely?

Dr. SZILARD. It is certainly less sensible; yes; provided we can get the arrangement. I am not advocating dispersal, but it is a necessary step within the framework of a policy which is merely based on "preparedness." No preparedness makes any sense without it. If we have to anticipate an attack of this sort, we have to disperse.

Senator TYDINGS. If we get into a war of that type, just having a big Navy, Army or Air Force, while they are essential, as compared to previous wars, without the ability to carry on and supply them by the dispersal of plants all over the country, preparedness is only an illusion?

Dr. SZILARD. Exactly.

The CHAIRMAN. The committee will meet in executive session at 2:30.

(Whereupon, at 12:30 p. m., the committee recessed.)

ATOMIC ENERGY

WEDNESDAY, DECEMBER 12, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Johnson, Tydings, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The committee will be in order.

Dr. Simpson, it is my understanding that you, Dr. Williams, and Dr. Weinberg have more or less collaborated on this presentation this morning.

Dr. SIMPSON. We prepared our testimony separately but have worked it together so that it presents complementary material, and there might be some advantage in hearing all three together before questioning us; but that is up to the committee to decide.

The CHAIRMAN. In other words, what you prefer is that we hear the three of you and then line you up and ask you all three questions; is that the idea?

Dr. SIMPSON. Yes; that would be preferable.

The CHAIRMAN. I think, unless the committee has some objection, it would be practical.

Now, will you proceed, Doctor, and tell us who you are and why you are here.

STATEMENT OF DR. JOHN A. SIMPSON

Dr. SIMPSON. My name is John A. Simpson, an experimental physicist associated with the atomic-bomb project for almost 4 years. I am working at the metallurgical laboratory plutonium project and am a member of the Nuclear Studies Institute at the University of Chicago. I am chairman of the executive committee of the Atomic Scientists of Chicago, and a member of the Federation of Atomic Scientists.

Senator AUSTIN. How old are you?

Dr. SIMPSON. Twenty-nine, sir.

The CHAIRMAN. How old were you when you went to work on this project?

Dr. SIMPSON. About 25, between 25 and 26.

The CHAIRMAN. Thank you.

Dr. SIMPSON. The nature of the problems which lie before this committee is in many respects unique in our history. The issues are of great complexity due to the intertwining of a difficult scientific and engineering field with a political problem of the highest order. It is the obligation of all scientists and engineers to offer their aid in the scientific and technical aspects of these problems.

I have come here today to represent the common opinion of the overwhelming majority of scientists and engineers who have had the privilege of sharing in the development of the atomic bomb.

One of the unexpected byproducts resulting from the development of atomic energy is the changed attitude we scientists have toward the social implications of our latest efforts.

Senator AUSTIN. Do you mind stating when that crystallized so you would be able to say, "I now speak the sentiment of the profession"?

Dr. SIMPSON. Yes, I would, sir. In the next two or three pages [consulting prepared statement] I have brought this out rather carefully.

Senator AUSTIN. Go ahead.

Dr. SIMPSON. I should like to discuss briefly this attitude and the evolution of our thinking about the bomb. These ideas are common to almost 2,000 men, who have, as individuals, widely varying scientific and political backgrounds.

It is startling even to those of us who have shared in this thinking to realize the existence of this unanimity of opinion on both the facts of the bomb and their inescapable social and political implications.

As scientists, we have always preferred to see the results of our studies used for constructive rather than destructive purposes. We have been aware, as many others have been, that man's control of the forces of nature, if rationally exploited, could provide all nations with ample livelihood. However, we have not heretofore felt it our responsibility to strive for this rational use of the fruits of our labor. This responsibility we willingly left to the people and government of our Nation.

There are two reasons for the marked change in our attitude. Never before have we been so clearly and directly responsible for new forces of destruction unleashed upon the world. The development of the atomic bomb was the result of the initiative of certain prominent scientists who succeeded in persuading the authorities that nuclear physics contained undreamed-of military potentialities. Had they not been successful in so persuading our Government, we would still be living in the quaint old world of blockbusters and rocket bombs.

Another reason for the change in our attitude is that the advance embodied in the atomic bomb goes far beyond the discoveries of gunpowder, dynamite, poison gas, or radar. Atomic energy goes far beyond the realm of burning coal and falling water and exploding dynamite; it lies in the realm of the forces which power the sun. These forces are now in the hands of men and, unless men can control them, the end of our civilization may not be far distant.

Our ideas about the meaning of the atomic bomb to our Nation and to the world did not develop overnight—they are the result of a considerable period of evolution. During the early days of the project we spent little time thinking about the possible effects of the bomb we were trying to make. What little thought we did give to this problem

involved discussions only with a few friends within the project. In the latter part of 1944, however, it became increasingly evident that we had made great strides in our program and that there was every likelihood of reaching our goal. It was then that the scientists became increasingly interested in considering the possible consequences of success. What would happen if the atomic bomb worked?

Within but a few months, in early 1945, this increased interest expressed itself in the form of discussions among small groups within the laboratory. These discussions were crystallized in short memos, which became the basis for further discussions throughout the laboratory. As was only natural, some men were more actively interested than others; Dr. Szilard, for instance, proposed some particularly interesting possibilities.

During the meeting of the United Nations at San Francisco, many of us hoped that the necessity of controlling possible weapons of an importance comparable with that of the atomic bomb would be taken into consideration in setting up the structure of the UNO. Despite the fact that great strides had been made in bringing the nations together, we could not help but fear that these steps might still not prove sufficient to control the bomb. By May and June, more and more people were becoming excited about the problem, and larger discussion groups were meeting in the laboratory, always remaining well within the security regulations.

What were these discussions all about? They centered not only upon the effect of the bomb upon the security of this Nation and the world, but also upon the possible ways in which the bomb might be used initially to create the most favorable conditions for lasting peace. In fact, a poll was taken in the laboratories to determine how the scientists felt about the first use of the bomb; how it might be used mostly wisely to end this war and to prevent another one in the future.

As a result of these discussions, there developed among the many men of all the laboratories a strong sense of responsibility—a responsibility which in many respects is unique in history, because, for the first time in history, a new age lay in the hands of a relatively few men unknown to the rest of the world. The developments resulting in the atomic bomb were in many respects strange and new. It was evident that only with the greatest difficulty could our present society assimilate the facts and act upon the implications which this new age brings forth. Could such a group of men thrust upon the world such new developments, without assuming the obligation of informing our people concerning the changes they must face if they are to survive?

That obligation is being assumed by the overwhelming majority of scientists. For, after the bombs were dropped on Hiroshima and Nagasaki, and after the wave of wonderment and confusion which followed, there arose a rising tide of thought among the men in the laboratory which showed an astonishing unanimity of opinion. Men who were isolationist in spirit, men who were convinced that war had a place in society, men of every shade of political thought, were all brought together. And this union of thoughts and ideas resulted not only from the all-compelling facts, but also from the fear that a completely uninformed and unprepared people might not recognize the problems which beset the whole world as well as our own country. This unanimity of opinion was remarkable in that documents inde-

pendently prepared by at least three of the project sites showed precisely the same views and recognized exactly the same set of facts.

Thus, a few weeks after the bomb was dropped there spontaneously developed loose organizations at Los Alamos, Chicago, and Oak Ridge, formed by the research men who had been considering the social implications of the bomb. These organizations were formed because the need for them had become apparent to us. From the reaction of the public to the news of the bomb and to the announcement that a new age was close at hand, we saw that the people of this country had completely failed to understand what atomic energy would mean to them in the very near future. We felt very strongly that we would have to start an effective educational program to correct this lack of understanding, and we felt that some sort of organization would be necessary. So we appointed committees for writing factual articles, for preparing speeches, for studying possible legislation, and for considering peacetime applications. And as these developed, it was only natural that the sites began to exchange information about their activities. New York soon joined, and, in recent weeks, scientists and engineers from the gaseous-diffusion project and the electromagnetic project joined with the existing groups.

All of us, at the various sites, felt that it was essential to start a program of giving to the people of this country the facts about the atomic bomb, and the meaning of these facts as they affected the future peace and security of the world. It was obvious, too, that this program of education would have to be on a national level. With such a program in mind, the associations from the six sites met in Washington to help alleviate the present lack of general education on the atomic bomb. But ever-increasing numbers of scientists outside the atomic-bomb projects have been organizing around this problem all over the country—in Cambridge, in Pasadena, in Philadelphia, and elsewhere. They are men of science in all fields of specialization, and they have been getting together in making the educational program more effective and of greater aid to our Nation. They are scientific men with special training, but they are also citizens. It is in this dual capacity that they come together at this time to offer their services to the Nation. As citizens it is our responsibility to see that our people and our Government are fully aware of the social implications of the atomic bomb.

But what are the facts that have convinced all of the scientists and what do they imply for all men who are willing to reason from these facts? They have all been brought before you in previous testimony by J. R. Oppenheimer, H. C. Urey, L. Szilard, H. A. Bethe, and P. Morrison, all of whom are members of this new federation. Let us review a few of these facts:

1. Atomic weapons are effective weapons for warfare. Their effectiveness can be increased to the point where any nation can destroy any other nation with atomic bombs.
2. In the business of warfare, atomic weapons are cheap to use against an enemy.
3. The distribution of uranium and thorium over the earth shows no possibility of complete control of raw material supplies by the United States.

4. There is no lasting security in attempts to keep the sole possession either of the science from which the bomb was created, or the unique technical developments of the project.

5. Other nations can also make useful atomic bombs after a relatively short period of development.

6. We do not foresee in the future any countermeasures or military defense against the atomic bomb.

From these facts and from other facts as yet secret we derive the following inescapable implications:

1. In a world of nations having atomic bombs, the advantage of an undeclared war to an aggressor nation is enormous.

2. The weapon is so effective against concentrations of people and industry that no fear of reprisals will be sufficient to prevent its use.

3. No nation under present conditions can maintain its pride and place in the world until it too has atomic energy and has atomic bombs.

4. Once a nation builds an atomic bomb stock pile large enough to demolish the major cities of potential enemies, no more military advantages result from larger stock piles. As time goes on, all nations possessing bombs will tend to become military equals.

5. In any atomic armament race, the United States in the long run will find itself in a very unfavorable position, due to highly concentrated population and industry.

6. No nation can withstand a large-scale atomic-bomb attack. It may lose a sizable portion of its population in a few hours of warfare.

7. In the immediate future, before other countries also have bombs, the United States must always take the lead in reshaping international affairs to obtain world security.

These facts and implications bring into sharp focus the alternatives which face us today. We have only the two choices—either the eventual destruction of a large portion of the population, or the chance for survival. To follow the latter course appears obvious. But, we will succeed in this course only if we are willing to feel our way, step by step, along the path that seems to increase the probability for world security. We will fail if we refuse to act simply because we cannot know in advance exactly how much world security our action will bring.

The United States has a fleeting opportunity to insist on the only solution acceptable to a nation committed to peace. It has in the past month demonstrated to some extent its desire to take such a lead. Irrespective of other international agreements, we feel that international or world control of atomic energy is essential to the maintenance of peace. Such a system of effective controls implemented by inspection should be considered immediately, because to introduce controls into the world at the earliest possible moment gives us the greatest possibility of successful operation. Once other nations promiscuously build atomic energy plants throughout the world, the introduction of an inspection system will be more difficult.

We realize clearly that the over-all feasibility of international control and inspection of atomic energy installations is a political problem of great difficulty. At the same time we recognize that a portion of that problem involves the technical feasibility of inspection and control throughout the world. The men of various specialties on the

project and elsewhere in the country could offer their special abilities to the committee. It is, however, not only for the scientists associated with the Manhattan District to consider the problems of inspection, but men competent in discussing airborne missiles and rockets, control of strategic materials, and the economics of engineering processes must also contribute their knowledge.

The present procedure for compartmentalization and secrecy of information makes it impossible for them to work together effectively on this problem. A major portion of the information needed to appreciate the properties of an effective system of inspection and controls is secret and cannot be assumed known to this committee.

It seems to us that there are at least three ways out of this impasse. First, the Manhattan project, or our Government directly, could authorize an expert committee to receive and digest the material from selected scientific contributors. Second, this Senate committee could hear all the testimony of the individual experts and attempt on their own to integrate the information which they have obtained. Third, this Senate committee may arrange to appoint and direct a special committee of scientists and engineers to receive, study and integrate this material. Our men and the results of their thinking on the technical portions of the problem are at the disposal of the committee. For a few weeks we have planned to have experts in the plutonium project, the gaseous-diffusion project, the electromagnetic project, the centrifuge project, the thermal-diffusion project, along with the bomb-manufacture project, study the problems which they are peculiarly capable of analyzing. This is to be done at the earliest possible date in separate classified reports. This program has been proposed in the full realization that unknown to us a similar or more adequate program may be in existence.

We realize that this will not solve the problem of world control of atomic energy. The integration of the scientific and political facts and thus the most probable solution of the over-all problem rests in the hands of our statesmen.

Senator AUSTIN. I have a foreign relations matter that is very important, and I want to ask you before I go whether this voluntary coming together of the scientists which you have described here spiritually, mentally and physically, as it were, has broken down in fact the departmentalization of the knowledge?

Dr. SIMPSON. No, sir; I do not think so. To some degree we are ignorant of the details of each other's problems. It is natural, however, that as scientists we do know a lot of the fundamentals of each phase of the project and can more or less understand what problems we must attack in these various fields.

However, the fields are separate and we have not made any attempt to break down security.

Senator AUSTIN. Then there are secrets in respect to this subject which are not available to any one person except a person at the top level of organization. Is that right?

Dr. SIMPSON. That is correct, sir.

Senator TRYBING. You point out only two alternatives in your very thoughtful and very helpful testimony. I think there might be three. First of all, we can have an arms race with atomic bombs. That is one alternative.

Secondly, we can turn over the control of atomic energy and atomic bomb making to some international organization with inspection and all that that implies.

Thirdly, we could prohibit the manufacture of atomic energy and have our inspection for that purpose.

Have you given any thought to the latter alternative?

Dr. SIMPSON. I had assumed that my statement was made somewhat more general, and that my second statement would include both of your latter statements.

Senator TYDINGS. The reason I asked you that is that a great many of the men who have come before us picture the horror of this next war fought with atomic energy, what it will do, destroy so many cities, and so many people. We have also had men who have publicly testified that a large percentage of the manufacture of the bomb will already be in being if peacetime atomic-energy plants are licensed, that the step from there on taken from the peacetime use to the construction of the bomb will be, let us say, a relatively short one compared with the whole project, and therefore if you release or if you license atomic energy even under world control you are pretty near to the proposition that any nation may make a bomb or may make several bombs, aren't you?

Dr. SIMPSON. I think there are two points which I would like to mention in regard to that. No. 1, I think, is a political one, and I cannot testify as an expert on that.

Senator TYDINGS. None of us can.

Dr. SIMPSON. I believe we have all made the underlying assumption, or have made the assumption implicit principally because we have never really taken an interest in this political field before. The definition of aggression on the part of a nation is the time of the immediate breakdown of controls. It is not 3 months, not 6 months from the time that they start to get away from controls, but the following day that something has to be done.

Senator TYDINGS. Let me put it to you this way to give you an illustration that may not happen, but which will focus your attention to what I am driving at.

Let us suppose that international controls have been carefully thought out and agreed to by all the nations of the earth. Let us suppose that atomic plants for peacetime usages under that system have been licensed. Let us suppose that these plants are at the moment constructed in some six countries on the face of the earth. Let us suppose that those plants have been in operation for 3 years.

Now the inspector goes to country B, and mind you, all the plant is not in one place; it is somewhat like our situation, with 5 or 6 different operations. But he goes to country B and he finds that everything is just as it should be.

Now, immediately upon the leaving of that inspector, some of this atomic energy in the form appropriate is used to manufacture a bomb in that country at once, or 10 bombs, or a hundred bombs, and those bombs can be constructed within 6 months after the last inspection took place; the time has gone by, and the inspectors are not quite as careful as they might be.

Now, one of two things would happen. A nation that had the bomb would evidently be making it for some particular purpose, and

that would likely be a surprise attack. Then we would have nothing with which to counteract that. You couldn't send the UNO in there to beat a nation that had atomic bombs in quantity, because it would be rather difficult.

The second thing is that if you found it out before those bombs were so used, that would be an act of aggression which you would have no counterstroke equal to the stroke held by the country that had breached the contract with which to immediately interdict it. What is your thought on that?

Dr. SIMPSON. The point is that I am not convinced that the inspection system should provide for inspection only once every 6 months, or once every 3 months.

Senator TYDINGS. Let us assume it this way, that in spite of the inspection, enough material has been sequestered and taken to manufacture 100 bombs.

Dr. SIMPSON. I believe the inspection system must be such that the possibility of this is reduced to a minimum.

Senator TYDINGS. I agree with you, but suppose it doesn't work out that way?

Dr. SIMPSON. Then you have the additional assumption that you have developed a plant in which the men know how to assemble the bombs, they have had practice doing this thing and can carry out the job in 6 months. I believe that most of us feel that it will be a period of 3 to 6 months before you start making the bombs once you pull the material out of the unit, but that it will take perhaps 6 months to a year in addition to develop enough atomic bombs to wipe out a number of cities or all the cities of any given nation that may be under attack.

Senator TYDINGS. But every one of the scientists who have appeared before us, including yourself, and quite properly, conceive that if we have an atomic war, the future of civilization, to say the least, is seriously jeopardized, and yet we keep clinging to the idea of letting these guns be passed around; the only thing we don't put in the gun in the cartridge, and you can get the cartridge in not too long a period.

I would like to get your advice on whether you think it wouldn't be wiser to outlaw the entire manufacture of atomic energy, which will give us the greatest chance of safety, plus inspection?

Dr. SIMPSON. This is certainly not true of very small atomic energy installations, because you have a different problem. You cannot produce enough material in a reasonable length of time.

In the large-scale job, I think the majority of us believe we must do that, because this is the fundamental issue. But I think there should be this consideration taken into account: That is, it is possible to design a unit for atomic energy which is designed very unfavorably for removing fissionable material in a short period of time.

Let us consider the Hanford pile. I think what I can say about it is the following, that the Hanford pile was designed to produce material with a byproduct of energy, and it might be concealed to the world under the guise of producing power with a byproduct of plutonium. The Hanford pile was designed to remove that material as easily as possible. You cannot remove that material and carry it around in a handkerchief. You have to have extensive and adequate installations to handle very intense radioactive material. If the

installation is inspected by a person competent to know, he will know that this installation can remove so many pounds per unit in a certain interval of time.

Now, if by international agreement we can agree that our power unit will be designed within certain principles which will discourage—

Senator TYDINGS. What you are doing in effect is saying that the degree of opportunity for the manufacture of the bomb is lessened by the program you outlined; but you will admit also that it permits a degree toward the manufacture of the atomic bomb which is greater than if you did not have the power plant at all:

Dr. SIMPSON. That is quite true.

Senator TYDINGS. In other words, we are opposed to grand larceny but not opposed to petty larceny, to make a humorous observation.

Dr. SIMPSON. That will depend upon our attempts to set up or study a control system. I don't believe we know enough about this problem, and that is in our proposition.

Senator TYDINGS. I am not saying I favor this program, but it is one of the things we have got to explore.

Take, for example, this phase of it. There are a few men at the top of this project, or maybe several thousand in the world whose mental development in many lines—and particularly the scientific line—is like comparing a mountain to a molehill when you compare them to the rest of us. Likewise, you have got to consider a country on the basis of its average population. Many nations have large numbers of illiterate people. Many nations have systems that we might call unenlightened according to our standards.

Now, you have got to project your inspection in the face of all those human equations, which are facts, just as the atomic bomb is a fact.

Visualizing that, do you think that it is possible for us to devise an inspection which will permit the manufacture of say 60 or 75 percent of the bombs for peacetime purposes?

Dr. SIMPSON. You are asking me a question I do not know the answer to.

Senator TYDINGS. I only want your opinion. You might change it a month from now.

Dr. SIMPSON. My personal opinion? I could not then talk for any of the other men I am trying to represent today.

My personal opinion is this, that we do not know with certainty whether we can succeed. We know that we have a chance to succeed and that is the only fact we do know. From a reasonably detailed survey of the technical system of inspection, we think that we can have an effective system provided certain political conditions are met. We therefore come back to your problem. Will those political points be met by all nations?

Senator TYDINGS. What is our greatest objective in this whole matter? The preservation of civilization, isn't it?

Dr. SIMPSON. That is correct.

Senator TYDINGS. Without that all benefits that flow from atomic energy are secondary to the preservation of civilization; therefore, if that is our greatest problem, what avenue of approach is best calculated to achieve that goal: prohibition with inspection, partial manufacture

with inspection, or uncontrolled production of atomic energy? There are three avenues open to us.

At this present point, which one of the three do you think offers the greatest hope for the preservation of civilization, not only now, but 20, 30, 40, 50, or 100 years from now, because if we license the use of atomic energy for peacetime purposes we are probably going to have it in existence for years and years to come with all the refinements and improvements that come with it. What is your opinion on my question in the light of those facts?

Dr. SIMPSON. I would say that as we carry out this experiment—which it certainly is—if we make it a calculated experiment, then in the immediate future our best possibility of success may be to immediately stop atomic energy production on a very large scale, on a scale that interferes with this problem.

Senator TYDINGS. Other than for scientific purposes?

Dr. SIMPSON. Yes; until the nations of the world do have an appreciation of this problem as we do. I do not think they understand this problem even as well as we do, as little as we know about it.

Senator TYDINGS. You have answered my question. In other words, the first approach is not to get out on thin ice and get too far from shore, but to stay near shore until the ice gets strong enough so that we can safely go further from the shore.

I therefore take it that you recommend to this committee that the first step toward the preservation of civilization or the control of atomic energy, whichever term you want to use, should be international prohibition supplemented by inspection until such time as a better plan offers?

Dr. SIMPSON. With minor modifications; yes.

Senator TYDINGS. Of course, there would be exceptions for scientific research, and so on, but not for the manufacture.

Dr. SIMPSON. This is my personal opinion and not necessarily that of the men I represent.

Senator TYDINGS. In questioning most of the gentlemen who have preceded you, in one form or another I think they all pretty nearly arrive at the conclusions you expressed; at least I got that impression.

Dr. SIMPSON. I believe we differ only in the details, the minor details in this issue.

Senator TYDINGS. But I can leave my questioning with this thought, that we ought not to venture into the field of the manufacture of atomic energy nationally or internationally first. We ought to prohibit it and inspect, and then find out after that is done, for once it is started in many countries it will be more difficult to go back to the place we are now than it will after the plants are put in operation.

Dr. SIMPSON. Yes.

Senator TYDINGS. You get used to a thing, and then the edge of your fear is dulled and the edge of your imagination is dulled.

Dr. SIMPSON. Once we start producing atomic energy, I am afraid the process is irreversible.

The other point, as a result of that, I believe is this: We should act as fast as possible, consistent with the political situation, to institute international controls.

Senator TYDINGS. Is it your opinion that the point of view you have just expressed is the majority point of the men with whom you

have been associated and have described in your paper? It is your opinion—not that you are stating it as a fact?

Dr. SIMPSON. Yes, I believe it is the opinion of the group. No matter what we must do, we must at least give ourselves a chance for obtaining world security.

The CHAIRMAN. Doctor, admitting of course that this is a new force in the world, not a difference in degree but a difference in kind and admitting that you have to think of it in new terms, still admitting all the past history of civilization, no matter how desirable it might have been at the time, do you know of any advance in the history of science that was ever made that was capable of producing more energy, wealth, or more productivity, that has ever been suppressed?

Dr. SIMPSON. I think the answer to that is already implied in your question; certainly not. One of the most fascinating things about our recent achievement of reaching within the nucleus and attaining energy which is the energy which runs our stars is the fact that it is only the beginning of our knowledge. There is nothing comparable with it.

However, it should be pointed out that what we have learned in the past was really the logical prelude to this study; and one of the encouraging things is that the discovery of atomic energy logically is an advancement in our ability to think and to do things. I think we can all hope that as citizens and as thinkers in the field of politics and relations among men that we begin to note a forward trend in our thinking that way also.

It is not quite so clear to us that we are following a line of advancement in our relations with other men. I hope that it becomes more clear in the next few years.

The CHAIRMAN. Doctor, I would not attempt to denominate what it is in human beings which has insisted throughout history that full advantage be taken of anything that will do the things that I have mentioned, such as increase wealth. Whether you want to call it instinct or urge of the species, or what you may call it, you nevertheless have to contend with it, do you not?

Now, there are over 2,000,000,000 people on the face of the earth. There are 400,000,000 in China who carry on their backs loads that we put in railroad cars or motortrucks. There are 400,000,000 people in India who live at the most primitive level of starvation.

Now, we are a rich country. We have power and energy in abundance. To hold to that proposition it seems to me that because we are fortunately situated and in order to attain the highest degree of security we are going to insist, if we can, on prohibiting its development.

I just suggest the difficulties of maintaining that point of view when we measure it against a somewhat less perfect system of security that would come from peacetime manufacture. That is really the problem, isn't it? And that is not altogether our problem to solve, is it?

Dr. SIMPSON. No; I agree, first, that the United States must take the lead, but they must also bring in all nations to discuss this problem. Also we have not implied from the discussion that Senator Tydings and I had that we are going to stop development. At the present time I believe it is possible to carry out almost unlimited scientific developments, and, secondly, to carry out certain engineering devel-

opments under international authority at some one location where all nations may come together to work on this problem.

I don't see that you are excluding the possibility of future development. I think that all you are doing is holding up your development of engineering programs until the various nations understand this problem and the control system gains the respect of the nations. After all, all nations will not have the same respect for this control system, no matter how good it is. You must see it in action before you have confidence in it.

Senator TYDINGS. Doctor, you are familiar of course with the fact that throughout history there has been a war about every 10 or 20 years. Indeed, that is a very liberal spacing.

You are likewise familiar with the fact that the war is still going on in many parts of the globe, even after the two or three big wars are over.

You are likewise familiar with the fact that disarmament hasn't taken place, and while we all hope that the world will some day have nobody carrying a gun, it is a long, long way off.

Now, knowing all those things, what reason is there to believe that if atomic energy is licensed for peacetime purposes that when some event happens 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100 years from now that will bring on another war—I am not just thinking for 20 years—almost instantly, I will say, after atomic energy becomes commonplace it will not be used to destroy civilization?

We have to think of this problem not only for 10 or 20 years, but 40, 50, or 100, as far as our imagination is capable of thinking. What is there in the picture that would lead one to believe that civilization can exist if atomic energy is used 75 years from now in a world war?

Dr. SIMPSON. I don't know the answer to that, but I think the only thing I can say is this: Over a period of 100 or 200 years, I cannot see the difference between licensing atomic energy and prohibiting the development of atomic energy industry. I think they will both smooth out to the same classification.

Senator TYDINGS. I think you have missed my point, and maybe that is my fault.

You and I, both, know that there have been many movements to end wars since the beginning of time. We have had alliances of the churches to do it. We have had economic alliances, military alliances, every kind of alliance.

Now, of course, we have never had a real honest attempt to do it such as we have now in embryo in the UNO; but if you start out to license atomic energy before you create a climate where peace is almost certain—not only in theory but in practice—has been proved to be almost certain—if you start the manufacture of atomic energy for peacetime purposes before that time, where do you come out in the event the machinery breaks down?

Dr. SIMPSON. Well, if it is agreed that the machinery will break down after a study of an inspection system—and this comes back to the question we were discussing a short while ago—then we will have to hold off on our very large scale or industrial applications with regard to power until such time as we feel reasonably certain of success. I think that was really implied in our discussion.

Senator TYDINGS. Most of the men who have preceded you—or a great many of them—have told me in private that they wish there had been some way to prevent the discovery of atomic energy. They would rather it had never been discovered when they think of the future implications of it.

It has already been discovered, and there is no use thinking about that; but the thing is: Where do we go from here?

If I had the state of mind that it is too bad it had ever been discovered because of its implications, my next thought would be to crush it out and keep it crushed out.

Dr. SIMPSON. You cannot do that, but what I think you can do is create a situation which gives you the best chance for introducing controls.

Senator TYDINGS. But prohibition should come until that situation is developed; otherwise, you are letting the horse out of the stable before you have girthed the bridle on him, and you cannot ride a horse with no bridle.

Dr. SIMPSON. It is still to be determined, I believe, at which stage you have an industrial plant or an experimental unit. I think that can be defined within fairly close limits.

Senator TYDINGS. My opinion at the moment is—and I am not committing myself to any final conclusion—but you have got more faith in mankind than I have been able to mass up to the moment for letting this deadly force out any time that I can see in the foreseeable future without almost a certainty that when another war comes—and, God, let's hope we can prevent it—that it will be used and used quickly.

Dr. SIMPSON. I like to think this way—that I have more faith in succeeding in this whole problem if we attack it with the idea that we do not know how far we will succeed, but since that is the only course of action open to us, at each step we must decide what we know about the problem and act accordingly. Tomorrow it may be different.

Senator TYDINGS. I did not mean to imply that we should not try, but I think we ought to try with the knowledge that the task is not as easy as many people think it is. I think it is darned near as difficult as discovering atomic energy, in the first place.

Dr. SIMPSON. I believe scientists think it is more difficult.

The CHAIRMAN. Doctor, I don't want to be accused of being hopelessly idealistic, but letting my mind run back over history, certainly back to the Crusades, those wars were fought for the most part over ideologies between, of course, the Moslems and the Christians.

Since that time wars have largely been based upon the desire of "have-nots" to have.

Economic factors have been the basis of them.

Letting ourselves perhaps dream a little—and I guess we have to dream some in this problem—if through the peacetime use of atomic energy we could increase the living standards of the "have-nots" of the world, do you not believe, or have you thought of the possibility, that that might reduce the occasion for war?

Dr. SIMPSON. I am a little skeptical of what atomic energy will do for the world in the next generation or two generations. I am thinking now in terms of all the population of the world. We have had steam power, we have had electrical energy, we have had the energy from electronic forces now for a century, and we have not been able to

solve their economic problem. We haven't yet solved the problem of distribution or production of goods among all the peoples of the world.

Senator HICKENLOOPER. Right at that point, we have made, as compared to a hundred years ago, unbounded progress, haven't we—unimagined progress?

Let's go back 100 years before the use of electronics and all those things which go with it affecting labor and work performance, and the ease and convenience of things are unimaginably better than they were at that time, aren't they?

Dr. SIMPSON. Yes; I would say in the major countries, but I am thinking also of all of those other nations that are really just beginning to get their teeth into this industrialization problem.

Senator HICKENLOOPER. They still use wheelbarrows in most parts of the world.

Senator MILLIKIN. Those countries to which you now refer have no present capacity for war, atomic or otherwise; isn't that correct?

Dr. SIMPSON. My impression is that this is probably so. It is, however, also true that with the introduction of relatively few men in engineering and science they can be converted to atomic energy development without this intermediate step, by bringing in materials and manpower.

Senator MILLIKIN. Assuming a little further the thesis of the chairman of our committee, we have evolved from where the average man controlled one or two horses to where he is driving several hundred horses.

The CHAIRMAN. It isn't a fixed thesis.

Senator MILLIKIN. He has now evolved to the point where he is driving several hundred horses, but that has not abated in any particular his war-making ability or his war-making desire. So, if we took these regions that now have no development, that are barbaric as far as modern economy is concerned, and lifted them to our own level, it certainly does not follow that they will become peaceful while the rest of us are war-loving.

Dr. SIMPSON. I think so. Human nature is the same all over the world in many respects.

Senator MILLIKIN. Now, I think you have put your dagger right into the heart of the question.

Dr. SIMPSON. May I make one statement with regard to these undeveloped and relatively backward countries where atomic plants have, in many respect, unique application. Many of them are backward because they don't have water power, don't have adequate supplies of coal in the right places for getting a job done, and therefore large industrial atomic energy plants in the next decade or 30 years may very well vitalize these countries, or bring them up among the nations of the world; and that is, of course, one factor to consider.

Senator MILLIKIN. I am not challenging that thesis. I am challenging the thesis that if that came about that automatically would make them more peaceful.

Senator HICKENLOOPER. I would like to pursue just a little further the question raised by Senator Tydings on the matter of prohibition.

Every new discovery in science has been rudimentary at first and with great rapidity has extended its limits.

With telephone they talked between rooms at one time, and now we talk around the world. It is the same way with armaments and with all our scientific beginnings.

It is inconceivable to me that science will stop experimenting in this new field which they have just scratched, regardless of whether it is in this country or abroad; and it seems reasonable, at least for the sake of argument, that we can prohibit the commercial manufacture of this stuff and still, in the advancement of science and experimentation, develop methods that are so infinitely much cheaper and much more available and readily productive of this stuff in the future purely through the experimentation of science; so that within a very short time science, either here or abroad or some place in the great universal field of science, may develop merely in the laboratory methods of the manufacture of atomic energy in quantities—that is, this material in quantities—so that it will be a very slight effort indeed to turn from that to the almost immediate manufacture of bomb material for warfare.

I suppose only time will tell whether that will happen or not, but the point I want to make is that if we have this prohibition I wonder if we don't have a very short time indeed in which to get our house in order under this prohibition.

We may be able to prohibit for a short time the manufacture of this material for war; but there comes a time, if we believe history—I mean if history is going to repeat itself—when the efficiency in this field of investigation will be so great—when that time will come I don't know; 10, 15, 25, or 50 years make little difference if we are trying to save the world from destruction—that this very human nature you are talking about may look forward to some bandit nation or some outlaw group using this immediately convertible material, based on the advances of science, for warlike purposes.

It appears to me at the moment at least that we have a very short time to put our house in order and establish the beginning of these understandings on a firm basis, because I have little faith that we can dilly-dally along for a long period of time and more or less let nature take its course.

Dr. SIMPSON. Yes; the time is short.

Senator HICKENLOOPER. I don't know. I am not saying that Senator Tydings has adopted this as his theory necessarily, but you have been arguing the point to develop it, as I understand it. I have little faith in the eventual or long-range success of prohibition.

In my opinion, I think we can prohibit for a while, but we have got to eventually consider in our own minds the very potent possibility that prohibition will not work for too long a time.

Senator TYDINGS. Give us 10 more years probably as a universe.

Senator HICKENLOOPER. We have got to have a period in which we can prohibit successfully until we can establish a program and then get it working.

Dr. SIMPSON. If we don't utilize the short time we have to make the most effective system operate, and I believe we were talking about the immediate period, then we contradict ourselves because we are following on one hand one philosophy and also trying to follow on the other hand another philosophy of thinking.

Senator TYDINGS. Having our cake and eating it too.

Dr. SIMPSON. Yes. In one case we say we must do whatever is possible at any given moment to increase the possibility of success. Then, on the other hand, we say, "But let us take our time, because we don't know exactly what is coming." These two philosophies are incompatible.

Senator HICKENLOOPER. Do you know of any scientific development or discovery that has ever been made that anyone has ever thought might have some potential war possibility as a matter of defending ourselves that has not been thoroughly explored either by science or engineers, or both?

In other words, haven't we taken scientific development and immediately turned to see how it can help us in war?

Hasn't that been a natural development in self-preservation?

Dr. SIMPSON. I don't think that has been true of the scientists.

Senator HICKENLOOPER. I am talking of the whole field.

Dr. SIMPSON. Well, it is natural. I think that there are certain fluctuations in the length of time between a discovery and its military use. Sometimes it has taken a long time to understand that a particular development has a military application. At other times military application aided the scientists.

Senator HICKENLOOPER. He might have a knife with which to cut meat, but at the same time he has thought it might be good to kill somebody with and made use of it.

Dr. SIMPSON. I would like to make one statement regarding what you said, namely, that science isn't going to stop, no matter what kind of laws or controls you have, and say this: If people are thinking about any system of international control and inspection which you sit down and work out and say, "Here it is, gentlemen; we have thought about this problem for 4 years, and we think this is good enough to last 20 years," then I think we will fail. I think that what we must do is say, "Let's set up a system after careful study, set it up and provide for methods for changing the control system so that as new developments are found out all over the world this control system will reshape itself so as to take into account the developments of the future." We don't know what is coming next.

Senator TYDINGS. We are liable to raise the point there that what the control system is doing is unconstitutional.

Dr. SIMPSON. I do not quite understand that.

Senator TYDINGS. You see, we are delegating power to the control council to take jurisdiction over a certain amount of our internal affairs. I am not arguing against the wisdom of it, but we have got a system that is so set up. That may call for certain renovation of our industrial machine.

Our Constitution provides that every man shall be secure in his person, his papers, his house, and his effects. That is in there. Nobody is advocating that we take it out; there it is, and he can go into court and say, "This is my castle."

Therefore, when this supergovernment says, "Look here, we don't care what your Constitution says, we are going to send 2,500 men over into your country to go through everything," we may say, "How about that?" and so may other countries.

I am not arguing about the wisdom of it, but we humans don't always build as wisely as we think. We build for a generation or

five generations, and we have done a pretty good job when we can go that far along, because our Government is the oldest unchanged government in the world today.

That being so, we have got to approach all of this solution with a thorough knowledge of the limitations that are here, there, and everywhere. I don't mean that we should stop in trying to preserve civilization; but it isn't just like saying $X + Y = Z$. It is $X + 2 - Y$ over 12 times 367 divided by 472 equals Z to the 20th power. That is how complicated it is.

Dr. SIMPSON. You are raising the question now of giving up certain rights that we have always assumed we have. If it is necessary to give them up, we say give them up, but there is one point I would like to bring out with regard to the development of science. It should be possible, without changing our ideas, at least among the scientists, to provide for free exchange of scientific information and the right of publication.

Senator TYDINGS. You scientists confuse me terrifically, and I don't want to interrupt you. You come in here and say—and I understand why you come and I agree with you—that if atomic war comes in the future, 40 cities will be destroyed, 40,000,000 people will be killed, then there will be retaliation and so many cities will be destroyed, so many millions killed, and then the Army will come in and fight this out with the old-style weapons.

That is the prospect, and yet you say, "We know that, but we would like to edge in on that situation as far as we can."

The very fact that you start to edge in on it makes the horror of what you picture come that much nearer. If it is as bad as you say it is, then we ought to fight it out. If we have got pneumonia in the community, and it is a contagious disease, we ought to fight it out. I cannot see this temporizing with it.

Dr. SIMPSON. No; I believe you perhaps misunderstand. I was referring to only one little phase of that over-all problem. Anything we have to do to make this thing function, or to help make it function, we must do.

Senator TYDINGS. Suppose your alternatives are this in theory, because none of these are 100 percent—but suppose your alternatives are prohibition against the manufacture of atomic energy either for peacetime or for wartime uses, coupled with an international agreement against its manufacture, coupled with thorough inspection to prevent its manufacture, coupled with penalties for a breach of the agreement, and your other alternative is to license, in the world as we know it and in the world as it has been, the manufacture of atomic energy for peacetime purposes with the knowledge that when you do that you are 75 percent on the way toward constructing bombs?

What, as a matter of common sense, just taking the two theories without going into all the various implications that ought to be considered, is your choice in that situation?

Dr. SIMPSON. Our choice is obviously to take the former course, the one where we keep prohibition up until we have a reasonable assurance that our control system is functioning.

Senator TYDINGS. But there is nothing in the world in the past which has given us that vista so far.

Dr. SIMPSON. I think there is one other possibility, though; namely, that in the near future it will be possible to license certain types of power plants without getting 75 percent close to your atomic bomb.

Senator TYDINGS. Well, suppose you get 25? With men like they are, you know you let men have shotguns to go hunt ducks and rabbits and one thing and another, and once in a while you see where a fellow has used a shotgun to kill somebody. If a shotgun is an individual weapon, used from one man to another, you can afford to take a chance; but when you use the atomic bomb you are putting into the hands of the murderer something that will kill 40,000,000 people with one discharge of the gun, and I don't want that kind of murderer to be at large.

Senator HICKENLOOPER. I think the chairman raised a question a moment ago that goes right to the bottom of this thing. I don't think we can discuss this fully right now, but we have devoted so much time to talking about treaty prohibition of this potent weapon. It seems to me I recall we have had agreements to scrap battleships and cut down calibers of guns, and we agreed that we wouldn't invade the other fellow's territory, and so on.

Now, as long as we were not hungry in this country, as long as we didn't feel that we were being abused in this country with some of our rights being taken away, we cut down and went toward the road of peace in armament.

But other countries in the world, rightly or wrongly, began to believe that they were abused either through food or through economics, and the treaties we had made, the prohibitions solemnly entered into and specifically put on paper, the promises that were made were immediately scrapped.

Senator TYDINGS. Your comparison is not the one I had. You see, we didn't have prohibition; we only had the right to have a little of what we wanted. When we kept a part of our battleships and kept a part of our armies and a part of our military air forces, and all that, we were always ready; the only difference is, instead of having 100 atomic bombs we allow each nation to have 10.

Senator HICKENLOOPER. My thought is this: There is a problem beyond the question of agreement and treaties. There is the problem of the underlying human causes as to why people fight. The average man doesn't go out and shoot another fellow with a shotgun unless he has a pretty emotional reason.

Senator TYDINGS. Labor and capital are fighting a war right now without bloodshed, and the only reason they are fighting is that someone wants to get something the other fellow's got, whether it is a hundred million dollars, a house, a farm, or whatever it is. Therefore, I say that the world has absorbed so little of the Sermon on the Mount that if you allow 10 wolves to escape in Havre de Grace, Md., instead of a thousand, you have got a problem; and I don't want any of them. You have got a problem, and the only way I see to handle this problem is to realize you have got a weapon. I am not binding myself, I am thinking out loud. I may change my whole idea of this and so may you tomorrow, but we have got to discuss these things in order to get them out of our system.

If you eliminate all the armies and all the navies and all the air forces and all atomic bombs and all artillery, then you have got some chance for peace.

Senator HICKENLOOPER. But they are fighting with bamboo staves in Java today.

Senator TYDINGS. They are fighting with something that will do very little damage; but what we are fighting with is something that cannot only do damage, but can destroy 1,900 years of darn hard efforts.

Senator HICKENLOOPER. There is no question of that, I merely based that on the fact that the chairman mentioned that there are other elements that would contribute to the success of treaties we hope to get—human elements.

Senator TYDINGS. I don't see at the moment any hope of the world eliminating war—and I don't mean in the next 5 minutes, because it cannot be done—until all armaments of every kind and description, except those limited to the United Nations, are all that are in existence in the whole world. Anything else is temporizing with the situation.

The CHAIRMAN. What is troubling me is that if we can prohibit the controlling weapon of war, then I see no reason why we cannot prohibit all weapons of war.

Senator TYDINGS. The thing is as logical. Why sit up here talking about eliminating the atomic bomb and leave the buzz-bomb and the bacterial germ and poison gas and the rocket and all the other things we are working on? You say, "Well, I am not opposed to destroying 20,000,000 people, but when you get down to 40,000,000 I draw the line." That is virtually what we are saying.

The CHAIRMAN. Senator, the elimination of other weapons of war would of course reduce the potency of this weapon of war.

Senator TYDINGS. Knowing we are all thinking out loud, I want it distinctly understood that these are not my ultimate opinions; I am just groping, and I may change my whole approach to this on subsequent testimony, but I want to say this: Considering that the average big world war lasts 2, 3, or 4 years—we have had two that lasted 4 years—and the atomic bomb is now known as a thing that can be produced, in the next war it is certain to be used in spite of all the prohibitions you can make, because no nation is going down to defeat that has got one big sock left in the right arm. Therefore, if we are going to approach this rationally, we have got to consider almost total disarmament if we want peace. If we don't want it, then all well and good.

The CHAIRMAN. Senator, I have the feeling that we would like to bar its peacetime use. My present feeling is like King Canute down at the shore trying to push the waves back. You see, your thesis is based upon the proposition, as I see it, that prohibition all over the world is possible, but control is not. I cannot follow that.

Senator TYDINGS. If your objective is world peace—Good Lord, I have heard that word uttered so often in the last 6 years, that I have almost gotten to call my right arm the word "peace," it is so closely woven to everybody's anatomy. If our objective is world peace, we are not going to achieve it by the simple outlawing of the atomic bomb, anymore than you are going to have an outlawing of everything else and supplement that with world-wide inspection. The logic of the thing flows that way.

If you start a war without an atomic bomb in existence anywhere, before that war is over it is sure to be used. No nation could afford not to build a plant in case the other nation did build it.

Then, when some nation was threatened with extinction, or wanted to save human life, we would go over and wipe out that nation or they would wipe us out.

So, if we want to limit the use of the atomic bomb, it seems to me world disarmament is the only way to do it.

The CHAIRMAN. You will remember it was you who called my attention to the fact that Litvinoff, in 1926 at the Disarmament Conference when there was talk about limiting cruisers, stated: "I thought we were here to disarm; and the way to disarm is to disarm."

Senator TYDINGS. It is quite true Mr. Litvinoff came before the League of Nations and said, "This is a disarmament convention; I propose that the world disarm"; and that is exactly where we are today. We are sitting here talking about disarmament without being willing to disarm.

Senator MILLIKIN. The nation that has no armament has always advocated disarmament, and that was the basis of Litvinoff's plea; Russia was not armed at that time.

Senator TYDINGS. That is right, and now Russia is.

Senator MILLIKIN. I don't hear Litvinoff asking for disarmament.

The CHAIRMAN. I haven't heard of Mr. Litvinoff in some time. I wish he were present making the same kind of speeches.

Senator TYDINGS. I am trying to think my way through this thing, and I certainly haven't gotten to any place where I want to get off the train yet. Here we are all talking about the horrible destruction of this thing which must be controlled, and we have two alternatives. One, it is bad, but we will play with it a little bit; the other is we are adopting a course which will make sure that it will be used if the League of Nations or the UNO falls down.

Senator HICKENLOOPER. In other words, we are saying that a few little healthy minor wars aren't bad, but we don't want a major one with the bomb.

Senator MILLIKIN. Would you say, Doctor, until we reach this stage of perfect world cooperation that we should keep our own bombs and our own manufacturing facilities?

Dr. SIMPSON. No; I don't think that is consistent with trying to attain this world cooperation.

Senator MILLIKIN. What would you say we should do with our own stock of bombs as they are in existence or as they may develop if we continue to make them?

Dr. SIMPSON. Suppose I make my own personal proposal on that to see how it would shape up. It has been stated that we have atomic bombs, that the Uranium-235 plants are in operation, and plutonium project is still running.

Senator MILLIKIN. Assume that.

Dr. SIMPSON. Yes. If we agree that the best possibility of getting in the immediate future some cooperation among the major nations of the world is by being certain that the atomic bombs are not assembled or that there are no atomic bombs, then we can do one of two things: We can shut down our plants and throw away our material, or we can take that material and distribute it to other scientific laboratories of the world. If one-half kilogram is distributed to each of many of the principal laboratories of the world, that material cannot be used for destructive purposes.

The CHAIRMAN. But it can be analyzed, Doctor, with great help to the recipient, can it not?

Dr. SIMPSON. I don't understand that. It will be material that is known already. The men know what that is, and they will know anyway the number of its properties, even from ordinary cyclotron research.

Senator MILLIKIN. I would like to hear all your reasons, but I will put a little plug in at the moment. I want you to explain at some point why we should do that.

Dr. SIMPSON. All right. I will explain that later. That is one possibility. Another possibility is to push ahead in our own research by making available to the universities and to the Government laboratories in our country the material that would go into this bomb to produce new types of power plants that use this enriched material. That is another possibility that would prevent the use of bombs at the moment.

This does not, however solve the problem.

Senator MILLIKIN. As Senator Tydings points out, that takes you three-fourths of the way along to an atomic bomb.

Dr. SIMPSON. Not these power plants that are developed; they would not be that type at all. It would be practically impossible to take this material from them in a short time without definitely planning such a thing.

Another step, of course, is to merely discard your material, but how do the other nations know you have done that? We cannot assume that they trust us.

Now, what do you suppose that any of these proposals offer to the other nations? How are they going to determine our program for themselves? Are we going to institute the beginnings of an inspection system and let the UNO try working it out in the United States? Are we going to propose to bring these people in who could calculate closely what the plant produces from its design, the way the machines operate and the number of days of operation?

Senator TYDINGS. There were a lot of stills during prohibition days, Doctor.

Dr. SIMPSON. That is right.

Senator MILLIKIN. I am oversimplifying, but I would like to get a sharp focus on this simple thing: Assuming that we do not trust the rest of the world, until that moment of trust comes should we dispose of our bomb stock pile and our plants for making bombs?

Dr. SIMPSON. I cannot answer that question, because I don't see any way of starting out on the assumption that we cannot trust the world to hunt for a solution of our problem. I just cannot see any solution to this problem at the present time.

Senator MILLIKIN. Do you trust the world in its present posture?

Dr. SIMPSON. No; but I trust the world, at least if we make a determined effort, to look for some solution in the immediate months following. We do not necessarily have to give up our bombs tomorrow or by February 15, or something like that. We have to start the ball rolling, and if making things move faster means that we have to throw away or unassembled our bombs, if we have them all assembled, I cannot see any other way out.

Senator MILLIKIN. Doctor, that puts the burden on you of demonstrating that if today we disposed of our stock pile and destroyed our plants that that would bring about a state of trust and confidence in the world.

Now, make a demonstration of that, please.

Dr. SIMPSON. I cannot, and I know of no man that can do that.

Senator MILLIKIN. That is a sheer matter of faith?

Dr. SIMPSON. It is a matter of trying to develop the only course open to us. I don't believe that we have made an effort to do that.

Senator MILLIKIN. Suppose we did. Suppose we destroyed our stock piles, destroyed the plants that make them, and invite the world to come in and satisfy itself that we have done so.

Will you please explain to this committee what assurance we would have that it would reform the human nature of the world and its war-making tendencies, and that we would have nothing further to fear as far as the atomic bomb is concerned?

Dr. SIMPSON. I cannot offer such assurance.

Senator MILLIKIN. It comes back to an act of faith, doesn't it?

Dr. SIMPSON. It comes back to this: There is another possibility. We certainly face the imminent development of a full-fledged armament race over the period of the next few years.

Senator MILLIKIN. Let's take the next step. You haven't demonstrated, and you say you can't. I have suggested a way out as a sheer act of faith, and I am not disparaging faith except that I would not allow my own country to become insecure, or what I thought was insecure, on a sheer proclamation of faith.

Let's take a look over the world, without mentioning specific countries or specific controversies. If we today destroyed our bomb pile, do you think that that would cure the situation, let us say, in China?

Dr. SIMPSON. I think that no single step would cure any situation.

Senator MILLIKIN. Do you think it would cure the situation in Burma?

Dr. SIMPSON. No.

Senator MILLIKIN. Do you think it would cure the situation in the Dutch islands? Do you think it would solve the question in Iran at the present time? Do you think it would solve the questions in the countries bordering on Russia? Do you think that if we did that we would solve those questions?

Dr. SIMPSON. To date we have not made enough of an effort to get any evidence one way or the other whether we can obtain a solution by making, as one of the many steps that we propose, the unassembling of any bombs we may have.

Senator MILLIKIN. Suppose we invited the representatives of the world into this room and said, "Gentlemen, we are going to make the sublime gesture of all history. We are going to destroy our bombs. We are going to destroy our bomb plants. We are doing this as an act of faith, as a gesture to enlist your faith to bring about a state of true world cooperation, a true state of peace."

They would all get up and applaud. They would be delighted, of course, because they haven't got bombs.

But would that act of faith change them in their hearts? Would it change the whole attitude of the world toward war and peace, which I suggest is the worst it has been in our history. I respectfully sug-

gest in that connection that the problems of this world are worse than they were at the beginning of the last war, and worse than they were before the beginning of World War I.

Do you think an act of that kind would change the fundamental facts that are leading to these conflicts?

Dr. SIMPSON. You make a very interesting argument, but I cannot agree that any single step or any few steps or gestures will create that condition.

Senator MILLIKIN. Let me put it to you this way, Doctor: Suppose you had complete power to do what you wanted to, that you could assemble the nations, that you could make any kind of an agreement that you wanted to between the members of the nations of the world. What would you do at this moment respecting the atomic bomb? Assume you had a blank check that you could maneuver this thing the way you wanted to. What would you do?

Dr. SIMPSON. This is answering a question which is theoretical, but I will make an attempt to point out two or three things on my mind.

Senator MILLIKIN. This not entirely a theoretical question. We are going to have a meeting over in Moscow in the very near future which I read in the papers will touch this subject.

If you could do exactly what you wanted to do at that meeting, what would you do?

Dr. SIMPSON. First of all I think you must have an educational program, at least an explanation of the problem involved. I do not think all nations, or even the heads of the governments, thoroughly understand the problem of the bomb itself and some of the technical facts behind it.

Senator MILLIKIN. You would educate?

Dr. SIMPSON. No. 1.

Senator MILLIKIN. Let's assume you kept the heads of state there until you could educate them, and now they know as much about it or more than we do here. Where would you go from there?

Dr. SIMPSON. The second detail is one of asking them how they would solve this problem, what part they would play in this. They realize after all, whether they say so or not, that they want to get into atomic energy developments.

Senator MILLIKIN. Wouldn't you say they would unanimously say, "We want you to get rid of your bombs."

Dr. SIMPSON. I agree they would say that.

Senator MILLIKIN. They would all say that, of course.

Dr. SIMPSON. Surely.

Senator MILLIKIN. Now that is the next step. They have said, "Now, Doctor, we want you to get rid of your bombs and destroy your bomb plants."

Now, where do we go from there?

Dr. SIMPSON. I think that we have to say that this is a possibility that we are at least willing to consider, but that this has been our first meeting. I don't know of any other meetings they have had aside from Britain and the United States. This is the beginning. In a period of 6 months we have an opportunity to reach some understanding of this problem. Certainly in 6 months man can reach some sort of understanding of the problem.

I do not think that in an interval of 3, 6, or even 9 months that our bomb production is shifting the opinion of other nations as quickly as we think it is. I do think, however, we are in error in stating that we are building bigger and better bombs.

Senator MILLIKIN. Now we are sitting around the table, and you have made that suggestion. During that 6 months, what are we going to do?

Dr. SIMPSON. I don't know. I would like to know what the results of that initial conference would be before defining the next step.

Senator MILLIKIN. So we are right back to where we are here?

Dr. SIMPSON. Yes.

Senator TYDINGS. Doctor, I would like to ask you a question.

As we try to think this problem through, and certainly it is a most difficult one, it seems to me that the logic of all you have said, and particularly since you have had your colloquy with Senator Millikin, is that for the time being our principal task is to get the first essential step, which is to get a treaty on the prohibition of the use of atomic energy in any form, plus inspection. That is primary, and all the other things must come after that by international agreement rather than to try to control it in its initial stages and find that it is beyond our grasp because we have tried to control it by jumping to the middle step in the stair instead of getting on the first. Am I wrong?

Dr. SIMPSON. No; I think it would be very interesting.

Senator TYDINGS. Why did you say to Senator Millikin, then, in answer to his question, which is the question we are all asking ourselves, this: Gentlemen, we have atomic-bomb plants and we have atomic bombs. We don't believe any other nations have them. If you will give us a treaty giving us your solemn obligation that you won't manufacture these bombs and will not permit plants to be built, plus terms of inspection which are satisfactory to us, we will consider that and attempt, if we can implement it, and so on, to make it satisfactory and prohibit it in our own country.

That is the logic of your testimony, isn't it?

Dr. SIMPSON. Yes. I would like to clarify one or two things you said. One is the treaty and how long it may exist before the system is in operation.

Senator TYDINGS. But you have got to have a beginning. Our trouble now is in this muddled world to get a beginning on this problem. Do you think that that beginning—and I don't mean in all its refinements, but in the rough idea to be refined later—is the right approach?

Dr. SIMPSON. Yes. If this came out of the Moscow meetings I think we would be very happy.

Senator TYDINGS. My second question is, suppose that agreement was in the process of being discussed. Would the people of America support giving up their atomic bomb plants and factories in the world as it is today under such a proposal, and if they wouldn't obviously Congress wouldn't.

Dr. SIMPSON. I don't know the answer to that.

Senator TYDINGS. You see, this is the thing where science cannot be quite as exact as it might be in some other things.

Dr. SIMPSON. I am not talking as a scientist now. For the last hour you have been talking to me just as a citizen of this country, and not an entirely well-informed one in this field.

Senator TYDINGS. But you do think prohibition is the first step, or don't you think it is the first step, supplemented by inspection?

Dr. SIMPSON. Well, I believe it is. I almost hate to use the word, because many times it denotes something you plan to extend for almost an unlimited length of time. It is the step to make now.

Senator TYDINGS. You have got to make a beginning. In other words, suppose you were Secretary of State Byrnes and you were going over to this council and you had this problem. You had possession of the plants and you had the bombs. What approach can he make to solve this problem? He probably would like to know. I would like to know if it were I that were going, and what I am thinking about is what other approach can you make at that time? Is there another approach, and if so, what is it?

Dr. SIMPSON. I don't know any other approach. I think that this is a step forward as we look at it today, on December 12, 1945. Two or three days later some nation may do or say something which will modify our opinion on that matter.

Senator TYDINGS. What I mean is that all of you gentlemen quite properly have said you are not going to leap up to the top of the stairs and solve this problem in one leap. It is going to be made by successive steps.

Now, what is the first step?

Dr. SIMPSON. This may be. Legally, treaties are the things by which you agree to carry out this mechanism, which is very well if you can get an agreement which means that international control will work. That, in itself, is very important, because there are political issues involved there; in fact, they are almost all political. Then, you have created a great first step, and these steps must come fast.

Senator TYDINGS. It seems to me the logic of what you have said here, and what everybody else has said, is this, boiled down: Here we are faced with an atomic bomb armament race. Here we are faced in the next war with obliteration of our people and devastation of our cities, the killing of millions of people because of atomic bombs and atomic energy, and the world is in a terribly unsettled condition. Something has got to be done about it.

The first step, it seems to me, is to stop everything, provided other nations will stop everything and submit to inspection.

Now, is that your thought and is that, in your opinion, the thought of the men who have thought about it, the other scientists?

Dr. SIMPSON. I think the men will support that. That, at least, is my thought at the moment.

If that could come out of the Moscow agreement and be tentatively proposed to the UNO, that would be a great step.

Senator TYDINGS. But here is what I am ultimately driving at. Your paper is excellent, and I think it is one of the best we have had. We have had some fine papers that have been read here, both in open and in executive session.

The thing that we all agree on is that it is a big problem and the implications are terrific; but so far as I know, except in the most general way, nobody has outlined what the first step ought to be, and obviously, and we cannot go from the first to the second floor until we build the first step.

Dr. SIMPSON. I think the hesitancy on the part of the men you have been hearing in the past 2 weeks has been a justified one, that we don't know enough about the political problem.

Senator TYDINGS. None of us know; none of us can know. You know as much, let us say, about Burma or India or China as most of us know. We all get our news from the press.

What I hope your organization will do, and I hope the chairman will ask you to do, is after deep thought and discussion within the limits of Army regulations and secrecy to give us what you consider to be the plan of approach of the scientists of America and those who are associated with you, step 1, 2, 3, and 4; not that you won't make mistakes in it, but it will be the best thought that you can contribute to our efforts here.

The general statement of what is going to happen if we don't do something—we are all sold on that. What I am taking home with me every night is, "Well, how do we start this thing; how do we get rid of it?"

I want to get rid of the feeling of frustration. I want some door open some place in the room where I can get out of here and get into an atmosphere where I am making progress.

If your organization in exchanging its many views, which I think is very helpful because you are reaching a more mature thought, were to arrive at some program with steps 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, and so on, as far as your imagination and your reasoning goes, that would be something concrete that we could then mull over and study and we would begin to make progress.

The trouble is we are all learning what this thing is, but nobody is telling us what to do about it.

The CHAIRMAN. Doctor, Senator Tydings wants the door open, and I share his desire to open the door.

Would you say that we would be opening it at least a crack, just as far as a crack in the door, if we were to announce that we had stopped making bombs and had closed down that portion of the project which has to do with transferring of fissionable material into bombs, but we were continuing to manufacture the fissionable material with the hope that it would be devoted to peacetime purposes? I do not mean plants so much as I mean medical research. Do you think that would be a step forward?

Dr. SIMPSON. My answer, of course, will be immediately attacked. I think that is not what you call a step forward, but at least it is a trend forward. I think that throughout the world, whether or not nations trust us, they at least know that some of the things we say are true, that the things we say, we do; and this certainly may be one of them.

If we say it and we do it, I cannot in history see any error in our judgment on that point.

Senator MILLIKIN. I am afraid, Doctor, there will be nobody to write that history.

Dr. SIMPSON. As I say, that statement was open to attack, and I knew it.

The CHAIRMAN. That is the most gloomy prophecy of all, Senator.

Senator MILLIKIN. As I interpret the doctor's general tenor, he rests his thesis on far more faith than I would be willing to indulge in. I do not mean to indulge in human prophecy, but I seek to indulge in the kind of light Senator Tydings is talking about.

May I make a suggestion, Doctor?

Dr. SIMPSON. Yes, please.

Senator MILLIKIN. The scientist, as I see it, and as I get it from the testimony that we have had, is an idealist. He is in a true sense—and I am not using this in a disparaging sense—an internationalist. He is, because he is accustomed to interchange and meeting people from all over the world. His specialty is science. He works in the field I have described, and therefore he does not specialize in human nature and in the causes of war and therefore underweights that when he proposes a practical solution. He proposes a solution naturally out of his own environment, out of his own way of thinking; it couldn't be otherwise. Therefore, perhaps a committee of this kind might be said to be trying to fit a jigsaw puzzle. We have got a piece from the scientists which is perhaps too big. We have got a piece from the military, which is perhaps too big. We may have to whittle those down, both of them, because we have got to make a picture that will fit the frame of human nature, that will fit the posture of the world as it is; and if I were to take the liberty of making a suggestion to the scientists, I don't believe they have given enough weight to the way this world is, to the way people are, to the enormous revolutions that we would have to accomplish in the way people are—not as we would like to have them—in order to make a strictly scientific program work. I don't say that in a disparaging sense. Personally, I am delighted to get the testimony of witnesses like yourself. I myself say frankly that I have got to discount it somewhat, just as I have to discount somewhat the testimony of the military, because I don't think any of the special pleaders have taken into consideration enough things that must be taken into consideration.

But it certainly would be helpful to us, if, as suggested by Senator Tydings, someone came in here and gave us a practical program that not only fits science but fits human nature, fits the problems of the world as they are.

The CHAIRMAN. You have given some consideration, I presume, not in any way in derogation of what Senator Millikin has said, to what an atomic armament race would be if it is allowed to go uncontrolled?

Dr. SIMPSON. We have tried to interpret that in terms of what human nature is like and what it will do. I think there is just one point to make, that at no time are we saying that what we propose is a sure way out. All we are trying to say is that maybe there is a chance here. With the other course, we don't see any chance. We see the end result. The other way we do not see the end result. Our set of facts may lead us to destruction, but at least the facts include also the possibility of extended periods of peace. Therefore we say we are experimentalists, not in the sense of social experimentalists but in the sense that at any time in history we shall sit down and discuss the problem dispassionately. We must weigh the human values, the political issues, and the scientific facts involved, and then we may be able to state, "Now, if we do this there may be a chance that this will create a better condition." We must do this.

Senator TYDINGS. Doctor, I would like, with the permission of the chairman and other members of the committee, to extend to you a request that your organization, composed of scientists and engineers and others who have exchanged these views, and you, or whoever is ap-

appropriate, assuming you will transmit this request to them, will think on this problem collectively in such fashion as they can and give to the chairman at the earliest possible date the best considered program which your group can derive for steps 1, 2, and 3 at least in a very difficult series of steps, the initial steps and any others that you might think of that would follow from there particularly with reference to the question of prohibition, treaties and inspection at this juncture as contrasted with either an armament race on the one hand, or partial international agreement with licensing of peacetime atomic energy on the other.

Senator MILLIKIN. Would you let me offer an amendment?

Senator TYDINGS. Gladly.

Senator MILLIKIN. I would like to have one more thing in that, and that is a specific statement as to at which point we destroy our bombs and level our bomb-making plants.

Senator TYDINGS. That would be a very welcome suggestion, where when we take these progressive steps the point comes that we can in justice to ourselves and our world obligations take the hazard of leaving our country possibly defenseless and relying on treaty and inspection.

If the chairman would permit that request or would make it himself, I would appreciate it, because in groping for a beginning of this thing I find my greatest difficulty not what I want to achieve eventually, but how to start to achieve what I want to achieve eventually.

The CHAIRMAN. I will be very happy to endorse that request as chairman.

As I told you yesterday, Senator, and informed the committee, the scientists are busy on a tremendous project, and that is the inspection system, which they undertook at my request and hope to have done right after the first of the year.

I would like to call your attention to the fact that they have not moved into this field extensively that you now suggest they move into because—and if I am in error you can correct me, Doctor—there was a feeling on the part of the scientists, a modest feeling that I don't think they should have had, although they have been criticized by some Senators and Congressmen that I have heard personally for daring to come in to suggest in the political field.

Senator TYDINGS. I think they ought to be welcomed.

The CHAIRMAN. I agree with you, but you know and you have heard, too, criticism of the scientists on the ground that they were men of science and were not versed in political science, only in the natural sciences. I think they have been aware of that problem, and that they did not want to get out of their field of natural science fearing that they might destroy their influence with those who criticize them for doing the other thing.

I feel exactly as you do, and I hope Dr. Simpson takes it up with the group, that in the light of this discussion that sentiment will disappear, and they will go forward on the program with full assurance that we will welcome the kind of paper that Senator Tydings and Senator Millikin have suggested.

I want at this point to pay a great tribute to Dr. Simpson and to his associates in this Federation of Atomic Science, who have seen the terrific implications of that which they have wrought. I don't

believe that this country is awakened yet to the possibility and the implications, but without them we would be much further back along the road, and they are deserving of great credit.

Senator TYDINGS. I want to reecho what you have said in praise of the gentlemen who are before us. I think that every one of them has made a distinct contribution, and I hope they won't mind a little battering, because the objective is so worthwhile that any little scratches or cuts we may get in trying to achieve the ultimate result are minor compared with the benefits that may go to mankind.

I am very hopeful that it won't take too long for the scientists to congeal on at least what they can agree on as the first two or three steps, because if we had something more concrete than generalizations, I believe with your great knowledge and experience and background in this thing and the vision and the thought you have put on it, we will make a little more progress toward an ultimate solution than we otherwise might make.

The CHAIRMAN. Thank you very much, Doctor.

This shows the difficulties of trying to run on schedule. We had hoped to hear three of these young men this morning. It is now 12 o'clock, and I do not think we had better start with another witness.

If it is agreeable, we will meet at 2:30 to hear the other two gentlemen in open session.

Tomorrow we are to hear from representatives of the Navy Department, more particularly Commodore Parsons who dropped the bomb over Hiroshima.

We will recess now until 2:30.

(Whereupon at 12 noon the committee recessed until 2:30 p. m. of the same day.)

AFTERNOON SESSION

(The committee reconvened at 2:30 p. m., pursuant to the noon recess.)

The CHAIRMAN. The hearing will come to order.

Which one of you gentlemen is coming first? Are you, Dr. Williams?

Dr. WILLIAMS. Yes, sir.

The CHAIRMAN. All right, proceed, Doctor.

STATEMENT OF DR. CLARKE WILLIAMS

Dr. WILLIAMS. Thank you.

The CHAIRMAN. You are a member of the Federation of Atomic Scientists?

Dr. WILLIAMS. Yes.

The CHAIRMAN. You go right ahead, Doctor.

Dr. WILLIAMS. Very well. Shall I introduce myself?

The CHAIRMAN. Yes. I would like to have the record tell who you are.

Dr. WILLIAMS. Yes, sir.

My name is Clarke Williams. I am a physicist. I have been on the faculty of the College of the City of New York since 1930. For the past 4 years I have been engaged on the atomic bomb project—for the

most part in New York City. I am a member of the executive committee of the Association of Manhattan Project Scientists, which is the New York branch of the Federation of Atomic Scientists. This is my statement.

As Dr. Simpson has already pointed out, the atomic bomb scientists and engineers have shown a surprising unanimity of opinion in their belief in the need of an international control of atomic energy.

It seems fairly clear to us that such control involves a rather complete inspection system carried on by some international agency. Because of the ease with which an assembled bomb can be concealed, the only way to create a world-wide feeling of security against atomic bomb attacks is to insure that no bombs are being constructed. Such insurance can be secured through an efficient inspection to detect violations of the regulations of the international control agency.

In order to set up such an inspection, two phases of the problem must be solved; one phase is political, the other technological. We realize that the over-all question of international inspection is primarily a political one. The two phases, however, are completely interrelated, and really require simultaneous solution.

The political problem concerns itself with such questions as the setting up of an international control agreement; provision for the free access of inspectors to all critical points; and provision for enforcement of regulations. Problems such as these must be solved before any inspection force can operate effectively enough to produce a feeling of security throughout the world.

The other phase of the feasibility of inspection is the technological one. An answer must be secured to this question: Is it feasible to inspect operations of various sorts in all countries so that there is very little possibility of clandestine production of fissionable material or diversion of such material produced in legitimate plants?

I have discussed the problem of international inspection with a large number of my associates in the New York laboratories and in the gaseous-diffusion plant at Oak Ridge, Tenn. I have also had the opportunity for such discussion with representative scientists from the other groups within our federation. I have found it generally true that within the limits of his own field, each scientist feels that techniques for inspection can be worked out. However, the compartmentalization is so complete that no one person is in a position to consider the feasibility of inspection covering the whole range of methods for producing fissionable materials.

Senator MILLIKIN. Mr. Chairman, at that point I would like to interject a question.

It is this, that at least one of our distinguished witnesses has said that, regardless of the compartmentalization which was put into effect on this problem, despite that compartmentalization, they knew what was going on. As I understand it, I gathered the impression that the compartmentalization was only a subterfuge.

Dr. WILLIAMS. Well, as far as views on nontechnical subjects are concerned, there is an interchange of ideas. As far as the technical material which is classified as secret, there is practically no interchange of ideas.

I would say that my experience has been that all the people I have worked with on this project have been quite punctilious in observing

the restrictions that have been imposed upon them by the Army. They did this although they may not have approved all of those restrictions. They conformed. I think there has been no deliberate attempt to evade the regulations.

Therefore, we are not in a position to know the technical details which are necessary for a complete discussion of this problem. I think I will present that aspect of it later on in my testimony.

Senator MILLIKIN. It follows then that departmentalization is a good idea for wartime. It worked for the duration of the war.

Dr. WILLIAMS. Yes.

Five different methods of obtaining fissionable materials were successfully developed in this country. Dr. Simpson has indicated that it would be desirable that the testimony of the experts in these different fields be integrated in some manner to be determined by your committee. Most of the information that would be needed in developing a feasible inspection system is now secret and compartmentalized. Should a group of scientists and engineers be selected to make a suitable integration, they should have access to all the necessary material and have the opportunity for free discussion with experts in all fields. I might interject that at the present time this is not the case.

To illustrate my point, I would like to indicate the sort of questions that would be raised in considering the feasibility of inspection of a gaseous diffusion plant for separating Uranium-235. I have chosen this example, because I have been working on the development of this method for the past 4 years. Some of the questions raised, however, will be applicable to the other methods as well.

The problem can be divided into two parts: First, to insure that no material is illegally diverted from existing known plants; and second, to discover any attempts to build and operate a secret diffusion plant. If a plant is operating, openly or secretly, one basic check that may be suggested is to keep an inventory on all uranium from the ore reserves, through the mining, refining and processing, to the final product and wastes. If this is feasible, it would be a very powerful method for preventing the misuse of products of the diffusion plants. Specialists in the fields of geology and mining, in metallurgy, in uranium and fluorine chemistry, and in the gaseous diffusion process itself would all be needed to work out this problem.

The problem of developing methods for the discovery of a secret plant involves a detailed knowledge of all the components that go into such a plant, such as pumps, instruments, special materials, etc. Some of the components may be unique in their construction or in the materials from which they are made, and may, therefore, be relatively easy to identify. It might then be simple to determine whether they were being diverted from legitimate uses to secret diffusion plants.

For example, there are several thousand centrifugal pumps in the gaseous diffusion plant. These pumps have certain characteristic features such that anyone with some familiarity with centrifugal pumps could recognize them in any factory. There are only a few manufacturers in this country that could build such pumps. To build several thousand secretly would be very difficult, unless it were done on a very small scale. The delay attendant on small-scale production would involve a long period of plant construction, again increasing the probability of detection.

Senator MILLIKIN. Mr. Chairman, I would like to interject.

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. Could you take a normal pump and modify it to suit this purpose?

Dr. WILLIAMS. I don't believe so.

Another characteristic item in a diffusion plant is the barrier material. Here is a unique material which has to be made and fabricated on a large scale. Such manufacture would be extremely difficult to conceal.

The amount of power needed to operate a diffusion plant is large. Power experts can determine whether such quantities could be diverted from existing electrical networks without the possibility of detection by competent inspectors. As an alternative, the power could be produced directly from fuels available at the site. In this case, the power expert could determine whether equipment could be secretly manufactured and installed without the likelihood of detection.

Engineers who have been instrumental in laying out the present plant could give details as to how extensive the preparation of a plant site must be. This would indicate to experts in photoreconnaissance the difficulty of building such a plant secretly in such a way as to escape detection by aerial or other systematic surveys of all remote territories.

It is also pertinent to question whether a diffusion plant which was already completed and hidden could be detected. Improvements will undoubtedly be made in the design of the various components of these diffusion plants, which will certainly result in an increased plant efficiency. This would make it probable that any plants built in the future could be more compact than the present one, and hence much more difficult to locate once they have been secretly completed.

The CHAIRMAN. Doctor, would you be good enough to give us your opinion on whether the diffusion method is the most efficient method.

Dr. WILLIAMS. I am not competent to answer that question, because of the fact that there was this compartmentalization that we have talked about. I do not know anything about the efficiency of any other method.

In the fact that such plants would be more difficult to find once they are built lies a powerful argument to hasten the setting up of an inspection system on a world-wide basis.

In addition to the inspection of all physical aspects of atomic-bomb plants and their raw materials, there may be feasible methods of inspection involving the scientific and technical personnel necessary to develop, design, and operate such plants. The questions that must be answered to determine the feasibility of these methods involve the following points:

1. The possibility of making a complete check of all the scientific and technical personnel in every country to insure that no important number are being secretly trained and diverted for the development and construction of large-scale atomic-bomb plants.
2. Any intended violation by a given country of the international-control agreement will, of necessity, be known to some of the scientific and technical personnel in that country. Because of their overwhelming desire for maintaining the security of the world, we feel that there will always be a certain percentage of these scientists and technical

men who will report violations to the international-control commission. On this account, international and national laws should encourage and offer definite protection to those who report violations.

3. In order to prevent the secret disappearance of key scientific and technical personnel and in order to detect discoveries and developments which may lead to new methods for the production of fissionable material and atomic weapons, it is desirable that there be a rather thoroughgoing interchange of scientists and technical men. In addition, as a further safeguard, there should be complete freedom of publication of all scientific and technical discoveries and developments.

Undoubtedly no system of inspection could be absolutely certain to prevent secret production or diversion of fissionable material for illegitimate uses. However, under a good inspection system, the chance of evading inspectors becomes small, small enough in fact that in all probability the risk of being caught in a violation would act as a sufficient deterrent to keep any nation from such an attempt. Furthermore, a good inspection system would create among all nations a greater feeling of confidence in the behavior of their neighbors. Such a feeling of security would in itself render the secret production of atomic armaments much less likely.

While the scientists and engineers seem to feel that an international system is technically feasible, it is nevertheless quite clear that an adequate study of this problem has yet to be made. Statements concerning feasibility have been based upon the limited information available to individuals. A complete picture involves the ideas and information of many experts, within and without the atom-bomb projects. Until some means of coordinating this information is provided, the integrated analysis of the feasibility problem cannot be made.

The CHAIRMAN. As I understand it, Dr. Williams, you have requested that the next statement be heard, that you prefer that the other gentleman, Dr. Weinberg, read his statement before either of you is called upon for questioning.

Dr. WILLIAMS. I think that would be more satisfactory, because some of the questions that are raised by the following statement are pertinent to what I have said here.

The CHAIRMAN. Is there any objection?

Senator AUSTIN. No, but I would like to ask one question. I do not know whether he can answer it or not.

You spoke of a provision for enforcement of regulations in your formal statement. Did you have anything concrete in your mind?

Dr. WILLIAMS. No, sir; the only thing that we felt was this, that if any regulations were set up they would not mean anything unless there was some way of enforcing them.

At to the nature of the agency that would be set up, we have not felt that we were competent to pass upon that. It would be in the nature of a judicial and policing force. We do not feel that we are competent to say how such a thing should be set up.

However, it does seem to us that in order to implement anything in the nature of inspections that there must be some way of enforcing the regulations.

Senator AUSTIN. Evidently, you did not have in view any military enforcement.

Dr. WILLIAMS. No. It does not have to be military. In fact, some of the violations in the future might very well be made by individuals rather than by nations.

Senator AUSTIN. Yes. Have you discussed the question of protection for informers?

Dr. WILLIAMS. Only slightly. It is also evident to us that if a particular group in a country attempts to divert materials to an illegal use, there will also be a group of people in that country who will not approve of it and who will want some way in which they can make their knowledge known. There will have to be some sort of mechanism set up to protect them.

Now, I do not know just how that would have to be done, whether it would have to be part of the UNO or just what the mechanism would be. We do feel that something of that nature would have to be included in the international agreements.

Senator AUSTIN. Thank you, Doctor.

The CHAIRMAN. Don't go away, Dr. Williams. Dr. Weinberg.

STATEMENT OF DR. ALVIN M. WEINBERG

The CHAIRMAN. Dr. Weinberg, you are originally from Chicago. You have been working on the plutonium project in Chicago and Oak Ridge since 1942.

You are another representative of the Federation of Atomic Scientists?

Dr. WEINBERG. That is right, sir.

The CHAIRMAN. All right, Doctor, proceed.

Dr. WEINBERG. The last time I spoke to your committee was when you all paid us a visit at Oak Ridge. I am afraid my remarks then were a little lengthy, considering the fact that the hour was late. I didn't quite consider how late it was but it was later than I realized, since you were on faster time than we were and, unfortunately, my remarks were lengthy. However, I will confine myself this morning to the written testimony.

I am Dr. Alvin M. Weinberg. I am 30 years old. I am a theoretical physicist originally from the University of Chicago. I have been with the plutonium project at Chicago and at Oak Ridge since January 1942. Prior to that I worked in the field of biology. At present I am chief of the theoretical physics section of Clinton laboratories in Oak Ridge.

The previous speakers have dealt with the difficult political and technical problems which atomic power and its control have posed for us. I will talk about what we can hope for from atomic power, assuming that these problems have been solved.

The CHAIRMAN. That is some assumption.

Senator MILLIKIN. He is taking the easy part.

Dr. WEINBERG. Pandora's box at the moment is just shut tight and I am just tipping it up so that you can see what is inside.

Senator TYDINGS. If you tip it too much you could loose the whole contents.

Dr. WEINBERG. The atomic era began December 2, 1942, when the first nuclear chain reaction was established in Chicago. It came at a time when one problem—the winning of the war—was important to the exclusion of all else. The relatively few scientists and technolo-

gists who had access to the details of atomic "know how" were thinking about bombs instead of power plants. And these men represented a very small fraction of America's technical personnel. Most scientists were hardly aware of the significance of Oak Ridge and Hanford.

The urgency of war problems has left little time for the few scientists with sufficient knowledge of nuclear engineering to reflect about the future possibilities of nuclear energy. The extreme compartmentalization in the organization of the work has denied the latest facts concerning uranium deposits from those scientists who need those facts to establish the economic feasibility of uranium power. And the exclusion of nonproject scientists from technical knowledge because of wartime security has made really original ideas about future applications—ideas which come from new blood—remarkably scarce.

We thus stand at the threshold of the new era with ideas for applications of the power source which are generally very much less revolutionary than the atomic bomb itself. Nevertheless, the field is so enormous that even the applications which we have already thought about—without trying, one might say—form a lengthy list.

In the very long run we can expect nuclear fission to compete on a strictly economic basis with ordinary power sources. But nuclear power as contrasted to coal power is unique in perhaps five essential respects. It is in the exploitation of these features of uniqueness rather than in particular economic advantages that we can expect the immediate future of nuclear power to lie. I list these distinguishing characteristics and their implications for peacetime as follows:

One: The release of nuclear power is accompanied by the production of enormously intense radiations.

At Hiroshima many people were killed by the gamma and neutron rays emitted by the atomic explosion. At Hanford, Oak Ridge, and Chicago, the chain reacting piles are shielded by enormous concrete or steel shields. But the same rays which cause such damage in massive doses can, like the rays from the sun, have therapeutic effects—when given in moderate doses. Certain types of cancer yield to neutron radiation of the sort that is emitted by our chain reacting piles. Such piles can be built immediately for large-scale radiation therapy for the simultaneous treatment of perhaps 100 patients at each pile. In this capacity piles would serve, on a very much enlarged scale, the same function as large hospital X-ray therapy units.

A second application of high intensity radiation is to industrial chemistry. Just as plants synthesize sugar under the influence of sunlight, so many other chemical reactions—some of considerable importance industrially—can be made to proceed in the intense radiation field of a chain reacting pile.

Two: The release of nuclear power is accomplished by the production of radioactive substances in enormous quantity.

For the first time mankind has at its disposal radioactive materials in sizeable quantities.

Senator TYDINGS. May I ask you, there, whether that would mean that we are pretty well independent of radium, then?

Dr. WEINBERG. Yes, sir.

Senator TYDINGS. So this would be a substitute for radium.

Dr. WEINBERG. It would be a substitute for radium. It would be radium magnified by an enormously great factor.

Senator TYDINGS. So that the radium supply becomes of less importance from now on than it was 10 years ago.

Dr. WEINBERG. If I had stock in a radium factory, I probably would sell it.

Senator TYDINGS. That was a good answer.

Dr. WEINBERG. A chain reacting pile can render practically all of the elements radioactive. It is like a modern King Midas who turns common substances into radioactive ones instead of into gold, although even gold can be made by irradiating mercury. The uses which we can foresee for these radioactive atoms are medical, scientific, and industrial. For example, the waste from the Hanford plant contains enough radioactive material to supersede radium completely in its uses as either a medical therapeutic agent or as a means of industrially testing the soundness of metal castings.

From the scientific viewpoint the importance of radioactive tracers—that is, atoms, particularly carbon, which have been rendered radioactive by neutron bombardment—cannot be exaggerated. One of the most important problems of science is, "How do plants manufacture sugar out of carbon dioxide, water, and sunlight?" If man could duplicate this photosynthesis process, first in the laboratory and then on an industrial scale, the bountifulness of the earth would be multiplied indefinitely. The world's fuel and food supply would be assured as long as the sun continues to emit light. The most powerful tool at the chemists' disposal for understanding, and perhaps eventually duplicating photosynthesis, is radioactive carbon, a byproduct of nuclear power. If, as a result of our greatly increased production of radioactive carbon the riddle of photosynthesis is solved, that, and not power plants or atomic bombs, will stand as the greatest achievement of nuclear power.

Besides radioactive carbon, other isotopes will be useful for general chemical research, and possibly also for routine control of industrial processes and routine diagnosis of certain diseases. There is every reason to believe that the large-scale production of radioactive isotopes for chemical, biological and industrial users will develop into a very considerable industry, perhaps comparable to the present-day pharmaceutical industry.

Three: The release of nuclear power requires no oxygen.

The atomic fire at Hanford burns without oxygen. Here is an ideal fuel for use in a submarine; with it a ship can travel as fast under water as on the surface. The navy of the future, if there is any such, will consist of submarines which will travel a thousand feet below the ocean. The safest place on this tortured planet, should an atomic war break out, will be deep below the surface of the ocean.

Senator TYDINGS. Below the bottom, won't it? [Laughter.]

Dr. WEINBERG. I would not know the exact figure, sir, but my guess on that would be that if you were one mile below the surface of the ocean, you would be safe in two ways: one, they would have the problem of finding you; and two, after they found you, they would have the problem of blowing you out of there.

Senator TYDINGS. I should think that finding you would be the bigger problem.

Senator MILLIKIN. What is the pressure below the surface?

Dr. WEINBERG. Well, that would depend on how much below the surface. It is one atmosphere of pressure for every 32 feet of water. I think the limit would be 30 atmospheres or 50 pounds per square inch; it might be about 500 pounds per square inch.

Senator MILLIKIN. This new development might revolutionize submarine warfare?

Dr. WEINBERG. I don't know, sir. You see, at present one of the reasons why a submarine—I have spoken about this to some Navy people—at present the limitations of the power plant limits the construction design of the submarine.

If the power plant can be multiplied indefinitely, as might be the case with atomic power, then the construction of the submarine could be modified.

Senator MILLIKIN. Do you know the greatest depth that divers have ever gone to under the sea?

Dr. WEINBERG. My recollection is that it was around 300 feet; I may be wrong. Of course, there are the bathospheres.

Senator MILLIKIN. I am thinking of the bathosphere.

Dr. WEINBERG. With the bathosphere, I think it would be beyond that, but I do not know.

Senator JOHNSON. With regard to submarines, would not the resistance of the water to a forward movement be somewhat of a problem?

Dr. WEINBERG. No, I do not think that that counts. That is not the function, particularly, of the depth below the ocean. As a matter of fact, in some respects the depth might result in an increase in the speed of the submarine, a greater speed than on the surface.

You see, on the surface we have what is known as the surface wave. The ship, so to speak, has to slice its way through the water, it goes forward by the breaking of the surface itself; it cuts its way through the water.

Senator JOHNSON. Well, in the air they are increasing their speed by going into the stratosphere, where there is less resistance. I was wondering whether the same principle would apply to water. I should think that in the water the resistance would be greater the farther down you go. However, that is not important. I do not want to bother you with these matters. Proceed, Doctor.

Senator TYDINGS. Apparently, that is one of those scientific facts we are supposed to accept and not ask why.

Dr. WEINBERG. Four: Nuclear energy is extremely concentrated.

One round of fissionable material releases as much energy as several million rounds of ordinary fuel. Nuclear power will, therefore, be particularly advantageous wherever the bulkiness of ordinary fuels is undesirable. Regions of the earth such as the Arctic, in which the cost of fuel transportation makes large-scale power or heating development unfeasible could be supplied, economically, with nuclear power.

Space travel, which has until recently been deemed fantastic, must now be considered more seriously. But progress will be made only when the rocket experts are allowed to speak freely with the atomic power experts.

Five: The release of nuclear power is accompanied by the production of more fissionable material.

At Hanford, U-235 is destroyed but plutonium, which is also fissionable, is produced. Thus a nuclear power plant is unique in that at the

same time it burns up its fuel, it produces new fuel. The emphasis on nuclear power can therefore be shifted somewhat: Either one can consider the fissionable material to be a byproduct of the power or, as at Hanford, one can view the power as a byproduct in the production of fissionable and radioactive materials.

From this point of view the economics of nuclear power is rather more like the economics of water power than that of coal power. We often build dams for flood control, irrigation, soil conservation, and the like; the power which they produce is in these cases secondary. It is not too important whether the power would compete with coal power! the dams are built, anyway. Similarly, we shall build plutonium factories in which the power is a byproduct. These plants will, like dams, have a multiplicity of uses.

They will produce plutonium for use in specialized power plants. They will produce radioactive materials for technology and medicine. They will yield facilities for scientific research. The cost of the power will not determine whether or not we build the plant, so long as the production of the fissionable material is considered a desirable end in itself. And I have no doubt that, even without the atomic bomb, plutonium will always be valuable as an atomic fuel in services such as ship propulsion.

In order to produce plutonium in quantity, an enormous amount of power must be dissipated. We can conceive of a vast complex of large nuclear installations whose many functions include both plutonium and power production. We can properly compare this complex to, say, the Tennessee Valley Authority; it would have a multiplicity of functions comparable to that of any of our large hydroelectric systems. This "atomic authority" would most naturally be located in a region which is not endowed with water power and is not now served by private or public power. It could serve as the basis for industrial development of the region in somewhat the same way that TVA serves parts of the Southeast.

In these remarks I have outlined what to me appear reasonable lines of development for atomic power. There remains the question what can the Congress do to create conditions in which the development will flourish.

Right now there are two problems hampering the development of atomic power. First, because of security, because of general uncertainty, we are appallingly low in trained personnel. One distinguished physicist—the man who conceived and to a large extent designed the Hanford plant—has estimated that there are not more than 15 men in the entire country who have at this moment a sufficiently quantitative grasp of the process to direct adequately the development of a new nuclear power plant. This does not mean that the field of nuclear power is particularly difficult.

Senator AUSTIN. You mean 15 men in all the world?

Dr. WEINBERG. My point is that there are only at this time, I would say—and I am corroborated by this distinguished physicist here—that there are only 15 men in the entire world, if you like, who are sufficiently familiar with all the details in the present process to go right out and start developing it.

That, however, does not mean that there are not—well, there are probably in the order of several thousands of people who, in a year

or so, boning up, if you like, would be able to duplicate the achievement.

Senator JOHNSON. Where are they?

Dr. WEINBERG. Well, most of them are connected with the plutonium project and with the bomb project.

Senator JOHNSON. Are any of them in any other country?

Dr. WEINBERG. The 15 of which I spoke are in this country. In Canada, I would say that there are—well, some.

Senator JOHNSON. You mean on this continent?

Dr. WEINBERG. Yes; there are some.

Senator MILLIKIN. Well, would there be more or less than that number of men, speaking of those who could build bombs. You are speaking of the development of the power plants?

Dr. WEINBERG. I would say there are about an equal number. However, I would say this, without desiring to belabor the matter particularly, I would guess—although I do not know—I would guess that to develop a bomb and build a bomb is probably more complicated than to develop how to build power plants.

Any competent physicist can learn in a matter of a year or so all that has been developed in the past 5 years. But, with security regulations as they are, there is no opportunity for outside individuals to become acquainted with our technical "know how." And nuclear technology will develop normally only when any qualified person with an original idea has access to the data which will enable him to develop his idea.

The second problem is more serious. The previous speakers, the whole previous testimony, has dealt with the profound international implications of atomic energy. On the other hand, the international aspects will determine our domestic atomic energy development. A satisfactory control system will enable us to relax our security regulations and atomic power will develop normally. Without a control system, the development will be stifled by secrecy and by fear.

Evidently a nuclear power plant which by its very nature is also an atomic bomb plant must be controlled very much more drastically than a present-day steam plant. There are those who suggest that a complete halt in the development of atomic power plants is the only way to insure against the use of atom bombs. If, by not building power plants we could really avoid war, I would agree with such proposals. But atomic power can cure as well as kill. It can fertilize and enrich a region as well as devastate it. It can widen man's horizons as well as force him back into the cave. We cannot, and we must not keep atomic power in a Pandora's box—afraid to open it because we fear what might happen if it is misused. Rather we must develop atomic power, and we must develop the power to control it.

The CHAIRMAN. Now, Doctor, I will turn you over to Senator Tydings. [Laughter.]

Senator TYDINGS. Do you think that we ought to try to develop atomic power for peacetime uses if we can do so without threatening the future of civilization? Is that a fair statement?

Dr. WEINBERG. I agree completely.

Senator TYDINGS. Our first problem, however, is to ascertain whether or not the first is possible, before we explore the second alternative.

Now, knowing the world as you know and as you have known it throughout your life, could you give us your opinion as to what should be the 1, 2, or 3 steps which we should immediately take to make certain that the international things can be so worked out as to permit the domestic use of atomic power?

Dr. WEINBERG. Well, Senator, it seems to me that there are various fundamental assumptions which mankind must make at this point.

Senator TYDINGS. Yes, but don't let's take those things, don't let us talk about what ought to be. Let us talk about what there is.

Dr. WEINBERG. Good.

Senator TYDINGS. I agree with you. I would like to see crime and war and unbridled selfish avarice, if you want to compound adjectives and nouns—I would like to see all those things eliminated; but let us look at the world as you and I know it.

Dr. WEINBERG. It seems to me that since we must look into the question of control if the alternatives which you stated this morning—

Senator TYDINGS. At least, we agree that control must come before atomic power can be manufactured?

Dr. WEINBERG. That I agree with 100 percent.

Senator TYDINGS. Then, our problem is simplified. How, in the present world do you suggest that we go about this control initially—not ultimately, but right now?

Dr. WEINBERG. Right now? I would probably agree, although I am not completely sure that—

Senator TYDINGS. Doctor, we are in a way simply thinking out loud. We appreciate that you might wish to revise your opinion after you give it more thought. We appreciate that.

Dr. WEINBERG. Well, then, I would like to say that what I will say is not a solution, probably, taking the present instant, with the world in the sorry state in which it is.

Probably, the best thing that we could do would be to announce that we would establish a control and that, as a prelude to that control we will stop all atomic development, assuming that all other nations do likewise.

Senator TYDINGS. That is it, assuming that all other countries do likewise.

Dr. WEINBERG. That is right, that they do likewise.

Senator TYDINGS. And assuming that the other nations will allow us to inspect them and that they will have comparable rights for their own countries?

Dr. WEINBERG. Yes.

Senator TYDINGS. You are pretty definite about that.

Dr. WEINBERG. Yes.

Senator TYDINGS. You are pretty sure that that would be, at this present stage of your thinking, you would say that that would be your original suggestion?

Dr. WEINBERG. Yes.

Senator TYDINGS. Now, what would you do next?

Dr. WEINBERG. I would like to add one thing, though, in that connection: It does not seem to me that that is a solution, however.

Senator TYDINGS. I am not saying that it is.

Dr. WEINBERG. And if you will allow me to say very definitely why I do not think that it is a solution, I will say this: That means that, instead of starting the war with atomic bombs, you will finish the war with atomic bombs, and I am not sure whether finishing the war with atomic bombs would be better than starting the war with atomic bombs.

Senator TYDINGS. Well, if you finish it with atomic bombs, the man is more exhausted, and, therefore, he will succumb more quickly than if you started when he was fresh.

Dr. WEINBERG. That is true, sir, but we do not know how bad the atomic bomb of the future will be. I don't know. I am not an expert.

Senator TYDINGS. Without going into too much detail, let us assume that we had effected a treaty with the leading nations of the world and had set up an inspecting force which, together with their pledged word will, we hope, solve the thing temporarily.

Now, what is our next step?

Dr. WEINBERG. Well, I think we would have to see—Isn't the question really—

Senator TYDINGS. I will define it further. Say that it works for 3 years, just to make our approach a little easier. Say it was working splendidly. Now, what would you do next?

Dr. WEINBERG. I would like to say that I think the next step would be the following:

That, with the experience in the control, the drastic control which you suggest, with the experience gained by that control—and it will be a drastic control, we will still have to go into the country and snoop around, so to speak—with the experience we have obtained from that drastic control, I would like to hope that eventually it works so well that we can gradually release or allow the development to flourish more strongly.

Senator TYDINGS. To put it in a summary, we would have this situation: We have it where it has worked. I will say that we seem to be getting along pretty well and cooperating.

Now, I suggest that you assume that we release this energy not only for medical and research purposes but for power plant operation as well, as our first step. Let us just assume that our first step, that we are taking that step.

That would mean that there would be construction of this particular kind of a plant under these circumstance, with this sort of inspection.

Now, we have got the power plant, in the 3 years, or after, in operation. Now, what would you do next, assuming that we have these power plants and they are working splendidly?

Dr. WEINBERG. In that case I would say that the problem is essentially solved, if you are having peacetime atomic plants working properly, and we are assured that people are not making bombs on the side.

Senator TYDINGS. Well, let us assume that they are not making bombs. Suppose 6 years have gone by and that our first steps, to all intents and purposes, are successful. What do we do next?

Dr. WEINBERG. I would suggest that if our first two steps are so successful, then we will have succeeded in eliminating war by that time; it will be equivalent to eliminating war.

Senator TYDINGS. In the meantime, I think it would be only fair to say that during those next 6 years, while these things are taking place, we are still maintaining our Navy and our Air Force and our Army and that most of the other countries, in varying degrees, are doing the same thing.

Assume that there has been, during this period, no war in the world and the peacetime inspection looks like it is working all right.

Now, what makes you think that you have eliminated war?

Dr. WEINBERG. Well, the peacetime inspection, as you would have me assume, has been working all right.

Then, it would seem to me as if the very first act preceding the next war, assuming that we do have this control, the very first act of the next war would be the rejection of this control, which means that the control would be no longer working—the control would be lost.

Senator TYDINGS. In other words, the inspection would break down as soon as the nations went into a warlike attitude?

Dr. WEINBERG. Exactly, sir; exactly. In that case, as I said, we would start the war with atomic bombs, rather than finish the war with atomic bombs.

Senator TYDINGS. You understand none were being made when the war breaks out.

Dr. WEINBERG. Well, if you like, I can conceive of the following situation——

Senator TYDINGS. Well, let us assume that none were being made when the war breaks out.

Dr. WEINBERG. Good. Then, country A says, "We will throw your inspectors out." Country B says, "Very well, we will throw your inspectors out."

Senator TYDINGS. They will knock them all out. Perhaps that is the first thing they will do.

Dr. WEINBERG. Probably they will shoot them. Then, does it not seem that the situation will be that immediately thereafter the race will be on?

Senator TYDINGS. Well, Doctor, I am asking you this not to be contentious in any way. It is that I am very much interested in your point of view. I, like yourself, am trying to travel this road and pick up the stones of reason in one hand or the other. That is my hope.

What you are arguing for and what the hope of the world is, is complete outlawing of war.

Dr. WEINBERG. War has been obsolete for a long time.

Now, we have really shown that it is obsolete.

Senator TYDINGS. Now, do you think that this prohibition of the atomic bomb is only by degree more important than the elimination of the battleship?

Dr. WEINBERG. Absolutely not. It is not more important in degree. The atomic bomb did not create wars.

Senator TYDINGS. So, we are back to this point, that what we want in the beginning, if we can get it—not today or 6 months from now, but assuming that the world quiets down someday—according to you is complete international disarmament?

Dr. WEINBERG. Exactly.

Senator TYDINGS. There is no hope of using atomic energy in peacetime for peaceful purposes, with the threat of war hanging over us,

unless you want to exterminate civilization. That is what your testimony seems to logically conclude.

Your testimony indicates that atomic bombs are something that will come in if war comes.

Dr. WEINBERG. Exactly.

Senator TYDINGS. And, therefore, the best thing to do is to eliminate the means by which you can make war, of which the atomic bomb is the most important means.

Dr. WEINBERG. And eliminate the desire to make war.

Senator TYDINGS. Then, your line of reasoning is that there should be world disarmament, plus international inspection to enforce international disarmament. You also say that the atomic bomb is going to be used inevitably. Am I wrong?

Dr. WEINBERG. I agree 100 percent with what you say.

Senator TYDINGS. All right, Mr. Chairman.

Thank you, Doctor.

The CHAIRMAN. Doctor, of course, we are only one of I-forget-how many sovereignties in the world. How many are there?

Senator MILLIKIN. About 50.

The CHAIRMAN. So, any policy that we lay down must of necessity be accepted by the other nations of the earth.

You have laid down before us a very entrancing vista that opens up to peacetime use of atomic energy. The thing that disturbs me is that while we here who have this large development of atomic power might well forswear the vista and the possibilities, I am wondering as to the willingness of the other peoples of the earth to go along with us on that proposition, where they have not got the bomb and we have got it.

Dr. WEINBERG. If they really felt that the alternative to forswearing—let me come back to Senator Tyding's point, that whether or not you prohibit atomic energy simply determines whether the war is going to be started with atomic bombs or finished with atomic bombs.

If the countries in the world were really convinced, first, that there is the danger of extermination from atomic bombs—

Senator TYDINGS. And you believe there is?

Dr. WEINBERG. I believe there is, sir.

Then, it would seem to me that if they felt further that, by forswearing development of atomic energy, they could decrease this possibility—although, of course, they cannot because then the war will be finished with atomic bombs instead of started with atomic bombs—then, I think they will be willing to come to an agreement.

I think, in the present practical situation, they would certainly be willing, because we have the bombs and they do not.

Senator TYDINGS. Could we just say this, that in any war in the future between the major powers that may take place any time before 6 years, the overwhelming odds are that atomic bombs would play a part in it?

Dr. WEINBERG. I would not like to come to that conclusion, but I am afraid I will have to.

Senator TYDINGS. I think we can accept it.

Dr. WEINBERG. That is right.

Senator TYDINGS. The only way to stop atomic bombs is to stop war.

Dr. WEINBERG. Exactly.

Senator TYDINGS. So, then, our atomic bomb is incidental to a greater problem, which is that we have got to stop wars because we have developed instruments which have made war unprofitable.

Dr. WEINBERG. So unprofitable that everybody realizes it.

Senator TYDINGS. I am not interrupting you, Mr. Chairman?

The CHAIRMAN. Not at all.

Senator TYDINGS. How would you go about stopping war?

Dr. WEINBERG. I would—here, of course, I am simply stating an opinion.

Senator TYDINGS. That is all right. Nobody has the answer in his hip pocket. We merely want your view on it.

Dr. WEINBERG. Yes; there are two problems it seems to me. One is the immediate problem of what we can do now. We do not have too much time in which to decide.

Senator TYDINGS. Right.

Dr. WEINBERG. If things do not improve and if things do not improve in a hurry, we will have this atomic war before we can turn around.

First, we have the problem of temporizing to give ourselves time to get the people of the world educated to realizing the fact that war has really become obsolete.

Senator TYDINGS. How would you do that? How would you reach the millions of people that we want to reach? Do you suggest that we send around people who will make speeches—and will they be permitted to do that?

Dr. WEINBERG. I wish I knew how you would really do it.

Senator TYDINGS. It boils down to the fact that we have got to do it through the heads of the governments first?

Dr. WEINBERG. Exactly.

Senator TYDINGS. That is what you were trying to get at?

Dr. WEINBERG. Exactly.

Senator TYDINGS. And you hope that that education, that realization, will trickle down little by little and that you will secure the objective you have in mind?

Dr. WEINBERG. Exactly.

Senator TYDINGS. And unless you have that cooperation of the heads of the governments, to start with, it is going to be pretty hard to reach the masses?

Dr. WEINBERG. Exactly.

Senator TYDINGS. So, the first problem is for everybody to agree that there will be no more war talk; and then go to work to implementing that.

Now, how would you implement that?

Dr. WEINBERG. As I say, the problem has an immediate aspect—

Senator TYDINGS. But your ultimate objective is disarmament, is it not?

Dr. WEINBERG. Yes.

Senator TYDINGS. There is no use in saying, simply saying, that you are not going to war. It is no more use than saying that you are not going to go hunting and yet keep shotgun shells in your house, hang your shotgun over the door, and have your hunting coat hung up alongside your shotgun.

Dr. WEINBERG. I tend to agree with you. I tend to agree with you. It seems to me that the only immediate means of attacking the prob-

lem, as far as I, a layman in the matter, can see, is, for instance, to work through the UNO organization.

But I do not see that the UNO organization will be a permanent solution, because I have the vague impression that the gentlemen involved in that, at least some of them—

Senator TYDINGS. Let me interrupt you again, because I think that maybe I can short-circuit a little what you have in mind, if you have it in mind.

This agreement between the heads of the governments first, the problem of the UNO would be the immediate one, if they tackle it initially—you would have to get a treaty?

Dr. WEINBERG. I should think so.

Senator TYDINGS. In other words, if the heads of the governments made the treaty and called upon the UNO to implement the treaty, with such preliminary work that the governments themselves might do, you would have more progress than if you turned it into a situation where they would have to go through these things in their own ways. Do you agree?

Dr. WEINBERG. Yes.

Senator TYDINGS. What is our immediate problem then?

Dr. WEINBERG. I would say our immediate problem, to put it very specifically and bluntly, is that we get together with the various nations that are really involved in the matter—our Nation, England, Russia, probably France, probably China—

Senator TYDINGS. Some six or eight, let us say.

Dr. WEINBERG. Yes.

Senator TYDINGS. At least.

Dr. WEINBERG. Yes, at least.

Senator TYDINGS. And have them agree with us that, in order to avoid war, there should be mutual disarmament?

Dr. WEINBERG. And to make such agreements as regularly have been made for many, many years.

The point I would like to make and which I think everybody has to appreciate now, is that people will have to see that they really mean the statements and agreements that they will make.

Senator TYDINGS. And we will have to make sure that they mean what they say, in case they don't mean them.

Senator MILLIKIN. You mean, by attacking them if they did not mean them?

Dr. WEINBERG. That is a question which is somewhat difficult to answer.

Senator MILLIKIN. Cold logic reaches that conclusion?

Dr. WEINBERG. Not necessarily, for this reason. We hear people say that an atomic war will necessarily wipe everyone out. I would say that that statement is 95-percent accurate. There is a 5-percent probability that that statement is not completely accurate.

So, rather than fostering, rather than precipitating a war, before an overt act or something that approaches an overt act has been made by another nation, I would prevent rather than precipitate a war, rather than precipitate an armaments race, even if it were a nuclear armaments race. I would not wait for it.

Senator JOHNSON. May I get a repetition of that last statement? It is rather a startling statement. Say it again, please.

Dr. WEINBERG. Well, the question, as I understand it, resolves itself into: At what stage of the break-down in international relationships should we attack?

My feeling is that the American people historically would not like to interpret the stage which would justify attack to be an early stage but rather a late stage.

I would not like to see us go out and drop 100 atomic bombs, let us say—I don't know when but in the near future—just because we were thinking that such and such a country is at present clandestinely doing research on atomic bombs.

Senator MILLIKIN. Mr. Chairman, let us focus that a little more.

Let us suppose that we found out definitely that a country was clandestinely building and was about ready to have atomic bombs.

In cold logic—politically, I am asking a very abstract question—but in cold logic, would we be warranted in wiping that country right off?

Dr. WEINBERG. It is a question of what stage we would wipe it off.

Senator MILLIKIN. You would not wait until they attack us?

Dr. WEINBERG. Certainly not.

Senator MILLIKIN. So, you would be warranted, under those circumstances, in cold logic, of making the first attack?

Dr. WEINBERG. Probably; but I am certainly not here to judge at what stage.

Senator MILLIKIN. No; but we would, to put it simply, attack prior to them attacking. We would not wait until we were attacked, as we were in the Pacific.

Dr. WEINBERG. I should hope not.

Senator MILLIKIN. Now, basic to this disarmament which you and Senator Tydings have been discussing, would you say that there must first be a removal of the causes of war?

Dr. WEINBERG. Very certainly.

Senator MILLIKIN. Would you say that prior to the time that the causes of war had been removed, at least between the principal nations of the world, that we would be safe in destroying our stockpile and destroying our plants?

Dr. WEINBERG. It seems to me, at the present moment, that we are in an exceedingly safe position. We have the largest Navy, probably the strongest air force. We have the atomic bomb—but I don't think that we have the will to use the atomic bomb.

Senator MILLIKIN. I am not so sure that I disagree with you. I certainly would not want to affirm the proposition, at least in our present stage of affairs in the United States that we should coldly and ruthlessly make the first attack with an atomic bomb.

It might be that there would be an advantage, it might be the logical thing to do; but politically, I would not want to make the argument that we should do it at this time.

I come back to what I said before. If you are going to get rid of the atomic bomb, in our hands or in someone else's hands, don't you have to get rid of the causes of war? Is that not the base upon which you have to build?

Dr. WEINBERG. Exactly.

Senator MILLIKIN. In other words, get rid, by treaty, of the festering causes of war?

Dr. WEINBERG. Yes. As I say, either the bomb begins or ends the war.

Senator MILLIKIN. So, that is the state of the world today. If we have no hope, within 4 or 5 years of eliminating the causes of war, at least among the principal powers, then what should we do with reference to our atomic bombs?

Dr. WEINBERG. At this moment?

Senator MILLIKIN. At this moment and over the next 4 or 5 years.

Dr. WEINBERG. So far as I know, the other powers do not have the atomic bomb. So far as I know, there is no danger from attack by the other powers. So far as I know, in atomic bomb technology, we are far ahead of other nations. So far as I know, the number of atomic bombs which we can make, probably, will be greater—although I don't really know—than the other nations can make in the near future.

Therefore, it seems to me that we do not, in fact, reduce our military potential particularly, because our military potential includes not only the existence and the possession of the atomic bomb, but also the will to use it.

Senator MILLIKIN. But if you give it up, do you not lose your most powerful weapon?

Dr. WEINBERG. But the weapons we have at present are sufficiently powerful—that is what I want to say.

Senator MILLIKIN. Of course, what you mean is that you would like to secure your objective, using your present weapons.

However, why should we sacrifice a weapon which has all the power that the atomic bomb has, if we are contemplating that we might have to use it?

The CHAIRMAN. I would like to interrupt. Senator Millikin asked you about the elimination of the causes of war. Until they are eliminated, you would have to hold on to the stock pile of bombs that you have. If you do that, is it your thought that that stock pile would be one of the contributing causes or might be a contributing cause of bringing about a war?

Dr. WEINBERG. I think it is a cause in the same sense that any large-scale armaments are, because it creates suspicion, it creates fear, it creates distrust.

I do not see that we would lose, particularly, by giving up our stock pile at the present moment because, at the present moment, even without the atomic bomb, I do not think we would lose anything.

I think that is particularly true because we do not expect an attack—at least, I don't expect an attack and I certainly hope that this country is not going to war—at the present moment I do not see that we would particularly reduce our military position by giving up the atomic bomb.

Senator MILLIKIN. I will concede that. I assume that we do have a very large military superiority over any other nation, over maybe several nations, maybe over the rest of the world, in traditional, conventional weapons.

But I am asking you the naked question. If we anticipate the possibility of a war—and it is more than a possibility—I mean if a military man or a sane nation has reason to keep its powder dry, why should we surrender our best weapon?

Why should we sacrifice it if maybe we are going into another war? It would seem that it would be the more necessary to keep it, to use it instead of the traditional weapons of war, because with it you can accomplish the same objectives as you can with the conventional weapons of war and you can do it with a fraction of the men that would be required with the traditional means.

Let me go one step further. We have heard the reason advanced in justification for dropping the atomic bomb over Hiroshima and Nagasaki that it shortened the war.

If that reason is a good reason for applying the use of the bomb, why is it not a good reason to consider now?

Dr. WEINBERG. Might I answer your first question?

If by sacrificing these weapons we increase the probability of not having a war—and, by sacrificing these weapons I imply at the same time that there will be entered into an agreement whereby the other nations sacrifice their weapons—I would say, by all means sacrifice the weapons.

Senator MILLIKIN. All right; let us assume that we have sacrificed them. Let us assume that we have given up the atomic bomb, the stock pile, that we have destroyed the plants. Let us assume that we have assured ourselves that the other nations do not have bombs or plants.

Now, will that solve, will that remove the causes of war today?

Dr. WEINBERG. Obviously it will not. Obviously it will not.

Senator MILLIKIN. Well, then, you are right back to where you started. You can not make an assurance, you can not make an agreement—I am arguing now, I am not affirming, this does not indicate my view, I am just trying to draw out all the facts.

We will be where we were at the beginning of the war. There will be started the atomic race, and all the agreements, all the proclamations you have made, all the noble pieties that you utter will be futile.

Dr. WEINBERG. Could I reiterate once more the statement I have made?

The bombs at Hiroshima and Nagasaki have made the notion of war in modern civilization an obsolete one.

We have got to go on that basis.

Senator MILLIKIN. Mr. Chairman, I would like to suggest, when he says that the bomb has made war obsolete, that that was said after World War I.

I say that war is obsolete, theoretically. War should not be conducted under the causes of war, independent of the bomb.

I respectfully suggest that it does not resolve anything, it does not resolve a single cause for war.

What I am putting to you is, how far can we go along with our arrangements for disarmament before we remove the causes of war between the principal nations?

Dr. WEINBERG. We can go at it, it seems to me, by taking the question once more of whether or not the destruction of the bombs would help the situation.

I say that the destruction of the bombs would help the situation in the sense that it would tend to reduce one of the causes of war.

Now, what is the situation if we do not destroy the bombs?

Senator MILLIKEN. I think that is a fair question.

Dr. WEINBERG. Yes.

It seems to me that the natural course of events, unless, of course, we are going out and conquer the world today—which I, as an American, would not particularly like, although that conceivably is a course of events and that, of course, implies something very important—but unless we do not conquer the world today, we naturally would come to a situation in which everybody has atomic bombs. Then what do we do, sir?

Senator MILLIKEN. Well, then, we just multiply our attempts to try to find the solution.

Senator JOHNSON. You say the atomic bomb has made war obsolete. That is true and I agree with you.

However, just as soon as you don't have the atomic bomb, war comes back into style again, it is no longer obsolete. So long as you have the atomic bomb, then war is obsolete.

MacArthur said once that the cause of war was undefended wealth. I am not certain that he has not a strong point there.

If that is the case, we will always have to have armaments. I understood you to say a moment ago that there never would be another major war wherein atomic bombs would not be used and I thoroughly agree with that statement.

The CHAIRMAN. Doctor, we have got to move. I have got a couple of questions that I very much want to direct to you. I wish you would remain here, we will be back soon.

Senator TYDINGS. Mr. Chairman, I just want to interject to ask if there are any more witnesses today.

The CHAIRMAN. No. Off the record.

(Discussion off the record.)

The CHAIRMAN. We will be back as soon as we can.

(Whereupon, a recess was taken, after which the committee reconvened.)

The CHAIRMAN. We will come to order. Dr. Weinberg, will you come forward?

Senator JOHNSON. I think you had the last question.

Senator JOHNSON. Yes.

Our armaments for the postwar period are estimated to cost perhaps \$8,000,000,000 a year. That is for our Navy and Army and Marine Corps and all the rest of our armaments.

Now, this atomic bomb has been described by several witnesses as the cheapest and, I suppose, they mean the most effective weapon at a low cost, lower than any other kind of armament.

Why should we abandon the most effective weapon, as long as there are dangers of war, for obsolete and more expensive weapons?

It is pretty hard to put a matter such as this one on a dollar-and-cents basis and I do not want to do that; but efficiency is something more than a dollars-and-cents thing. When you get up into the expenditure of \$8,000,000,000 and you stop to figure how much \$8,000,000,000 will do to promote the happiness and comfort and everything else that all humanity needs in this world, it is not exactly a dollars-and-cents problem.

Why should we abandon this very efficient weapon and go back to other more expensive and less efficient weapons?

Dr. WEINBERG. Well, I think—I speak, of course, only as an individual, and let me reiterate that I am not an expert on these things, I am a physicist—

Senator JOHNSON. We enjoy your answers.

Dr. WEINBERG. Well, I am glad you enjoy them, sir, but there are at least 130,000,000 people in this country and I would say that perhaps half of them would be better qualified than I to answer these questions.

It seems to me that if, by abandoning this worst of all weapons—

Senator JOHNSON. Or the best of all, whichever way you look at it.

Dr. WEINBERG. Or the best of all weapons, depending on your point of view, you are really making a start, some progress, in eliminating one of the causes of war, if by that you are reducing the probability of another war, then I would say by all means do so.

One of the causes of war, I believe, although, again, I am not an expert, is armament, as well as a sentiment for war.

Now, let me explain when I say that we abandon the weapon, that I speak of what the situation will be when everyone has the weapon. When I say we should abandon the weapon, then that, of course, assumes that the others abandon it also.

Senator JOHNSON. But my trouble, the difficulty that I have in trying to analyze this very grave question is how to go about differentiating between weapons. How are you going to choose one weapon over another? How are you going to say that weapon A is all right but that weapon B is out?

Dr. WEINBERG. Well, we come back—I am sorry, but we always come back to the same point—that another war is essentially impossible, that, to my way of thinking, it seems to me that eventually we eliminate war and eliminate all weapons.

Unless we do, we have this situation. If we don't go into the next war with the atomic bomb, then the war will end with the atomic bomb; if we do not eliminate the atomic bomb, then the next war will start with the atomic bomb. I don't see any way of getting around that.

Senator JOHNSON. I follow you and I concur with you, except that I think that the atomic bomb is making war obsolete, making it impossible for any sane person anywhere on the globe to think of war.

Senator TYDINGS. Including Hitler?

Senator JOHNSON. Yes. Yes, including Hitler. I do not believe that Hitler, degenerate in his thinking as he was, would have dared to start a war if he knew that the United States had plenty of atomic bombs.

Now, I have got Hitler down in the lowest scale that it is possible to put any creature moving about in human form, but I think that even Hitler would have been afraid to start a war if he knew that somebody else had the atomic bomb ready to drop on Berlin.

Dr. WEINBERG. Does that not, sir, come back to the point, on which I really am not particularly qualified to speak and on which I don't think even the atomic bomb experts are fully qualified either, we can only give out opinions—isn't it then a matter of whether or not there is an extremely great advantage to the aggressor in an atomic war?

Senator JOHNSON. Oh, yes.

Dr. WEINBERG. If Hitler had—I agree 100 percent with you that if Hitler knew, say, that the French had an atomic bomb and he did

not have an atomic bomb, obviously it seems to me that he would not have attacked them.

But if Hitler had atomic bombs sufficient to wipe out 20,000,000 Frenchmen, half the French population, then I am not so sure.

It is a very great question, of how much of an advantage accrues to the aggressor.

My feeling is that the advantage which accrues to the aggressor is overwhelming—but, of course, I am not an expert.

Senator JOHNSON. I think it is obvious that the advantage is to the aggressor.

Going back to Hitler—and, of course, this is idle, except that we have to picture, we have to figure that the next war may be in the hands of outlaws, and that is why Hitler is important here. If Hitler was the last international outlaw that the world is ever going to see, then we can just forget about Hitler. But, perhaps, he will not be the last international outlaw and so we have to consider him as exhibit A in this picture.

Do you think that Hitler would have started out on a war if he knew that France and Britain and Russia and America all had atomic bombs?

Dr. WEINBERG. Well, you predicate, do you not, the assumption that he also had atomic bombs?

Senator JOHNSON. Yes; everybody—Germany, France, Britain, everybody.

Dr. WEINBERG. You predicate that everyone had atomic bombs?

Senator JOHNSON. Yes; that all of them had atomic bombs.

Dr. WEINBERG. Well, if Hitler had enough atomic bombs, if he thought that he had enough, I think he might.

Senator JOHNSON. You are saying that if he had more atomic bombs than all the rest of them put together and had the means of transporting the atomic bombs over the other nations—of course, I will not argue that with you because in that case he would have started an atomic war.

I am not picturing that much of an advantage to Hitler. I am picturing this, I am trying to think of it this way:

Hitler is going to start a war. He knows that he can destroy certain numbers of cities but he knows that also German cities will be destroyed, that all the cities will be destroyed in Germany and all the cities, perhaps, in France, England, and Russia, that all cities will be destroyed.

I just don't believe that even Hitler would start a war on that sort of a premise.

That is why I am trying to think that the atomic bomb is the agent of peace, because it is such a frightful weapon that no one, other than a crank, a fanatic—Hitler was a fanatic, would think of starting a war. However, Hitler had the proper backing in Germany. He was a fanatic, no question about that. But he had to have the backing of a lot of people, sensible people, before he could engage in a war. All the Nazis were not fanatics; some of them were pretty long-headed men, although they were bad, as bad as men can get in their conspiracy—but, at the same time, they were not fanatics.

Dr. WEINBERG. My feeling on that matter, and on that particular matter I have thought a little bit, is the following:

It seems that atomic weapons differ from all other weapons, in the sense that atomic weapons show what I call the phenomenon of saturation.

This point has been brought up many times that it does not make much difference whether Hitler, if it were a matter of Hitler saying there would be a war, had five atomic bombs with the rest of the world having 100 or 200 atomic bombs. If that were the case, Hitler would not start a war; I am inclined to agree with you completely.

But if it is a matter of Hitler having 3,000 or 5,000 as against the rest of the world having 100,000 atomic bombs, then it would seem to me that Hitler would be fairly certain that the advantage would still accrue to the aggressor because there would be no particular advantage in having 100,000 atomic bombs, having 95,000 atomic bombs more than Hitler if Hitler had 5,000 atomic bombs, because with that he can completely wipe out the rest of the globe.

Senator JOHNSON. But he won't be able to do that if they are properly distributed and if the nations used good judgment in the location of the atomic bombs. You cannot picture the thing as a case where everybody is going to be dead. You cannot picture it as a situation where everybody is going to wait for Hitler to come along, wait for Hitler to drop an atomic bomb on them.

The aggressor does have a tremendous advantage. There is no question about that. But he does not have an absolutely overwhelming advantage, even in atomic war.

Dr. WEINBERG. Well, I say that it seems to me very difficult to assess exactly what is the advantage that accrues to an aggressor. I think there is the point there that the atomic weapon does show the phenomenon of saturation. I think there can be no doubt about it.

Where that saturation point is, whether it is 50,000 bombs or 5,000 or 100,000 bombs, I do not know. My guess is—well, I don't know. It depends on so many other things and on what the bomb of the future will be.

Senator JOHNSON. I have just one more question. We will take the other end of this dilemma, where no one has any bombs and where we are going to outlaw and where we are going to prohibit the use of atomic energy.

I want to ask you a question that Senator Connally asked Dr. Langmuir, who was a witness before this committee: "According to your view, the industrial use of atomic energy according to the dangers you point out is a secondary matter, isn't it?"

And Dr. Langmuir replied: "It is almost trivial."

Now, is that your conception, too?

Dr. WEINBERG. I would say it is not my conception for a variety of reasons. For one thing, let me go back to a point which I raised in this memorandum which I read to you.

As far as I know, there is no individual in this country who has complete access to the latest data on the uranium deposits in the United States and the world, and who also has complete access to the data of what can be done with uranium and plutonium by way of power plants.

So, in making an economic comparison between uranium power and coal power, we are, immediately, at a very distinct disadvantage.

In the very short run, I think it is perfectly true that we can get along—well, we have got along very well without the uranium power plants.

In the very long run, we may very possibly be forced to a uranium economy, as opposed to a coal economy, simply because the coal may run out.

I do not think that one can say that the potentialities from the industrial point of view are trivial. They certainly are not.

Senator JOHNSON. Well, he said comparatively, relatively trivial, of course. He said that the dangers of war and the negative side of it, the war side of it, was so much greater than the positive, the constructive use, that it was trivial.

Dr. WEINBERG. Well, it seems to me—

Senator JOHNSON. That position was concurred in by Doctor—what is that name?

The CHAIRMAN. Dr. Szilard.

Senator TYDINGS. And also by Dr. Urey.

Senator JOHNSON. Yes; they concurred in that.

Senator TYDINGS. In other words, that we should remove the threat, that all these other things are incidental.

Dr. WEINBERG. Well, with such a distinguished array of scientists against me, I am afraid I should better pull in my horns.

Senator JOHNSON. No; that is why we like you as a witness, because you are not pulling in your horns, you are coming out into the open.

Dr. WEINBERG. In that case, I am afraid I am getting out on a limb.

It seems to me that one can get along with uranium power. On the other hand, as I have pointed out here, there seems to be a large number of interesting and useful and desirable things that can eventually be done with uranium power, and some in the very near future.

The point I would like to emphasize is whether or not you eliminate the uranium power plants does not determine whether or not the atomic bomb will be used in the next war.

If you have the plants and you make the bombs, the war starts with the atomic bomb.

If you do not have the plants, then the war is finished by the atomic bomb.

It seems to me that the question whether or not you have the plants is not really and completely a relevant question.

Senator JOHNSON. Well, I thoroughly agree with your conclusion. I am glad to find someone that I can agree with on that point.

That is all, Mr. Chairman.

The CHAIRMAN. Doctor, can you picture the state of mind of the peoples of the world if everybody was armed to the teeth with atomic bombs?

Dr. WEINBERG. Well, I can picture my own state of mind. Several of us on the project have felt particularly badly about the development.

One of the theoretical physicists with whom I have talked and with whom I have worked has said to me that the one thing that he considered the most difficult decision for him to make in connection with the development of the bomb was the fact that he had a young son.

Now, probably to many of us in this room the question of the atomic bomb will remain an academic question. I hope so. For the children

of the people in this room, I am not so sure that it will be an academic question.

The CHAIRMAN. Do you have any feeling that all creative work, all real productivity might cease on the face of the earth if the minds of the millions and millions of people in the world were filled with the overwhelming fear that they might be blown up to kingdom come before morning?

Dr. WEINBERG. I don't see how they will be able to do anything but be awfully scared.

Senator TYDINGS. Would it not tempt them to strike first so that the other fellow would not?

Dr. WEINBERG. I guess they would, in fact, be tempted strongly to strike first.

The CHAIRMAN. That would be an intolerable state of mind for the men, women, and children of the world, would it not?

Dr. WEINBERG. Speaking for myself, I would find it intolerable.

The CHAIRMAN. I would find it intolerable if, sitting on the floor of the Senate, I had to remember that there was a machine gun pointing at me and I did not know when it was going to go off.

Dr. WEINBERG. Yes. As you brought out when you made the analogy about the world being armed to the teeth with atomic bombs, I think we would find it intolerable.

As I say, if you have loaded machine guns in a locked room, we will have a situation where we would not trust each other. It would make no difference whether one man had a machine gun with 1,000 cartridges and another man had a gun with 100 cartridges.

Senator TYDINGS. Doctor, we are exploring a great many of the world's problems in these hearings and we have covered a good many of them this afternoon.

I take it that you say that, to remove the causes of war, you will have to put things in the minds first of people.

Some of those things that may be causes of war cannot be removed. For example, you can not have everybody agree in the matter of religion. There is nothing you can do about that.

I doubt if you could throw the United States open to all unlimited immigration, because so many people would come that then we would have a problem that would be a tremendous one.

We have got the clash of nationalism, races, divisions between creeds, economic and military arrayments, money and many other factors that we can not remove.

I take it that what you mean when you say that we must remove the causes of war is that wherever you have a glaring case that is susceptible to evolution, that the nations must try to find ways and means to alleviate the injustices that exist in that particular case.

For example, it would be pretty hard to tell the Dutch that they should get out of Java. It would be pretty hard to tell the British to get out of Indian Burma. It would be pretty hard to tell the French to get out of French Indo China.

Furthermore, in line with all the other imponderables, there are a multitude of things that will have to be rectified as much as it would be humanly possible to do it.

So, I am assuming when you say that the causes of war are to be eliminated, that you are taking the most conservative view of the

numerous causes of war, that you are thinking about the aggravations to justice rather than all the causes that enter into the picture.

Dr. WEINBERG. Well, I agree. On the other hand, it seems to me, to take—

Senator TYDINGS. That would be a worse problem, not to interrupt, once you accept it, than settling the atomic bomb itself, don't you think?

Dr. WEINBERG. I think so.

Senator TYDINGS. Then, just what do you mean when you say that we should try to eliminate the causes of war?

Dr. WEINBERG. Let me preface the following remarks again with the statement that I am not an expert. The person that should be talking about these things, I am afraid, should be a professor of international law. I am simply a citizen who is interested in these matters.

It seems to me that there are many situations in the world today in which there exist factors and forces which at one time were considered to be equivalent to war but which at present are not equivalent to war.

To give you an example, various religions—and you have mentioned religions—get along peacefully, whereas the same religions used to be continually fighting.

Now, I personally am inclined to believe that perhaps the most important reason for the elimination of the causes of war, in spite of the fact that the causes are still there, is the fact that there is a higher sovereignty which prevents both religions who used to go to war over religion which the individuals in those various religions adhere to and recognize.

So, it seems to me that when all is said and done, what we are saying when we say that we must eliminate war is that the only system which in the past has ever, in any sense, reduced the number of wars has been a system in which the sovereignty has been extended.

Senator TYDINGS. Well, to put my question rather bluntly, the elimination of the causes of war really means the elimination of the causes of war between the countries that are strong enough to make it. Is that right?

Dr. WEINBERG. Yes, sir.

Senator TYDINGS. I mean what goes on between a great and strong nation and some little nation is something that it is very difficult to get excited about, to raise a war about, even though there might be a great injustice being done there.

Eliminating the causes of war really refers to our getting along with the French, the British, the Russians, and those powers getting along with us.

You find then that the causes of war are limited to 5, 6, or 8 nations, in the final analysis. Is that correct?

Dr. WEINBERG. I think it is, sir.

Senator TYDINGS. And the great masses of the people of the world, who may have to live under the greatest injustices, they really may have nothing to say about it?

Dr. WEINBERG. Unfortunately that is true.

Senator TYDINGS. So, don't you just get this, that you have only to get the agreement between the strong people? Won't that determine what will be done and what won't be done?

Senator MILLIKIN. Would you say, Doctor, that as long as the causes of war do exist that, regardless of our weapons, there will be wars and that since we know of this powerful weapon for waging war, that someone else will start duplicating it, they will take the steps that we ourselves have taken, to provide themselves with the weapons?

Dr. WEINBERG. They will provide themselves with the weapons before or after war has started.

Senator MILLIKIN. Of course, a brutal nation would start as soon as the thought crossed the mind of those that directed that nation. Certainly other nations will come to it, they will start after the war has commenced. Isn't that correct?

Dr. WEINBERG. I am afraid that is correct. If we do not succeed in eliminating war, then evidently war will be atomic war. We always come back to that.

Senator MILLIKIN. Supplementary to what Senator Johnson was saying, I saw a very alarming thing in the New York Times today. There was a story of the showing to these fellows who are being tried at Nuremberg of moving pictures of the days of their glory.

Of course, it was one of the thoughts of showing that picture that they would contrast their present humble position with the position they were occupying in the days when they had their mass flags and banked bands and great crowds and all that.

The picture had just the contrary effect. They had a great time restraining themselves from getting up and applauding.

In other words, they had not learned a thing. They had not learned yet that they had been defeated.

Now, when you have that sort of an upside-down philosophy on life, so long as that is any place in the world, how can you rest assured of peace, no matter what idealistic plans you may have?

Dr. WEINBERG. Let me simply come back to the remark which I made to Senator Tydings.

In the Middle Ages there certainly were people who were outlaws and who made a living by war. There were various other groups which had, they thought, to go to war with each other over problems which they thought simply could not be resolved.

Yet, when the higher authority was established over them, a higher authority with force, then, these unresolvable difficulties which ordinarily led to war still remained unresolvable, it is true, but they did not lead to war any longer.

Senator MILLIKIN. Of course, the Middle Ages were full of minor wars. There is hardly a period in world history when we haven't had wars in some degree.

The Roman Empire kept the world in its longest period of peace through force, the overwhelming force of arms.

The British Navy kept the world at peace in modern times for the longest period of time through overwhelming force, the force of the British Navy.

That has a direct significance to what we are talking about today.

In other words, if you are feeling belligerent, Doctor, I don't believe that you would go out and slap Joe Louis in the face. I think you would rather be looking for a midget for a punching bag.

I merely am bringing that up because we have the overwhelming force at the moment.

Will that keep the world at peace or will it invite an armament race?

Dr. WEINBERG. I think I agree completely with you, that a sovereignty which has force, a greater force than any other states under the sovereignty have—I agree that, historically, that is the only possible way to keep peace, it is the only way peace has been kept in the world.

I do not think I agree that that implies that the United States, say, should go out and be that authority.

Senator MILLIKIN. I am not drawing that conclusion. It is something to think about in this problem.

We have either got to keep that overwhelming force or we have got to work out a transference which will be equally satisfactory. Is that correct?

Dr. WEINBERG. I don't think that we can keep that overwhelming force, sir, for the reason that the other nations will have that force in a very short time.

Senator MILLIKIN. That is true, relatively. That has been true, relatively, through all history.

It may not follow. When Spain tried to get the sea power away from Great Britain, they did not get the sea power from Great Britain. When the Dutch tried to take away the sea power of Great Britain, they did not do it. Many nations have tried to take on the same armament that gave Great Britain her superiority but it did not work.

Let me make this suggestion. I believe that if a man wanted to make a cold-blooded argument—and I am not making it; I am merely tossing it in for consideration—I think it can be demonstrated that the possession by one nation of overwhelming force, in the light of history, is a greater conducive to peace than any other arrangement.

Dr. WEINBERG. Either one nation or, if you like, a super-nation.

Senator MILLIKIN. That brings us to some harsh realities.

I am afraid that we would not start—it has been suggested here many times that we probably would never be an aggressor in that kind of a situation.

But suppose it was determined today, as our national policy, that we were going to keep an overwhelming amount of atomic energy at our disposal for war-making purposes.

We would either have to keep that superiority or it would fizzle out on us.

If we adhered steadily to that intent, then we would have to come to the cold-blooded decision of annihilating anybody that challenged our overwhelming force. Is that correct? And, in this kind of a country, do you not think it would be exceedingly doubtful that we would make that decision?

Dr. WEINBERG. I do not think that we could maintain overwhelming superiority in atomic forces. I say that for the reason that, to my way of thinking, atomic weapons follow the phenomenon of saturation.

If we had, say, 10,000 or 50,000 or 100,000 bombs, that does not mean that we have, say, five times or more force than a nation which has, perhaps, only 1,000 bombs.

Senator MILLIKIN. I think we can use that as an example. That might be true; but if they had 100, then the whole preponderance of weight would be with us?

Dr. WEINBERG. One hundred? I agree; but there is a point at which the thing saturates.

Senator MILLIKIN. I agree. That brings me to the suggestion I made awhile ago, that if we were going to be brutally realistic about this thing, the moment our superiority was challenged, we would have to move, or there would be no point in going on.

Dr. WEINBERG. If we thought that that was a feasible method of procedure, I agree.

Senator MILLIKIN. If we said that we were going to keep the world at peace by preserving sheer overwhelming force in atomic energy, we would then have to reach the conclusion that if anybody threatens to become an atomic power, we would have to annihilate him?

Dr. WEINBERG. That is essentially equivalent to conquering the whole world.

Senator MILLIKIN. Yes, in the sense that Great Britain conquer the world by obtaining naval superiority in the day when naval superiority had the greatest effect.

Dr. WEINBERG. Except that this time I am afraid—I am afraid that we would actually have to go out and kill those people. I, as an American, do not like that.

Senator TYDINGS. We have the atomic bomb. Is it not true that we retain the largest navy, the largest and I hope the most efficient air force? Is it not true that we retain those weapons simply because we want to be strong in anything for any conceivable emergency, that we want to be ready to knock the aggressor?

Dr. WEINBERG. That is true, but—

Senator TYDINGS. Well, then, if that is so, all we have done if we eliminated the atomic bomb is to get down from 212°, which is the boiling point, to about 160° or 150°, which is still pretty warm.

Dr. WEINBERG. It would perhaps lower the lower temperature to 20° or 30°, because it seems to me that with ordinary weapons—well, if we have a navy, say, four times as large as everybody else, if we have an air force four times as large as anybody else, maybe we still would not have really overwhelming superiority.

Senator TYDINGS. Let me see if I have summed up your view. You said that if we had another war it would either start or finish with atomic bombs. You say that will be so whether you outlaw or do not outlaw the atomic bomb. Am I right on that?

Dr. WEINBERG. Yes.

Senator TYDINGS. You likewise feel that this problem is incidental, considering the atomic bombs, to the proposition of eliminating war, that that is the major, No. 1 problem.

Now, what reason, except in degree, assuming that my summations of your thought are correct, what reason is there, except in degree, according to the thought that you are voicing here, of eliminating the atomic bomb, unless you go along and eliminate the next most potent weapon, unless you eliminate them all?

Dr. WEINBERG. I agree. It would be a matter of degree, but it would be a very large degree.

Senator TYDINGS. Yes, this is the greatest danger to tackle first.

Dr. WEINBERG. By far the largest.

Senator TYDINGS. But your logic tells you that you cannot stop with the atomic bomb.

Dr. WEINBERG. We cannot.

Senator TYDINGS. We cannot stop with the atomic bomb, because the other weapons, the buzz-bombs and the incendiary bombs which have ruined so many cities in the world were simply doing what one atomic bomb would do with less effort?

Dr. WEINBERG. Exactly. They are both doing the same thing.

Senator TYDINGS. So, therefore, in your plea today—I do not mean the whole plea but the basis, the core of your plea—is—and I am willing to help as much as anybody—your plea is to outlaw war because the prospects of the consequences of the next war are too horrible to contemplate.

As a precedent to that plea, I believe that your thought is that world disarmament is what must be done. Am I wrong?

Dr. WEINBERG. No; I agree.

The CHAIRMAN. Doctor, I do not want to keep you any longer, but there is one important sentence in your statement which I would like to explore very briefly.

You say:

The second problem is more serious. The previous speakers, the whole previous testimony, has dealt with the profound international implications of atomic energy. On the other hand, the international aspects will determine our domestic atomic energy development.

Now, one of the purposes of the setting up of this committee, as I understand it, is to explore the domestic as well as the international aspects of this question.

The effort was made by the War Department to enact legislation on this subject of domestic consumption, as it were; that is, to take care of our domestic problems.

Now, what has been bothering me the last week or so is how you can set up any program for domestic atomic energy development until you know what the international situation is going to be.

Dr. WEINBERG. I do not think one can. I think the two are so closely interrelated that a domestic solution without an international solution is impossible and an international solution without a domestic solution is impossible.

The CHAIRMAN. Well, now, suppose we enacted a bill today over in the Senate to set up a commission to handle what might be called the domestic phases of the matter.

This commission, if I understand you correctly, would not be able to determine a policy of continuing to operate these plants, continuing to make finished materials, in the absence of some international clarification of the subject?

Dr. WEINBERG. Yes, sir.

The CHAIRMAN. Do you agree with that?

Dr. WEINBERG. Yes, sir.

Senator TYDINGS. Doctor, there is one more thing. We are all thinking out loud. I would like to have you assume, as I know you would want me to assume, that everything that you are saying in response to these questions, in 24 hours, after deliberation, you might want to

modify what you are saying now—we are merely speaking in an exploratory vein.

Let us suppose that we accomplish this world situation you are advocating. Let us suppose, then, that the Indians in India want independence. Without any armaments existing in the world, suppose they start a march, 50,000 or 100,000 of them. We would have perhaps another affair such as they had 75 or 100 years ago, where an attempt was made to assassinate all British.

Now, let us suppose that takes place not only there. The movement catches fire and it takes hold of the masses in many other of the similarly situated countries.

In that case, would the international police force intervene to put down the rioting and keep the status quo, or would you attempt to find—well, what would you do?

Dr. WEINBERG. If the international sovereignty is a real sovereignty, then I would hope, although, of course, we do have civil wars—I would hope that long before they had started to march, that they would have gone through the international channels, the judiciary bodies, and so on, that would then exist, so that their particular problems could be settled peacefully.

Senator TYDINGS. But the point I make is that they are not settled peacefully. Would there not be a civil war?

They would not need weapons. I mean there would be no armaments, they would not need weapons, they would only need their hands.

What it would amount to, maybe, if we had disarmament, if it took place, would be that immediately these nations would be turned loose.

Now, suppose that if they were turned loose, that there was a fight for power in those nations which does become civil war. What side would the United Nations Organization take? Which one of the two factions would they attempt to stamp out if they begin to fight and they use and improve the available weapons and if the thing spreads around the globe?

Dr. WEINBERG. I am afraid I cannot answer that.

Senator TYDINGS. That is a perfectly logical consequence, in my opinion, if you disarm the world. You will find that the tenants will take over the house, they will occupy the house and tell the landlord that he cannot come back any more. What will you do when the tenants begin to fight over who is to have the house? What are you going to do when there is a good, big row going on and it spreads to other places similarly circumstanced? I wonder what the United Nations Organization will do. I imagine that maybe they will just let the riot subside unless it overlaps into some other country.

Dr. WEINBERG. I am afraid that I really do not advocate complete anarchy in the sense that there will be no force at all.

Senator TYDINGS. No, there will always be the international force, I understand. When the other nations are disarmed, there would always be the Security Council with 200,000 or 300,000 men, or 600,000, whatever is necessary, with airplanes or whatever is necessary. It may be atomic bombs, even.

Now, if you start wiping out all the injustices in the world that you and I might agree should be wiped out, there would be not only India and Java, the Dutch East Indies, the American mandated islands and

border troubles and Lithuania and Estonia and Latvia, and all of those places. Possibly even Palestine might come in there.

When you have got all those things breaking loose, and if there is no armament, no restraint, nothing, no police force, except a man with a big hickory stick and a helmet and nothing more, probably not even a revolver, what happens to the United Nations Organization? I mean, when we achieve our dream, where are we?

Dr. WEINBERG. Would we be any worse off than, say, the 48 States are at present, with a supreme authority which essentially has the final police power?

Senator TYDINGS. Well, do you think that the 48 States are comparable to the countries which I, without intending any criticism of the existing situation, have designated?

Dr. WEINBERG. I am not an expert on American history, but if I remember correctly, Vermont and New York were almost at war several times before the Thirteen Colonies got together.

Senator TYDINGS. It is purely in the field of theory, but sometimes it is well to know where you are going to arrive when you start to go some place.

Dr. WEINBERG. Well, to that I must again say that I must answer in general terms. I want to say that it would be rather presumptuous of me, who, as I say, a physicist, to try to answer those questions.

Senator TYDINGS. Well, we are all just as green as you are, Doctor, in this field of world peace. There is no man, no one man, who knows the answer, and it is only by common counsel that we can learn.

There are so many injustices that I might think should be corrected in the world. You, on the other hand, might not agree with me on many of them. There would be cases where you would say that the injustices were terrible and I would not agree with you.

Now, if we disarm completely, that situation will encompass nations. I have no doubt, if you eliminated the force of Great Britain that civil war would break out in India, maybe not immediately, but it would break out; and it would be the same in some other countries.

You would find that there would usually be three men who wanted to be boss and the situation would only permit of one man being boss, who will hold that job.

Senator MILLIKIN. Senator Tydings, I would like to suggest that if the international force disintegrated, pretty soon we would have complete world chaos.

Senator JOHNSON. Doctor, I have just one little question. I don't think it will take you very long to reply to it. I note that you say in your statement that the atomic era began December 2, 1942, when the first nuclear chain reaction was established in Chicago.

Do you anticipate that that statement will ever be challenged as a historical fact? Do you think it is going to stand up?

Dr. WEINBERG. It will be challenged as a historical fact if we have another, atomic, war. In that case the atomic era will be supposed to have started July 16, when the first atomic bomb blew up.

It will not be challenged if we do not have an atomic war. We will have other atomic power developments, naturally, and in that case

December 2, will be the date when the first peacetime atomic chain reaction was established.

The CHAIRMAN. Well, Doctor, you have had quite a workout.

Dr. WEINBERG. I have had, sir.

The CHAIRMAN. We thank you very much.

Senator TYDINGS. I wish we could all go home with this question solved so that we could get a night's rest in comfort, for one night at least.

The CHAIRMAN. Thank you very much, Doctor.

We will meet again at 10 o'clock tomorrow morning in this room.

The committee is adjourned.

(Whereupon, at 5 p. m., an adjournment was taken until 10 a. m., Thursday, December 13, 1945.)

ATOMIC ENERGY

THURSDAY, DECEMBER 13, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Johnson, Millikin, Hick-enlooper, and Hart.

Also present: Vice Adm. W. H. P. Blandy, Deputy Chief, Naval Operations for Special Weapons; Rear Adm. William R. Purnell, Assistant Chief of Naval Operations for Matériel; and Rear Adm. Lewis L. Strauss, special assistant to the Secretary of the Navy; Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The committee will be in order.

Gentlemen, we will let you handle your presentation in your own way.

Admiral STRAUSS. Mr. Chairman, we have two introductory paragraphs, with your permission.

The invitation to the Navy to appear before your committee this morning has not afforded sufficient time for the preparation of a formal statement, but in the light of the fact that the Navy does not appear before your committee to urge any special position, advocate any particular point of view, nor sponsor any pending legislation, there would not appear to be any purpose in a statement beyond such as may be elicited in the course of response to your questions.

The Navy is represented here today by Vice Adm. W. H. P. Blandy, Rear Adm. William R. Purnell, Commodore W. S. Parsons, Dr. Ross Gunn, and myself.

Admiral Blandy, formerly Chief of the Bureau of Ordnance, until very recently in command of amphibious groups in the Pacific, is now Deputy Chief of Naval Operations, his special duties being in charge of all interests in the Navy in atomic energy, guided missiles, and related matters.

Admiral Purnell is Assistant Chief of Naval Operations. From the outset of the Manhattan project, he has been the principal Navy representative on the Military Policy Committee for the atomic projects.

Commodore Parsons is Admiral Blandy's principal assistant. He combines the background of the Regular officer with that of the physicist. He has been associated with the development of the Man-

363

hattan enterprise since May 1943. He took the first atomic bomb to the Pacific and supervised its delivery all the way to the target.

Dr. Gunn is attached to the Naval Research Laboratory, where, at his suggestion and under his direction, the separation of the uranium isotope, or more properly the enrichment of uranium, was first successfully performed on any appreciable scale and many months before any other project had been inaugurated.

As for myself, I am special assistant to the Secretary of the Navy and have been serving as the Navy member of the Interim Advisory Committee on Atomic Energy.

We had expected, if you had no specific plan as to how you wished us to present the Navy aspect of this, to open with Dr. Gunn, to follow him with Commodore Parsons, Admiral Purnell, and Admiral Blandy summing up.

The CHAIRMAN. Admiral, that will be quite satisfactory, I am sure.

I presume that the Navy is conducting rather intensive research and study into the integration of this weapon into future naval operations. I understand, of course, we could hardly expect any testimony on that score today, although I do not want to restrict any testimony that you might need along that line. We would be glad to have it.

I was of the opinion that perhaps that work might be proceeding rather expeditiously and that after we return from the Christmas holiday we would hear the Navy again, either in open or executive session, as you gentlemen would determine, on your thoughts on the integration of this matter into the Navy's program for the national defense.

I wish you would proceed along those lines, if you would.

Admiral STRAUSS. We certainly will welcome the opportunity to appear again, Senator, whenever it is the pleasure of the committee, and I think with respect to those specific points you mentioned, if they should come up today, that Admiral Blandy and Admiral Purnell will be those witnesses who would be qualified to discuss them.

The CHAIRMAN. I might say further to you gentlemen that we have been leaving with the witnesses, of necessity, the election, if they are asked some question they feel should be answered in executive session, to just say so, and we will afford that opportunity. No offense will be taken if you say just that.

All right, Admiral.

Admiral STRAUSS. Dr. Gunn.

STATEMENT OF DR. ROSS GUNN, TECHNICAL ADVISER TO THE NAVAL ADMINISTRATION OF THE NAVAL RESEARCH LABORATORY

Dr. GUNN. Mr. Chairman, I think I would like to open my remarks by explaining to the committee the reasons lying behind the Navy's interest in this problem, in relation particularly to the work of the Naval Research Laboratory.

Admiral Blandy and Commodore Parsons will be more interested in the bomb, but our original approach was in a little different direction, which we knew had a direct bearing on the bomb problem.

I think a good many of us have been considerably alarmed in the last few years at the rate at which our coal and oil reserves were disappearing. We emerged from the war, and even though the Navy

had oil reserves of various kinds we have cut into those reserves in a very deplorable manner.

I think that future generations will probably have something to say about our waste of the tremendous hydrocarbon reserves, oil and coal. The utility and usefulness of coal and oil under present-day developments in organic chemistry cannot be measured in terms of what they will do to run furnaces, boilers, and engines. The amount of oil and coal available is distinctly a fixed quantity. We are not getting any more. It takes millions of years to make it, and when it is gone, it is gone.

A good organic chemistry industry can make medicines, oils, lubricants, plastics—thousands of things that modern man and civilization requires and must have.

Many of us have worried about that, as I said, and within the last 15 or 20 years we have realized that there were other sources that might be tapped. Some of us were not at all surprised when, early in 1939, the conversion of the uranium nucleus was observed and energy from that transformation was made available.

As I see it, the main function of nuclear transformations is to take on the job of turning the world's wheels and driving its ships. In spite of the awful manner in which it has been presented to the world, I, for one, welcome it as giving a promise of a longer civilization than we would have ordinarily looked forward to; because at the rate we were going we certainly wouldn't have fuel to turn the wheels of industry in another 500 years.

One of the jobs of my Mechanics and Electricity Division at the Naval Research Laboratory is to explore the fundamental aspects of power production, utilization, storage, and conversion. We have spent years studying special methods of power production and conversion that were suitable for special naval applications. We have explored the use of special fuels, new methods of power storage, new types of engines that will achieve a particular objective; for example, the range and speed of a military ship is of the utmost military importance, and many an engagement at sea has been broken off under otherwise very favorable circumstances because the fuel supply was getting low and the ship didn't have enough fuel. Many a man has lost his life and ships have been lost while refueling at sea under adverse weather conditions or in the presence of an enemy submarine.

Obviously, if a fuel were available that was powerful enough to provide power for a capital ship, for example, for a year or more, such a fuel is obviously invaluable to the military services and will increase the military usefulness of that ship to a major degree.

We need more power; we need more speed. Our present capacity to carry energy, if you please, is limited by the bunker size and what fraction of the ship's displacement we can assign to fuel. The Navy's installed horsepower of large units that are constantly in operation is measured in tens of millions. It is the largest single user of such power in the world, and for this reason the Navy has a profound interest in all aspects of power conversion.

We had been alert to the implications of nuclear power even before the announcement of the uranium fission, and we actually had under way in March 1939 work at the Naval Research Laboratory looking toward the utilization of nuclear power in ship propulsion.

I would emphasize again that the interest of the Naval Research Laboratory, which I particularly represent, has been in the practical utilization of nuclear power rather than the bomb aspects.

Admiral Strauss thinks that it might be worth while for me to review what we have done at the Naval Research Laboratory on this program, and I think I can summarize it very quickly and tell you why we want to use it.

Of course, the announcement that triggered off this recent change in our thinking was the announcement by two Germans of the fission of uranium and the further suggestion that this fission could be promoted by the fission of another particle, which had happened a short time before. In other words, we promote what we call a chain reaction. In January 1939 that announcement was made, but we were uncertain as to what part of the uranium material was important. There are two kinds of uranium in ordinary uranium, 235 and 238.

Senator HART. Was that January 1939?

Dr. GUNN. That was January 1939 when it was announced in this country. Many of us had been on the alert for this; and I must say that you should recognize that the scientist, since he has accepted the so-called Rutherford atom, has known that energy of this order of magnitude was going to be available sometime if we just knew how to unlock it. The energy was there, but we didn't know how to make it available.

On March 17, 1939, there was a discussion at the Navy Department, with both Navy and Army officers present, and scientists of the Naval Research Laboratory, of which I was one. A meeting was held, at which Professor Fermi and Professor Pegram, of Columbia University, were present. Fermi was known to me as a highly competent physicist, unexcitable, conservative, and while he did not definitely state that uranium chain reaction would take place—and this is a critical matter—he was fairly sure it would from all the data he had.

A few days afterward, in company with our Director, Hollis M. Cooley, a captain in the Navy at that time and, incidentally, son of Dean Cooley at Michigan, I went to Admiral Bowen, who was Chief of Engineering at the time, and asked for a minimum amount of \$2,000 to get the work going on this project.

Our analysis showed, and it has been borne out completely, that there were three or four main problems to solve, one of which was the determination of which part of the uranium was the effective one. We now know what that is.

The next problem was to separate out the effective components, the so-called isotope separation problem; and the other one was to produce suitable chemicals that would permit this separation. One just cannot throw uranium into a hopper and separate it out. It is a big technical problem to do it actually.

We realized that if we could get enough of the active material together we could, if the theoretical people were right, take thermal energy from the so-called pile and convert it through the use of an engine into a propulsion system. We realized that if we could get very pure material it probably had application to a bomb, but that was not the laboratory's specific interest.

I have cited one case in which we are interested in nuclear power; namely, the case in which we would like to increase the range and speed of our surface ships. There is another possibility which appeal-

ed to us even at that time, and that is in a submarine. The great limitation in a submarine, as we have determined as a result of our experiments at the laboratory, is the fact that one must take down in a submarine not only the fuel but also one must take down the oxygen. That is true even in a battery, for in a battery operation you take down essentially oxygen in one plate and metallic lead in the other. In general, that limits the range and submerged speed that one can get, because one must provide volume and weight for the fuel and volume and weight for the oxygen with which to burn it.

Now, the utility of atomic power in submarines lies in the fact that one takes into the submarine one material only, and out of that one material it is possible to promote a nuclear reaction which will give you heat.

Moreover, the fact that the amount of energy per atom is so tremendous in a nuclear reaction means that this thing is going to be concentrated. It is hard to think of any ship more concentrated than a submarine; so, in a sense, the uranium conversion has direct application to the submarine problem. It is a possibility at least.

I don't think it is necessarily desirable to go into the details of this matter except to point out that, if there is any particular use for nuclear power, the submarine certainly suggests itself as a good place to try it.

With the foregoing background in mind, I would like to put on the record that on June 1, 1939, after analyzing this problem and making arrangements for cooperation with Prof. Jesse Beams at the University of Virginia, a memorandum was sent to our director on the possible uses of uranium power in the Navy.

Later on, various letters were sent out, but the important thing, I think, is to point out that even as early as February 1940, in cooperation with Professor Beams at Virginia, we had secured modest amounts of enriched uranium. By modest amounts I am thinking in terms of a gram or so.

By July 1940 we had actively set up a program in cooperation with the Carnegie Institution of Washington, the University of Virginia, and Columbia University, a forward-looking program that would ultimately lead to a power-producing pile.

We financed the work with the help of the Bureau of Ordnance, the Bureau of Ships, and the Army Ordnance at that time to an extent of about \$40,000, and the work was coordinated entirely through the Naval Research Laboratory.

As a result of that work two or three things emerged which bear repeating.

The Carnegie Institution contract—the Department of Terrestrial Magnetism, this was—was to support a new method of isotope separation which Dr. Philip H. Abelson had examined and run some preliminary experiments on. It looked like a good wartime way of doing it, and our support put that method on its feet. We built a pilot plant at the Naval Research Laboratory and drew off samples of modest amounts for analysis. These showed that it was a practical method.

The CHAIRMAN. Is that the thermal diffusion method?

Dr. GUNN. That is the liquid thermal diffusion method.

The CHAIRMAN. What date was that?

Dr. GUNN. That contract was in effect and we were working with them in July 1940. The liquid thermal diffusion pilot plant at our laboratory—and this work was finally transferred to our laboratory along with Dr. Philip Abelson—was set up and operating in December 1942, and operating on such a basis that the data that we obtained at that time were later shown to be essentially correct.

It also happened that in December 1942 General Groves was invited to our laboratory and saw our outfit.

We gave to him the quantitative data that we had at that time, and suggested that it might have an important bearing on the national production. However, the Army took no action on our method until June 1944, which was 18 months later.

As a result of our work, and being sure that we had a method which was tolerably good, we went ahead with the help of the Bureau of Ships, and in June 1943 we recommended that we build a plant in Philadelphia, but construction was not started until November 1943 because we couldn't get the authority to do it. That plant was finally put in operation and we were taking samples off of it, in July 1944. We had some difficulty getting raw materials, but that was finally straightened out. I think the success or nonsuccess of that plant should not be discussed here.

This review of our part in the production of uranium isotopes is given, sir, to emphasize the fact that we are actively interested in power and its utilization in the Navy, particularly the special problems that face the naval service. We think that by means of our very early work we have shortened the time it took to produce the critically required material. If we had not worked on the thing at the start and early supported these university people we think perhaps the national production might have been delayed.

The CHAIRMAN. Doctor, how much money has the Navy spent altogether?

Dr. GUNN. The Naval Research Laboratory, including the experimental work at Philadelphia, expended \$2,000,000. To that \$2,000,000 should be added an amount which, as close as we can estimate, is about \$1,000,000 assigned to the Naval Boiler and Turbine Laboratory at Philadelphia, direct from the Bureau of Ships.

The CHAIRMAN. That would be \$3,000,000 altogether?

Dr. GUNN. That would be about \$3,000,000 that the Navy itself put into it.

The CHAIRMAN. What contact did you have with the Army on the problem between the first meeting that you had, which I believe was in 1939 with Army Ordnance? What meetings did you have with the Army or they with you in the interim period up until General Groves was shown what you had done in December 1942?

Dr. GUNN. There was established a committee, the S-1 Committee of the NDRC, which had an Army representative. At one time General Styer was on it, and they had, I think, two other representatives from time to time. The chairman of this committee was Dr. Briggs, who was then Director of the Bureau of Standards. The Army was informed of the work carried on by the committee through their representative.

The CHAIRMAN. Were you on the committee?

Dr. GUNN. I was on the committee for a time.

The CHAIRMAN. Did you report to the committee as to what the Navy was doing on it?

Dr. GUNN. The chairman of the committee was kept in touch with everything that we did.

The CHAIRMAN. That is Dr. Briggs?

Dr. GUNN. That is Dr. Briggs.

The CHAIRMAN. When was that committee set up?

Dr. GUNN. I am sorry, sir, I don't know; but you will find that in the Smyth report.

Senator HART. To connect up some of this early chronology, Doctor, the first witness before this committee gave a good deal of data covering the chronology of those early years.

I believe you stated that your first move outside your laboratory in order to get started was on March 20, 1939. Is that correct?

Dr. GUNN. That is correct.

Senator HART. Doctor, have you any idea as to when the President was first acquainted with the possibility of atomic fission?

Dr. GUNN. I understand that there was a meeting with a Mr. Sachs—I judge that is the man you refer to—on October 11, 1939.

Senator HART. Insofar as you know, did the Navy Department ever make these ideas known to the President prior to Dr. Sachs, whom you mentioned?

Dr. GUNN. I would not know about it, sir, if they had. I was too far down the line.

Senator HART. Do you recall receiving anything from Dr. Einstein in August 1939 that antedated or postdated your original undertaking of this problem?

Dr. GUNN. As far as I know, our laboratory never received any communication from Professor Einstein. In part answer to your original question, the Director of the Naval Research Laboratory did send to the Secretary of the Navy on November 13, 1939, a general review of our interest and proposals in this matter.

Senator HART. In case it ever was called to the President's attention directly by the Navy Department, who would know?

Dr. GUNN. I think Admiral Bowen, who was Chief of the Bureau of Ships at that time. The laboratory was operating under the Bureau of Ships, and he would be the man who would know.

Senator HART. You mentioned Dr. Sachs. In his testimony he stated that during those early steps, I believe in 1939, there had been an adverse report by the technical adviser of one of the services in the summer of 1939, and it was because of that that he, Mr. Sachs, went directly to the Commander in Chief, meaning the President.

Do you think that technical adviser could have come from your laboratory?

Dr. GUNN. I am sure that he wouldn't have come from our laboratory.

Senator HART. Did you hear Dr. Sachs' testimony?

Dr. GUNN. I read parts of it; yes, sir.

Senator HART. Do you know or have you any opinion as to why he said that there was a previous adverse report?

Dr. GUNN. I haven't the slightest idea why he would say it. I suppose that was his experience.

The CHAIRMAN. Doctor, when you met with Fermi and Pegram on March 17, 1939, did you put them under contract, or was any arrangement made with them for them to work on this problem?

Dr. GUNN. No, sir; not at that time.

The CHAIRMAN. You had great confidence in Fermi?

Dr. GUNN. We think very highly of Fermi. He was an experimenter in nuclear physics, and was an outstanding exponent at that time.

The CHAIRMAN. Was any arrangement made that Fermi and Pegram be put under contract and the Columbia project be started?

Dr. GUNN. That came later.

The CHAIRMAN. When?

Dr. GUNN. We made arrangement to set up the Columbia contract with our laboratory in July 1940.

The CHAIRMAN. In February 1940 you had gotten one gram. Now, where was that gram produced?

Dr. GUNN. I misled you, sir, in my testimony there. That was one gram of a 10 percent enriched sample, and that was produced at the University of Virginia. That was not pure metal, which you apparently interpret my testimony to mean.

The CHAIRMAN. But in July of 1940 you had concluded a contract with Columbia University?

Dr. GUNN. That is correct.

The CHAIRMAN. Was it the Navy that set up the Columbia project?

Dr. GUNN. The Naval Research Laboratory was the coordinating agency for the Bureau of Ordnance, the Bureau of Ships, and the Army Ordnance. The Army was in on that allotment of funds at that time.

The CHAIRMAN. Did you have any correspondence with Fermi and Pegram between March 17, 1939, and February 1940?

Dr. GUNN. I am quite sure we did. I had considerable correspondence with Pegram, and I think it fell in that interval.

The CHAIRMAN. I understand, Doctor—I am not certain of this, and I do not make it as an assertion of fact—that when Fermi and Pegram went to see you people in the Navy on March 17, 1939, they came away from that conference much discouraged, and that it was as a result of that discouragement that they got in touch with Dr. Sachs, who in turn got in touch with the President.

As I say, I don't vouch for that at all, but that is my recollection either of testimony or conversations to which I have listened.

Dr. GUNN. I think that is a fair deduction from what happened. You gentlemen must realize that this picture looks a great deal different today than it did look then. Here was a group of scientists who had been looking for something like this, but we didn't quite believe it. We didn't object in the least to the conversion of nuclear energy. It was conceded that energy was there all right, but the chain reaction, the idea of one molecule tripping off another, and that one tripping off another, and the same thing going on in a chain, was distinctly something that placed us in the position of being "from Missouri." We weren't sure of it.

I think everyone would be discouraged. I was discouraged. The laboratory didn't go into this work with the idea that the result was all going to fall out in a year or so. If we had known—and that is the point—that there was actually going to be a sustained chain reaction,

we would never have got a chance to look at it. There would have been thousands of scientists working on it immediately.

The CHAIRMAN. Well, it was after Roosevelt, in the spring of 1940, had the meeting with Sachs that things began to happen.

Dr. GUNN. Well, unfortunately that is the way you get money to do a job in the Government service.

Senator HART. May I correct you, Mr. Chairman? I think that that date was October 1939.

The CHAIRMAN. October 1939? My recollection was confused. It was after the fall of France that additional effort was put in, and it was after that that things began definitely to happen.

Dr. GUNN. That is right.

Senator HART. Doctor, during those early days in the spring of 1939, did you or your associates or any one up in the Navy Department pay very much attention to the possibility of fission as a weapon rather than a source of power?

Dr. GUNN. Not very much attention to it specifically. We realized the two important solutions would fall out together, sir, and we knew that if we could solve the power problem the bomb application would automatically come out with a very small amount of additional work.

The CHAIRMAN. Doctor, how big were the contracts that you first made?

Dr. GUNN. Our first contract went to the Carnegie Institution. We tried to give them some money, and they said, "No; we don't like to take a contract; we will do it for you for nothing."

Finally we prevailed upon them to take a contract in the amount of \$2,500, which was simply to cover the costs of some work that Dr. Abelson started there. That contract was dated November 3, 1940. As I say, they did work for us without charge and as a public duty.

Columbia University, on July 18, 1940, entered into a contract for \$29,700, and on the same date, July 18, 1940, we entered into a contract with the University of Virginia for \$13,000.

The work at Virginia was under the control of Dr. Jesse Beams. The work at Columbia was under Professor Pegram, and that at the Carnegie Institution was under Dr. John A. Fleming.

The CHAIRMAN. After General Groves took the thing over, how close was liaison kept with the Navy on this thing?

Dr. GUNN. There was liaison, sir, but I think it was one way; down at my level it was. Probably there was liaison farther up, but I did not experience it.

The CHAIRMAN. You mean you didn't know what was going on in the project?

Dr. GUNN. I had no idea what the Army was doing.

The CHAIRMAN. You had no idea?

Dr. GUNN. Except by making a guess. Being a scientist, I could make an intelligent guess.

The CHAIRMAN. Did you have any idea that there was a two billion dollar project under way?

Dr. GUNN. I don't know how much it was. I know it was a pretty big project, because we couldn't get additional people after it got under way.

The CHAIRMAN. General Groves is in Army Engineers, isn't he?

Dr. GUNN. That is correct.

The CHAIRMAN. Do you have liaison with the Engineers? Does the Navy have liaison in this branch with the Engineers or with Ordnance?

Dr. GUNN. That I cannot answer. I don't know of it. It didn't reach to our laboratory. I can only speak of what happened at our laboratory, sir; I cannot speak for the Navy as a whole on that matter.

The CHAIRMAN. Are you the Chief Physicist for the Navy?

Dr. GUNN. No; I am superintendent of two divisions at the Naval Research Laboratory, the Mechanics and Electricity Division and the Aircraft Electrical Research Division.

The CHAIRMAN. You were the fellow in the Navy that ought to know about this, weren't you?

Dr. GUNN. That is right.

The CHAIRMAN. You didn't know about it?

Dr. GUNN. I didn't know about it.

The CHAIRMAN. Did you make any attempt to find out?

Dr. GUNN. Yes, sir.

The CHAIRMAN. When you did, what were you told?

Dr. GUNN. I just didn't hear anything, sir; that was all.

The CHAIRMAN. How did you make the attempt—by letter or by phone?

Dr. GUNN. By direct personal contact, and I tried to write letters.

The CHAIRMAN. You tried to write them?

Dr. GUNN. I wrote letters, sir; I am sorry.

The CHAIRMAN. Did you get answers?

Dr. GUNN. No.

The CHAIRMAN. Acknowledgments?

Dr. GUNN. Yes.

The CHAIRMAN. What was in the acknowledgments?

Dr. GUNN. That the matter under consideration would be taken up with higher authority.

The CHAIRMAN. As far as you know, it never was?

Dr. GUNN. As far as I know, it never was. I think those are questions that should be directed, sir, to the military members of this naval representation.

The CHAIRMAN. Well, you have the Smyth report, though?

Dr. GUNN. Yes, sir.

The CHAIRMAN. Maybe that is what they were waiting for.

Senator JOHNSON. I should like to ask if you are familiar with the thermal diffusion set-up at Oak Ridge?

Dr. GUNN. No; I have never seen the gaseous diffusion plant, sir. In the early days before it was reorganized I had a good, full acquaintance with what was being done, but along about the time war began—December 6, 1941—the S-1 Committee was reorganized and we were disassociated from the project. I don't know what happened after the war began.

Understand, sir, that our laboratory has really done only one part of this job. We set out to take on the whole thing, but we did one job apparently too well, and we spent the rest of the war doing that one job.

Senator JOHNSON. What do you mean by saying "apparently too well"? I didn't know any job could be done too well.

Dr. GUNN. We have worked out a successful method for producing the fissionable material, and the country urgently needed it. That is what we did. We turned it out.

Senator JOHNSON. That is some other material?

Dr. GUNN. No; this is the separated isotope of uranium.

Senator JOHNSON. And they kept you on that particular job; is that what you mean?

Dr. GUNN. That is right.

Senator JOHNSON. Doing that particular job?

Dr. GUNN. That is correct.

Senator JOHNSON. Was that a fundamental part of the whole operation?

Dr. GUNN. Yes, sir; that was a fundamental part of it. There were three ways of doing it, three ways of separating isotopes, as summarized by the Smyth report.

Senator JOHNSON. At least three ways.

Dr. GUNN. At least three ways—I am sorry—the electromagnetic method, the gaseous diffusion method, and the liquid thermal diffusion. Our process was the liquid thermal diffusion process, and that is the one we worked on.

The CHAIRMAN. When you say "liquid," do you say that instead of the steam plant?

Dr. GUNN. Instead of the gaseous.

The CHAIRMAN. There is a thermal diffusion process—isn't that what they call it?

Dr. GUNN. They are both thermal, both the liquid and the gaseous are thermal diffusion processes.

The CHAIRMAN. What does the Smyth report say they used?

Dr. GUNN. They used all three.

The CHAIRMAN. The thermal process?

Dr. GUNN. They used both our system, the liquid, and the gaseous thermal diffusion, both of them.

Senator HART. I think the Smyth report limits its description of the gas diffusion to "gas." They don't mention "diffusion" in the title.

The CHAIRMAN. That is what confused me.

Mr. CONDON. Perhaps I ought to say here that your question, Senator, refers particularly to the thermal diffusion plant at Oak Ridge, I suppose, and that is the liquid thermal diffusion method that was developed by the Navy, I believe.

Senator HART. I think, Mr. Chairman, that in most of our description, and possibly in Dr. Smyth's report, the word "liquid" is left out of the description.

The CHAIRMAN. That is what confused me.

Senator MILLIKIN. I would like to know now whether the plant at Oak Ridge is a liquid thermal-diffusion plant, or whether it isn't?

Dr. GUNN. Oak Ridge has three plants, sir; one of every kind.

Senator MILLIKIN. And is there a liquid thermal diffusion plant there?

Dr. GUNN. There is.

The CHAIRMAN. Were you consulted about the construction of that plant?

Dr. GUNN. Yes, sir. Dr. Abelson went down there and spent some 2 or 3 months, and 10 of our men spent some months down there to help operate it and get it organized.

Admiral PURNELL. You designed it, didn't you?

Dr. GUNN. We designed it; yes, sir.

The CHAIRMAN. When you were applying for information, was it about other methods of separating the isotope?

Dr. GUNN. Well, sir, I was charged apparently with the research work that the Navy was doing at that time, or at least I thought I was, and I was trying to look at the problem as a whole. Naturally there were certain parts, and when you got one part going, you naturally turned to the next part to try to get that going. I wanted to find out in general what we should be doing.

Naturally I was trying to see the picture as a whole, sir; and I was interested in knowing what was going on so that in laying out my program of work I would not duplicate what other people were doing.

Now, it was suggested that we go ahead and get this information ourselves, but I was brought up to think you should not waste your money, and I didn't want to duplicate effort. I wasn't going to be a party to spending millions of dollars, or even one hundred thousand, to duplicate some work I knew my fellow scientists were doing elsewhere. It didn't make sense to me, so I refused to expand our work at that time because I was forced to work in the dark.

The CHAIRMAN. Does that mean that you were compartmentalized?

Dr. GUNN. Oh, I was compartmentalized all right.

The CHAIRMAN. Was that for security reasons?

Dr. GUNN. I think, sir, that should be addressed to Admiral Purnell.

The CHAIRMAN. All right.

Senator MILLIKIN. I should like to invite your attention, Doctor, to the fact—it appears to be a fact on the record—that the Germans did not compartmentalize. They were all working on an over-all basis, with the result that they never got anything done by the end of the war.

The CHAIRMAN. Do you think that follows as a result, Senator?

Senator MILLIKIN. I think you could argue that the method used of compartmentalizing, while offensive to science, resulted in the objective.

Senator HART. Might I say, Senator, that possibly instead of describing it as compartmentalized, that the scientists were managed.

Senator MILLIKIN. I can understand why that would be offensive, and I can also understand why it might be a good thing if you were seeking in a short time to produce a certain result.

Dr. GUNN. I don't believe scientists are as temperamental as some people say they are. We all recognize that there is a valid reason for security. There are two reasons for it, one to keep the enemy from finding out what you know, and also to keep the enemy from finding out what you don't know.

I think most scientists are willing to "play ball" on that basis when it is necessary.

Senator HICKENLOOPER. I understand, Doctor, that the chief efforts of the Naval Research prior to the time that this set-up was an over-all proposition, the Oak Ridge plant had been established, and so on, were devoted entirely to the development of the liquid diffusion method of producing this material, and that under your direction the Navy did go on until this method was perfected.

Let me ask you if in that development of that process you suffered any restrictions of accessibility to methods and to means directly affecting that particular process?

What I am trying to get at is whether you were restricted in information or in working in that particular process, or whether the restrictions applied to the gas diffusion method and the electric method and the plutonium development.

Dr. GUNN. But, sir, I would point out to you that we were developing this information. No one else in the world had it, and obviously we had access to our own information.

Senator HICKENLOOPER. I realize that. I am not discussing the question of the advisability of restriction of that information. I am trying to see if I can narrow it down to what was restricted and what wasn't, on the theory that if they adopted a strict compartmentalization philosophy as to this development program—whether we agree with it or not—there might have been at least some plausible reason as to why it should be done for the over-all project.

I am wondering whether the restrictions you have referred to on information applied to any information that you needed or that you wanted which applied directly to the liquid thermal diffusion process. Were you restricted as to that?

Dr. GUNN. There was no outstanding limitation. We had some difficulty in getting things we wanted, but they were straightened out ultimately. Of course, we had to do some fighting to get them.

Senator HICKENLOOPER. I would presume those difficulties would increase in proportion as you got into other fields where you meet, as Senator Vandenberg called it, an iron curtain.

Dr. GUNN. I never saw an iron curtain, but I think I understand what that means.

Senator HICKENLOOPER. He gave a very graphic description of the iron curtain. That is a question I wanted to get clear in my mind.

Senator MILLIKIN. The iron curtain in your business, Doctor, is when they tell you, "This will be referred to higher authorities."

I got the impression from something you said, Doctor, that on the whole you view this development of atomic energy as beneficent to the world rather than as harmful to the world.

Dr. GUNN. I am satisfied that is correct.

Senator MILLIKIN. That, of course, depends on whether we can harness the destructive features of it.

Dr. GUNN. That is correct.

Senator MILLIKIN. If we could harness the destructive features, then we would have nothing but the beneficent features left, and that, of course, opens the whole problem we have before the committee. It has been repeated here several times that when you use atomic energy for power purposes you are three-quarters of the way along toward using it for war purposes.

I think you have probably already answered the question that I intended asking you. If we cannot control that next, last step, then perhaps it would be better if we didn't take the first three steps. What would you say as to that?

Dr. GUNN. I don't know. That is a hard question, sir. I think I will leave that to the statesmen to answer.

Senator MILLIKIN. I won't press it further.

Senator HICKENLOOPER. I think the doctor is a citizen, and so are we all. I would value his opinion, if he cares to give it.

Senator MILLIKIN. It happens I have to leave in a moment, and I want to ask two or three questions of the doctor.

Let me ask you this, doctor: Who were the nuclear scientists working with you at the time you conducted these early experiments?

Dr. GUNN. I was the only one that was qualified in the early days, and I finally hired away from the Carnegie Institution, after we had a contract with them, Dr. Philip H. Abelson, who was the codiscoverer of element 93 and he has been with me throughout this operation.

Senator MILLIKIN. Are you familiar with the testimony of Dr. Sachs?

Dr. GUNN. I have read parts of it, sir, but I would not say I was familiar with it.

Senator MILLIKIN. As I understood his testimony, he portrayed a picture of a neck-and-neck race between the scientists of various countries to make a weapon out of atomic energy and that he sold that picture to the President specifically on the ground that Germany was about to develop this kind of a weapon at most any moment.

Are you aware of the fact that we have had testimony that at the end of the war Germany had not even commenced to build a plant?

Dr. GUNN. That is correct.

Senator MILLIKIN. You spoke of this energy as a substitute for our dwindling resources in oil and coal. Would you say that we have suffered, considering the amount of coal we have, a serious depletion of coal?

Dr. GUNN. Not of coal, but distinctly of our oil reserves.

Senator MILLIKIN. But we do have very well-known methods expanded and developed by the Germans during this war of making oil out of coal, so that if we did not have this substitute method, and even if we ran out of oil, we could fall back on coal as a source of all the fuel oil we could possibly use over the long foreseeable future. Is that not correct?

Dr. GUNN. That is correct.

Senator MILLIKIN. Would there be any control factors in a pile in a submarine or a boat that might get out of control in the event of a hit which would cause larger damage than is now caused if you hit your steam plant or something of that kind?

Dr. GUNN. I would prefer to answer that in executive session, sir.

Senator MILLIKIN. What other nations, if you care to say, are working on this problem from the naval power standpoint?

Dr. GUNN. I have no direct information on that question.

Senator MILLIKIN. As far as you know, no other navy maintains a research program with the specific object of developing power for naval vessels?

Dr. GUNN. Right.

Senator MILLIKIN. Thank you very much, Doctor.

The CHAIRMAN. Doctor, did Naval Intelligence furnish you, from time to time, or at any time, with any information as to what was going on in Germany with regard to this project?

Dr. GUNN. No, sir; I never asked them for any information on the subject. I didn't think Naval Intelligence was informed in this matter.

The CHAIRMAN. I gather from your testimony, Doctor, that at least in this project there was no unification of the Army's and Navy's efforts in the matter?

Dr. GUNN. I think there was somewhere, but it didn't drift down to me. I didn't experience it.

The CHAIRMAN. And you were chief of the nuclear development—

Dr. GUNN (interposing). I was chief of one part of the work.

The CHAIRMAN (continuing). Having to do with nuclear energy, and nobody else in the Department except yourself was in charge of that work?

Dr. GUNN. I am glad to say that, throughout this whole matter, Commodore Parsons, who is here before you, was definitely associated with it, and I felt quite happy that the Navy had someone who was fully informed and, if anything important came up, the Navy had access to it, at least. Whether I had it is beside the point.

The CHAIRMAN. You didn't get it from Commodore Parsons?

Dr. GUNN. I will let you ask him that question, sir.

The CHAIRMAN. All right.

Senator HART. Mr. Chairman, I wonder if I might get an answer from either Admiral Purnell or Commodore Parsons to my question about whether or not the President was informed through the Navy Department of these early developments. Do you know, Admiral Purnell?

Admiral PURNELL. No, sir; I cannot answer that. I did not get here until July 1942, sir.

Senator HART. Does Commodore Parsons know?

Commodore PARSONS. I first heard of the project in May 1943, so it was far along before I got in on it.

The CHAIRMAN. If you would like the answer to that question, Senator, perhaps for the record they can furnish that information.

Senator HICKENLOOPER. Dr. Gunn, I would like to ask your opinion, partly in your capacity as a scientist, and partly in your capacity as a citizen—who is, I think, generally a pretty smart fellow—because I would value your opinion as such.

First, as a scientist, do you know of any substantial or revolutionary scientific discovery with tremendous potentialities for the good of humanity that has ever been discarded or has, in fact, ever been curtailed so far as scientific investigation is concerned?

The point of my question is: Are we going to stop investigating this atomic field from a scientific standpoint in spite of anything we may do in the way of laws, agreements, or anything else? Is science going to stop that?

Dr. GUNN. Well, I don't think you can stop progress. I think the answer to that is so obvious that it requires no discussion. We never have stopped it and never will. For short periods of time there have been impediments but averaged over a long period of time such discoveries have always proceeded.

Senator HICKENLOOPER. I think the answer is obvious, too, but we have a record to file here, and I wanted to have your opinion on that.

Now, as a scientist, and also as a citizen who undoubtedly has given some thought to general political aspects as life goes on, do you believe—considering human nature, considering the magnitude and the technicalities of this thing, or a combination of the political and scientific fields—that it is reasonably feasible or possible to continue with scientific investigation to the limit of our ability as we learn more, to develop this atomic field of energy, and to devise some human way to limit it to the development of energy for the public good and to stop,

control, or prohibit that last 25 percent, after you get the material, from going into bombs?

Dr. GUNN. Well, sir, that is a tough question, and I want to answer that as a citizen.

Senator HICKENLOOPER. We have got to answer that here.

Dr. GUNN. As a citizen, I am not too happy about the proposals made by some of my fellow scientists. I would like to have one question answered before I go along with their recommendation on international agreements.

If there is any basis to scientific endeavor, it means that if we perform an experiment five times and get a certain answer, the basis of our belief is that if we do it the sixth time we will get the same answer, or the tenth time, unless the fundamental variables have changed.

When people talk about international agreements, I would like to ask them to give me a quantitative figure of the probability of an international agreement lasting 25 years, 50 years, or 100 years. And if that probability isn't finite and of appreciable size, then I say we should not do the experiment over again. That is all I know about it, sir.

Senator HICKENLOOPER. I don't think there is any difficulty in the mind of anybody as to what we should do with this thing. We should prohibit its use as a weapon. It is easy for anybody to say that. I don't mean to say that is exactly what you said, but that is the end result here.

We should prohibit its use as a weapon because of the horror and the vastness of its destructive power; but between having this awful thing on our hands, and what we should do with it, and how we should accomplish that result of prohibiting its use for the destruction of humanity, are some of the questions that this committee is going to be called upon to try to answer.

Manifestly, in my mind, science is going on to experiment. You cannot stop it. You couldn't stop it in the electrical experimentation, and electricity has been used to kill people. You couldn't stop it in gunpowder, although it has peacetime uses and is beneficial; yet it has gone into the field of destruction and killing, and countless other things.

Radio investigations, electronics, and all those things with their vast peacetime good have been turned to some of the most terrible killers that we have when man feels he is in danger.

Now, this can go to a point where it will produce energy. It will produce materials that can be beneficial to medical research and public health. It will ease life and probably give us a lot of comforts at some time in the future, and yet there is always that last 25-percent step there through which the material that will bring the benefits can be taken in order to bring about the most destructive thing that we yet know.

I think if we did have some kind of a snub we could put on that thing to snub it right down to the uses for benefits, of course that would be one answer. If we could stop it, or stop some dishonest nation from violating its contracts, or doing things of that kind, to use or divert some of this to the weapon stage, well and good. If we cannot, then what?

Dr. GUNN. Well, sir, we are all looking for a snub to be applied at the right time. The trouble is rascals fix it so there is grease on the snub.

In figuring the probability of international agreements lasting long periods of time, I would like to set over against that the probability of unilateral agreements lasting over long periods of time.

The Monroe Doctrine has lasted for a long time. It was not an international agreement; it was a one-man agreement. I think that is the only way.

Senator JOHNSON. Backed up by force, Doctor.

Dr. GUNN. Yes; backed up by force.

Senator JOHNSON. And it was only as good as the force back of it?

Dr. GUNN. That is correct.

Senator HICKENLOOPER. I would like to go into the matter of inspection, and I am not trying to cross-examine you.

Dr. GUNN. I am glad to be cross-examined, but I don't know anything about it.

Senator HICKENLOOPER. Neither do we. You have nothing on me, at least, in that respect.

Inspection has been discussed here, and manifestly that is a very plausible field for discussion. It gives a very plausible answer on the surface: "Sure; go in and inspect all these people, and the minute you find them diverting, do something to them."

What?—that is anybody's opinion, but that can be worked out.

I don't know whether you have gone into this sufficiently, or whether your experience in this field has been sufficiently extensive in the weapon end of the thing to say that, but if you would care to give an opinion, do you believe that it will be feasible to establish such an inspection system that can detect and immediately make available the information as to the diversion of this material in that last 25-percent step at a reasonably early period in its diversion before people can start making bombs that will go off?

Dr. GUNN. I don't think any scientist really knows the exact answer to the question you have propounded, but I think it can be done.

We have powerful instruments—Geiger-Mueller counters, we call them—which detect quite a small amount of material, and if backed up by adequate and competent and continuously observant personnel, I think it could be controlled. The trouble is, of course, that someone will perhaps grow careless.

I would put it this way: I think it is not impossible; I think it would be a hard job.

Senator HICKENLOOPER. Have you thought a great deal about this inspection?

Dr. GUNN. No, sir; I honestly don't know anything about it.

Senator HICKENLOOPER. Thank you, Doctor.

Senator HART. May I ask any of the witnesses to answer this, whichever one knows most.

The Navy Department has given out a statement dealing with future experiments, using the bomb against a ship or ships. I would like to ask if, in planning this experiment, the Navy Department intends to make full use of all the scientific knowledge and experience available in this country?

Admiral BLANDY. No final plans have been approved, Senator, for those tests. We are in the act of planning them now. We have not come to that particular bridge yet, but we certainly will.

Senator HART. My question is: Do you intend to use all of the talent which is available in making the detailed plans for this experiment?

Admiral BLANDY. I wouldn't say that we intended to use all of the talent available in the entire country. I think that might be an unwieldy organization. But we do intend to consult the scientists whom we consider qualified and responsible in that matter; yes, sir; particularly to take care of the hazards involved.

Very thorough study will be made of the hazards in planning the details of the test so as to minimize the danger not only to those of us involved but to anyone else.

Senator HART. Will there be full cooperation with General Groves' organization?

Admiral BLANDY. Yes, sir.

The CHAIRMAN. Admiral, when do you prophesy that this test can be held?

Admiral BLANDY. We have set no exact date, but I think we can do it sometime in the coming summer.

The CHAIRMAN. Has a joint board been set up?

Admiral BLANDY. There has been established a Military Advisory Board to General Groves. There also has been established a committee for planning the test, but that committee has not completed its work.

The CHAIRMAN. Has the personnel of that committee been announced?

Admiral BLANDY. The personnel of the committee has not been announced; no, sir.

The CHAIRMAN. Do you intend to announce it?

Admiral BLANDY. It would not be in my province to announce that. It is a committee under the Joint Chiefs of Staff.

The CHAIRMAN. I wish you would take it up with the Secretary and let the committee have a statement as to the personnel, what branch of the service they represent, which is going to supervise the test.

Admiral BLANDY. I will do that, sir; but, as I say, that cannot be done yet because the exact organization has not been determined, the organization for executing the test and for appraising it. It is in the process of being determined now, and I am sure the names of the personnel involved will be published as soon as that work is completed.

Senator JOHNSON. Is it planned to make this test in the nature of a depth bomb and also in the atmosphere above the sea?

Admiral BLANDY. Studies are being made of both of those phases, but, as I say, the details of the test have not been completed.

Senator JOHNSON. I want to ask the Doctor a question. He made reference to a submarine using uranium power. I presume that the problem of eliminating the death rays or gamma rays has been overcome for that purpose?

Dr. GUNN. Sir, I think that ought to be discussed in executive session. It is a technical matter.

Senator JOHNSON. A physicist testified yesterday and suggested that it might be advantageous, especially in wartime, for sea traffic to be all done by submarines, or to be largely done by submarines; that is, large ships moving below the surface of the sea, escaping the storms and the waves and other resistance.

Have you made a study of the propulsion of very large cargo ships?

Dr. GUNN. Sir, I would rather delay that to an executive session. I think we should observe, however, if the enemy doesn't know where

you are, they are not going to drop a bomb on you; and if you are in a submarine, they wouldn't know.

Senator JOHNSON. Yes; I think that is quite obvious, and that is one of the reasons why the physicist suggested that that held great possibilities for the future protection of transportation.

Dr. GUNN. I won't disagree with him.

Senator JOHNSON. This same physicist testified yesterday that the atomic era began on December 2, 1942.

You have testified to the chronological development of this whole matter. Do you agree that historians will say that December 2, 1942, was the date the atomic era began?

Dr. GUNN. I would like to word that as the "beginning of the era on the earth." Atomic processes have been taking place in the stars for a great many millions of years.

Senator JOHNSON. And have probably taken place on earth, too, before man came here; but that is the historical date?

Dr. GUNN. I think that is correct. That is the date at which the first pile was started. It operated very weakly, but it showed that the numerical calculations were substantially correct.

Senator JOHNSON. And the chain reaction was in effect?

Dr. GUNN. The chain reaction did in fact take place. If we had known that one simple fact, irrespective of all technical developments—if we had known this one simple fact when uranium fission was first announced, I think we could have gone ahead a great deal faster, and the scientists would have been willing to recommend a greater expenditure of money more rapidly if we had been sure of that one thing. That was the crucial experiment.

The CHAIRMAN. Doctor, as I take it, you believe that the liquid thermal diffusion method that the Navy developed and operated in December 1942 on a laboratory scale, which General Groves saw in December 1942, had a material bearing upon the development of the process?

Dr. GUNN. Yes, sir.

The CHAIRMAN. As I understand your testimony, and I want to get it straight, the Army, however, took no action until 18 months later?

Dr. GUNN. On our method, sir. They had other methods they were actively pushing, but on our method they took no action.

The CHAIRMAN. On your method there was nothing done for 18 months?

Dr. GUNN. That is right. Our method had the serious objection that it took a great deal of steam to operate it. We recognized that it is not a method one would normally select in peacetime, when one had plenty of time. It had the recommendation of being exceptionally clean. We felt, weighing all the factors, and having the steam boilers in the country, it offered a practical solution that looked better to us than anything else that we had seen.

Naturally we were prejudiced, and thought it was pretty good. I think the other methods are good, and I am amazed at what they have done with them. I think the Manhattan project did an amazingly good job in the time they had to work on it.

Senator MILLIKIN. Doctor, from the testimony of one of our previous witnesses the impression was brought to my mind that if you explode an atomic bomb at great depth you would produce a sort of marine earthquake. I assume that the Navy has a vast store of infor-

mation and experience on the effect of underwater concussion. Am I correct in that?

Dr. GUNN. That is correct in terms of ordinary explosives, sir; but we have no data, obviously, on the atomic explosive.

Senator MILLIKIN. If you know the forces that are released at a given moment at a given depth in the water, you can calculate with reasonable accuracy how far that will extend and what the effects will be within an area?

Dr. GUNN. That is correct.

Senator MILLIKIN. Would it be appropriate in open hearing to ask you whether you gentlemen have made calculations on the effect of the atomic bomb if dropped at depth and if dropped at less than depth in an assumed disposition of naval forces?

Dr. GUNN. Some rough and highly speculative calculations have been made. I honestly don't recall the final results, but they lead to results which we would infer from simply the land data, I think.

The CHAIRMAN. How do you gentlemen now wish to proceed?

Admiral STRAUSS. We would like to offer Commodore Parsons' testimony, Mr. Chairman.

**STATEMENT OF COMMODORE W. S. PARSONS, ASSISTANT TO THE
DEPUTY CHIEF, NAVAL OPERATIONS FOR SPECIAL WEAPONS**

Commodore PARSONS. I came into this project at a fairly late date in its career. It was, I think, the 5th of May in 1943.

I was informed by Admiral Purnell that I was assigned to this project and was instructed by Admiral King as to the security limitations, which were of course paramount at that time.

The CHAIRMAN. Commodore, wouldn't it be a good thing if you were to tell us about your previous experience that led the Navy to bring you into this work?

Commodore PARSONS. All right; I will do that.

I was assigned to the duty of experimental officer at the Naval Proving Ground at Dahlgren, about 40 miles down the river, in August 1939, and was associated with some of the original NDRC ordnance experiments which began in the fall of 1940.

Senator HICKENLOOPER. Mr. Chairman, I would rather have these alphabets interpreted.

Commodore PARSONS. That is the National Defense Research Committee originally, which later transformed into the Office of Scientific Research and Development, as far as the parent organization was concerned.

That, of course, as the war proceeded, led into more and more scientific and accelerated ordnance development, especially experimental ordnance, and in April 1942 I was called to Washington for additional duty, which turned out to be about 5 days a week as Special Assistant to Dr. Bush in connection with the development of the radio proximity fuse. That was development in which, you might say, the electronic initiative was taken by the section under Dr. Tuve, and the backing and enthusiasm for the production were taken by the Bureau of Ordnance and the Navy Department; so it was a fair combination to put an experimental officer from the Navy Proving Ground into the middle of the scientific organization, so that he was wearing two caps.

That led to taking the fuses into battle in January of 1942. I made it a condition to get down there, presumably with a one-way ticket; but it turned out to be a two-way ticket.

I came back, and this project descended on me in May of 1943, I think partially as a result of saying good-bye to Dr. Bush.

I think the ordnance concept of the project was crystallized somewhat in April of 1943. The physics laboratories at Los Alamos were then under construction, and a committee went out there, composed of Dr. Tolman as chairman and quite a few scientists and engineers who had experience in ordnance developments. During the war they advanced the idea that the ordnance work would have to be so closely integrated with the physics work and the chemistry that a proving and testing ground would have to be constructed in the immediate vicinity of the laboratory and presumably under the direction of the laboratory. That led to getting an ordnance engineer nominated for the job of Ordnance Division leader at Los Alamos.

The set-up at Los Alamos was not conducive to the immediate construction of proving grounds for heavy ordnance work, being 50 miles from the nearest railroad and having ravines and mountains all around; but it was possible, with the priority and urgency of the project, to get results in spite of that.

I would say throughout 1943 there was very little except theory to go on. We finally forced ourselves to design one or two types of workable bombs, and then having hypothesized them we built models of them and got started that way in actual work with B-29's in the early spring of 1944.

The concept of the laboratory turned out to be good, but about one-tenth of what we actually needed in terms of men and materials. It expanded, I think, from the original idea of 70 good physicists to many times that number, and a lot of lesser talent besides.

By the middle of 1944 we were getting active materials from Oak Ridge and Hanford, and experiments in physics threw more light on the design that was required. We made some very discouraging discoveries in physics which controlled our ideas of design, but nevertheless there was always ahead a good chance that the thing would succeed in at least one way, making a bomb.

We organized the delivery group of aircraft in September 1944, and from that time on we were training our delivery B-29 crews, and at the same time experimenting in the perfection of the bomb itself.

By the spring of 1945 we had the active material coming in faster and faster, and the experiment, fortunately, the ordnance experiment, also bore fruit; and it was possible by the early spring to take the first step to go to an advanced base and start the laboratory buildings and assembly buildings which were essential to the building of the bomb in battle.

Parallel with that, we prepared for the test in the desert, which we hoped would be a test of a bomb which could be delivered in battle and not some monstrosity which could only be set up over 2 or 3 acres of ground. Of course, we assumed that the test we made in New Mexico would succeed, and we had all of our groups en route to the Marianas when the bomb went off in New Mexico. It did succeed, and we were ready to go in less than 21 days.

The CHAIRMAN. In other words, Doctor, from the time that you entered the project there was the hardest kind of work to get it out as quickly as you could, and there was no delay at all that you can tell us about except the delays that were consequent to the difficulties of the project?

Commodore PARSONS. That is right.

The CHAIRMAN. And the bomb was delivered as quickly as it possibly could be delivered?

Commodore PARSONS. Yes. I think the material which went to Hiroshima probably had not been 3 weeks out of Oak Ridge, out of separation, or Hanford. It was going that fast.

Senator HART. Commodore, to carry you back a little, you used the word "monstrosity" just now.

Do you mean that there had to be a great deal of adjustment of ideas between the ordnance engineering personnel and the scientists who had to devise the means by which the bomb would be exploded?

Commodore PARSONS. No; I don't think there was much adjustment, if you mean friction in the adjustment. It was an absolute confirmation of the need to have the engineering on the bomb done with the physicists and by the physicists.

With the changes being made as they were in that development, the basic engineering had to be done practically by the Nobel-prize-winning physicists who were developing the bomb. It turned out that way. An ordinary engineer is about two stages removed from the furthest advances in nuclear physics, obviously, and that was the integration that we had to have.

Senator HART. It was decided that the bomb should be used from a plane. Did you take great part in deciding upon the dimensions, and so on, of something that would be practicable of use?

Commodore PARSONS. Yes. We worked on the problem beginning in December 1943, trying to settle on something which could be carried by an existing airplane. The B-29 was then a secret, and it had a lot of weaknesses which were eliminated in the next year, I would say; but we adopted the B-29 without serious modification as our airplane. We realized that if we built something that could only be carried in an airplane which had to be tailored to it, we would probably not make the war even if the bomb was developed. So we forced ourselves to take an existing successful airplane as the carrying vehicle.

Senator MILLIKIN. Commodore, may I ask whether the advance base was necessary to accommodate the airplane or the peculiar nature of the bomb?

Commodore PARSONS. The advance base was not necessary to accommodate the airplane, because they already had in the Marianas almost a thousand B-29's based there. It was the most tremendous concentration of air power that I think has ever occurred, and we just cashed in on that.

Senator MILLIKIN. But the bomb problem itself made it necessary to get as close to the target as possible, without going into the bomb problem? I mean, could you produce the same result from San Francisco, assuming you had the proper plane?

Commodore PARSONS. Staging it across, you mean? Oh, yes.

Senator MILLIKIN. Could you have assembled your bomb at San Francisco and carried it from San Francisco to the target, assuming

you had the plane to do it, as well as you could from your advance base?

Commodore PARSONS. Yes.

Senator MILLIKIN. In other words, the proximity of the base to the target is not an essential factor so far as the bomb is concerned?

Commodore PARSONS. That is correct.

The CHAIRMAN. What is the distance of that nonstop flight from Tokyo to Washington?

Commodore PARSONS. I think it was 6,500 miles.

The CHAIRMAN. How far would it have been from the Aleutians down to Hiroshima and Nagasaki and back again?

Commodore PARSONS. I don't know, sir.

The CHAIRMAN. Does anybody know that, approximately?

Admiral PURNELL. I think it is approximately the same as from the Marianas.

The CHAIRMAN. You mean it is approximately the same distance from the Aleutians down to Hiroshima as it is from the Marianas up to Hiroshima?

Admiral PURNELL. Yes. I would have to look it up, but it is in that neighborhood.

The CHAIRMAN. So far as we can see, there would be no reason why you couldn't take the bomb from the Aleutians down there and return to base?

Admiral PURNELL. I would have to check that, but I think it is close.

Commodore PARSONS. If the distances are comparable, that is a correct assumption.

The CHAIRMAN. Of course, Commodore, with the improvement in airplanes that are projected, the possible distance for flight round trip is going to be much greater; don't you think?

Commodore PARSONS. Yes, sir.

Admiral STRAUSS. Mr. Chairman, I don't know whether I made it clear in my introductory description of Commodore Parsons that he was the weaponeer on the plane which delivered the initial bomb. He was present in person.

The CHAIRMAN. Well, I gather from that, Admiral, that you think it might be advisable to go into the experience itself.

Admiral STRAUSS. No; I simply felt my introduction was deficient in making that point clear.

The CHAIRMAN. Perhaps you should tell us about it, Commodore.

Commodore PARSONS. Well, I think I might say why that idea was sold originally. It is, I think, a sound philosophy in ordnance design to have the person who is responsible for the design, the reliability of the design, and the workability of the design, at all times have in the back of his mind that he is going to see it into the initial battle use. It has, let us say, a sobering effect on the ordnance designer, and I had had that philosophy in mind in other weapons.

It is such a good philosophy that I sold that idea to General Groves early in the game, so I had my ticket written about the summer of 1943 for that job.

The CHAIRMAN. You released the bomb personally; did you not?

Commodore PARSONS. No; I didn't pull the lever. I was there, and the identification of the target was confirmed with me.

Senator MILLIKIN. You prepared the bomb, didn't you, Commodore, for the job, without going into detail?

Commodore PARSONS. You mean in the airplane after the take-off?

Senator MILLIKIN. Yes.

Commodore PARSONS. I had an assistant who made the electrical tests on the bomb in flight. I went into the bomb bay and performed an assembly operation on it after the take-off, and then also supervised the final preparations which took place just before we climbed to delivery altitude.

We were about 20 minutes before the final climb which would put us at delivery altitude over the Empire and decided to make it a final bomb then and there, and of course we could have gone into reverse if we had to go back, but we made it a bomb about 20 minutes before we climbed to delivery altitude, and made final tests about 10 minutes before we reached the target.

Senator MILLIKIN. I had read that you did a lot of practice before you tried it on that trip.

Commodore PARSONS. Yes; we had to do that to prove each component, and unfortunately we didn't have all the components at the same time, so we had to make a large number of tests. It was so large and so apparently adequate that my assembly crews said they could hardly believe it was anything but one of the old practice bombs, because it involved all of the nonexplosive components.

Senator MILLIKIN. Tell us some more about that.

Commodore PARSONS. I would say there is another advantage in having the ordnance designer go along, and that is that when you cannot inform the crew of the nature of the design or anything except that it is an extremely powerful bomb, it is also steadying to the crew to have the ordnance designer riding with them on the delivery flight.

Senator JOHNSON. Did you see the bomb as it exploded? Were you looking in that direction, or could you feel the impact?

Commodore PARSONS. We certainly felt the impact. We were about 11 miles away, I believe.

Senator JOHNSON. And you felt the impact?

Commodore PARSONS. Yes; we felt two shocks; one, the direct path, and the other the first reflection from the ground.

To answer your question about whether I saw it go, I did not see the one on Hiroshima actually function because we had just completed a maneuver to get a lot of distance between us and the bomb, and that put our tail toward the bomb. The only one who could see it clearly at that time was the tail gunner.

Senator JOHNSON. Was the light so bright it blinded him?

Commodore PARSONS. I know this: He had his polaroid goggles set to maximum extinction, and he was also looking down into his machine gun when the bomb actually went. He got quite a lot of flash, anyway.

I got a flash through the side window, which indicated that the sky was sufficiently bright, even looking 90° from the bomb, to give you a flash through full-extinction polaroid goggles. That was at 8:15 in the morning, Japan time.

At 5:30 in the morning, New Mexico time, I was looking at the first atomic bomb from a B-29 rehearsing the Hiroshima job, and the flash there was tremendous, of course, because it wasn't in competition with

the sun. It lit up the whole sky, and it also went through these goggles, not quite blinding but almost blinding through full-extinction polaroid goggles.

Senator JOHNSON. How far away were you at that detonation?

Commodore PARSONS. I think we were about 28 miles slant range.

Senator JOHNSON. Did you feel the impact?

Commodore PARSONS. Barely. It was a very soft impact which was only felt by myself, the pilot who felt it on his controls, and the bombardier. The rest of the crew did not notice it at 28 miles.

The CHAIRMAN. How much of a toss did you get over Hiroshima?

Commodore PARSONS. Well, the crew who had been over Germany a lot and had been in heavy flak said it was just like a very close—about 20 to 25 feet—heavy antiaircraft shell bursting.

The CHAIRMAN. Was it like hitting an air pocket at all?

Commodore PARSONS. It is sharper than that. With an air pocket you usually have a slight warning. This thing came just like a blow.

I think Ashworth, who was over Nagasaki, said it was as if the B-29 were being beaten by a telephone pole.

Senator MILLIKIN. Did the flash have any unusual color?

Commodore PARSONS. We couldn't tell the color, because we were seeing it through these goggles. If you look at an electric arc through those goggles, it looks bright purple; and that is what this thing looked like, bright purple, like a tremendous electric arc.

Senator MILLIKIN. If you had looked at normal flak through the same goggles, would it have appeared the same?

Commodore PARSONS. The bursting of an antiaircraft projectile? No; I think it is much on the blue side. It is so hot it is like an arc rather than the color of a detonating explosive.

Senator MILLIKIN. If you looked at a big TNT explosion on the ground through those same glasses, would there have been any difference in the appearance of the flash?

Commodore PARSONS. It is very different, really. TNT will give a ball of fire which is red, I think, at night; and this is white or blue.

Senator MILLIKIN. The colored movies gave the effect of a very weird sort of light, at least weird because it is different, I suppose.

Admiral STRAUSS. Polaroid goggles depend on alined quinine crystals. They transmit only one color at extinction.

Senator MILLIKIN. Let me ask you this, Commodore: Assuming that we want to develop atomic weapons, in time, am I correct in the assumption that they could be delivered in a routine way, the same as a normal bomb, or will they always require sort of personal attention and handling in addition to that which you give to a normal bomb you are dropping out of a plane, let us say?

Commodore PARSONS. Well, I think they will always require attention by highly qualified people until nuclear physics is as common as ordinary explosive chemistry is now.

Senator MILLIKIN. You believe that in the evolution of the subject, if we evolve—if you would call it that—that you could deliver the bomb with a rocket or a pilotless plane?

Commodore PARSONS. I certainly do.

Senator HICKENLOOPER. I know we had some discussion the other day about the investigations in either Nagasaki or Hiroshima by a scientist who was over there investigating.

I don't believe his discussion as to the extent of this light was in executive session, was it? Didn't he discuss that in open meeting here about the question of this priest who was 3 or 4 miles away?

The CHAIRMAN. That is my recollection.

Senator HICKENLOOPER. As I recall Dr. Morrison's testimony, he said there was a priest about 4 miles away from the point of explosion of this bomb that went off over Nagasaki—one of the two places, anyway—and he said that the priest was apparently looking right in that direction, at that explosion, about 4 miles away on the ground, and he said they had no record or evidence of any effect on his eyes in any way, shape, or form, no blindness nor temporary blindness, as I recall.

He didn't say that there was not any, but he did not have any statement to make on that. It was my impression that being that close and looking right at it, at the tremendous blinding flash, from all we have read and heard, it should have some perhaps permanent effect on his eyes.

Commodore PARSONS. Well, I don't quite understand that priest's experience. I should think his feeling would be that he was blinded for half a day, or something like that.

Senator HICKENLOOPER. As I recall Dr. Morrison's testimony, there was no special emphasis laid on that, and I think he said there was a bright light, but they didn't have any record of any particular outstanding effect on this man's eyes. They got a direct report from a priest who had gone down there to help get some of the people out of there.

Commodore PARSONS. That does not quite check with the experience of one man who did not have blinders on his eyes in the New Mexico test. I don't know just how far he was away, but something in the order of 6 miles, and of course it was 5:30 in the morning and his eyes were dark-adapted, so he was in a position to be blinded much more easily than someone in the middle of the day with the sun shining. That man didn't recover for a day and a half.

Senator HICKENLOOPER. In all fairness to the statement that was made the other day, I think Dr. Morrison said they didn't have too much special data on that, but as far as he knew, there was no unusual effect, nothing that they had recorded as any general effect on the eyes.

The CHAIRMAN. I think that was General Groves, Senator, who had the letter from the Jesuit priest. He is the one who told us about that.

Senator HICKENLOOPER. As I recall it, it was a scientist, and I believe it was Morrison who had actually gone over there to view these things.

Commodore PARSONS. Two of our people in the delivery airplane, who were sitting up in the forward seats, the copilot and the bombardier, did not have their goggles on; they forgot to put them on. Of course, we were heading away from the thing, and they got the impression of a tremendous flash, but that is all. They were not damaged. They were not looking directly at it.

Senator HICKENLOOPER. It would be bad to have a blind copilot on a trip like that.

The CHAIRMAN. Because of business on the floor, we will have to recess. There are some other things that we will want to hear from

you, Admiral Purnell and Admiral Blandy, at 10 o'clock tomorrow morning, if that will be satisfactory. And, of course, Admiral Strauss, we want to hear from you.

Admiral STRAUSS. Will you want Dr. Gunn back again?

The CHAIRMAN. No; I believe not.

Admiral STRAUSS. Or Commodore Parsons?

The CHAIRMAN. I think, Commodore, unless you have something particular you want to tell us, that will be quite satisfactory.

I take it we will not be very long with you gentlemen tomorrow.

Admiral PURNELL. Frankly, Mr. Chairman, most of the information that I have has been covered by General Groves and Dr. Bush; that is the work of the Military Policy Committee; and as far as my part of the Navy effort goes, representing the Navy in the project, I can put it this way: It was probably the easiest job I ever had in my life. I had a White House overriding priority plus Admiral King back of me. I don't know of anything that could make work easier for you than that.

I can answer Dr. Gunn's statement on the information, but, in fact, General Groves could do it much better.

I passed on the requests that he sent up, I think, through Admiral Mills. They were taken up in the Military Policy Committee and discussed, and also the reports that were made of the process at the laboratory were passed on to the examining board which was set up under the scientific end of the project. It is my recollection that Dr. Briggs was the liaison man, and when any information was secured in the project which was considered to be of value to Dr. Gunn in his research, it was supposed to have been passed. At what time, I haven't any information. I could probably get it.

Senator MILLIKIN. Mr. Chairman, it would probably be more appropriate for executive session, but I should like to hear from somebody in the Navy as to the Navy's role in the possible development of atomic energy as a weapon, offensively and defensively.

Admiral BLANDY. I think I should probably answer that, Senator, because those are my present duties.

Senator MILLIKIN. Do you think that should be in executive session?

Admiral BLANDY. I think so, but some of it I could answer in open session.

Senator MILLIKIN. We could make a start with that in the morning.

The CHAIRMAN. We will recess until 10 o'clock tomorrow morning. (Whereupon, at 12:15 p. m., a recess was taken until 10 a. m. Friday, December 14, 1945.)

ATOMIC ENERGY

FRIDAY, DECEMBER 14, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Russell, Connally, Byrd, Johnson, Austin, Millikin, Hickenlooper, and Hart.

Also present: Dr. Ross Gunn, technical adviser to the naval administration of the Naval Research Laboratory; Commodore W. S. Parsons, assistant to the Deputy Chief, Naval Operations for Special Weapons; Edward U. Condon, scientific adviser; and James R. Newman, special assistant to the special committee.

The CHAIRMAN. This morning we will hear from Admiral Blandy. Will you go right ahead, Admiral.

STATEMENT OF VICE ADM. W. H. P. BLANDY, DEPUTY CHIEF,
NAVAL OPERATIONS FOR SPECIAL WEAPONS

Admiral BLANDY. My connection with the subject of atomic energy lies in the present and the future rather than with past developments.

On the 13th of November of this year the Chief of Naval Operations, with the approval of the Secretary of the Navy, established a Deputy Chief of Naval Operations to coordinate within the Navy Department all matters relating to research, test and development of atomic energy, guided missiles, and related devices, and to represent the Navy Department in Army-Navy and other composite organizations dealing with the same matters.

I was ordered to duty in that capacity on the 22d of November.

It might be worthwhile to give a brief résumé of my service, which apparently prompted the Navy Department to order me to that duty. I have been throughout my career both a combat-line officer and, since immediately after the last war, a postgraduate in ordnance engineering. From February 1941 to December 1943 I was Chief of the Bureau of Ordnance of the Navy Department, and from January 1944 until July 1945 I commanded a group of the amphibious forces under Admiral Turner and participated in the campaigns of Kwajalein, Saipan, Palau, Ulithi, Iwo Jima, and Okinawa. From July until November 1945 I commanded the cruisers and destroyers of the Pacific Fleet.

I have had my present duty such a short time that it has naturally not been possible to formulate a complete policy for the approval of

the Chief of Naval Operations and the Secretary of the Navy regarding development of these special weapons, but consistent with such limitations as may be imposed by Executive order, national law, and international agreement, it is my intention to utilize atomic energy to the fullest extent for naval purposes. That utilization will, of course, include atomic power as well as atomic explosives.

The exact manner in which we will use them, of course, is not even well known yet, and I would not be able to disclose in open session even our particular present plans.

At the present time I think that practically any one's idea as to how these things can be used for naval purposes will be more or less conjectural, even on the part of the officers most expert in the knowledge of atomic energy.

The tests of the atomic bomb against naval vessels, which we hope to conduct this coming year, will constitute a general guide toward what we may expect when bombs of certain type utilizing atomic explosives are placed in certain positions with respect to ships.

The CHAIRMAN. I take it, Admiral, you are not going to wait for the actual tests in order to formulate a plan of integration based upon what the physicists tell you they think the tests will be.

Admiral BLANDY. A plan for integration for what?

The CHAIRMAN. Of the atomic bomb into the future Navy.

Admiral BLANDY. That is quite correct.

The CHAIRMAN. My point is that I don't think you ought to wait until next summer until you actually run a test before thinking about how the thing is going to be integrated, but rather, based upon what the physicists tell you now, integrate it as far as possible and improve it by the tests. That is only my reaction, for I would assume you would approach it that way.

Admiral BLANDY. I am glad you brought that point out, Mr. Chairman, because that is exactly what we intend to do. We intend to go ahead and get confirmation of what we now predict will happen when the tests are conducted.

The CHAIRMAN. Have you gone pretty well along on those predictions, Admiral?

Admiral BLANDY. I haven't, personally, but the scientific personnel, both civilians and officers, have done so.

I would like to say one thing, Mr. Chairman, in extension of my reply to a question you asked yesterday. The Planning Committee, which is planning those tests, is composed of officers from all interested branches of both services.

The CHAIRMAN. Including the Army Air Corps?

Admiral BLANDY. Army Air Forces, Ground Forces, Navy Surface Forces, and Navy Aviators.

The CHAIRMAN. Admiral, do you suppose that after we come back in January, and in executive session, it might be possible for you to have here the officers and civilians who have been computing for you, shall we say, the life expectancy of surface ships in view of this thing? Would you have it in shape at that time?

Admiral BLANDY. I would like to have time, Mr. Chairman, to take that under advisement.

The CHAIRMAN. We will keep in touch with you on that.

Admiral BLANDY. I would like to make this comment now, though, in that connection, not directly in reply to your question, but because

there seems to be an impression that the usefulness and the reason for existence of a certain type of vessel or aircraft or weapon is determined by what can destroy it. That is a fallacy which seems to be quite common. Actually what renders a ship obsolete is not what can destroy it, but what can replace its function. Now, so long as that ship is needed to perform an essential function, it makes no great difference what can destroy it. If a badly needed ship is destroyed, we will replace it.

Take the aircraft carrier in the recent war, for instance. The aircraft carrier was a comparatively vulnerable ship, especially with all the gasoline and other inflammables aboard, and explosives in the form of bombs and ammunition. Nevertheless, when our carriers were sunk we replaced them with other carriers, because nothing else could do the job. The same is true of aircraft. Just because they are shot down, we do not stop building them.

Senator JOHNSON. But if the destruction is so effective that a ship cannot perform a useful function, then of course it becomes obsolete; so you do have to take into consideration the element of destruction.

If a navy can be destroyed before it can perform any useful function, then of course it becomes obsolete just as the bow and arrow did. I do not mean to infer that I believe that that is the situation.

Admiral BLANDY. In such case, we would become an entirely continental Nation and have to defend ourselves from our own territory.

Senator JOHNSON. But I don't think that is the situation.

Admiral BLANDY. I would like to point out, Senator, that there are, of course, numerous ways in which ships can be destroyed, but the question of probability comes in, too. The cheapest and easiest way to destroy a ship is, of course, by a match, but in order to do it you have to get the match into the powder magazine. That is fantastic, but ships actually have been destroyed by time bombs placed in their magazines when they were in a navy yard. The British had one destroyed that way in the last war. She got out of drydock and up to Scapa Flow, where she blew up; and the only explanation was a time bomb planted by German agents.

Senator JOHNSON. But of course that brings into play the element of personal failure, and personal failure never will be entirely eliminated, but relatively so, and it has been.

The feeling about such a thing as the atomic bomb is something that no human being can do anything about.

Admiral BLANDY. But the atomic bomb still has to be delivered into close proximity of the ships.

Senator JOHNSON. That is correct.

In connection with your reply, I want to ask if there is any defense against the atomic bomb?

Admiral BLANDY. There is no defense that I know of, Senator, at the present time except destruction of its carrier.

Senator JOHNSON. To intercept the carrier.

I also want to ask, Admiral, if you think there will ever be another great war, a world war, in which atomic bombs will not be used?

Admiral BLANDY. Any answer I would give to that, Senator, would be merely a guess.

Senator JOHNSON. Yes; I am certain of that; but you are an expert.

Admiral BLANDY. That would require not only a knowledge of weapons, but probably a greater knowledge of human nature than I

possess. I would say that the chances are pretty strong that in the unfortunate event of another major war atomic weapons would be used.

Senator JOHNSON. They are so effective that it just seems out of the question to me that if we do get into another war, one side or the other, and perhaps both sides, will not be using them. I cannot picture a world war in which they will not be used because of their vital effectiveness.

Senator HART. Admiral, in connection with Senator Johnson's original question to you, it is perfectly true that, over the vast reaches of the ocean, goods and men are going to be transported in peace and in war, and on the surface of the ocean.

In your estimation that is correct, is it not?

Admiral BLANDY. Yes, sir.

Senator HART. And in the event of war, with that transportation absolutely a necessary part, men will be fighting from, and on, and in, ships no matter what weapons are in existence to destroy them. Is that the case?

Admiral BLANDY. That is my belief, Senator.

Senator HART. Even if there were no surface warships at all, built as such, men still would be fighting from ships by means of guns or torpedoes or whatever can be thrown onto them when hostilities begin. Is that right?

Admiral BLANDY. I think that is highly probable; yes; so long as the sea is used for transportation. It is conceivable that the time might come when we no longer need to use the surface of the sea; but that time is certainly very far into the future.

If the sea were no longer needed as a highway and everything traveled by air, then you would no longer need fighting ships on the sea, because control of the sea would be unnecessary.

But I believe that the potentiality of any nation to make war is dependent on three, and only three, factors: her manpower, her materials, and time. If two opposing nations were equal in those three factors, the one will win which makes the most profitable utilization of all three of those factors.

It may be worth while, in order to gain time, to do what would ordinarily be uneconomical in the utilization of manpower and materials. That is, you may consume them at an extremely rapid rate, but if you gain time in war—which is all important—it might be worth while. It might be worth while, for instance, to transport armies completely by air, when and if that can be done, and keep them supplied by air over large expanses of sea, even though it could be done much more cheaply by surface ship so far as consumption of manpower and materials is concerned. The determining factor in this case would be time.

As I said before, however, this is looking pretty far into the future, and for a long time to come we are going to need to use the surface of the sea. It is and always has been the Navy's primary mission to gain that use for ourselves and to deny its use to the enemy; and that is what we did in the last war. We had to use the sea to get materials and troops to Germany and to the islands in the Pacific, and we had to defeat the German submarine on the one hand, and all arms of the Japanese Navy on the other to gain that use. We also had to deny the use of the sea to Japan in order to keep her from bringing

raw materials into Japan and sending out men and materials to the bastions of her stolen empire.

The CHAIRMAN. I am glad that, when you said the things we need are manpower, materials and time, you didn't say money.

Admiral BLANDY. Well, money is only a medium, I think. The fundamentals are manpower, materials and time. Money is a means of utilizing those things.

Senator JOHNSON. Before you leave that point, I would like to express the hope that the Admiral includes science with the three elements. I presume that is in the manpower.

Admiral BLANDY. That is part of the manpower. That is the brain power that lies in the manpower. There is also the will to win, but I consider that, too, as part of the manpower.

The CHAIRMAN. Admiral, I am not in any sense a military or naval strategist. I know nothing about it, and I approach it from that viewpoint, and when I try to think about it I realize my lack of background.

It does occur to me, however, that when these tests are run, in order to reassure the American people, it might be well to have a civilian board of scientists review the tests before they are run, a board that might be appointed by the President. I just throw that suggestion out, because there is going to be a tendency, you know, for a lot of people to say: "Well, the battleship boys want to keep their battleships. The aircraft boys want to keep their aircraft carriers."

It strikes me it might be a good idea to have some review by this board. What do you think about that?

Admiral BLANDY. Mr. Chairman, I heartily concur, and I shall convey your suggestion to the Planning Committee.

As I said yesterday, I am not doing all the planning for this thing; it is a joint effort of the Army and Navy. The Planning Committee's work hasn't been completed or approved, but I happen to know that they do contemplate a very similar thing, except I believe that the board will be composed of civilian scientists and officers, because it is possible that the civilian scientists alone might draw some incorrect deductions from a military standpoint without the guidance and assistance of some military and naval officers. But they certainly will be included for planning the tests, for conducting the tests, and for appraising the results.

Senator JOHNSON. Mr. Chairman, I don't want to pose as an expert or a crystal gazer, or anything of that kind. However, it does seem to me that it is apparent that atomic energy has driven the ships off the surface of the sea, but at the same time it has provided the means whereby ships below the surface of the sea can operate effectively by giving them the power. I don't see how a ship on the surface can resist the atomic bomb, but that doesn't mean that navies are obsolete provided they will adopt a new technique. If they will go below the surface, they will still be in the picture. If they don't, it will be just too bad.

Admiral BLANDY. There are a lot of people who will agree with you, Senator. I think I will wait for the tests.

Senator JOHNSON. Yes, I will wait for the tests, but the physicists and experts have convinced me that ships on the surface of the sea are going to be ducks on the pond, and I want to see them go down below where they cannot be seen and reached by the atomic bomb.

Senator HART. Mr. Chairman, may I supplement Senator Johnson's ideas in this way: I am thoroughly in agreement with him except I think that he does not realize how big the pond is, how much room there is to cover on this pond, which throws back to the element of probability which Admiral Blandy put in the picture.

You naturally have to take a risk, but if what is to be obtained by taking that risk is commensurate, then you take it and remain on the surface of the sea.

Senator JOHNSON. Yes; I think that is a very strong point and, if I were defending against a foreign power using atomic bombs, I would much prefer them to waste the atomic bomb sinking one ship than I would to have them drop it in the center of New York City, just on the point of effectiveness.

Of course from that point of view, a few ducks on the pond nicely scattered might serve a very useful purpose as a protection to our cities.

Admiral BLANDY. Mr. Chairman, if I may I would like to say one more thing about these tests. Insofar as I have anything to do with it, my own attitude is entirely objective. I don't want to prove anything; I don't want to disprove anything. I want to get the truth so we can come out with the best possible result.

The CHAIRMAN. That is the spirit I want to promote—not to prove anything, but to go at it as a scientist goes at it to analyze the thing and find out objectively, under the best possible conditions, what are the facts.

Admiral BLANDY. In other words, I want it to be a test and not a contest.

The CHAIRMAN. That is very well said, I think, very well said.

I feel as Senator Johnson does. Senator, you are not a naval expert and neither am I, and we probably disagree with Senator Hart. I feel, too, that it is going to be pretty tough on the surface ships—but we obviously cannot take any action on it until the tests prove or disprove that belief.

Senator JOHNSON. And then prove the other belief, too, the constructive belief of building ships that can withstand the atomic bomb, and I believe it can be done.

The CHAIRMAN. You mean surface ships?

Senator JOHNSON. No; I mean go down under where the atomic bomb cannot reach them or cannot discover them.

Senator HART. Then, you will get the submarines into the papers in the next war.

Admiral PURNELL. I might add that it may be the best vehicle for delivering it when it takes a rocket form.

The CHAIRMAN. Are you through, Admiral?

Admiral BLANDY. Yes.

The CHAIRMAN. Admiral Strauss.

Admiral STRAUSS. You were in the midst of Admiral Purnell's testimony when we adjourned yesterday, Senator.

The CHAIRMAN. Admiral, the last thing I remember you said was that you had a pretty easy job because you had a White House priority and backing by Admiral King.

Was it easy because of that, or was it easy because you didn't have very much to do?

STATEMENT OF REAR ADM. WILLIAM R. PURNELL, ASSISTANT
CHIEF OF NAVAL OPERATIONS FOR MATÉRIEL

Admiral PURNELL. It was easy because all I had to do was to ask for it.

The CHAIRMAN. Ask for what?

Admiral PURNELL. For the Navy support to the projects, and I got it, with no questions asked.

The CHAIRMAN. You were the Navy's representative upon the Interim Military Policy Committee?

Admiral PURNELL. That is right, the Military Policy Committee.

The CHAIRMAN. Were you in pretty close touch with that development at Oak Ridge?

Admiral PURNELL. I have been to Oak Ridge, yes, and I knew what they were doing.

The CHAIRMAN. When did you first go down there?

Admiral PURNELL. January 1944, I think it was.

The CHAIRMAN. Did you know before that what was being done down there.

Admiral PURNELL. Yes, sir; I was detailed by Admiral King late in August of '42, and I became a member of the Military Policy Committee when it was formed in September of '42.

The CHAIRMAN. Did Dr. Gunn's requests come to you?

Admiral PURNELL. They came through me, yes.

The CHAIRMAN. And you transmitted the information you got to Dr. Gunn?

Admiral PURNELL. I didn't get any.

The CHAIRMAN. You didn't get any?

Admiral PURNELL. No, sir, it didn't come back to me.

The CHAIRMAN. To whom did it come back?

Admiral PURNELL. There were two different boards of scientists appointed at different times to study the reports from the laboratories, and also, when specific requests were made, I delivered those to the Military Policy Committee, and I think they were delivered to Dr. Bush—either Dr. Bush or Dr. Conant.

The CHAIRMAN. What I am trying to find out, Admiral, is, after you delivered your request to the Military Policy Board, what did they do then?

Admiral PURNELL. They were then passed to these two boards that were appointed, and as I remember it Dr. Briggs was the chairman of one of these boards, and he was also designated as the liaison to pass information to the laboratories.

The CHAIRMAN. Admiral, you were the top fellow in the Navy on atomic energy?

Admiral PURNELL. Yes, sir; I was the senior one.

The CHAIRMAN. You were the senior member?

Admiral PURNELL. Yes, sir.

The CHAIRMAN. Did you receive response to your requests for information that were transmitted by Dr. Gunn through you?

Admiral PURNELL. I received reports at the Military Policy Committee meetings that that was being handled and looked out for by those boards that were appointed and by Dr. Briggs.

The CHAIRMAN. Yes, but you asked for information; did you get it?

Admiral PURNELL. The laboratory asked for it, and I delivered the request, because I was the Navy representative on that committee.

The CHAIRMAN. But did you get it back?

Admiral PURNELL. Not through me, no, sir. I was told it was being handled by the scientists through Dr. Briggs.

The CHAIRMAN. They were supposed to give it back through some other channel to Dr. Gunn?

Admiral PURNELL. Direct, yes, as far as I know.

The CHAIRMAN. But Dr. Gunn has testified he never got it.

Admiral PURNELL. Well, it was the understanding, I think, with the Manhattan project that information that was considered by the scientists to be of value to the research laboratory would be passed to them. That was my understanding.

The CHAIRMAN. So you never got any, so it was never of any value.

Admiral PURNELL. I never got any, no, sir.

The CHAIRMAN. Do you know of anybody else who got any?

Admiral PURNELL. No, except the assurance I got that it would be handled; that is all.

The CHAIRMAN. But it wasn't handled.

Admiral PURNELL. Well, I take Dr. Gunn's word for that, yes.

The CHAIRMAN. You were in constant touch with Dr. Gunn?

Admiral PURNELL. No, sir.

The CHAIRMAN. At least he kept asking you or furnishing you with memoranda of things he would like to be provided.

Admiral PURNELL. They usually came through Admiral Van Keuren.

Dr. GUNN. And Admiral Mills.

Admiral PURNELL. They were passed to me in letter or memorandum form and I delivered them to the Military Policy Committee.

The CHAIRMAN. I can see them going up, Admiral, but I cannot see anything coming back.

Admiral PURNELL. In the first place, I don't think they would let that information get very far out of the regular channel. The channel that was established for the passing of that information was through Dr. Briggs to the laboratory to Dr. Gunn.

The CHAIRMAN. Then, in other words, Admiral, you were a one-way street. You took it up, but it didn't come back through you.

Admiral PURNELL. It didn't come back through me, no, sir.

The CHAIRMAN. As far as you know, the only way it came back was through Dr. Briggs to people that were interested?

Admiral PURNELL. That was the established channel for the flow of information.

The CHAIRMAN. Who were the people who were interested in the Navy?

Admiral PURNELL. The Bureau of Ships, due to the fact that the Research Laboratory was under the Bureau of Ships at that time.

The CHAIRMAN. Who was in charge?

Admiral PURNELL. Admiral Cochrane and Admiral Mills.

The CHAIRMAN. Where are they now?

Admiral PURNELL. They are here, sir.

The CHAIRMAN. We had better hear them.

Admiral PURNELL. Frankly, I think they are in the same position that I am, that they passed them to me and I passed them to the Policy Committee, and then they were studied by the scientists. What happened after that, I don't know, sir.

The CHAIRMAN. In other words, are you saying that Admiral Mills and Admiral Cochrane did not get anything back?

Admiral PURNELL. No, sir; I don't think that channel was established. It was later on in the project.

Senator HART. Mr. Chairman, I was likewise having something of a misconception of what the Policy Committee, of which Admiral Purnell was a member, were doing as regards research. My understanding from what he says now is that it was really a higher level concerned with the production and what was to be done from the military standpoint; and it was rather natural that between scientists the channel should be direct. Is that right, Admiral?

Admiral PURNELL. That was the plan on which we worked; yes.

The CHAIRMAN. I confess—and I may be stupid about it, Admiral—that I have not got the set-up at all clear in my mind, and I want to get it clearly set up.

Dr. Gunn was in charge of the laboratory. He was your chief man in nuclear physics.

Admiral PURNELL. He was on the power end, Mr. Chairman. He was not in the explosive end at all.

The CHAIRMAN. Who was on the explosive end?

Admiral PURNELL. No one in the Navy. That was entirely in the Manhattan District project.

The CHAIRMAN. You had nothing to do with atomic energy for explosive purposes?

Admiral PURNELL. Entirely, but not for power purposes. That is, the Manhattan District devoted very little attention to a development for power.

Senator MILLIKIN. Mr. Chairman, may I make a suggestion?

To avoid confusion both ways, let me suggest that the witness be asked to describe the chain of authority upward for power and upward for weapons, as far as the Navy is concerned, from the laboratory up.

Admiral PURNELL. There was really no organization for the development of power.

Senator MILLIKIN. I am speaking now only of the channel of communication from the laboratory up to wherever it went on the power side and on the weapon side.

Admiral PURNELL. On the power side, it came up from the research laboratory through Admiral Van Keuren to the Bureau of Ships.

Senator MILLIKIN. Who was the Admiral?

Admiral PURNELL. Admiral Van Keuren was in charge of the research laboratory. Then Admiral Mills was detailed to handle it in the Bureau of Ships. He usually brought it personally to me.

Senator MILLIKIN. Then it went to you?

Admiral PURNELL. Yes, sir.

Senator MILLIKIN. Then where did it go?

Admiral PURNELL. I took it personally to the Military Policy Committee. It never went into what we call correspondence channels.

Senator MILLIKIN. Now, if anything were to come back, what happened?

Admiral PURNELL. Then the Military Policy Committee, primarily under the direction of Dr. Bush aided by Dr. Conant, set up boards or committees—I don't recall just what they were called at the time—first, to study the process that was developed at the laboratory, and next to go over the reports of their progress, and then in ordinary conversation at the committee's meetings there would be discussions.

Senator MILLIKIN. You are talking about scientific meetings?

Admiral PURNELL. The Military Policy Committee meetings.

The CHAIRMAN. Of which you were a member?

Admiral PURNELL. Yes, sir.

Senator MILLIKIN. Do you mind if I get clear where that sat in the hierarchy?

Admiral PURNELL. I had better start down from the top, then. The first committee established was the one under the Vice President. I am not sure of the composition of that committee. It was Mr. Wallace, the Secretary of War, General Marshall, Dr. Bush, and I think one other member.

Senator MILLIKIN. That is what you referred to when you referred to the military committee.

Admiral PURNELL. No, sir; that was the Presidential committee.

Senator HART. I think that set-up is described in Dr. Smyth's book.

Admiral PURNELL. That is right.

Senator MILLIKIN. I think we ought to have it here, because we have got so much confusion as to what this channel of communication is.

Admiral PURNELL. Now, under that committee, which passed on very general topics, the Military Policy Committee was set up by the President. Dr. Bush was the chairman, General Styer was the Army member, I was the Navy member, and Dr. Conant was alternate to Dr. Bush. General Groves was executive officer of that committee and in direct charge of the project. The questions of policy, the decisions of processes to be followed, and expenditures, what plants should be built, and the size of them and when they should be added to, a discussion of the reports made, and what we could expect from each one of the processes, and so forth, were the questions that were handled by the Military Policy Committee.

Senator MILLIKIN. Starting then from the laboratory, that went up through you to this Military Policy Committee?

Admiral PURNELL. Yes, sir.

Senator MILLIKIN. Now, if anything were to come down—and I understand nothing did come down—it would come through those same channels?

Admiral PURNELL. No, sir; those were not official correspondence channels. That was merely a way of getting a request from the laboratory to the policy committee.

Senator MILLIKIN. If that policy committee had decided to send something back, what possible channels might it have used?

Admiral PURNELL. The committees to study the reports and the requests from the laboratory were set up by Dr. Bush, I think. I would not say that for sure. General Groves may have set them up, and, I presume, on recommendation of Dr. Bush. I think Dr. Briggs was chairman of both of those committees, except one report which was

very technical and very scientific. I am not sure but what Dr. Tolman was the chairman of that.

Now, Dr. Briggs was the contact between those committees and the Naval Research Laboratory.

Senator MILLIKIN. If the committee wanted to send word back to Dr. Briggs, it would have normally sent it through that contact?

Admiral PURNELL. Yes, sir.

Senator MILLIKIN. And so far as you know, no word came back through that contact?

Admiral PURNELL. No, sir. The only assurance I got was the fact that when information was available that was of value to the laboratory in their work it would be passed to them.

Senator MILLIKIN. Then, may it be fairly concluded that the policy committee to which you referred presumed to determine what the naval laboratory should or should not work on?

Admiral PURNELL. Well, the scientists did, and we approved it.

Senator MILLIKIN. That is what I mean.

Senator AUSTIN. Admiral, do you participate in it?

Admiral PURNELL. In the policy committee, yes sir.

Senator MILLIKIN. Should we trace out the weapon angle of this? As I understand it, the Navy was not interested in the weapon angle; or am I wrong in that?

Admiral PURNELL. We were decidedly interested in it.

Senator MILLIKIN. You did not work on it?

Admiral PURNELL. The work particularly that Commodore Parsons did was, I should say, as important as almost any part of the bomb.

Senator MILLIKIN. Is there any question before the committee, Mr. Chairman, as to whether we should trace out the channels as far as the weapon end is concerned.

The CHAIRMAN. I think not. I think it is pretty clear as to what the situation was there. I was just trying to find out why Dr. Gunn, who had requested information from time to time that would be helpful to him, hadn't gotten it. Apparently the liaison back from Dr. Briggs was never established.

Admiral PURNELL. I don't recall that any specific information was ever requested. It was reports on what the laboratory was doing. Then the scientists judged, knowing what we did, from the Manhattan District whether anything discovered there would help progress at the Naval Research Laboratory.

The CHAIRMAN. Did you ever get anything back, Dr. Gunn?

Dr. GUNN. No official information.

The CHAIRMAN. No official information?

Dr. GUNN. That is correct.

The CHAIRMAN. Did you ever talk to Dr. Briggs about the results?

Dr. GUNN. Many times, and I asked for information from time to time, which apparently we were not to receive, and he said, "Take that up with your naval representative."

Senator CONNALLY. You say you didn't get any official information. Did you get any unofficial?

Dr. GUNN. There was some small amount of information going around which bore on the problem; that is correct.

Senator CONNALLY. Well, it was from authoritative sources, wasn't it?

Dr. GUNN. Not necessarily.

Senator CONNALLY. Well, it wasn't hall talk?

Dr. GUNN. No; that is correct.

The CHAIRMAN. Do you have anything further, Admiral?

Admiral PURNELL. No, sir; I don't think of anything.

Commodore PARSONS. I might give an example of how the information went in the other direction from the Naval Research Laboratory.

We wanted to know something about the separation of isotopes by the method that they were developing, so Dr. Oppenheimer wrote a letter to General Groves saying that this information would be of value to us and requesting that it be obtained.

General Groves turned that request over to Dr. Conant, who, I think, through Admiral Purnell or Admiral Mills, requested the reports. The reports came almost immediately. That was the channel we used.

The CHAIRMAN. Who did the reports go to?

Commodore PARSONS. To Los Alamos.

The CHAIRMAN. You are talking about furnishing them to Los Alamos?

Commodore PARSONS. I am saying I was at Los Alamos, you see. We conceived the need for that report, and that is the way we got it.

Senator CONNALLY. What report?

Commodore PARSONS. It was a report on progress on the separation of isotopes.

Senator CONNALLY. In the Naval Laboratory?

Commodore PARSONS. That is right.

Senator JOHNSON. Mr. Chairman, I want to ask Admiral Purnell a question or two in regard to the liquid thermal diffusion plant at Oak Ridge.

You say you visited Oak Ridge several times?

Admiral PURNELL. No, sir; I have only been there once since the project got started.

Senator JOHNSON. But I understood yesterday from Dr. Gunn's testimony that the Navy was particularly interested in the liquid thermal diffusion process.

Admiral PURNELL. Yes, sir.

Senator JOHNSON. Did you concur in the present status—not saying what the present status is—of the liquid thermal diffusion experiment at Oak Ridge? Did you concur in that, or are you in accord with what is done there now?

Admiral PURNELL. Yes, sir. If you remember Dr. Gunn's testimony yesterday there was a small pilot plant—you would call it that wouldn't you, Doctor?

Dr. GUNN. That is correct.

Admiral PURNELL. There was a small pilot plant here at the Research Laboratory. Later that was expanded. In its relation to Oak Ridge it was still a pilot plant. It was built at Philadelphia at the boiler laboratory on account of the availability of steam.

The design and construction of the plant at Oak Ridge were made directly from the pilot plant at Philadelphia and designed by Dr. Gunn and Dr. Abelson, I think. Dr. Abelson trained the men to operate the one at Oak Ridge, and on that line of the development came directly into the Manhattan project.

The CHAIRMAN. I take it, Admiral, that the output from the Navy was good, but the intake wasn't very much?

Admiral PURNELL. Well, it probably wasn't on the power side, and there was no need for it on the explosive side. We were primarily interested in getting a bomb.

I am not a scientist and I cannot judge it, but I saw no hope whatever of harnessing atomic power during this war, or even for the next war; I don't know. Now, the power development was primarily what the Research Laboratory was studying and working on.

When it became known that they could use the product from the liquid thermal diffusion to increase the output of the electromagnetic process at Oak Ridge, that was when that development was drawn into the Manhattan project.

The CHAIRMAN. I have only one further question.

Dr. GUNN, how many requests did you make in writing?

Dr. GUNN. I don't know how many were made in writing, sir—perhaps three or four.

The CHAIRMAN. How many did you get back?

Dr. GUNN. I think any information that I wanted amounted to zero.

Senator CONNALLY. Is this a post-mortem over who did it between the two services, the Army and the Navy?

I knew they were in a squabble about uniting or being divided, but I didn't think it went to the point of what had happened already.

The main thing was that you got the bomb, didn't you?

Admiral PURNELL. Yes, sir.

Senator CONNALLY. You couldn't have two outfits working on it at the same time very successfully?

Admiral PURNELL. Yes; and I think if there was a slip or if I slipped in passing information—it was not my channel to pass it down—I would attribute it to the fact that we were after a bomb, and we knew that power could be developed in time after the bomb was used.

Senator CONNALLY. Certainly power is secondary or "third-dary" or "fourth-dary" to me. I don't think the power is of any great consequence at the moment, but I hope that the Army and Navy will show a little more spirit of cooperation without fussing at everybody after it is all over and the bomb has been discovered.

I have always supported the Navy and am a big Navy man; but I think they ought to be big too.

Senator JOHNSON. Mr. Chairman, I would like to direct the question which I asked Admiral Purnell to Dr. Gunn.

Without saying anything about the present status of the liquid thermal diffusion process at Oak Ridge, are you entirely satisfied with the present status?

Dr. GUNN. Yes; I think that the operations down there have demonstrated that it is useful. The question that you ask is really two-fold, one a technical one and one a practical one.

I think it is fair to say that the scientists are not satisfied with any method of isotope separation. We think they are all rather expensive, and in that sense we are unsatisfied.

But in terms of what we have, I think utilization at Oak Ridge was entirely satisfactory.

Senator JOHNSON. My question is more whether or not the liquid thermal diffusion process had its day in court?

Dr. GUNN. Yes, sir.

Senator JOHNSON. And had its opportunity?

Dr. GUNN. Yes, sir.

Senator JOHNSON. Thank you, Doctor.

The CHAIRMAN. Admiral Strauss, have you anything to add?

Admiral Strauss. No, sir.

STATEMENT OF REAR ADM. LEWIS L. STRAUSS, DEPUTY CHAIRMAN OF THE ARMY-NAVY MUNITIONS BOARD AND SPECIAL ASSISTANT TO THE SECRETARY OF THE NAVY

Admiral STRAUSS. Mr. Chairman, I think I am the least important of the Navy witnesses. I should perhaps qualify myself for being here, as Admiral Blandy has done. I am not expert in either the strategy or the policy of the matter. My interest in the subject began as early as 1938 when I set up a foundation and started work in a laboratory at the California Institute of Technology that had been turned over to me by the Institute, on the production of isotopes by bombardment of the familiar elements with high-speed particles from a surge generator of special design that I constructed together with some friends of mine; and when the successful experiment in atomic fission took place in Germany a year later, we naturally turned to that as a more direct method of producing the materials we sought, the purpose of which was primarily to facilitate research and eventually therapy in the field of cancer.

When I reported for duty in the Navy in 1941 I had the good fortune to be assigned to Admiral Blandy, whom I served as principal staff assistant when he was Chief of the Bureau of Ordnance. I have since been an adviser and assistant to the Secretary of the Navy in these and related matters.

I relieved Under Secretary Bard upon his resignation as the naval member of the Interim Advisory Committee on Atomic Energy. My function here has simply been to organize this testimony.

I doubt whether I have any information that is of value to your committee; but such as it is, it is at your disposal.

The CHAIRMAN. The Medical Bureau of the Navy has been very progressive in times gone by. Have they done any experimental work, as far as you know, in using this for medical treatment?

Admiral STRAUSS. I am unable to say, sir; but I think it would be an interesting field to explore, and Vice Admiral McIntire, if called before this committee, would be qualified to testify.

The CHAIRMAN. Is there anything else, Admiral?

Admiral STRAUSS. I have nothing to add, sir.

Commodore PARSONS. Some question was raised about the possible squabbles about cooperation between the Army and Navy.

I was naval officer from the middle of Naval Ordnance and sat in the middle of the councils of the Manhattan District as associate director at Los Alamos, and I would say the cooperation was almost ideal. That included the Air Forces, also, the Manhattan District, the Navy, and the Air Forces.

I think Admiral Purnell will bear me out. The whole question was winning the war and getting the bomb into the war as fast as possible.

The CHAIRMAN. I am glad to hear that.

Gentlemen, if there is nothing further to add, we will thank you very much, and will be seeing you again.

The committee will meet again on Wednesday morning at 10 o'clock to hear testimony from some industrialists and engineers who have been in the process of getting prepared.

(Whereupon, at 11 a. m., the committee recessed until 10 a. m., Wednesday, December 19, 1945.)

ATOMIC ENERGY

WEDNESDAY, DECEMBER 10, 1945

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Johnson, Tydings, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward U. Condon, scientific adviser, and James R. Newman, special assistant to the special committee.

The CHAIRMAN. The committee will be in session.

Mr. Creedon.

STATEMENT OF FRANK R. CREEDON, FORMERLY WITH STONE & WEBSTER ENGINEERING CORP.

The CHAIRMAN. Mr. Creedon, you are from Stone & Webster, and I believe you took considerable part in the Manhattan project.

Mr. CREEDON. Yes, from January 1, 1944, to January 27, 1945, I was the resident manager for Stone & Webster Engineering Corp. in charge of the construction of what we called Y-12. My association with Stone & Webster Engineering Corp. consisted of this special assignment only. I have not been associated with Stone & Webster since January 27, 1945.

The CHAIRMAN. Y-12 is the gas diffusion plant.

Mr. CREEDON. No, that is the magnet plant.

The CHAIRMAN. The electromagnetic?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Now, sir, I imagine the committee will have some questions to ask you, but I would like to have you go ahead and tell us about what you did, how difficult you thought it was while you did it, and possibly you can give us some estimate as to how long you think it would take any other industrial nation—without being specific about it—to accomplish the same thing.

Mr. CREEDON. Prior to my part in this job, I was the Deputy Rubber Administrator under Mr. Jeffers in charge of the synthetic-rubber construction program, and, prior to that, for the Army engineers, in charge of the construction of all munitions plants. Therefore I had seen a great many of our very large construction efforts during the war.

From the standpoint of complexity and magnitude this was at least $2\frac{1}{2}$ times the size of the largest war project that I know of. As for

98000 O - 49 - 4

407

complexity of installation, it was also the most complex and the most difficult to install.

Some of the problems and difficult design and installation phases were, I think, that we had to design and install a vacuum system that was more nearly perfect than any vacuum system that I know of that ever was installed on any construction project.

Senator AUSTIN. May I ask a question there for identification?

The CHAIRMAN. Surely, Senator Austin.

Senator AUSTIN. Was this electromagnetic system one where great care had to be exercised about cleanliness and absence of moisture?

Senator AUSTIN. Signs on the floor, "Do not spit here"?

Mr. CREEDON. Yes, sir.

Senator AUSTIN. All right; that just helps to bring the picture back to memory.

Mr. CREEDON. Also the oil system was an extremely difficult problem because of the nature of the oil and the extent of the system. It was very difficult to get a tight system and to get satisfactory circulation.

Some of the very difficult problems involved were the design of what we call magnets, the design of bins or tanks, the design of manifolds, the design of diffusion pumps, the design of vacuum pumps, and it was a matter of designing and installing something that we had never had any previous experience with—and I don't think anybody else did, either.

The CHAIRMAN. Did you have charge of building any of the synthetic-rubber plants?

Mr. CREEDON. All of them, sir.

The CHAIRMAN. Would you give us a comparison of the difficulties encountered in that? After all, that was a somewhat new field, too, although the ground, I believe, had been plowed somewhat in making synthetic rubber.

Mr. CREEDON. Yes; I could say that the design and construction of Y-12 was much more difficult than the design and construction of any of our synthetic-rubber plants in that it was, as I say, embarking on things that had never been done before from an engineering standpoint.

Senator HART. Mr. Creedon, have your experiences led you into touch with the state of industries similar to yours in other foreign countries, so that you have a fair acquaintance with their abilities?

Mr. CREEDON. No, sir.

The CHAIRMAN. Mr. Creedon, is there anything else that you would like to tell us about your experience there? How many men were under you at any one time?

Mr. CREEDON. At the peak?

The CHAIRMAN. Yes.

Mr. CREEDON. Approximately 30,000.

The CHAIRMAN. Roughly, how would you divide those 30,000?

Mr. CREEDON. I would say 6 percent, or thereabouts, administrative, probably another 4 or 5 percent strictly engineering, and the balance would be supervisors, superintendents, mechanics, and laborers.

Senator AUSTIN. May I ask a question at that point?

Were the same men used for operations who were employed for construction of these delicate machines with fine pipes that had to be welded with great accuracy and strength?

Mr. CREEDON. No, sir.

Senator AUSTIN. So that you had to have a construction gang on there first to put them in?

Mr. CREEDON. Yes, sir.

Senator AUSTIN. Now, as to maintenance, they had to be maintained with great care all the time, didn't they?

Mr. CREEDON. Yes, sir.

Senator AUSTIN. Did Stone & Webster handle that?

Mr. CREEDON. That was handled by the operator, Tennessee Eastman Corp.

Senator AUSTIN. Your connection then with that electromagnetic plant ended with the installation, did it?

Mr. CREEDON. Well, we completed the installation and turned an operating plant over to the operator and stood by with mechanics for a short period in order to help tide over and help them take up the maintenance; yes.

Senator AUSTIN. There must have been a period of education in there; that is, from the engineering to the operating transactions there must have been a liaison to understand that plant?

Mr. CREEDON. Indeed, for example, in operating the complicated oil system, their people came in and worked beside our people while we operated the various valves, and so forth and so on, until they became familiar with the system.

Senator AUSTIN. Now, from the laying of the foundation to the putting on of the finishing touches to the plant, how long did it take?

Mr. CREEDON. Approximately 2½ years.

Senator AUSTIN. And during the 2½ years you had the service of how many men on construction?

Mr. CREEDON. Well, our peak on construction was roughly 28,000.

Senator AUSTIN. In this transaction, what factor did research and special skill play? Was it an indispensable thing in the construction of this plant to have men who had the special skills to try the plant out in advance and make a picture of it?

Mr. CREEDON. Yes, they had, of course, to study out and prepare and present basic scientific data.

Senator AUSTIN. Did Stone & Webster handle all of that? Were they the people who furnished the ideas that went into this plant?

Mr. CREEDON. No; they were furnished by the scientists.

Senator AUSTIN. And Stone & Webster did not have them on their pay roll?

Mr. CREEDON. No, sir.

Senator AUSTIN. Thank you.

The CHAIRMAN. In other words, the scientists were the architects, and you were the contractors?

Mr. CREEDON. No, the scientists were not the architects. The scientists furnished the rough basic scientific data, and then Stone & Webster had to take that basic scientific data and convert it into designs and drawings.

The CHAIRMAN. Now, did you have a crew of mechanical engineers to do that job?

Mr. CREEDON. Oh, yes. All drawings for procurement or for construction were by others than the scientists.

The CHAIRMAN. What did you do after you got those drawings made? Did you go back to show them to the scientists and go over them together before you actually proceeded to work?

Mr. CREEDON. In certain drawings the scientists collaborated, and then the operator collaborated very extensively in practically all drawings.

The CHAIRMAN. You do a world-wide business, don't you—Stone & Webster?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Who is the man in your organization who could give us the best bird's-eye view of the state of engineering and mechanical accomplishments around the world, and the ability of the other firms around the world to compete in the field with you?

Mr. CREEDON. I would say Mr. J. R. Lotz, the chairman of the board.

Senator AUSTIN. I have a question on this organization set-up. Is there any one man in the organization of Stone & Webster who handles all of these different foreign projects?

Mr. CREEDON. They all head up under Mr. Russell Branch, the president of Stone & Webster Engineering Corp.

Senator AUSTIN. For instance, for China you have a person who has charge of the Far East, do you not?

Mr. CREEDON. I do not know.

Senator AUSTIN. And for European service, Spain, for example, you have somebody who attends to that particular activity of Stone & Webster in Spain?

Mr. CREEDON. I do not know.

Senator AUSTIN. You also have many different subsidiary companies that handle the different activities in the foreign fields?

Mr. CREEDON. I do not know.

The CHAIRMAN. I wonder if you would talk with Mr. Lotz and Mr. Branch, Mr. Creedon, and tell them that we will be interested in hearing from them after the Christmas recess.

I think, Senator Hart, that is what you would like particularly, and you, Senator Austin—a sort of over-all view.

If you will talk to them and tell them we will be in contact with them, we would appreciate it. Ask them to come down; it won't take them very long.

Senator AUSTIN. Does Harry Arthur have anything to do with these activities in foreign fields?

Mr. CREEDON. I do not know.

Senator MILLIKIN. After your consultation with scientists, then you would lay this out in the form of drawings and specifications? That would be your own function?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. And then of course the job would be to translate that into actual machinery?

Mr. CREEDON. Yes; that is correct, to place orders against those designs.

Senator MILLIKIN. In a normal large construction job, of course, you try to conform to standard materials as much as possible?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. And that greatly facilitates the job if the standardized materials are available?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. I think you have made it rather clear, but I would like to emphasize it if it isn't clear, that the design of this particular plant to which you have been referring got almost completely outside the field of standard design and standard materials. Is that correct?

Mr. CREEDON. That is correct, sir.

Senator MILLIKIN. And when you get outside of that field, I assume that you have special problems of metallurgy, for instance in the making of a valve. Is that correct?

Mr. CREEDON. Generally speaking we used standard valves.

Senator MILLIKIN. I don't care to name any particular machine, but aside from a few standard things of that kind, the main features of your plant were especially designed and required unstandard materials; is that correct?

Mr. CREEDON. That is correct, sir.

Senator MILLIKIN. And that in turn involved an enormous amount of specialized know-how, didn't it?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. Ramifying, you might say, through almost all of our industrial specialties in this country?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. Is there any country in the world today that has available to it that specialized know-how and the industry that would be available to make these specialized products?

Mr. CREEDON. Answering your question this way, I don't think that this project could be built without several great industrial companies; for example, to name three of them, General Electric Co., the Westinghouse Co., and Allis-Chalmers Co.

Senator MILLIKIN. Is there any country in Europe that either has in its own organization or has available to it in Europe in any one or more countries of Europe the know-how that we have been describing, and the specialized industry that could provide or set up a plant of this kind without great long delay?

Mr. CREEDON. So far as I know; no, sir. As to whether or not anybody in a foreign country could do, for example, what it was necessary for General Electric to do, or for Allis-Chalmers to do, I think that the representatives—which I believe are present—from those concerns could answer that better than I can, sir.

Senator MILLIKIN. Let me get your opinion on this: Supposing that X country in Europe wanted to assemble a plant of this kind. Could it, by shopping around, do an assembly job, get something, let us say, in Y country and something else in Z country and something else in A country? Would it be feasible to shop around and finally assemble a plant?

Mr. CREEDON. You mean including shopping around in the United States?

Senator MILLIKIN. Let us exclude shopping in the United States for the time being.

Mr. CREEDON. I don't believe that a plant similar to this could be built in a foreign country without the aid of concerns in the United States.

Senator MILLIKIN. You have in mind Switzerland, France, Belgium, Holland?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. And what is left of Germany?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. Sweden?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. Could Great Britain do the job?

Mr. CREEDON. Without the United States, no, sir.

Senator MILLIKIN. Could Great Britain do the job with the aid of other European countries?

Mr. CREEDON. I don't believe so.

Senator MILLIKIN. Thank you very much.

Senator AUSTIN. How about Canada?

Mr. CREEDON. I don't believe so, not without the aid of our great concerns in America.

Senator MILLIKIN. I assume you would qualify your answer to this extent: That given limitless money and limitless time they probably could build up the necessary techniques and the necessary industries to do the job?

Mr. CREEDON. Oh, yes; certainly.

Senator MILLIKIN. Could you put a time factor, or is there a time factor in your own mind as applicable to the various hypothetical situations that I have portrayed to you? Supposing any continental country in Europe started out to reproduce this plant. Supposing it had the money to reproduce it, and suppose it could shop around in Europe, continental, and Great Britain.

How long would it take to make a fair replica of what you have created here?

Mr. CREEDON. I don't know enough about the situation in foreign countries to give an intelligent answer to that question.

Senator MILLIKIN. Then you judge it would take a long time?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Have you traveled extensively in Europe?

Mr. CREEDON. No, sir.

The CHAIRMAN. Have you ever been in Europe?

Mr. CREEDON. No, sir.

The CHAIRMAN. Have you ever done any construction work outside of the United States?

Mr. CREEDON. No, sir.

The CHAIRMAN. You really haven't much of a basis for those answers, Mr. Creedon, have you?

Mr. CREEDON. I believe that is correct, sir.

Senator AUSTIN. Let me interpose at that point: I understood your answers as such that you can apply them to the United States. It would take a long time to begin at the beginning and reproduce one of these plants right in the United States with all our facilities, would it not?

Mr. CREEDON. Yes, sir.

Senator AUSTIN. About how long?

Mr. CREEDON. You mean to reproduce one of these plants in America?

Senator AUSTIN. Yes, starting at scratch here. Suppose we had wiped them out and they no longer exist, and we want to start over. How long would it take to reproduce a plant for this electromagnetic process?

The CHAIRMAN. Knowing what he knows now?

Senator AUSTIN. Yes, exactly, with your advantages now.

Mr. CREEDON. An all-out effort on the part of America and American industry?

Senator AUSTIN. Oh, no. I cannot imagine another war. We are going to stop that, so we probably wouldn't get an all-out effort.

But in peacetime, suppose that we had been so wise or unwise as a Congress that we decide we will just efface these things, we will wipe them out. By and by we are provoked to start afresh in peacetime without all that propulsive power of war. How long would it take us to erect an electromagnetic plan equally as efficient as the one that you did?

Mr. CREEDON. Oh, approximately 4 years.

Senator TYDINGS. May I ask a question, if you have finished, Senator?

Senator AUSTIN. Yes; I have.

Senator TYDINGS. Assuming that in the next year or two some country would come to your concern and to other concerns associated with you and make an attractive contractual offer to do similar work as the work which you have just described, how much would you lengthen your estimate of the time necessary to complete the plant, assuming there was reasonable cooperation and availability of the materials necessary to a foreign country?

Mr. CREEDON. And reasonable cooperation in getting, for example, materials that were needed from America?

Senator TYDINGS. Well, my question envisages a situation where you would have all the cooperation which a foreign government could give you, a great power that was in a position to make attractive offers to those who might want to supply the information, the technical and scientific knowledge, and was in a position to buy that in the world market so that there would be a reasonable flow of information that you might want to get to do this?

Mr. CREEDON. I should think it might take—

Senator TYDINGS. A year or two more, would you say?

Mr. CREEDON. Probably 7 or 8 years total.

Senator TYDINGS. In other words, to condense my own question, if your concern was hired to do this work in a foreign country and there was reasonable availability of material and science, you feel that you could do the work in 6, 7, or 8 years?

Mr. CREEDON. Perhaps 8 years, yes.

Senator TYDINGS. Now, assuming that there is unlimited money behind this project in a foreign country, what impediments do you see to completing such a plant if the foreign nation in mind could buy the advice, the scientific and engineering skill that it required to construct the plant?

Mr. CREEDON. The difficulty would be in that event the procurement of the necessary equipment, and so forth.

Senator TYDINGS. Well, suppose, for example, that I was the foreign agent having charge of this, and I would come to your concern and say, "I would like to employ your firm to do a particular job, one of the jobs or all of the jobs connected with this operation, and I will give you cost plus 15 percent profit and would arrange the exchange so you can take your profit back to your own country by deposits in your own country from month to month."

Would you undertake it?

Mr. CREEDON. I couldn't answer that. It would have to be either the chairman of the board or the president of the company.

Senator TYDINGS. Assuming that you were the chairman of the board or the president of the company, would you undertake it?

In other words, my question is simply this: What is to stop a foreign country from hiring your concern or any other concern at attractive prices to do the work?

Mr. CREEDON. If I were the chairman of the board or the president of the company, I would not take it; no, sir.

Senator TYDINGS. You would not take it for patriotic reasons?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. But assuming that the government didn't ask you, that the government simply said, "You are not in a position to turn over any information that you have learned in connection with this project, but you are at liberty to build in accordance with any blueprints or specifications that are furnished you in advance."

Would you then take it?

Mr. CREEDON. No, sir.

Senator TYDINGS. Is there any conceivable circumstance where you feel you would take it?

Mr. CREEDON. No, sir.

Senator TYDINGS. Suppose there is an agreement for the control of peacetime atomic energy, an international agreement, and our Government consents to the exchange of information for the manufacture of peacetime atomic energy, and that you were then offered this proposition to build a plant in accordance with that agreement. Would you then take it?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. It has been testified here in public hearings that a large percentage of the difficulties of manufacturing the atomic bomb are eliminated by the manufacture of peacetime atomic energy. Do you follow me?

Mr. CREEDON. That is correct, sir.

Senator TYDINGS. Now, that being so, and if there was an international agreement for the control of peacetime atomic energy, would you then take it—assuming there was an international treaty which permitted you to do it?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. There wouldn't be any reason why you shouldn't, as far as the Government had established the policy?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. Just as a layman and as an engineer and as a citizen, do you think it would be wise that knowing the devastating potentialities of the atomic bomb we should make such a treaty for the peacetime manufacture of atomic energy?

Mr. CREEDON. Well, if plants will be built to manufacture atomic energy in peacetime, it would take very little to convert them, and I would be a little worried about that.

Senator TYDINGS. I take it your answer means this: That if you consent to the peacetime manufacture of atomic energy on an international basis or treaty arrangement, that in effect you have consented to the possible manufacture—60, 70, 75 percent, or some place in there, let us assume—of the bomb itself?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. So that if you are opposed to the manufacture of the bomb and you invade that field of peacetime atomic energy, you really have given up three-quarters of your opposition to the manufacture of the atomic bomb, have you not?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. Do you know how long it might possibly take from the time the manufacture of atomic energy for peacetime purposes was completed to taking up the remaining processes necessary to manufacture the atomic bomb?

Mr. CREEDON. Approximately a year, or 15 months, or something like that.

Senator TYDINGS. So that if the manufacture of peacetime atomic energy is permitted, you are within a year or less of the manufacture of the atomic bomb, should any nation desire to do so?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. So I would take it from all your answers that in your opinion, if we have an agreement for the peacetime manufacture of atomic energy, we come pretty close to the possibility of the manufacture of the atomic bomb?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. As a policy, have you given any thought as to whether or not we should try to stop the manufacture of peacetime atomic energy, having in mind the potential development of the atomic bomb from such a preliminary step?

Mr. CREEDON. No, sir.

Senator TYDINGS. You haven't given it any thought?

Mr. CREEDON. No, sir.

Senator TYDINGS. That is all, Mr. Chairman.

Senator JOHNSON. Mr. Chairman, may I ask the witness one question following Senator Tydings' questions?

The CHAIRMAN. Yes, sir.

Senator JOHNSON. Under what restrictions and limitations are you operating at present as to the engineering know-how, other than your sense of patriotism?

Mr. CREEDON. I don't know the answer to that question, but I could find that out.

Senator JOHNSON. You don't know whether you are free to reveal or divulge any of the know-how?

Mr. CREEDON. I am practically certain that we are not to divulge anything whatever.

Senator TYDINGS. Either at home or abroad?

Mr. CREEDON. Yes, sir.

Senator JOHNSON. And that is a restriction placed on you, perhaps, by General Groves?

Mr. CREEDON. Yes, sir.

Senator MILLIKIN. I would like to ask whether that is by way of verbal instructions or written instructions?

Mr. CREEDON. I am unable to answer that. I don't know.

I know this much: That Stone & Webster would not give any information of any kind to anybody without getting clearance.

Senator MILLIKIN. Of course, I know you would not, but I think that Senator Johnson has opened up a very pertinent inquiry. Personally, I would appreciate it if you would—if it is agreeable with

the chairman—write the chairman whether your instructions to that effect do rest in writing or just verbal understandings.

Senator TYDINGS. And for how long a time they are to run.

Senator MILLIKIN. And it might not be a bad idea to send the instructions themselves.

Senator JOHNSON. Yes; we would like to know what all the conditions are.

Senator MILLIKIN. Has your concern made any studies on the dispersal of industry?

We have had a lot of testimony that we are so concentrated industrially in this country that we are subjected to extra-high hazards so far as the use against us of the atomic bomb is concerned.

Mr. CREEDON. To my knowledge, Stone & Webster have not made studies pertaining to dispersal of industry.

Senator MILLIKIN. Is there an engineer or any concern that might be able to give us expert testimony on that?

Mr. CREEDON. Offhand I can not think of any.

Senator MILLIKIN. It is a very speculative subject, of course, and I should not be surprised if it were a virgin field.

Senator HICKENLOOPER. Senator, I wonder if Mr. Creedon made himself completely clear in answer to your question as to whether or not Stone & Webster had made any surveys.

As I understood his answer, he said, "To my knowledge they have not."

Now, did you mean that you have knowledge that they have not, or that so far as you know they have not?

Mr. CREEDON. So far as I know.

Senator MILLIKIN. You were not indulging in a double negative.

The CHAIRMAN. Mr. Creedon, several of these integral parts were manufactured by General Electric, Westinghouse, and Allis-Chalmers?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. And Chrysler Corp.?

Mr. CREEDON. Not on our project, not Chrysler; but the first three were on our project; yes, sir.

The CHAIRMAN. Chrysler did great work in another one of the methods?

Mr. CREEDON. On the Carbide & Carbon project, I believe.

The CHAIRMAN. Of course these are great plants employing thousands and thousands of workers?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Some of the items that they manufactured are large, and some of them, I take it, are small in size?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Capable—many of the important ones—of being lifted up and taken away in a man's overcoat pocket; is that true?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. Do you know anything about the care that is taken at these three plants to see that that does not happen?

Mr. CREEDON. No, sir; I have not been connected with the project since January 27 of this year. I don't know just exactly what is done.

The CHAIRMAN. During the time of your connection with it, were you acquainted with any precautions that were taken at these three great plants with thousands and thousands of employees to prevent the contingency that I spoke about happening?

Mr. CREEDON. People walking out of the plants? Yes. To get out of the project you had to go through a gate where there was a guard.

The CHAIRMAN. You are talking about the Manhattan project now?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. I am talking about back at these plants where they were manufactured.

Mr. CREEDON. I don't know the situation at Allis-Chalmers, General Electric, or Westinghouse, sir.

The CHAIRMAN. That, to say the least, would be a source of "information," would it not?

Mr. CREEDON. Yes, sir.

The CHAIRMAN. To any unfriendly person who was trying to get that information, and also trying to get a sample.

Mr. CREEDON. Yes, sir.

Senator TYDINGS. I have one more question.

Mr. Creedon, without qualifying yourself as an expert or world traveler, you are in the engineering field and, of course, have a pretty fair comprehension of the engineering ability and technique and thoroughness of other countries, because sometimes you do compete; isn't that correct?

Mr. CREEDON. Yes, sir.

Senator TYDINGS. Without naming them, and assuming the money was available, over a period of 8 years, what countries would you conceive from an engineering standpoint of being capable of manufacturing atomic energy—assuming the money was available, that they had the basic technique, and so on, and knowing the fact that this can be produced. How many countries do you assume would be capable of making atomic energy, if the money were available?

Mr. CREEDON. I don't believe I am qualified to answer that question.

The CHAIRMAN. Anything else, Mr. Creedon, that you would like to tell us?

Mr. CREEDON. No, sir.

The CHAIRMAN. Thank you very much, sir, for coming down.

We are now to hear from Mr. H. E. Thompson, vice president of the Carbide & Carbon Chemicals Corp.

STATEMENT OF H. E. THOMPSON, VICE PRESIDENT, CARBIDE & CARBON CHEMICALS CORP.

The CHAIRMAN. Mr. Thompson, Senator Austin would like to put in the record some facts concerning your qualifications.

Senator AUSTIN. In what capacity did you serve through Carbide & Carbon Chemicals Corp. in the erection of the plant or plants for the gas diffusion project?

Mr. THOMPSON. My work in connection with the K-25 project concerned itself with the engineering from the time we came into the project and agreed to act as operators of the plant when it was completed. That date was in December of 1942.

Senator AUSTIN. What had you been doing before this project was undertaken that gave the Government access to you as especially qualified to enter upon this project? What had you been doing with respect to the national defense?

Mr. THOMPSON. I entered this project as a member of Carbide & Carbon Chemicals Corp., but I believe that we were considered in

connection with this project in part because of our contribution to the synthetic-rubber program.

Senator AUSTIN. What companies, other than the parent company, were involved in the construction of the gas diffusion plant or the operation of it?

Mr. THOMPSON. The gas-diffusion plant was engineered by a subsidiary of the M. W. Kellogg Co., known as the Kellex Corp., organized purposely for that job.

We were selected as the operators, but coming into the program early in its development, we were asked to join with Kellex and work with them in the engineering to approve the drawings as they were made, and assist in other ways, so that when we finally got the plant it would be also our idea of what such a plant should be.

Our Bakelite Corp. also had quite a bit to do with one of the important phases of the gas diffusion process.

Senator TYDINGS. Let me ask you there if the Bakelite Corp. is a subsidiary of yours.

Mr. THOMPSON. The Bakelite Corp. is a subsidiary of Union Carbide & Carbon Corp.

Senator TYDINGS. Is that the one Dr. Baekeland was president of?

Mr. THOMPSON. Yes; Dr. Baekeland is now dead.

Senator TYDINGS. But his son carries on.

Mr. THOMPSON. Yes.

Senator AUSTIN. What did the Bakelite Corp. have to do with this?

Mr. THOMPSON. The Bakelite Corp. worked particularly on the diffusion member that in many respects forms the basis of the diffusion process.

Senator AUSTIN. Did Carbide & Carbon Chemicals Corp. enter into this project?

Mr. THOMPSON. Yes; through its work with Kellex in engineering and designing the gas diffusion project and plant. Other subsidiaries of Union Carbide & Carbon Corp. were involved in other phases of the entire project, however.

Senator AUSTIN. Now trying to visualize them all, I would like to know with what authority you speak here as a witness. Were you an advisory engineer in all these activities?

Mr. THOMPSON. No, I was not. My engineering work was principally in connection with the K-25 project.

Senator AUSTIN. And that is the gas diffusion plant?

Mr. THOMPSON. Yes.

Senator AUSTIN. Its business was to separate 235 from 238, was it?

Mr. THOMPSON. Yes, sir.

Senator AUSTIN. And that was a method that was pursued throughout the effort to produce the bomb, wasn't it?

Mr. THOMPSON. Yes, sir.

Senator AUSTIN. It was one of the four known methods of separating 235 from 238?

Mr. THOMPSON. That is correct.

Senator AUSTIN. Now, did you have anything to do with the material end of this transaction, such as with the United States Vanadium?

Mr. THOMPSON. Oh, other units of the corporation had a great deal to do with other parts of the program.

The United States Vanadium Corp. was responsible for a very large part of the raw material. The Linde Air Products Co. developed means and carried out processes for conditioning that raw material so that the desired final product could be obtained.

Senator AUSTIN. In this canopy of the parent company, did the electrometallurgical activity also come?

Mr. THOMPSON. The Electro Metallurgical Co. made, I believe, a large part of the uranium metal that was used in the project, both the Tennessee project and the west coast project.

Senator AUSTIN. In addition to that, is it true that your parent company had to do with the graphite production that was used in this process?

Mr. THOMPSON. It is true. The National Carbon Co. developed and made huge quantities of the graphite that was used in the Hanford plant and the electromagnetic plant.

Senator AUSTIN. Speaking only in a general way, what do you say the contribution of Union Carbide & Carbon was to the production of the bomb?

Mr. THOMPSON. My feeling is that without the joint effort of all of those companies we would not have had the atomic bomb.

Senator AUSTIN. That is all.

The CHAIRMAN. Will you go ahead and describe to us further, if you wish, the work that you did.

I might ask you this first, Mr. Thompson: Have you engaged in any foreign work at all personally?

Mr. THOMPSON. No, sir; except to the extent of working with some of our Canadian subsidiaries.

The CHAIRMAN. Has Union Carbide & Carbon Corp. plants in foreign countries?

Mr. THOMPSON. Yes; some.

The CHAIRMAN. Where?

Mr. THOMPSON. Our Carbide & Carbon Chemicals Corp. has a plant in Canada.

The CHAIRMAN. Any in Europe?

Mr. THOMPSON. No, sir.

The CHAIRMAN. Any in South America?

Mr. THOMPSON. No, sir. Some of the other companies have plants abroad for the manufacture of batteries in many parts of the world, for the manufacture of carbide and ferro-alloys in Norway, and for the manufacture of some other products with which I am not acquainted; I think some carbon and graphite activities at certain points.

The CHAIRMAN. You mean subsidiaries of your parent company have plants in Europe in which they manufacture certain articles?

Mr. THOMPSON. That is correct.

The CHAIRMAN. Are they rather extensive operations?

Mr. THOMPSON. No, sir; they are not. The carbide plants and alloy plants in Norway, I believe, are the largest.

The CHAIRMAN. Do you know how many men, approximately, they employ or have employed?

Mr. THOMPSON. I do not.

The CHAIRMAN. Were they taken over by the Germans during the occupation?

Mr. THOMPSON. They were, sir; in occupied territories.

The CHAIRMAN. Who has them now?

Mr. THOMPSON. We have them, I think.

The CHAIRMAN. Now, that the Norway Government is back again?

Mr. THOMPSON. Yes, sir.

The CHAIRMAN. Have you traveled extensively yourself around the world?

Mr. THOMPSON. I have never been abroad except to Canada.

The CHAIRMAN. You have been educated as an engineer. What college did you graduate from?

Mr. THOMPSON. I graduated from the University of Illinois in engineering in 1914, and joined the Linde-Air Products Co. as a research engineer at Buffalo in 1917.

The CHAIRMAN. I believe there have been some estimates given by the contributing companies to the War Department as to the time that they believe that this job could be done in other countries in the world. Did you participate in that estimate to the War Department?

Mr. THOMPSON. No; I did not.

The CHAIRMAN. Did you know about it?

Mr. THOMPSON. I heard about it afterward. Within the past week someone asked me if I had answered that question. I had not been asked.

The CHAIRMAN. Mr. George Harrison, of New York was the chairman of the committee that gathered that information, was he not?

Mr. THOMPSON. I believe so.

The CHAIRMAN. The chairman of the New York Life Insurance Co.

Mr. THOMPSON. Yes.

The CHAIRMAN. But you do know that your company furnished such an estimate to that committee?

Mr. THOMPSON. No; I really don't. The gentleman I was speaking to was with a different company; he had been asked.

The CHAIRMAN. As I understand it, Mr. Thompson, General Groves at our request contacted you personally?

Mr. THOMPSON. Yes, sir.

The CHAIRMAN. I might say for the record that General Groves suggested these witnesses, Mr. Creedon and Mr. Thompson, and also the other two witnesses who will be before us.

Have you had access to that information specifically that was given to that committee?

Mr. THOMPSON. No, sir.

General HART. Mr. Thompson, in connection with those subsidiaries which do business in Europe in particular, is there any engineering or development done by those plants, or do they get all of their know-how from America?

Mr. THOMPSON. All of it comes from America.

Senator HART. They do no research and no engineering whatever in those countries?

Mr. THOMPSON. That is correct.

Senator HART. Are any of those companies in any sort of affiliation with industries owned by the countries in which they are located?

Mr. THOMPSON. So far as I know, none of them is so connected.

Senator HART. It is entirely a matter of competition, and they have no connection whatever?

Mr. THOMPSON. That is correct.

Senator JOHNSON. Did I understand you to say, Mr. Thompson, that Carbide & Carbon Chemicals Corp. was selected to handle this

work because of their experience in the manufacture of synthetic rubber?

Mr. THOMPSON. I said that I felt that perhaps our accomplishment in the synthetic-rubber program had had something to do with considering us as the operators of the gas diffusion process.

Senator JOHNSON. Did you yourself have something to do with the manufacture of synthetic rubber?

Mr. THOMPSON. Yes. Our company's contribution to the synthetic-rubber program was the production of butadiene from ethyl alcohol. Our principal operation was the plant at Institute, W. Va.

Senator JOHNSON. The United States might be classified as a "Johnny-come-lately," so far as the manufacture of synthetic rubber is concerned, might it not?

Hadn't other nations such as Germany and Russia reached a high state of perfection in the manufacture of synthetic rubber?

Mr. THOMPSON. I think that is true. I believe that for various reasons they were in the synthetic-rubber program or business long before we were. We got into the synthetic-rubber program as a matter of necessity.

Senator JOHNSON. If they were expert in the manufacture of synthetic rubber, they are well on their way toward an important step in the diffusion process, the gas diffusion process?

Mr. THOMPSON. No; I rather question that. I don't believe there is any connection between the two.

Senator JOHNSON. Mechanically or scientifically or otherwise?

Mr. THOMPSON. No, sir.

Senator JOHNSON. That is, knowing how to manufacture synthetic rubber would be of no assistance in the manufacture of the gas diffusion process?

Mr. THOMPSON. No, Senator. I think that the real point there was that Carbide & Carbon Chemicals Corp. had set up a schedule for bringing butadiene plants into production that seemed almost impossible of fulfillment; yet their experience in building processing plants was extensive enough so that they carried their program through completely on schedule.

My reference to the rubber program was not based on any process similarity between producing butadiene from alcohol and the gas diffusion process.

I believe that the experience we had in putting over the butadiene-from-alcohol program, which was one of the biggest the country had ever seen in the process industries up to that time, qualified us to give service in this gas diffusion process.

Senator JOHNSON. Not because of the similarity or know-how, because of your record for getting the job done?

Mr. THOMPSON. Yes, sir.

The CHAIRMAN. You were up to your neck in this synthetic rubber process?

Mr. THOMPSON. That was the principal Government plant activity of the Chemicals Co. until the work on this project came along.

The CHAIRMAN. Now, I have it in the back of my head that the know-how on that was developed in Russia. Were they not the first country to develop synthetic rubber out of alcohol?

Mr. THOMPSON. It is interesting that some of the early patents on the production of butadiene from ethyl alcohol were Russian and that

some of the first research work in that field had been done by Russian scientists.

The CHAIRMAN. And they were in production on that before we were, were they not?

Mr. THOMPSON. That is correct.

The CHAIRMAN. That is a tremendously complicated piece of business in itself, is it not?

Mr. THOMPSON. On the other hand, the production of butadiene from ethyl alcohol is not a process which is particularly complicated.

The CHAIRMAN. You would think so if you looked at a picture of one of those plants.

Mr. THOMPSON. Well, the business of getting a high yield and of producing high quality material, of course, is something different again. I believe the plants that we built were much more efficient than any that had gone before.

The CHAIRMAN. Have you ever seen a tire made in Russia out of this process?

Mr. THOMPSON. No.

The CHAIRMAN. Have you ever seen a sample of the rubber?

Mr. THOMPSON. No.

The CHAIRMAN. Did you make use of those basic patents in any way in the operation of your plants?

Mr. THOMPSON. Not in the work that we did. Our process for producing butadiene from ethyl alcohol was developed by our own research group. It involved new catalysts and new operating conditions and gave considerably higher yields than the published processes before that time.

The CHAIRMAN. But the Russians had rolled their vehicles on their own rubber tires made out of the ethyl-alcohol process before we went into production on them?

Mr. THOMPSON. That is correct; yes.

Senator HART. May I carry that on a little further?

Do I understand, Mr. Thompson, that although the Russians did have the basic patent and were perhaps the first in the field, that as compared with our own accomplishment they still were in a rather crude stage although they were producing rubber? Is that a correct statement?

Mr. THOMPSON. I think I would modify it to a certain extent. You may remember that the United States sent a group to Russia to learn about their synthetic-rubber operations and they sent a group here. The exchange of information was not too extensive, but the Russian plants were certainly operating and they were making good butadiene; and they used that as a raw material to make good synthetic rubber.

I may say that the work of our company in that field concerned itself with the raw materials, butadiene and styrene, rather than with the process of making the copolymers or the finished rubber articles.

The CHAIRMAN. Considering the difficulties of making rubber through this process, in order for the Russians to have even engaged in the production that they did they must have had some accumulation of engineering personnel and scientific personnel to put that together. That would naturally follow; would it not?

Senator JOHNSON. I would like to ask to hear that question again.

The CHAIRMAN. I say the knowledge that we have that they were first in the field and they did make them, whether efficiently or not,

presupposes that they had a group of engineering brains, engineering men with capability, gathered together in order to do that job?

Senator JOHNSON. Yes; undoubtedly.

Senator AUSTIN. Did the Linde Air Products Co. contribute to this gas diffusion process at all?

Mr. THOMPSON. They contributed a great deal to it, not only in the matter of personnel, but in the matter of additional work on the very heart of the gas diffusion process, the diffusion membrane, if you will.

Senator AUSTIN. That is one of the key elements in the plant; is it not?

Mr. THOMPSON. It is the basic one, without it, there would be no gas diffusion process.

Senator AUSTIN. How are they related to the Carbide & Carbon Chemicals Co.?

Mr. THOMPSON. All of these operating units that I have mentioned are subsidiaries of Union Carbide & Carbon Corp., which is the parent company.

Senator AUSTIN. Did they have to do with the vacuum system?

Mr. THOMPSON. The Linde group did not have to work with that particularly. The chemical group, the operators of K-25, were the ones that worked on that problem.

Senator AUSTIN. Looking at it as an over-all picture, then, Union Carbide & Carbon dealt with both the research, the design, and the engineering?

Mr. THOMPSON. Yes, sir.

Senator AUSTIN. On the gas-diffusion system?

Mr. THOMPSON. Yes, sir.

Senator AUSTIN. Did Chrysler Corp. produce anything for this gas-diffusion system?

Mr. THOMPSON. They did. They produced the diffusion units, called "diffusers," of which there were a great many of great complexity, a job that required all of the skill and the art of American line production such as is used in making automobiles, and Chrysler did an excellent job.

Senator AUSTIN. In the operation, after the plan had been erected, what part did Carbon & Carbide Chemicals Corp. contribute to the output of the plant?

Mr. THOMPSON. Are you referring to the Tennessee plant for diffusion?

Senator AUSTIN. Yes; the Tennessee plant. I have that in memory, as I visited it with this committee.

Mr. THOMPSON. The operation of the K-25 project at Tennessee was entirely under Carbide & Carbon Chemicals Corp. from the very beginning to the very end.

Because of the arrangements that were made with respect to Kellogg and Carbide & Carbon working jointly from the very start, Carbide & Carbon Chemicals Corp. was busily engaged at Knoxville long before there was much of a plant there to operate. Our work started when ground was broken, practically, and continued until the final unit of the first part of the project was in operation.

That contribution required selecting from our various groups operating men of the right qualifications, not only to operate the plant

but to see that it was in shape and ready for proper operation when that time came.

Senator AUSTIN. Who is the man who is in charge of that plant down there all the time; who stays on the job?

Mr. THOMPSON. The one in charge of that entire operation is Dr. George T. Felbeck. The man in charge of the entire contribution of our corporation to all phases of the atomic energy project is Mr. J. A. Rafferty, vice president and a member of the executive committee of the parent corporation.

Senator AUSTIN. You are a vice president of that corporation?

Mr. THOMPSON. In charge of engineering; yes, sir.

Senator AUSTIN. Are you also vice president of Carbide Chemicals Corp.?

Mr. THOMPSON. Yes, sir.

Senator AUSTIN. If you hold any other position in this set-up, what is it?

Mr. THOMPSON. I am also a vice president of Bakelite Corp.

Senator AUSTIN. I want to say to you that the contribution that your great company made to the production of this bomb was a very great contribution, in my opinion.

Mr. THOMPSON. Thank you, Senator Austin.

Senator HART. As an engineer, Mr. Thompson, does that Tennessee plant, K-25, as far as its magnitude and complexity are concerned, represent about as large a task as you ever undertook in your professional capacity?

Mr. THOMPSON. Yes, Senator; it is; and I would like to say a few words on that subject, because I believe that it is an outstanding accomplishment in the whole field of engineering as it applies to major process industry plants.

There are many kinds of engineering that have been carried out on gigantic scales successfully, and they vary greatly in the character of the work and the character of what is produced. It is one thing to spend a lot of money building roads or traffic systems, and quite a different kind of thing to build hydro-power plants and the things that go with them. It is another kind of thing to build multiple-part plants like automobile plants.

The process industry phase of engineering, I believe, is something in which we in the United States have perhaps had more experience than in most places. The growth of our chemical industry has been rapid in recent years. The growth of our refining industry has been equally rapid, and the development of those industries has called for a type of engineering which involves hundreds of thousands of individual parts, procured in thousands of different places, all of which must be at the site at the right time and in the right order. They not only have to be there, but they have to be properly warehoused and stored so that when you want a certain one of them you know where to go to get it.

We have been carrying out rather good-sized engineering jobs in Carbide & Carbon Chemicals Corp. for sometime with quite a bit of success, and as time has gone on, we have, I think, improved our system. The best test that we had of it was in our contribution to the raw materials for the rubber program. It worked beautifully there.

But what did we have there? We had well worked out research back of what we were about to do; we had built a pilot plant that had been

making a ton a day of butadiene for several months; we had been able to modify our design and engineering in the light of all the information gained in that way, so that the results we achieved in putting those plants into operation were more or less in the bag. We knew that, provided that we could get the materials and parts. I mention that as background.

I should like now to speak of this gas diffusion process for separating U-235 from U-238. Here was a case where research and development engineering and design were all going ahead at the same time. It is true that from a standpoint of scientific background that work had been started, I guess, in 1940 or '41, but at the time we were invited to act as operators of K-25 at the end of December in '42, while there was a lot of good theory back of that project, there wasn't the type of research and development that big plants are built on quickly.

Nevertheless, there was put together there a group which functioned and produced in a better way engineeringwise than any group I have ever seen. The project involved more money by far than any of the projects with which any of us had worked before.

You were called upon to design a diffusion plant before you knew what the diffusers looked like. You were called upon to lay out a plant that had thousands of pumps or blowers in it before you knew that you could get pumps and blowers to work under the conditions that were imposed because of the nature of the materials you were dealing with.

We were called upon to go out and build whole plants, such as the Allis-Chalmers plant to make these blowers, such as the Houdaille-Hersey plant to make barriers, such as the Chrysler plant to make diffusers, after you had the material; and here was this complicated thing proceeding on all fronts at the same time.

I think it is quite remarkable, the record that was made, and it is a record that goes to the credit of a vast number of contributing companies and to the Army. Their skill in getting material for this project was one of the most remarkable things in the war effort.

Actually, ground was broken for the power plant on June 1, 1943. The first boiler was in operation in March 1944.

The ground was broken for the diffusion plant on September 1, 1943, and the first process gas was put into that unit in February 1945.

In that time all the basic materials and pieces of equipment for that tremendous plant were being worked out. Not only that, but here was a plant that was to operate at a reduced pressure, with the dangers of leakage of air and moisture, and all those things. I might say that chapter X of the Smyth report gives a very interesting account of the facts surrounding the gas diffusion process.

So far as the scientific background and the early problems being faced, that plant was brought into operation requiring standards of tightness that had never been heard of before, tightness in a system that had as much as 600 miles of welding on pipes.

Senator HART. Rather large pipes, too?

Mr. THOMPSON. Many of them 30-inch and 24-inch pipes.

Strangely enough, too, there were times in that program when we were at the deadline with respect to some particular important fundamental part, and that part simply hadn't been produced, yet just before we hit the deadline—and this occurred not once but several times—we had not one solution but sometimes two or three.

We had in all of that many things. We had good procurement on the part of the Army. We were given priorities that I think ruined plenty of other fields of activity but helped us, and we had a fine engineering organization. To do that sort of a job required an engineering force of 2,000 men. Of that number, about one-half were of the service type, clerical, stenographic, accounting, purchasing, and guards; and of the remainder, there were about 600 in what we call engineering and design, about 200 field engineers, and about 200 engineers in the laboratories where research work was going on.

Perhaps one of the most important parts of the engineering organization concerned itself with procurement and expediting. The business of getting the thing that you need at the point at which you need it at the right time involved a whole force of men throughout the country ready to go into different plants, actually check the records of the vendors to see that they had ordered the things they needed to make what they were making, and in the event they hadn't ordered them, find out why, and sometimes carrying that to the second and third position, and following that up periodically.

Sometimes it required moving carloads of material from one plant to another to relieve log jams in machining operations, and so on, but all of that was carried out. The completion date scheduled for the last part of the diffusion plant, the K-25 portion of it—not including the K-27 project, which was added and is now being built—was August 23, 1945. The plant was actually completed August 5, 1945.

This achievement was the result of a major group effort, and a long list of names of those who contributed in a major way could be given. Limiting such a list to a bare minimum, one should mention Mr. P. C. Keith, executive in charge and technical head for the Kellogg Corp., Dr. George T. Felbeck, whom we had made top so far as Carbide & Carbon Chemicals Corp., was concerned, Mr. Keith's assistant, Mr. Albert L. Baker, and Dr. Felbeck's assistant, Mr. Hartsel Kensey. They and those under them should be mentioned as putting over the biggest engineering job that any of us had ever seen in the quickest possible time.

Senator HART. Mr. Thompson, in speaking in these superlatives, and so on, what would you say was the greater accomplishment—under size or under complexity?

Mr. THOMPSON. Complexity, I would say.

Senator HART. At the same time the dimensions of it are about as large as anything with which you have ever been concerned?

Mr. THOMPSON. By far the largest.

Senator HART. You are vice president and engineer of a company that engages in a very large business in this country?

Mr. THOMPSON. Yes.

Senator HART. Mr. Thompson, you have given us the figures of how long it took. What is your idea of the ability of any other country in the world being able to accomplish the result at all?

And if they were able to do it at all, about how long?

Suppose we assume that the know-how, insofar as that one vital membrane of which you spoke, was at their disposal, that they knew what it was. Is there any country in the world that could produce that plant at all, and if so, what is your guess as to how long it would take?

Mr. THOMPSON. The answer to that question, as you suggest, gets into the field of guessing. It is a matter of trying to put yourself in the position of the engineers in the other country to see where they would be in comparison to where we were during the period of our work.

To answer your question, I might say first that I am not acquainted with the methods abroad and their set-ups, although obviously those of us in my profession are aware of the accomplishment in other countries, and I am certainly not of the mind to underrate the ability of the engineers or the production groups in foreign countries.

I think it is also clear that now that the atomic bomb is a known reality the business of building up to it becomes somewhat simpler.

So first, to answer in a generalized way, I am satisfied that foreign countries would be able to produce the atomic bomb and would be able to go through the K-25 project. We are speaking now particularly of the K-25 gas diffusion project and you assumed that they had the diffusion matter solved.

Senator HART. That they knew what it was and would have to develop their own process of manufacturing it.

Mr. THOMPSON. Well, in answer to the first part of your question, I am satisfied that these foreign countries could produce after some time something that would be equivalent to our K-25 gas diffusion process.

I am inclined to think that starting even now, with all the funds they might need and with plenty of incentive, if they felt perhaps somebody else was going to use measures against them—with all those things, it would still take much longer than it took us to do the job.

I would say, just guessing, that it would take them twice as long as it took us to do it.

Senator HART. That would mean 5 or 6 years?

Mr. THOMPSON. Yes; and when we say how long would it take to do that job, of course that really needs definition, because we know that from the standpoint of research and exchanges between the scientists working in this field that something had been started in 1940; so that this August completion date in 1945 makes it a 5-year project from the concept to the operating plant. But you were not thinking of that.

Senator HART. You would not be beginning back as far as 1940.

Mr. THOMPSON. That is right; but it would seem to me that from the standpoint of taking scientific knowledge as it exists today and going into the problem of building an organization, to put over such a project with unlimited means back of you and plenty of incentive to do it, it would take other countries twice as long as it took us.

Senator HART. Mr. Chairman, I have one or two questions to ask the witness along other lines. Perhaps in the interest of continuity, other members would like to question along this line.

Senator MILLIKIN. I would like to question along the line of Senator Hart's question.

Assuming that we give some foreign country—the best-equipped foreign country to do the job, whatever it is—our blueprints, our specifications, our formulas from beginning to end, how long would it take, in your judgment, for that best-equipped country to do the job?

Mr. THOMPSON. Just to be sure that I have that question accurately, we are going to give them the blueprints, we are going to give them all the information?

Senator MILLIKIN. The specifications, formulas, and all of the information. We will put it in their laps, and they are to proceed.

Mr. THOMPSON. When we say we are going to give that to them, we mean not only with respect to building what is down there at Oak Ridge, but also with respect to these plants for building the parts that go into it?

Senator MILLIKIN. We will tell them everything we know, except that we won't help them in any way whatsoever to build the plant. They must find whatever they need outside of the United States.

Mr. THOMPSON. That includes the membrane and all of the things—the complete information?

Senator MILLIKIN. It also excludes their use of our personnel. We keep our personnel. We keep everything that we have in this country, but we turn over the blueprints, specifications, the formulas, and everything we can tell them about the know-how.

How long would it take the best equipped country that there is, outside of the United States, to do the job?

Mr. THOMPSON. To put it that way, Senator, I think if you went to the best equipped country, one skilled in that type of construction, that they would have a plant in two and one-half to three years.

Senator MILLIKIN. Let me ask you what, in your judgment, is the best equipped country, outside of this country, to do that kind of a job—excluding, of course, Germany and Japan?

Mr. THOMPSON. Well, I really cannot answer that question. I just don't know.

Senator MILLIKIN. Is there any yardstick whereby men in your business measure the rating of countries chemically and industrially?

Mr. THOMPSON. Oh, yes.

Senator MILLIKIN. Give us a general rating, then, of a half dozen countries of the world that occupy the top rank?

Mr. THOMPSON. Well, I think ratings of that kind you would put on the basis of the tonnage of their different products, and in a given field.

Senator MILLIKIN. Does Great Britain have a general chemical field, for example? Do they produce everything, generally speaking?

Mr. THOMPSON. Of course, they are not one of the strong chemical-producing countries, but they have a chemical industry and it is growing; they have done some fairly good work in hydrogenation of coal and producing synthetic petroleum, and so on, but it is not particularly a chemical-manufacturing nation.

Senator MILLIKIN. How about Belgium?

Mr. THOMPSON. I think that is perhaps too small.

Senator MILLIKIN. Holland?

Mr. THOMPSON. That again is over on other side.

Senator MILLIKIN. Sweden has some great specialities.

Mr. THOMPSON. We can open up there a little bit in certain types of operation, yes.

Senator MILLIKIN. Does Switzerland have any large general chemical industry?

Mr. THOMPSON. I don't believe so. I think they are more in the physical sciences.

Senator MILLIKIN. How does France rate in that kind of comparison?

Mr. THOMPSON. I don't think particularly strong.

Senator MILLIKIN. Does Russia have a general chemical industry, generally developed and ramifying rather widely?

Mr. THOMPSON. No, I would say not. Russia finds its name in the chemical literature frequently in an important way, but so far as the carrying-out of chemical manufacture is concerned, it of course is not developed to a large extent so far.

Senator MILLIKIN. Is there anything to the south of us of any great importance?

Mr. THOMPSON. I don't believe so.

Senator MILLIKIN. As of today we are by all odds many times over the most important chemical nation of the world, are we not?

Mr. THOMPSON. That is right; excluding Germany.

Senator MILLIKIN. I intended that to apply all the way through.

It would take a great long time, would it not, for for any other nation to catch up with us?

Mr. THOMPSON. Yes, sir.

Senator MILLIKIN. Again excluding Germany?

Mr. THOMPSON. Yes.

Senator MILLIKIN. Thank you.

Senator HICKENLOOPER. I would like to ask one question in connection with the subject Senator Hart raised.

Assuming our position in 1941—that is, whatever know-how and plans we had at that time—but assuming that we were not at war and assuming further that we thought we might have to get into war sooner or later, although it was not immediately imminent on that day or that month—we were merely in a state of rather intensive preparation in peacetime—starting from that point in 1940 or 1941, how long do you think, from an engineering standpoint, it would have taken us in peacetime, even under some urge, to have perfected these plants to the point that they were perfected in 1945?

Mr. THOMPSON. Your question assumes peacetime, a reasonable urge, but not the same urge that applied to this project.

Senator HICKENLOOPER. Let us suppose we start 3 years from now, or even today, with the idea that perhaps we are going to have to fight somebody very soon, that it is reasonable to believe that, or that we were vitally interested in preparing an unbreakable defense for our country.

Senator Millikin suggests a valuable addition to this question. Suppose we didn't have it, but we had the know-how we had in 1941 and did know that somebody else had the bomb and had done the job, but assuming peacetime conditions and not the full emergency of the presence of war.

Do you think, for instance, that we could have built the plants in the time that we did build them—or that we could build the plants in the time we did build them under our social, political, and economic peacetime situation and the industrial demands of peacetime, and so on?

Mr. THOMPSON. I think that under the conditions stated in your question, it probably would have taken us about 50 percent longer to have built those plants.

First, the preference rating and priority that was put back of this project was the like of which no one had ever seen before. There was never a time in peacetime when you could get things that you wanted as promptly as you could get them for this project. That is the first thing, and so I am assuming that in peacetime it would have been quite a bit more difficult to get what we have put into this plant than it was during wartime.

Senator HICKENLOOPER. In other words, Mr. Thompson, in peacetime—even admitting that you had the priorities and the authority of the Government to go after them and get them—still probably the peacetime demands on these vast hundreds of thousands of other operations that were producing materials that you needed might have slowed this thing down quite a little; whereas they would just cut through all red tape, all conditions of other business and other activities, in order to meet this intense emergency of war.

Mr. THOMPSON. That is correct, and I also think that even under the conditions stipulated in your question, you would not have gotten the drive on the part of the personnel working on this thing that you did get under wartime conditions. They were simply all out.

Senator HICKENLOOPER. That is the human element, the natural human element?

Mr. THOMPSON. Yes.

The CHAIRMAN. Do you think, Mr. Thompson, that the conditions stated in Senator Hickenlooper's question, namely, that some other country had the bomb, might be the compulsion that would exist to hurry your estimate of time necessary or to shorten the estimate of time necessary?

Taking you as an American engaged in this proposition and informed that other countries or another country had the bomb, have you given any thought to the fact that that proposition might hurry you in your efforts?

Mr. THOMPSON. There is no doubt that that fact alone produces tremendous incentive on the part of the other fellow.

The CHAIRMAN. It would produce that incentive in you, would it not?

Mr. THOMPSON. Unquestionably.

The CHAIRMAN. And the fact that it was peacetime or wartime or in-between time would be disregarded by you, would it not, in your efforts to get this thing into production?

Mr. THOMPSON. I think that is correct.

Senator JOHNSON. Mr. Thompson, the reasons we made such speed were, first, that we had a totalitarian war government; and second, we had the patriotic urge.

Now, can't you picture some other country, a totalitarian country, that would proceed with all the priorities which we had, and they might substitute—if they didn't have the patriotic appeal that we might—the emotion of fear; and don't you think they could speed up and perhaps reach the stage of efficiency which we displayed, other things being equal?

Mr. THOMPSON. I think that the question of their speeding up to their maximum within their capabilities and aptitudes unquestionably would be produced in other places under the conditions you mention.

I wonder, however, if there is any other country that has quite the grouping of aptitudes plus experience in their fields that we have

here. I am thinking of the whole business of multiple production, the same thing that made the automobile and the output of war airplanes. No other outfit has that to the same degree that the United States has developed it now.

That figured in a big way in making all sorts of underlying parts, the work of Chrysler and Allis-Chalmers in this field, the work of General Electric and Westinghouse in the project that Mr. Creighton spoke about, and the parts that went into our project—although special plants were not built for them. I mean to say that the business set-up, with experience back of it, able to translate over to making special things almost on a week's notice, is the type of thing that we have that I think no one else has.

Senator HICKENLOOPER. We have one other thing, in pursuit of Senator Johnson's question: The enemy was shooting at us; the bullets were flying. It wasn't a question of "we are pretty sure there will be a war next week, next month, or next year." We were right in the midst of the war, and the battle was on.

I think that may not be a completely controlling element, but it is a very substantial element in the ability to coordinate all of this know-how and the willingness of all our resources to at least make this thing a priority thing and devote its genius to that.

I think the presence of war is quite a thing in this or any other effort.

Senator JOHNSON. Yes; of course, plus the element of totalitarian approach. That is what we had.

Senator HICKENLOOPER. You can get the totalitarian approach in peacetime, you can get the orders issued in various ways in peacetime, but that last urge of the fellow over there on the other side of the hill shooting at you is something that comes only in wartime, right in the presence of war.

Senator HART. Mr. Thompson, are you disposed to alter your estimate of taking 5 or 6 years for any other country to achieve what we achieved in K-25?

Mr. THOMPSON. I still feel that is a good estimate, Senator.

Senator HART. There is one possible difficulty you didn't touch in that splendid statement about the accomplishment, which was in the field of metallurgy. Were there any great difficulties in that field?

Mr. THOMPSON. There were, and again the fact that in this country our metallurgy was well advanced and a living thing that merely had to be assigned to these special problems resulted in a great gain to the project.

Senator HART. What about the availability of the basic metals which came into the picture?

Mr. THOMPSON. The basic metals, of course, were of two kinds: (1) The material out of which the 235 was manufactured and (2) the materials of construction used in the plant itself.

I believe there is quite a bit of security requirements and secrecy thrown around the metal itself.

Senator HART. I didn't mean to bring in anything outside of construction.

Mr. THOMPSON. In the matter of construction, our metallurgy was most perfect, and it got into this project in several ways.

As to the materials of construction for the parts going into the diffusion plant itself, some were corrosive, which, if allowed to accumu-

late at a certain point, would become fissionable, which were highly poisonous; the metallurgy there was difficult and was only solved because of the groups we had to draw upon.

Again, in the metallurgy of certain phases of elements of the plant, the availability in this country of a trained and going metallurgical group solved those particular problems.

Senator HART. And when we asked you about other countries accomplishing that and you gave an estimate, did you have in mind the possible difficulties which they would encounter in the metallurgical field?

Mr. THOMPSON. I would say not specifically. I was trying to look at it in a general way, considering where they would be trying to do all of the things we did.

Senator HART. Mr. Thompson, you operated this K-25 plant. Is there anything you would like to tell us about the magnitude of difficulties in maintenance?

Mr. THOMPSON. I might say that there were a great many unknowns about the operation of the diffusion plant before it was put in operation. After all, it was impossible in the laboratory to test out in an effective way the effects that were to appear in time. There was no way of accelerating. There was the question, for example, of the diffusion members plugging up, and there was the question of their not being strong enough.

Most of those questions had to be answered by building the plant and putting it to work. Knowing that the failure of some of those things would be fatal to the project, the design incorporated every protection that seemed reasonable.

The operation of the plant might have been perfect from the standpoint of separation, but its life might have been too short. Fortunately, our experience so far has indicated that those matters that have to do with the life and the need of replacing and changing and taking out, and so forth, were well solved, or they were not going to appear, because we have a plant that is operating much better and will operate with much less maintenance than we suspected in the first place.

Senator HART. Then, from a practical standpoint, it has been neither troublesome nor expensive to keep up the maintenance?

Mr. THOMPSON. That is correct.

Senator HART. In the field of operation, is any great number of highly skilled personnel required once it was going, and were there any great difficulties in training them and getting them to carry along the work?

Mr. THOMPSON. In answer to that question, I want to say strongly, "Yes." Without getting into details that probably shouldn't be talked about, I think the approved and published statements thus far have indicated that this operation is one in which you have thousands of steps set one on top of another.

The kind of a separation you are making, you see, is a very sharp one. It is a delicate sort of a thing. It is more or less like running a distilling column, a rectifying column, with thousands of plates in it instead of 20 or 30; and if you disturb that complex unit, and not extensively, but every once in a while, at some point or another you

may never get it out of equilibrium. You might have a perfect plant and get a plant that wouldn't separate 235 from 238.

That comes down to control. The control that was worked out for this project was one of the big things that has been most successful. I believe that one of the problems that some other group, attempting to do what was done in K-25, would be brought face to face with would be the difficulty of operation and of maintaining that complicated system in equilibrium so that you can get your end product out at the right purity.

Senator MILLIKIN. Would it be fair to say that it was sort of touch and go as to whether, after this whole thing got into its rhythm and got to operating—as to whether what you wanted would appear at the other end? Of course, you expected it, or you wouldn't have built the plant.

Mr. THOMPSON. Senator Millikin, I think the matter was this: It was realized that running a complicated system of that kind had to be based on good control, and the control end of it received a tremendous amount of attention.

Senator MILLIKIN. But if somewhere along the line, as you pointed out, there had been some little failure, you would have gotten that whole gigantic thing going and nothing would appear.

Mr. THOMPSON. I want to correct that a little bit. I may have made a statement that sounded that way.

Actually, we can cut out quite a portion of it without upsetting the whole thing. The point I wanted to make was this: If your operation was ragged enough so that you had a disturbance at the lower end one day, the next afternoon one at the upper end and the next afternoon one in the middle, and you had that accumulation of disturbances, it wouldn't be a matter of touch and go, it would be a matter of eliminating, that series of disturbances before you produced.

Senator MILLIKIN. It seems to me you produced a perfectly marvelous result, not having a pilot plant to work with.

Mr. THOMPSON. Those of us who worked with it felt that that was so. It was the only time, of course, that anybody had ever spent sums of money like those without a full pilot plant back of you.

Senator HICKENLOOPER. I want to say first, Mr. Thompson, that I think your statement that it is a rather delicate operation is a masterpiece of understatement. I think that probably no one but you expert engineers and scientists can have any appreciation of the extreme delicacy of this operation.

But I did want to ask your opinion on this, to see whether or not this is a correct assumption: I assume, leaving Germany out of the picture because it was a diversified chemical, engineering, and manufacturing country, and at least for a substantial period of time it will be completely out of the picture, isn't it safe to say that our country all through this process, both before the war, afterward, and now, has by far the greatest diversification of industrial know-how, including chemistry, science, engineering, and all of the factors, of any country in the world; and that that is backed up by basic research in these major fields that in the aggregate and for all practical purposes in this thing was far in excess of any other country in the world?

Mr. THOMPSON. I am sure that is right.

Senator HICKENLOOPER. And it was that backlog of basic research over a long period of industrial development in this country that enabled you to know that if something were needed, even though it were new in design and even though it were just being conceived, that there was a segment of our industry that at least had gone far in research into the general basic fields involved in the production of that article?

Mr. THOMPSON. I am sure that is right.

Senator HICKENLOOPER. And you could call upon that in the most tremendously diversified industrial plant in the world, which was this country?

Mr. THOMPSON. There is no question about it.

Senator HICKENLOOPER. If you hadn't had that diversification, in other words if there had been certain new pioneering fields where we had no basic research on some of the fundamental problems, it would have been a more difficult problem to do this job. You would have to go out and build up that backlog of research, and things of that sort were in many sciences already available.

Mr. THOMPSON. I am sure that is correct.

Senator HICKENLOOPER. Although the research might not have been available to that particular problem, but to the type of problem that was available.

Senator HART. I think we might state for the record that to Mr. Thompson "basic research" doesn't mean exactly what Senator Hickenlooper may have had in mind.

You will recall in his testimony he was talking about engineering research after the basic research is completed, and then the engineers take over and make it work.

Senator HICKENLOOPER. Yes; I appreciate that. I probably didn't get my question down to a specific outline as well as I could, and perhaps I can't express it as I tried to conceive it in my own mind. I am no engineer and no chemist, and I cannot go into those things accurately.

The CHAIRMAN. Mr. Thompson, you could put every scientist off the Oak Ridge property and not let them come on there for the next 6 months and operate this plant, could you not?

You have a going plant operated, as it still is, by your company with an engineering and production personnel. The job now is to maintain it in production and operation. That is an engineering job.

Mr. THOMPSON. The answer to your question, as you put it, is "Yes"—definitely.

I might clarify, however, by saying that in the operation of a plant of that kind there are parts of the operating end of it concerning the laboratory phases in which we have Ph. D.'s trained in chemistry, and so on. Now, you are not thinking of men trained in chemistry as scientists. You are thinking of the research background. That is behind us, so far as the K-25 goes. Those gentleman are no longer needed.

The CHAIRMAN. That is right. In other words, you can make fissionable material with your organization today?

Mr. THOMPSON. That is correct.

Senator HICKENLOOPER. The need of the top-flight scientists today, as I take it, is for advance research on other and different methods, or other fields, and so far as the present operation is concerned, their job is done.

Mr. THOMPSON. That is correct.

The CHAIRMAN. Are there any further questions?

I have one question that I would like to ask of you and Mr. Creedon in executive session, which will take just a few minutes.

The committee will meet tomorrow morning in open session at 10 o'clock.

(Whereupon, at 12:15 p. m., the committee retired into executive session; to reconvene in open session at 10 a. m., Wednesday, December 20, 1945.)

ATOMIC ENERGY

THURSDAY, DECEMBER 20, 1945

UNITED STATES SENATE
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Johnson, Austin, Millikin, Hickenlooper, and Hart.

Also present: Edward V. Condon, scientific adviser, and James R. Newman, special assistant to the special committee.

The CHAIRMAN. Mr. Winne.

STATEMENT OF H. A. WINNE, VICE PRESIDENT AND MANAGER OF ENGINEERING IN THE APPARATUS DEPARTMENT, GENERAL ELECTRIC CO.

Mr. Winne, you are the vice president and manager of engineering in the General Electric Co.?

Mr. WINNE. Yes.

The CHAIRMAN. Mr. Winne, according to the staff's information, guided a large portion of the development and manufacturing work done by the General Electric Co. for the Manhattan District program. He is the author of articles on electric furnaces and electrical precipitation and steel mills. He has been employed by General Electric since 1910.

Mr. Winne, will you proceed to tell us what you think of the difficulties of the work that you did for the Manhattan District project, and something about it?

Mr. WINNE. I will be glad to endeavor to, Senator.

I suppose to clarify the situation it might help if I outlined briefly first the manner in which we participated, that is, very generally, the equipment which we furnished.

The CHAIRMAN. That is an orderly way to do it.

Mr. WINNE. I presume whatever I say here is public, so no classified information should be revealed.

The CHAIRMAN. That is right.

Mr. WINNE. Our connection with the project involved work for two of the main processes as described in the Smyth report, that is, the electromagnetic and the gaseous diffusion, so that my remarks will be confined primarily to those two methods.

437

Of course, due to the way in which General Groves rightly kept the different parts of the project compartmented, we did not have knowledge of all phases of even one of those two methods.

We supplied some standard equipment as well for the Hanford plant, but that was practically all of a standard nature. The major part of the equipment we furnished was that for the electromagnetic project which we termed the Stone & Webster job, because the over-all construction, and so forth, was handled by Stone & Webster.

I would like to emphasize that all the way through this project was given top priority in our organization. We put effort and people on it way beyond what we normally would on a project of the same dollars of magnitude, because General Groves had impressed upon us so thoroughly the importance of it.

For the electromagnetic project, we supplied among other things some high-voltage rectifiers, or cubicles as we termed them, a lot of transformers, switch gear, motors, and so forth. As an example of probably the most difficult part of our participation in that project, I might cite the high-voltage cubicles.

Each one of those was the size of a small room, and there were a great many of them. Each one involved around 7,500 different electrical components. I don't mean just screws, nuts, and bolts—that would run into the hundreds of thousands, probably, but different pieces of electrical equipment, such as instruments, tubes, transformers, motors, and so forth.

While, as I say, this was only a small part of the project, nevertheless it was necessary for us in our organization to use the facilities of practically every one of our works—the Pittsfield works, Schenectady, Lynn, Bridgeport, Fort Wayne, Philadelphia, Bloomfield, and our various research and general engineering laboratories. We even called on our subsidiaries, the General Electric X-ray Corp., which furnished a lot of vacuum tubes, and the Edison General Electric Appliance Co., which furnished a lot of heaters, and so forth.

In addition to that there were some 2,000 items which were obtained from outside contractors for each one of these numerous high-voltage cubicles.

The point I wish to make there is that we had—and this is typical, I think, of all American industry—the organization and the manufacturing facilities, and especially the background of technical knowledge, which enabled us to really contribute to the job and to get it through in the time it was required.

As illustrative of the necessity for that technical background, we found that when some of this equipment first went into service, we immediately had our hands and laps full of trouble, as was to be expected with anything as new and radical as this equipment was. We called upon one of our laboratories which had had, over the past 15 or 20 years, a very unusual background of experience along the line of this particular trouble, and there were about 25 engineers and test men who worked for several months carrying on a series of tests and investigations, as a result of which—just to show you the magnitude of the thing—the report covering the tests involved some 500 pages of typewritten matter and over a thousand what we term oscillograms, which are records made on very high speed recording equipment, and through which we found the sources of the trouble and were able to correct them in the equipment which was supplied.

Of course, one of the difficulties was that all the while this trouble was occurring, in order to meet the shipping schedules, we had to keep the equipments rolling out of the back door even though we knew that they would have to be changed afterward; but it was the only way possible to do the job in the time required, and when we found the trouble we had to go out in the field and correct it.

As another example, there was one particular phase of the equipment which we supplied which required very close control. Now, the type of control of which I speak—commercially, we think of an accuracy as within 1 percent as pretty good—we had to shoot for and obtain an accuracy of one-fiftieth of that, that is, 50 times as good, you might say. The only reason we were able to do that, I think, is because we had previously supplied from one of our laboratories a number of equipments to another branch of the armed services which were of an extremely special nature and were developed only after a lot of mental and manual travail, you might say, and we used elements from that particular specialized equipment to save the day on this Manhattan project and on this particular phase of it.

Again, what I am trying to emphasize is the fact that to do the job in the time that we did it—and I think when I say “we” I can say that I am speaking for all of the industries which participated, and certainly for General Electric—it was necessary that we have available that background of technical experience extending back over many years of engineering, design, and development, and production, as well as the facilities and the manpower to do the job.

On the gaseous diffusion plant, we supplied a lot of equipment in the way of turbines, a number of turbines, which were more or less special, and, again, to indicate right there the necessity for an already functioning industry, one of the first of those larger turbines was taken from another job which was partially completed. It was taken from that other job, some changes were made in it, and adapted to this job. Others were already in the schedule and coming along, which were diverted to this job.

Then, there were a number of transformers, switch gear, and so forth, but our main engineering contribution and the most difficult one was in connection with the instrumentation for the gaseous diffusion plant, and that we turned over almost entirely—as far as the engineering development work was concerned—to what we term our General Engineering Laboratory, which is an organization dating back a good many years with a very specialized personnel and facilities. They were called upon in a number of cases to invent, and in others to take ideas which were in the nebulous stage and bring them through the development stages into actual production. The result there was a large number of very special devices particularly adapted to this job which we would not have been able to produce in the time that we did had we not had this already functioning organization and facilities.

In addition, for the job we supplied a considerable amount of consulting service from scientists in our research laboratory, from technicians in our works laboratories, on such matters as welding and metallurgy, brazing, and that sort of thing.

96000 U - 49 - 6

While I think very high tribute, of course, is due to the scientists who initiated the work from which this project resulted, the actual consummation of the project—the production of the material and of the bombs—was in my opinion only made possible because we had American industry, American engineers, American equipment ready to function. The scientists had built experimental equipment for use in their laboratories, but to operate them they had, you might say, hundreds—and I think that is literally true—of Ph. D.'s and similarly trained people. Industry had to take these ideas and put them into commercial equipments, in quantities, which could be operated by girls with high-school training or less, and with a minimum of maintenance and with as nearly as possible continuous operation.

A great deal of credit is due not only to the industrial manufacturers but also the organizations, such as Stone & Webster and Kellogg, with whom we had principal contact, and there were many others, such as Tennessee Eastman, and so forth, for their work on the over-all project. I think the highest of praise is due to General Groves and his organization for the way in which they coordinated and pushed this whole project forward. I have sat in meetings with the General in which the personnel ranged from the scientists to the hard-boiled construction people, and he did a marvelous job of shoving the whole thing forward and getting it done.

Mistakes were made; we made mistakes. I think probably everybody connected with the project made mistakes. Because of the necessity for speed, it was done in a way that we normally would never think of doing an engineering and development job.

To take these high-voltage cubicles, for example, the ordinary way to proceed with that in our ordinary work would be to build one and put it in operation and see how it worked, and work the bugs out; and then from that build up the commercial designs for the remaining quantities, and go ahead and build them. But in order to meet the time schedule we had to start from the drawings on the paper and turn them out the back door, and then make such changes as were necessary later. While we can look back on it now and say we could start over again and do the job at less expense and perhaps in less time if we had the same urge—we couldn't do it in anything like the time we did without the urge of war, in my opinion; but looking at it from the other end, from the start, I do not know how the over-all job could be done any better than it was. I think it was a tribute to the Army, to American industry and everyone concerned with that—and I say that with due modesty for our part in it.

Senator AUSTIN. To what extent, were you dependent on the Army for materials?

Mr. WINNE. We very often had to call on the Army personnel to help us in expediting material from suppliers or component parts which we were getting from the outside. They were a great deal of help to us in that way.

Senator AUSTIN. You mean manufactured articles made by other concerns?

Mr. WINNE. That is right.

Senator AUSTIN. Were you dependent on the Army for raw materials?

Mr. WINNE. Well, I cannot answer that question definitely as to whether we ever had to call on them to help us get such things as steel

and copper. I am not sure, but I rather think we did; but I cannot say that with absolute certainty.

I know we called on them a great many times for component parts from other manufacturers, and, of course, we had to call on them to arm us with directives or AAA priorities where needed, and that sort of thing, so we could help ourselves to get the material.

Senator AUSTIN. In peacetime, that situation where you could depend on the Army would not probably exist, would it?

Mr. WINNE. That is very true.

Senator HART. Mr. Winne, this background of industrial knowledge, know-how, and ability to produce is also a part of a good many other firms in this country with which I assume you have a certain amount of acquaintance; is that true?

Mr. WINNE. That is correct.

Senator HART. Going back, you, I understand, have been with General Electric for 35 years. Going back to 1910, when you began, and which covers the period of our very great industrial advance which has put us out ahead of the world, what were the circumstances as you now see it which so impelled us that we did set up in this country this marvelous industrial establishment in the heavy industries? What were the compelling and impelling circumstances?

Mr. WINNE. I would say offhand the profit motive of industry, the natural desire of all industry to improve its products, to expand its field, and thereby expand its business and carry on development work. You perhaps know our slogan: "More goods at less cost for more people," which is a slogan which we have tried to live up to right along. I think that is perhaps the greatest motive. It is probably trite to say, but the free-enterprise system had a great deal to do with it, I feel.

I don't know whether that answers your question, sir.

Senator HART. Not altogether. Which particular field of industry do you look back upon as having developed the fundamentals of mass production, rapid production of various difficult articles? Would it be the electrical field, or some other?

Mr. WINNE. Well, I think in general we think of the automobile industry as having more or less led the way in quantity mass production.

Senator HART. Have you been able to keep in touch with the state of industry in other parts of the world, particularly in Europe, over the last generation or so?

Mr. WINNE. Only in a very general way, speaking of my personal knowledge.

Senator HART. Have you any idea as to how it happened that with the possible exception of Germany the rest of the world fell behind our ability in production, in our heavy-industry ability to produce? Where did the rest of them fall behind us so badly?

Mr. WINNE. That is a very difficult question to answer, sir.

Senator JOHNSON. Did they fall back or did we lead out?

Mr. WINNE. I don't think that any of them have fallen back. I think practically all countries have gone ahead, but I think we have gone ahead faster than the majority of the other countries.

Senator HART. Aside from the possible sociological aspect of the free-enterprise profit system, and so on, we must have had other advantages in order to have gone out ahead of the world so fast, don't you think?

Mr. WINNE. Of course, we have had the advantage of raw materials, I think, to a considerable extent, at least over many countries. Of course, there are other countries which are not yet so far developed as we which have also quite large resources of raw materials. But taking the more highly developed countries, such as England, unquestionably, of course, our store of raw materials is much greater than theirs. That undoubtedly has had considerable to do with it.

Senator HART. Looking into the future, Mr. Winne, what country in the world is most likely in your opinion to be able to overtake us if there is an urge to get into production of heavy industry?

Mr. WINNE. Judging by what one reads, and so forth, I should think the probable answer is Russia.

Senator HART. I believe your company has a good deal of representation in Russia, or has had?

Mr. WINNE. We have had some representation in Russia. So far as I know, we have no one there now.

Senator HART. Did you gather from those representatives any measure of Russia's ability to overtake us?

Mr. WINNE. No, I have not, sir. I am not in a position to give any valuable information on that point.

Senator HART. Thank you.

Senator HICKENLOOPER. Mr. Winne, may I ask your opinion on this: Suppose we started right now with the knowledge we had in 1941 or at the very beginning of this enterprise, and we knew that some other country had an atomic bomb actually completed, that they could make it, had the know-how and the process, and we wanted to start out to make an atomic bomb.

As I say, beginning with the information we had in 1941, in peacetime and not in the presence of war, what is your opinion as to the length of time it would take industry to do the job under those conditions?

I may go a step further and say that the point of my question is: Could we get the cooperation; could we get the intensive union of all industry, engineering, and so on, together to finally produce the thing in the time that we did—in peacetime?

Mr. WINNE. Of course, you must realize that my answer to this must be simply a matter of opinion, as obviously it cannot be based on actual facts.

Of course, on this project, the funds available were practically unlimited to get the job done.

Senator HICKENLOOPER. Let's assume that they are now.

Mr. WINNE. You are assuming also, then, that funds would be made available?

Senator HICKENLOOPER. That funds are available and priorities—or at least top orders for priorities—are just as strong as they were during the war.

Mr. WINNE. As I said, it is difficult to weigh what the effect on us would be of the knowledge that another country had atomic bombs ready to use if they wished to. It might put almost as much impetus behind us as actual war itself, but my belief is that it would not. I think it would probably take once and a half to two times as long, or something like that, under normal peacetime operations to do this job even with the funds available.

I just cannot conceive that in peacetime either the Government or industry would go ahead on the basis as I say we had to here, because of the urgent life or death nature of this job, almost, and be producing equipment while it was still in the very early developmental stages. That is entirely contrary to all normal industrial production.

Now, if you get enough urgency behind it, if we knew that atomic bombs were going to start coming over in a short time, if we didn't get something to combat them with, then you might possibly get speed of the same order of magnitude as we got in this case. There are so many intangibles.

Senator HICKENLOOPER. I am merely speaking to you as an engineer who has had a lot of experience in the human end of production. That is, you have to get human cooperation before you can turn out these things, and I am wondering whether a condition doesn't exist psychologically or otherwise in the presence of war, that is, in time of war, that probably enables these jobs to get done which even under the threat of war wouldn't be accomplished quite so fast?

Mr. WINNE. I think that is very definitely true. I think it would certainly take longer simply under the threat of war than it took us in actual war, and with the thought that possibly our opponents were only a jump behind us, or maybe not even a jump.

Senator HICKENLOOPER. In other words, when they are not actually shooting at you, there is a human tendency to be a little more certain about what you are doing—not to procrastinate, but to take a little more time and prove your theories.

Mr. WINNE. I think that same thing would apply to Congress in the allocation of funds to a thing like this. Don't you think so?

Senator HICKENLOOPER. Well, I have read the papers. I think it is true that in any human organization there are times when the urge and speed of accomplishment are a great deal more than at other times.

Mr. WINNE. I think, over-all, unquestionably it would take longer under any other conditions than it did under the war conditions, and it might be in the order of once and a half to twice as long, or something like that.

Senator HICKENLOOPER. Let me ask you this: Insofar as you have any knowledge or opinion on this, is there any country today—considering, of course, the devastation of German industry and its complete destruction—that can compare with our country in the whole field of basic research, engineering, over-all historical know-how in industrial and scientific fields of this kind?

Mr. WINNE. I think not, Senator, when you particularly bring in the manufacturing facilities and the engineering and technical background for producing the equipment necessary to produce the atomic bomb.

It is my personal opinion that there is no country today which could approach us on that.

Senator HICKENLOOPER. I am referring to the over-all picture now. Some might be able to make just as fine a piece of individual equipment as we could make here, and it is entirely possible that some country might make a finer piece of individual equipment than we are prepared to make here, but I am speaking of the over-all picture, because as I understand it, this operation is an over-all ramified operation in which all factors must be completely coordinated and must completely operate.

Mr. WINNE. That is my opinion, Senator; yes.

As I say, we had to call not only on practically all of our own organization, but on many other organizations in the country to supply parts just for the part which we supplied, and ours was only a portion of the total equipment used in the project.

Senator HICKENLOOPER. That leads me to just one more question. When a problem came up that you knew had to be solved in a comparatively unknown field, isn't it true that there did happen to be a segment of our engineering, or design, or industry, some place that had had some basic knowledge in that whole field upon which you could rely to develop this special thing?

Mr. WINNE. Very definitely so, Senator, especially within our own organizations. As I say, we called on our Pittsfield high-voltage laboratory when we ran into trouble in one place. We called on the General Engineering Laboratory. We called on other organizations. There was one particular part of this control in which we needed a very special vacuum tube. We happened to know that another company had a tube which might fulfill that requirement, and we found that they did; not all of the tubes they made did, but by selecting a comparatively small percent out of a great many they manufactured, we got the tubes that we needed to accomplish the desired results.

Senator HICKENLOOPER. In any event, if they had not had the particular tube, they had had some experience in the broad field of production that you wanted, and they very likely had the know-how to go ahead and develop the thing you would want.

Mr. WINNE. That is right, and we called on our General Electric X-ray Corporation for some very special tubes. We used the existing buildings, but we equipped and manned and put into operation a complete new factory for building large quantities of quite large-sized vacuum tubes that were required on this electromagnetic project.

Senator HICKENLOOPER. In other words, many other countries might have a certain portion of this field developed very highly, and yet on certain essential things they might find themselves at this point: "Well, we have no part of our industry that has ever explored that field very much; we have to start out and develop the whole thing."

Mr. WINNE. That is entirely possible, and I think probable. I could not say definitely.

Senator HICKENLOOPER. That would be a great factor in the final completion of this project?

Mr. WINNE. That, and also the mere magnitude of industry necessary to turn out the equipment required to do the job.

Senator HART. May I ask one more question?

Mr. Winne, comparing our industrial ability with others, and how we happened to get so far ahead, is it your opinion that our superiority has not been so much in the field of basic research as it has been in development research and our consequent superiority in working out designs for apparatus which lent themselves to production? Did our superiority lay in that, or are we also superior in our basic research?

Mr. WINNE. Well, Senator, I doubt if we have been greatly superior, at least in our basic research, to some other countries, but I do feel that we have been superior in our technical developments, our development of production methods and facilities for manufacturing highly technical and complex equipments.

As far as basic research is concerned, it is my feeling that we have not been much, if any, ahead of some other countries.

Senator HART. Is engineering research the proper term for the field in which we have been so superior?

Mr. WINNE. Well, you can term it engineering research, or engineering and technological development. There is a great deal of difference in definition as to the terms "research," "engineering," and so forth.

In our company we apply "research" primarily to fundamental searching into the unknown, you might say; whereas our "engineering development" is taking the results of research and putting those into practical use, and in developing the manufacturing facilities, and so forth, is where we primarily have been superior.

Senator HART. In your opinion, what other countries were on a level with us in basic research?

Mr. WINNE. Again, I have to rely largely upon reading, and so forth, and not from my personal investigation of their facilities, their work, and so forth, but Germany, in general, had done a very good job of basic research. England has carried on some outstanding basic research, and I think Russia has. Our Dr. Langmuir was over there a short time ago and was quite impressed with some of the research work they had been carrying on. I believe he outlined that to some extent to this committee.

The CHAIRMAN. Mr. Winne, have you traveled extensively abroad?

Mr. WINNE. No, I have not, Senator. I have not done any traveling abroad, that is, off this continent.

The CHAIRMAN. If you wanted to know the state of advancement of industries comparable to the one you represent, where would you go to find out?

Mr. WINNE. Do you mean geographically?

The CHAIRMAN. The various countries of the world. That information is probably better compiled in the Department of Commerce than any place else, isn't it?

Mr. WINNE. Well, of course, in prewar time we had, as a part of our general organization, what we called the International General Electric Co. which had representatives in most foreign countries and knew in a general way at least of the technological development in those countries. We cannot, of course, use those today, because we don't have the men abroad to the same extent, but we would have used that organization to find out what other countries were doing as well as we could.

The CHAIRMAN. Do you know about the facilities or the extent of the information in the Department of Commerce as to the development of industry in other countries of the world?

Mr. WINNE. I am not especially familiar with it, Senator, no.

The CHAIRMAN. It has occurred to me that they might be the best coordinator of that information.

Did you, as representing your company, make any estimate of the time that other countries might be expected to require to duplicate this performance to the George Harrison committee that was set up in the War Department to receive that information?

Mr. WINNE. No; I did not, Senator.

The CHAIRMAN. Do you know who in your company did make that estimate, or if anybody was called upon?

Mr. WINNE. I don't know that anyone has been called on, although they may have been. I don't know of any information of that nature that has been given to that particular committee, Senator.

Senator JOHNSON. Following the line of questions which have been submitted by the Senator from Connecticut, Admiral Hart, isn't it true, Mr. Winne, that the atmosphere here has been wholesome for the development of industry? Our educational program, the number of college graduates, and the number of technical schools and graduates from those technical schools, our free enterprise system together with the profit system, which is a reward for merit, and the attraction that our freedoms—the freedom of speech and the press which have permitted the friction of minds—have attracted scientists and technicians from all over the world to come to our country.

Haven't all of these things combined to make it possible for our industry to step ahead of the rest of the world, and isn't it really the combination of these things that has created the wholesome atmosphere for the advance of industry?

Mr. WINNE. I think I can wholeheartedly endorse that statement. Of course, as far as the technical colleges and industry are concerned, those two are interrelated. As industry has grown, its needs for the technically educated men have grown, and that has helped to increase the number of men in the colleges and the number of colleges. The two have more or less come up together.

Senator JOHNSON. The people in this part of the world may have what some folks call the creative mind or instinct, but don't you think that instead of having any superiority or any advantage over other peoples just as men were born naturally, that it had been because of these conditions?

Mr. WINNE. I think environment has a tremendous amount to do with that. That is, there are creative and brilliant minds in a great many other countries, as you all know. Of course, the brilliant people from other countries, many of them, have come to this country. I think the environment in this country—as you say, the free enterprise system, the profit motive, and so forth—has been primarily responsible for our progress. That is a rather trite statement, I know, but I think it is true.

The CHAIRMAN. Mr. Winne, radar was developed in England, wireless in Italy, fission in Germany, jet planes in Germany, V-2's in Germany, penicillin in England, synthetic rubber out of alcohol in Russia, and all of those things were put into production.

I am pretty proud of this country, too, but I do not want to get so proud as to believe that everything that has been done that is worthwhile in modern advanced technology and science has originated within the four corners of the United States, because it just isn't true.

Mr. WINNE. I would not claim that at all, Senator. That is why I said, in answer to the Senator's question, that there are brilliant minds in other countries as well as in this country. We have no monopoly on brains.

The CHAIRMAN. They have been able to translate their inventions into mass production, haven't they?

Mr. WINNE. I think not to the same extent that we have here.

Senator JOHNSON. That is the very point.

The CHAIRMAN. But you don't need mass production of atomic bombs, do you?

Mr. WINNE. No; but to produce a plant which in turn can produce atomic bombs in a short time you need essentially mass production facilities.

The CHAIRMAN. We did it in four different methods.

Mr. WINNE. That is right.

The CHAIRMAN. You, of course, would assume that any other country, the four methods having been proved, possibly would select one of those methods.

Mr. WINNE. I think any other country starting today has the advantage, Senator, that they know to some extent what we have done. They know we have been able to make these methods work. They possibly can analyze to determine which one, two, three, or all four are best, and to that extent would have a better start than we had.

There has been enough published on the basic researches, and so forth, to give other countries an advantage over what we had at the start of this project, it seems to me.

The CHAIRMAN. Keeping in mind that they would select one method, that they know that method would work, that they have been capable of doing these other things that I have mentioned, do you care to give any estimate for the record of how long you think any other country—being specific or not—could get into production on fissionable material?

Mr. WINNE. Of course, any such estimate is purely a guess.

The CHAIRMAN. I appreciate that.

Mr. WINNE. And purely a personal one. I feel that to do what we did in the time we did called for such diversified effort on the part of so many of our different industrial organizations—not from personal visitations or anything but simply from reading, as I said—no other country today can approach us in industrial facilities available; and therefore I feel that even granting that they would have somewhat of an advantage in the start it would take any other country considerably longer than it took us.

Now, whether that would be twice as long—and it might be on that order of magnitude I might think—again I want to emphasize that there are very few facts on which I am basing this. It is just a guess and a personal opinion. It might be once and a half; it might be three times as long—I don't know. I feel it would certainly be longer.

The CHAIRMAN. How long would you say it took us?

Mr. WINNE. Well, again, I can only cite our own experience.

We were given specifications on this equipment, and those specifications—I would emphasize—in turn were the result of long experiments in laboratories, and so forth. We were given specifications as to what it was felt was needed from us in either December of '42 or January of '43.

Now, again, that is only our part of the job. Of course, those specifications were changed many times as we went along, but that was really when we started to put the pencil to the paper to make designs for the equipments which we furnished about January of '43.

The CHAIRMAN. Are there any further questions?

Mr. Winne, thank you very much. I think your company made a great contribution to this project, and it was very kind of you to come down and talk to us today.

Mr. WINNE. We are glad to be of any help that we can.

The CHAIRMAN. Mr. Brown.

**STATEMENT OF EDWIN H. BROWN, VICE PRESIDENT IN CHARGE
OF THE ENGINEERING AND DEVELOPMENT DIVISION, ALLIS-
CHALMERS MANUFACTURING CO.**

The CHAIRMAN. Mr. Brown, you have been connected with the Allis-Chalmers Co. for 35 years, I notice, and you had some considerable experience with the Manhattan District project.

If the committee has no preliminary questions, I will ask you to go right ahead and tell us about your company's connection with the project and more particularly yours.

Mr. BROWN. The company had different orders and contracts with the Manhattan District and its representatives and contractors in excess of some 60, ranging from a very few dollars up to very large amounts.

The equipment furnished included nearly all of our standard products that went into the various projects. How much more equipment went into the mining industry, and others that were involved, we don't know.

Among these contracts there were two that I feel are pertinent to the subject of your committee in particular. One of them was for equipment having to do with the electromagnetic process, as described in the Smyth report, and the other had to do with electrically driven mechanical equipment for diffusion separation of gaseous products, both for equipment installed at the Clinton Engineer Works, Oak Ridge, Tenn.

Of the electromagnetic process equipment, we were the fabricators, the makers, the installers, and the developers of the manufacturing processes. We did not develop nor design the equipment. It was developed and designed, so far as we know, under the direction of Stone & Webster Corp. If I recall rightly, it was to them that we reported on the work in our plants. The principal electromagnetic equipment was of the heaviest type made by heavy industry. Its fabrication represented a difficult problem in our works, when we handled things up to the largest dimensions for machining, welding, and all the various shop operations, involving difficulty even in shipping and installation.

The actual manufacturing processes required the development of new methods. Some of them were beyond the scope of our experience, particularly in certain tolerances for welded products of the dimensions of this equipment.

This equipment, after shipment and installation with all the care that had been exercised by the various companies engaged at Oak Ridge, was contaminated by foreign matter, had to be taken out, returned to our plants, rebuilt with some additional fabricating development work being done, and returned.

The other particular contract which pertained to the processes of fission was for rotating pumping equipment for gases, electrically driven. On that work we were required to develop the apparatus, the design, as well as to manufacture, and we had to construct a plant in which to build the equipment. The difficulties I don't believe can be exaggerated. They drew on all the resources of the company, all of its personnel, all of its staff. I believe that for 8 months during

1944 our president probably took the job home to bed with him and woke up with it in the morning.

It involved the development of parts with surfaces, the accuracy and tolerance of which were measured in millionths of an inch, and the production of them by shop people in relatively large quantities. The basis of the design was worked out in laboratories with which we were not familiar. We were supplied initially with information, we understood, from Columbia and other places, perhaps some in Chicago, which was delivered to us, and we went on from there.

We have estimated at times that there must have been a corps of two or three hundred people in laboratories in different parts of the country supplying information regarding the results of the development we were carrying out. The job required the development of new welding, brazing, and soldering processes. It required repeated changes of material to get some parts that drew on the metallurgical knowledge of the country; to obtain metal parts that are accurate to tolerances measured in millionths of an inch and can be produced in a short time and be stable in operation. Some phases of metallurgy had to be learned as that job was carried forward.

There was a right-of-way for the company to obtain those services and to obtain material. There was complete freedom to make changes in material when it was necessary in order to get the job done.

The manufacture of this equipment required, in a large part of an appreciably large machine shop, maintenance of surgical cleanliness in connection with the work. The same problem of maintained cleanliness entered into the shipment of equipment; whether it could be shipped by truck, whether it could be shipped by railroad, whether it would have to be under temperature control. The erection and servicing of it at Oak Ridge required development there and the transfer of the knowledge from our shops and staff to groups there for maintaining and putting the equipment in service. This was a strain on everyone connected with this part of the project.

I believe, Senator, I have summarized the general conditions that pertained to these things. I want to assure you that I have not over-emphasized the difficulties that were experienced, the number of people that had to be drawn in to solve them—the complete staff of our company; we don't know how much of the staffs of steel mills and laboratories throughout the country were thrown into the work.

Senator AUSTIN. Mr. Brown, is it true that you were a troubleshooter for operation of this machinery that Allis-Chalmers Co. produced after it was installed in Manhattan District at Oak Ridge, Tenn.?

Mr. BROWN. Yes, sir; during the manufacture, development, and the initial efforts to put the plant into operation.

Senator AUSTIN. In your work, are you at liberty to say what type of trouble you found down there with respect to machinery that had to be corrected generally? I don't care for details.

Mr. BROWN. Practically all of the trouble was diffusing knowledge, spreading knowledge out over people. There was failure to know how to maintain temperatures, to prevent corrosion, to start and stop things, to condition them properly before starting them up. We had learned some of it in our plants. It had to be transferred there. The

solution was undertaken by the sending of men who had been trained in our place, the sending of laboratory men, the staff of the Kellogg Corp., and others to try quickly to extend this knowledge.

Senator AUSTIN. Speaking of the metallurgical side of the problem, did you find that you had to make material changes in the structure of this machinery, particularly the pumping equipment for gases after it had been installed at Oak Ridge?

Mr. BROWN. Yes, sir; it was started up with one material in one particular part that I recall. That material was changed even while they were operating—taking them out of service and changing them—more than once, and I think that the last of the units is being equipped with the final material now.

Senator AUSTIN. Did that process prolong the period required for the production of the bomb?

Mr. BROWN. Our knowledge was so limited, Senator, that I really cannot say as to that. That is, we didn't know what material our machinery was to handle. That had an advantage—it didn't let us diverge from curing the troubles with which we were faced.

Senator AUSTIN. Thank you.

Senator HART. Mr. Brown, in which of those two plants, the electromagnetic or the gas diffusion plant, as you now look back upon the history, did you have the greater difficulty in the production, looking back over the completion of the designs and the eventual supply of the apparatus?

Mr. BROWN. The greatest difficulty was that for the diffusion process.

Senator HART. Was that the pumps?

Mr. BROWN. Yes, sir.

Senator HART. Had anyone in this country ever made pumps that were as difficult to make and which were called upon for as hard a task as were those pumps?

Mr. BROWN. The general type of pump, Senator, was of known standards, but to suit it for this purpose it became different from anything that had ever been built, so far as I know, in the world. Certain parts and appurtenances were developed and applied to it that weren't in existence before, I believe.

Senator HART. The number of those pumps was great enough so that the production was decidedly a mass-production problem; is that correct?

Mr. BROWN. Yes, sir; that is correct.

Senator HART. Mr. Brown, in your long service with Allis-Chalmers, have you acquired much knowledge of the state of heavy industry in other countries?

Mr. BROWN. From time to time, I have, Senator, rising chiefly around circumstances or conditions in connection with our power-generating equipment, particularly.

Senator HART. Did your company, before the war, have representatives all over Europe, for instance?

Mr. BROWN. We had an office, as I recall, in London—a sales office, and also a sales office in Paris.

Senator HART. But that was for selling only?

Mr. BROWN. We had some arrangements for manufacturing our products in some European countries—I believe, France and England.

Senator HART. Did you, yourself, have much knowledge of what was going on in those offices or plants in Europe?

Mr. BROWN. No; not those particular plants. My European knowledge was based on visits to people regarding heavier types of apparatus.

Senator HART. I will ask you the same question I asked Mr. Winne.

To what circumstances do you ascribe the fact that the United States went so far ahead of the rest of the world in the production of heavy machinery, or all kinds of heavy industry?

Mr. BROWN. I can only answer for myself, Senator. I have an opinion, but I can't say that it coincides with that of my associates or my boss.

I think that this country has progressed industrially to the extent that it has because we primarily manufacture for our own use and under a system that enables a person with imagination or desire to meet a need or even create a need or change a desire into a necessity, such as has been done here with the automobile, the electric appliances, and everything like that.

Senator HART. Does that mean that it is altogether in your estimation a difference in markets, domestic markets?

Mr. BROWN. Again, may I repeat that I am expressing my own opinions and not those of my company.

Manufacture for export, of which we do a large amount in our company, involves such capital lay-out, credit arrangement, organization, and foreign connections that it doesn't enable someone with limited means, a good idea, and energy to meet or create demands for goods.

Manufacture for a home market enables a country industrializing itself, so I think, to create a need, by the reduction of prices, for its own equipment.

Senator HICKENLOOPER. In other words, Mr. Brown, we produce ample raw materials upon which to work, and we have an ample market for the genius of a free industry to operate, given the rewards of his effort?

Mr. BROWN. Yes, sir.

The CHAIRMAN. Mr. Brown, is any of the research that you use in your company done abroad?

Mr. BROWN. Well, we have some license agreements and some work within my experience where we have utilized research that was done abroad, engineering research particularly.

The CHAIRMAN. Out of what country did that arise?

Mr. BROWN. England primarily; they originated or developed the steam turbine. We have had consultants in Germany advising us on designs.

The CHAIRMAN. Switzerland?

Mr. BROWN. Yes, we have had connections with Switzerland which were quite close, in fact, at times.

The CHAIRMAN. Did you draw anything of benefit out of those connections in the way of improving your product?

Mr. Brown. Beyond question, I believe we did, Senator.

However, in dealing with licenses—take Switzerland for example—foreign licensors frequently want you under a license to do things exactly the way they do it. I don't believe most American companies do that when they have a license, and I know we do not.

The real benefit is shaded by the modifications we apply to such information and knowledge as we acquire from foreign sources.

The CHAIRMAN. Are there any further questions?

Thank you very much indeed, Mr. Brown.

The committee will now go into executive session.

(Whereupon, at 11:35 a. m., the committee retired into executive session.)

ATOMIC ENERGY

THURSDAY, JANUARY 24, 1946

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Johnson, Byrd, Austin, Millikin, Hickenlooper, and Hart.

Also present: Senators Peter G. Gerry, Francis J. Myers, and Leverett Saltonstall; Dr. Edward U. Condon, scientific adviser to the committee; James R. Newman, special counsel; and Christopher T. Boland, staff director of the committee.

The CHAIRMAN. The committee will come to order.

Admiral Blandy is appearing for the Navy this morning, to tell the committee about the proposed atomic bomb tests on some units of the fleet.

Will you proceed, Admiral?

STATEMENT OF VICE ADM. W. H. P. BLANDY, DEPUTY CHIEF OF NAVAL OPERATIONS FOR SPECIAL WEAPONS

Admiral BLANDY. Mr. Chairman, this statement is to describe the atomic bomb tests against naval vessels to be held this spring, in the Pacific. One of the most important problems in connection with these tests will be the maintenance of proper balance between public information and security. It is our hope to make available to science and to the public all appropriate information derived from this historic test.

By direction of the Joint Chiefs of Staff and with the approval of the President, the Army and Navy and qualified civilian scientists have been joined for this purpose to form a unit which is now known as Joint Task Force One, of which I have been named the commander. I desire to emphasize the fact that this is a joint effort in every sense of the word. My staff includes Maj. Gen. W. E. Kepner, United States Army Air Forces, deputy for aviation; Rear Adm. W. S. Parsons, United States Navy, deputy for technical direction; Maj. Gen. A. C. McAuliffe, Ground Forces adviser; Dr. R. A. Sawyer of the Manhattan district, technical director; Capt. J. A. Snackenber, United States Navy, chief of staff; Capt. R. Brodie, United States Navy, assistant chief of staff for personnel; Brig. Gen. T. J. Betts, United States Army, assistant chief of staff for intelligence; Capt.

453

C. H. Lyman, United States Navy, assistant chief of staff for operations; and Brig. Gen. D. H. Blakelock, United States Army, assistant chief of staff for logistics.

All of these officers have had distinguished records during the recent war and are thoroughly qualified to serve in these respective capacities.

The chart entitled "Joint Task Force One Staff Organization" shows the general organization of the staff. I would like to call attention here to the Evaluation Board, which will be composed of two civilians, two officers from the Army, one of whom will be from the Army Air Forces, two officers from the Navy, one of whom will be an aviator, and one member, officer or civilian, from the Manhattan district. This board will be appointed by the Joint Chiefs of Staff, the nominations being made by the Secretaries of War and the Navy for the purpose of appraising the results of the test. That is, it will be the duty of my task force to collect all information, and the duty of this Evaluation Board, which is not under me but is directly under the Joint Chiefs of Staff, to evaluate or appraise the results.

I have a liaison with the commander of the Manhattan district, Maj. Gen. Leslie Groves, who has technical direction of my deputy task force commander for technical direction.

The rest of the chart I think is self-explanatory.

Admiral BLANDY. The mission of Joint Task Force One is primarily to determine the effects of the atomic bomb upon naval vessels in order to gain information of value to the national defense. The ultimate results of the tests so far as the Navy is concerned will be their translation into terms of United States sea power.

Secondary purposes are to afford training for Army Air Forces personnel in attack with the atomic bomb against ships and to determine the effect of the atomic bomb upon military installations and equipment, both air and ground.

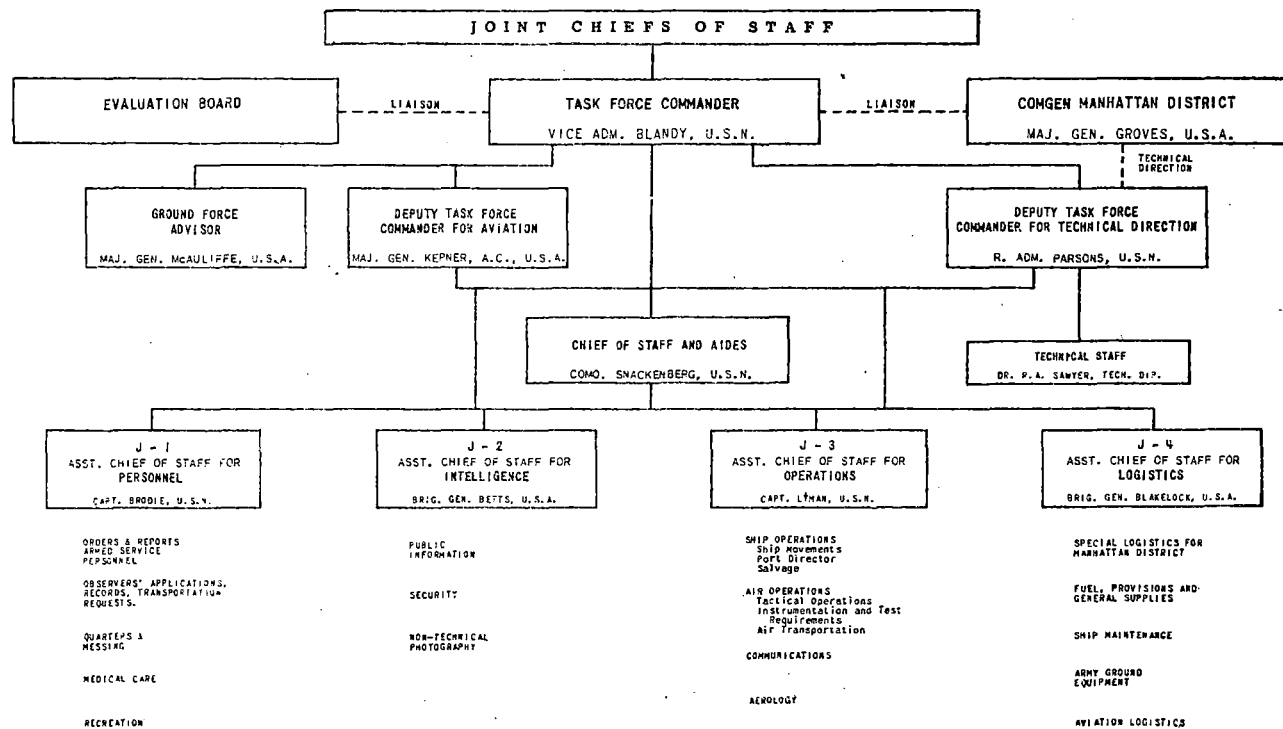

The Army Air Forces, in addition to making the actual air drop, will participate actively in the operation, with regard to air transport, collection of data, observation of results, and test of air force equipment. An Army Air Force general officer, Maj. Gen. W. E. Kepner, has been designated as deputy task force commander for aviation.

The Army Ground Forces will be given opportunity to test equipment, both on board the target ships and ashore. A general officer of the Army Ground Forces, Maj. Gen. A. C. McAuliffe, has been appointed special adviser to the task force commander for this purpose. The reason they will have equipment aboard the target ships is that it will not be possible to place the ships very close into shore, due to the shallow water in the location where the test will be held. Therefore, we will place tanks, artillery, vehicles, and so forth, of Army Ground Forces equipment on the decks of the ships to get them closer to the bomb.

The total strength of personnel of the joint task force will reach an aggregate of about 20,000, the naval crews of the operating and target ships constituting the majority.

I would like to show now the organization of the task force itself. There will be eight groups, task groups, under the task force commander. The first is the bomb and instrumentation group, which will include the bomb preparation unit and the instrumentation unit.

JOINT TASK FORCE ONE STAFF ORGANIZATION

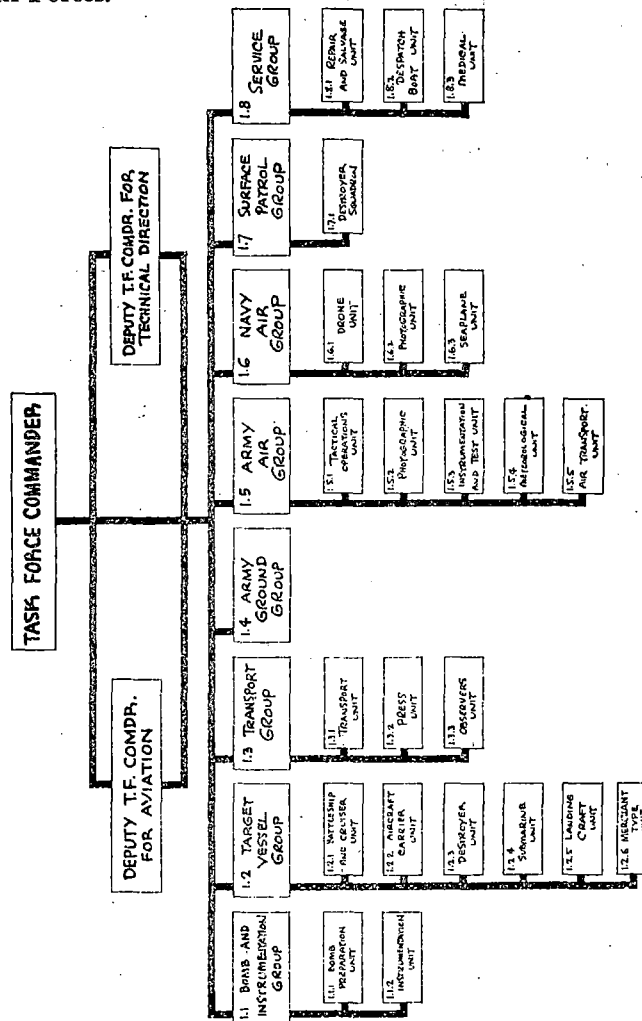

(The chart referred to reads as follows:)

ATOMIC ENERGY

455

That instrumentation unit will comprise several hundred personnel from the Manhattan district, the Bureau of Ordnance and Ships of the Navy Department, and various personnel from the Army Ground Forces and Air Forces.

JOINT TASK FORCE ONE FORCE ORGANIZATION

The target vessel group—I will give the actual list of ships later—comprises a battleship and cruiser unit, an aircraft carrier unit, a destroyer unit, a submarine unit, a landing craft unit, and a merchant type unit. They are not merchant ships but are merchant type ships. They will actually be ships of the transport type in the Navy. I used that term to avoid confusion with the actual transport unit in the transport group.

The next is the transport group, which comprises the transport unit, which will take the crews off the target ships and house them until they can go back on board such ships as survive; the press unit, and observers unit.

The next is the Army ground group, having charge of the assembly and placing of the Army ground equipment.

The Army air group comprises a tactical operations unit, photographic unit, instrumentation and test unit, meteorological unit, and air transport unit.

Next is the Navy air group, with a drone unit, a photographic unit, and a seaplane unit. I will explain later what the drone unit is.

The surface patrol group includes a destroyer squadron, the duties of which will be principally to patrol the area to keep ships out of the area for their own protection, and also keep them away from contaminated water, water containing radioactive substances after the test as that water drifts westward, and last a service group, including a repair and salvage unit, a despatch boat unit, and a medical unit which will include two hospital ships for general purposes and also any need arising from the test itself.

The schedule of target dates for this operation, which will be known by the code word "CROSSROADS"—and I would like to explain that we have chosen that merely for brevity in dispatches and other communications, and we chose it with an eye to its possible significance—now calls for the first test to be accomplished early in May, over target ships at an altitude of several hundred feet.

The second test is tentatively scheduled for July 1, and will be a burst at the surface of the water among target ships.

I might say here that that second bomb is placed on the surface rather than under the water, because the scientific personnel assure us that it will create more damage on the surface than it will at the bottom, and we are seeking to obtain the maximum effect of the bomb. The reason for their belief is that they think that very high waves, possibly 100 feet in height from trough to crest, will be created by the explosion on the surface, whereas if it were placed under the surface it would throw a great deal of spray into the air and would not be deep enough to get proper tamping to get the full effect of the bomb.

As they state it, placing the bomb on the bottom would be equivalent to placing an ordinary naval mine containing a few hundred pounds of TNT in about 2 feet of water. In other words, this lagoon which is 30 fathoms deep would be only a shallow dish for the atomic bomb. They also expect in that surface shot to get blast effect and some underwater pressure and shock damage.

The site of the test will be Bikini Atoll in the Marshall Islands. A complete description of this site and of the problems in preparing for its use is now available. Bikini is approximately 4,000 miles from San Francisco, about 2,100 miles southwest of Pearl Harbor, and also about 2,000 miles from Tokyo, and about 1,400 miles east of Manila.

This chart [indicating] shows the location of Bikini in the Marshall Islands group. It is about 300 miles northwest of Kwajalein, which will be our operating base for such operations that cannot be performed at Bikini. For instance, it will be used as an Army air base, because there is no landing field at Bikini. It is 200 miles east

of Eniwetok, which will probably have to be abandoned temporarily for the test, because the general flow of both air and water is to the westward, and from the air shot the contaminated cloud can get over Eniwetok in a matter of a few hours, being only 200 miles away.

In the case of water travel, the current may carry the radioactive substance in the water to Eniwetok in a matter of days or weeks.

This chart [indicating] shows Bikini Atoll. The maximum depth is about 30 fathoms. This green area [indicating]—and this is copied from a Japanese chart—shows water which has been wire dragged by the Japanese to determine the exact location of coral heads which project upward from the bottom in all of these Pacific atolls. That being insufficient in this area, I am requesting that the entire eastern half of the lagoon be similarly surveyed, and we will probably have to blast out the coral heads in certain spots so as to get the ships exactly where we want them.

The list of ships which we plan to use for this test includes the battleships *Arkansas*, *New York*, *Nevada*, and *Pennsylvania*; the heavy cruisers *Pensacola* and *Salt Lake City*; the aircraft carriers *Saratoga* and *Independence*, the latter being one of the cruiser type aircraft carriers built on a light cruiser hull.

I won't name all of the destroyers, but there are 16 of them, 8 submarines, and the following captured enemy ships: The German heavy cruiser *Prinz Eugen*, the Japanese battleship *Nagato*, and the Japanese light cruiser *Sakawa*.

The total number of target ships is 97, the remaining ships which I have not named being transports, landing ships of the tank type (LST's), landing craft, infantry type (LCI's), landing craft tank type (LCT's), and smaller landing bats—LCM's and LCVP's—which means landing craft mechanized and landing craft for vehicles and personnel.

Some of the latter small boats and larger landing craft will be beached; some will be afloat.

The total operating ships in the force, exclusive of the target ships, will number about 50, so the entire force comprises about 150 ships.

The target ships will be anchored and placed in a manner calculated to give effects varying from probable destruction to negligible damage among the various ships of each type so as to determine the effect of the bomb on various ships at various distances. The target ships will, of course, be unmanned.

Observers will include representatives from the United States armed services, Members of Congress, press, and United States civilian scientific groups.

The question of inviting representatives of foreign nations and foreign news services is under discussion by the Joint Chiefs of Staff and the Secretaries of State, War, and Navy.

The staff of the deputy task force commander for technical direction, Rear Adm. W. S. Parsons, who reports also to Maj. Gen. Leslie R. Groves, United States Army, of the Manhattan district, will include officers and civilian scientists experienced with the atomic bomb. In this regard, Dr. N. E. Bradbury of the Los Alamos Laboratory is primarily concerned with the bomb itself and Col. Stafford Warren of the Manhattan district is organizing radiological measurements and prescribing safety factors. So far as the tight schedule permits,

use will be made of all modern scientific techniques and equipment to observe, measure, and record the effects of the bomb. For example, "drone" aircraft—they are unmanned, radio-controlled—will be used to obtain close-up recordings of radioactivity; automatic motion picture cameras will record the explosions visually from ingenious heavily shielded shelters on the island ring which surrounds the lagoon.

Adequate measures will be taken to insure the safety of the personnel engaged in the test, the observers, the inhabitants of nearby islands, and chance travelers by sea or air.

The CHAIRMAN. Admiral, how many miles is it across the lagoon?

Admiral BLANDY. The lagoon is 21 miles long from east to west, and a little more than half of that north to south. Observing ships will not be in that lagoon at the time of explosion. We will be well outside at a safe distance from the atoll.

Repair and salvage facilities will be provided to effect repairs to target ships after the first test, to make seaworthy such targets as are to be returned to the United States after the second test, and to destroy such as would be hazards to navigation.

I wish to emphasize that this undertaking is not a combined or international operation, but rather a scientific experiment by the United States Government alone.

Furthermore, it is a scientific test and not a contest between the armed forces.

A test contemplated for a later period is a deep-water test in the open sea. The technical difficulties in conducting such a test will not permit its accomplishment in 1946.

(Admiral Blandy submitted to the committee the following letter, which was made part of the record:)

DEPARTMENT OF THE INTERIOR,
FISH AND WILDLIFE SERVICE,
Washington 25, D. C., January 23, 1946.

Rear Adm. W. H. P. BLANDY, United States Navy,
Deputy Chief of Naval Operations,
Special Weapons Branch, Washington 25, D. C.

DEAR ADMIRAL BLANDY: In accordance with the suggestion of the Secretary of the Interior, November 21, and the cordial invitation of the Secretary of the Navy of December 14, 1945, for representatives of the Department of the Interior to present information and advice concerning the areas where tests of atomic bomb against naval vessels may be conducted with minimum injury to fishery resources, our representative designated in my letter of December 21, 1945, has reported to me the tentative site for the experiment which the Navy Department has selected.

We have considered the possible dangers to the fisheries from the atomic bomb experiment, and have reviewed all available information concerning the importance of the fish supply in the area during the period of the year in which the experiment will be conducted. I am now reporting to you our conclusions based on these considerations.

While there are many aspects of the problem concerned with the damages resulting from concussion, from wave action, and from the release of radioactive materials, on which little information is available at the present time, but which we understand will be fully investigated, special consideration was given to the possible total damages from all of these effects on the whale and tuna fisheries of the central Pacific.

The records indicate that the site of the experiment tentatively selected lies outside of the normal migration routes of whales in the Pacific Ocean, and that whaling interests, therefore, will not be affected by the explosion. Information regarding the tuna fishery is much more meager, since the exact spawning areas of the tuna are not known. But such information as is available from

scientific literature and from recent explorations by fishery experts indicates that the proposed site of the experiment is not in a critical area with respect to tuna propagation, nor does it lie in important migration or nursery areas of other valuable food fishes.

It is recognized that the explosion of the bomb at or beneath the surface of the ocean will undoubtedly kill all forms of life in an area which, with reference to the specific locality, would be regarded as large, but in comparison with the vast extent of the waters of the central Pacific, would be very small. Such local losses must be regarded as trifling compared with the value of the strategic and scientific information that will be secured.

We are convinced, therefore, that not only has an area for the experiment been chosen where the fisheries resources are negligible, or are only of extremely local importance, but that in view of the safeguards which will be employed the fisheries of the Pacific Ocean at large, and particularly those of our Pacific coast, will suffer no appreciable damage whatever from the undertaking.

Sincerely yours,

IRA N. GABRIELSON, *Director*

Senator JOHNSON. I have two or three questions which, if they should be in executive session, just skip, Admiral.

Will any ship be equipped with the normal supply of explosives?

Admiral BLANDY. I can answer that question, Senator. Practically all of the ships will be loaded with some ammunition, but not the full supply. We wish to obtain the effect of the bomb upon the magazines and ammunition contained therein, but if we placed one ship in the group entirely full of ammunition, and that ship were to windward of the others, the fire started by that ammunition and by oil from the ships would undoubtedly obliterate all visual evidence at the time of the test, so I think we can get the necessary information without the full amount.

In that connection I would like to invite attention to the fact that there being no crews on board these ships, having the ships entirely full of ammunition would be equally artificial with having them empty as regards ammunition, because many a ship during the war had magazine fires start, but with the crew on board they were able to extinguish those fires by flooding the magazine before the fire could spread to all magazines.

Senator JOHNSON. You say the vessels will not be manned. Will any form of life be used, such as goats or guinea pigs, or other animals?

Admiral BLANDY. That question is now under debate. Some of the scientific personnel hope that they can get all the information required from instruments placed on board the ship which would indicate what would happen to the crews of the ships.

Senator JOHNSON. Such as temperatures and other data?

Admiral BLANDY. Temperatures, radioactivity, and so forth. But, as I say, that question is still under discussion.

Senator JOHNSON. This next question may be an executive question. Will the test be made with the plutonium bomb or with uranium-235?

Admiral BLANDY. It will be the Nagasaki-type bomb.

Senator JOHNSON. That is all, Mr. Chairman.

The CHAIRMAN. Admiral, do you know what the size of the naval building program is for this spring?

Admiral BLANDY. I do not have that information currently, Senator. I have had no direct connection with that.

The CHAIRMAN. But the Navy is completing certain surface ships, is it not?

Admiral BLANDY. I believe that to be the case.

The CHAIRMAN. There are some members of the Naval Affairs Committee here at our invitation, and, of course, some of the members of the committee are members of the Naval Affairs Committee. Senator Byrd, is there any extensive naval program?

Senator BYRD. In our opinion, yes.

The CHAIRMAN. It hasn't been acted upon?

Senator BYRD. No.

The CHAIRMAN. If no Senator has any other question, we will have the session closed, as we will want to talk with you some more, Admiral, in executive session.

The committee will now go into executive session.

(Thereupon, at 10:30 a. m. the committee retired into executive session.)

ATOMIC ENERGY

FRIDAY, FEBRUARY 15, 1946

UNITED STATES SENATE,
SPECIAL COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The special committee met, pursuant to adjournment, at 10 a. m., in room 312, Senate Office Building, Senator Brien McMahon (chairman) presiding.

Present: Senators McMahon (chairman), Byrd, Johnson, Austin, Millikin, and Hart.

Also present: Dr. Edward U. Condon, scientific adviser to the committee; James R. Newman, special counsel; and Christopher T. Boland, staff director.

The CHAIRMAN. The hearing will come to order.

We have invited Major de Seversky to appear today. All of the members of the committee, I think, have read an article which he wrote and which was published in a magazine of extremely wide circulation bearing upon the effects of the atomic bomb. We have also invited here General Farrell, Dr. Philip Morrison, Col. Stafford Warren, and Mr. Nitze, vice chairman of the United States Strategic Bombing Survey, perhaps the most expert of the Government people who have assessed the bomb damage.

Now Major, I presume that you can go ahead.

STATEMENT OF MAJ. ALEXANDER P. DE SEVERSKY

Major DE SEVERSKY. I have not prepared any statement, because the committee asked me to come, presumably to ask me some questions with reference to my article in the Reader's Digest. The only thing I have brought with me is a copy of the manuscript of the article from which the condensation was made.

The CHAIRMAN. Do you care to give us for the record a brief condensation in your own words of this article?

Major DE SEVERSKY. Yes; I certainly can relate to you the observations of my trip to Hiroshima and Nagasaki where the atomic explosions had taken place.

I went down there at the direction of the Secretary of War as a special consultant to the Secretary of War to study the effect of air power in the Pacific theater of operations. It wasn't any detailed study.

The CHAIRMAN. When did you go?

Major DE SEVERSKY. I left on the 25th of September and I got back on the 15th of November. I spent about 6 weeks in the Pacific theater. I visited Guam, Tinian, Iwo Jima, Saipan. I flew about

463

five times over Japan, back and forth, viewing practically all of the major cities of Japan from the air. I visited a score of cities on the ground. I flew about five times over Hiroshima and about five times over Nagasaki, because I was interested in certain aspects of the picture. I spent 2 days in Hiroshima, and 2 days in Nagasaki. Of course, that is not enough time to make a detailed study, but it was enough time to get a general picture, in view of my background and my previous experience. Just before that, I spent 5 months in Germany in the European theater of operation where I saw an awful lot of demolition of all sorts, and of course I saw some demolition even in the last war—World War I.

When the atomic bomb exploded I was in England. I was testing single-seater jet planes, because I was ready to go to the Pacific in a consultant capacity, particularly on that score. The reports that I read on the atomic explosions swept me off my feet, of course, as they would anybody else. I was very much interested to go and see what exactly happened out there. I am glad I went, because if I hadn't gone there I think I might have a distorted idea.

The picture that I drew from the usual information that was available to us through the press and radio was that the whole city was dissolved and went into dissolution in about one-millionth of a second and nothing was left but a crust of molten glass. But when I arrived out there, after seeing a great many other Japanese cities, the general appearance of Hiroshima—from the air at least—did not look any different from other Japanese cities that were burned out. Of course, the remarkable part of it is that it was done by one bomb, but I think the credit ought to be shared between the exceptional efficiency of the bomb and the exceptional flimsiness of the Japanese target.

I think it was very cleverly used at that particular point, because—using the military vernacular—it was the right force applied at the right time in the right place. I don't think that the same devastation and destruction would have occurred if the same bomb had been dropped in the same manner over a modern steel and concrete city.

Well, I conveyed this impression primarily because I felt that there was considerable misrepresentation and unwarranted hysteria going on in connection with what had happened or what could immediately happen. People began to feel as though the fission of hydrogen and oxygen might happen tomorrow; that our planet was going to be blown to pieces and therefore there was no use having any sort of defense, that we might just as well abolish all of our national-defense institutions, because the next war would be fought by a push button from some scientific laboratory. That was all talked about as though it were about to happen tomorrow, and that is the reason why I felt that I ought to convey my impressions as I saw them to make people realize that though the atomic bomb is a great development, a great achievement, it is not as fantastic as some or rather the majority of people imagined, and that we ought to keep our feet on the ground and approach the subject in a more sensible and cool way. This is the reason why I was prompted to write an article in the Reader's Digest.

This is, roughly, my statement as to my trip, what I saw, and the reason I wrote the article.

The CHAIRMAN. Now, do you care to highlight for us some of the statements of fact that you made in the article?

Major DE SEVERSKY. Is there any particular statement?

The CHAIRMAN. I will ask Senator Millikin.

Senator MILLIKIN. If I might, Mr. Chairman, I would like to ask a preliminary question.

Major, you have had a lot of experience with demolition and with demolition caused by bombs from airplanes. When that bomb lands and explodes, what are the physical forces that cause the demolition? I assume there is a blast.

Major DE SEVERSKY. Of course, there is a blast.

Senator MILLIKIN. Tell us about that in laymen's language.

Major DE SEVERSKY. Which bomb—just any bomb?

Senator MILLIKIN. Well, the B-29.

Major DE SEVERSKY. It depends on the bomb. If it is an incendiary bomb, it fires the substance; if it is a demolition bomb, there is a blast and heat. There is direct damage by the fragments, and of course the blast affects in a different manner different substances.

In the case of an atomic bomb, in addition to the blast and heat, there is also apparently some radioactivity, because the New Mexico experiment showed that there was.

Senator MILLIKIN. I am speaking now of the normal bomb intended to achieve destruction by blast and fragmentation. If you have that kind of bomb, aside from the damage done by fragmentation, you have damage done by blast, and possibly, I assume, by vacuum, suction and heat. Those things are measurable in terms of energy?

Major DE SEVERSKY. They certainly are.

Senator MILLIKIN. Could you say as a generality that you can translate the whole thing into terms of energy and force?

Major DE SEVERSKY. Well, it depends upon what you try to show. Yes; you can translate it into energy and force.

Senator MILLIKIN. And that is measurable, I assume, to men who are acquainted with the components of the bomb.

Major DE SEVERSKY. Unquestionably.

Senator MILLIKIN. Now, if you use a conventional bomb for demolition, you release a certain amount of energy, and the same thing happens, does it not, if you release an atomic bomb?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. The atomic bomb, as you have mentioned, has some special features of its own.

Major DE SEVERSKY. That is right.

Senator MILLIKIN. By way of a particular kind of radiation, and not a particular kind of heat but, I assume, a very intensified heat over the normal bomb which is a part of the energy that is released. Would you go with me that far?

Major DE SEVERSKY. Yes, certainly.

Senator MILLIKIN. Now, in referring to this article in the Reader's Digest, I assume we are referring to the article of February 1946, called Atomic Bomb Hysteria. That is the article to which you are referring?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. I have been very much interested in your statement which appears on page 121 of the issue of the Reader's Digest, and I quote:

It was my considered opinion, I told correspondents in Tokyo, that the effects of the atom bombs—not of future bombs, but of these two—

The two referred to, I assume, were the one on Hiroshima and the one on Nagasaki?

Major DE SEVERSKY. That is right.

Senator MILLIKIN (continuing to read):

had been widely exaggerated. If dropped on New York or Chicago, one of those bombs would have done no more damage than a 10-ton blockbuster; and the results in Hiroshima and Nagasaki could have been achieved by about 200 B-29's loaded with incendiaries, except that fewer Japanese would have been killed.

If you dropped an atomic bomb of the type used at Hiroshima and Nagasaki at the same level that you dropped the kind of normal bomb that you are speaking of, would the results be the same as you have mentioned here?

Major DE SEVERSKY. No. The probable results from the atomic bomb would be greater.

Senator MILLIKIN. Greater in proportion to the energy released?

Major DE SEVERSKY. Yes; provided energy was released in the proper direction. You can release the energy in the wrong direction, and you don't get any results.

Senator MILLIKIN. But I am assuming that we drop a normal bomb at X point at Y elevation and we drop an atomic bomb at the same point and same elevation. The damage, roughly speaking, would vary in proportion to the respective energies released; is that not correct?

Major DE SEVERSKY. Roughly; yes. But the result will not sometimes be even roughly the same.

Senator MILLIKIN. Now, would you be good enough to give us your calculations on which you assume that a 10-ton blockbuster, if dropped on New York or Chicago, would have done as much damage as at Nagasaki? Were you speaking here of the Nagasaki or the Hiroshima bomb?

Major DE SEVERSKY. I had spoken about both.

Senator MILLIKIN. Well, taking either one of them, would you mind giving us your calculations on which you have come to that conclusion?

Major DE SEVERSKY. I haven't made any calculations. It was my personal observation, based on experience. For example, we can ask an architect what is the dimension of this room. He probably can pretty well tell you within maybe 10 percent the length and width of this room. But if you want to know exactly, he has to bring in the instruments and measure it exactly to one millionth of an inch if you wish. That wasn't my purpose or my assignment. I am leaving such detailed study to the United States Strategic Bombing Survey, who are more expert in this field than I can consider myself. They worked in the field and undoubtedly will furnish us with the results that will leave no question as to the causes and effects.

My statement was based simply on my observations and my experience, just as I could say that this room perhaps is 25 or 30 feet wide, within a certain approximation. My purpose was primarily to show the American people that if an atomic bomb were dropped on New York or Chicago, these cities would not be wiped out to the ground completely and everybody in the cities be killed.

The CHAIRMAN. That isn't what you said, however, Major.

Major DE SEVERSKY. When I said it, I had in view one illustration I saw in one paper—whether American or English, I don't remember.

There was a circle drawn around New York that was similar in diameter to the devastated area of Hiroshima and which took in Manhattan, Bronx, Brooklyn, the boroughs of Greater New York. The article said this area would be lying in complete ruin and devastation and not a single person would live.

Senator MILLIKIN. I am probing what you said, not what somebody else said—

Major DE SEVERSKY. I am leading to that.

Senator MILLIKIN. Let me complete my statement, please.

Major DE SEVERSKY. All right.

Senator MILLIKIN. You said that in your judgment a single bomb of the type that you describe dropped on New York or Chicago would loose the same amount.

Major DE SEVERSKY. In the same manner; yes.

Senator MILLIKIN. Now, you state that that is a matter of judgment and you illustrate that type of judgment by saying that a man can look at this room and approximate its dimensions. But to do that, at least to put it in terms of feet or some other unit of measurement, he must know by feet or units of measurement.

Major DE SEVERSKY. That is right.

Senator MILLIKIN. Now, therefore, I assume that you had made calculations from which you would produce a statement of that kind, and that is why I ask you for those calculations.

Major DE SEVERSKY. No; when the reporters asked me that question, I certainly didn't pull out my slide rule and pencil and begin to calculate. I told them exactly my rough impression of the thing, and I think it served the purpose perfectly, because if some newspaper asked me if it were true that the Atomic Committee hearings were held in a room 10 miles wide and 50 miles long, I might say, "No; I don't think so." I might say, "It is about 50 feet wide and maybe 100 feet long," which is roughly twice its size.

Now, I might have made a mistake, but that certainly is nearer to the truth than stating that the room was 50 miles long and 20 miles wide; and it is the latter kind of exaggeration that I tried to correct. Somebody said that the atomic bomb was 20,000 times more powerful in its destructiveness than a single blockbuster. I don't agree with that.

Senator MILLIKIN. Wasn't the statement made that it is 20,000 times more than certain units of TNT? Hasn't that been the statement?

Major DE SEVERSKY. As I remember the statement, it was 20,000 times more powerful than one of our blockbusters.

Senator MILLIKIN. Major, again I would like to come back to the fact that I am not questioning someone who has said something except Major de Seversky. I am just trying to check Major de Seversky as to what he has said.

It is fair to summarize your statement here that one 10-ton blockbuster would do the same amount of damage in New York or Chicago as a mere matter of judgment on your part, unsupported by calculations?

Major DE SEVERSKY. Yes, sir; for a man of my experience in observing of demolition over long periods of time, I think it is fair. But if the committee later on will want to have any more accurate substantiation of my statement, I am perfectly willing to furnish it. If my calculations are going to show that it is equal not to one or two or three blockbusters, I still feel I was perfectly right in making the statement.

Senator MILLIKIN. Do you challenge, Major, the estimates of the various scientists as to the proportion of this power in relation to normal TNT power? Do you challenge that?

Major DE SEVERSKY. Of course not.

Senator MILLIKIN. You think they are correct in that?

Major DE SEVERSKY. Why, certainly.

Senator MILLIKIN. Would the application of that proportion to an atomic bomb dropped at the same place, at the same elevation, as against a normal bomb of the type that you describe dropped at the same place and same elevation bring you to the answer of 200 B-29's?

Major DE SEVERSKY. Well, that is an entirely different thing. When I talked about fire effect, I said that Hiroshima could have been burned in the same fashion as it was burned by a single atomic bomb by a raid of 200 B-29's loaded with incendiaries.

Senator MILLIKIN. Then you intended in that statement to limit your comparison to the incendiary effects, but not the general demolition effects?

Major DE SEVERSKY. Well, I think if out of these 200 B-29's 50 were loaded with high explosives and pin pointed on the main section of Hiroshima, which still stands intact, I think they could have done even a better job.

Senator MILLIKIN. If you are speaking in terms of fire, don't you believe that an atomic bomb, if the amount of heat attributed to it is correct, would do infinitely more damage in terms of fire if it were dropped on New York or Chicago than a single 10-ton blockbuster?

Major DE SEVERSKY. Well, it depends where it would have exploded. It depends on the altitude at which this bomb exploded. If it exploded at the same altitude as it exploded over Hiroshima, I don't think the fire hazard directly from the bomb would be very great.

I visited all the tall buildings in Hiroshima, and I found the paint on the railings and wooden doors of those penthouses was not even scorched. I saw a great many fragile objects. I saw sirens painted with silver paint which wasn't scorched. The appearance of the roofs of those high buildings in Hiroshima and some in Nagasaki, as far as I could see—and I have pictures of them which you may be willing to see later on, colored photographs that I took of those details—did not show to me any particularly high temperature.

Senator MILLIKIN. Well, in terms of comparison of temperature, if you released a 10-ton blockbuster at the same altitude that the Hiroshima and Nagasaki bombs were released, what would be the effect of these on large cities of the type you are speaking of, New York and Chicago?

Major DE SEVERSKY. I don't think you interpret my statement exactly right. What I tried to compare was the atomic bomb as it exploded over Hiroshima with a direct hit of a blockbuster.

Senator MILLIKIN. To your mind, is that a fair comparison?

Major DE SEVERSKY. Yes, it is. I am not comparing the weapons: I am comparing the results. I was trying to transplant the results of what had happened in Hiroshima if that bomb exploded in Chicago or New York in the same manner; it would not produce any more damage, or approximately the same damage, as a 10-ton blockbuster which scored a direct hit on a section of Chicago.

Senator MILLIKIN. Yes, Major, but would there have been any damage at all had you released a 10-ton blockbuster at the same altitude?

Major DE SEVERSKY. There would be some blast effect.

Senator MILLIKIN. What was the altitude of release at Hiroshima and Nagasaki?

The CHAIRMAN. That is secret.

Senator MILLIKIN. It was a considerable altitude, was it not?

Major DE SEVERSKY. It must have been. In New Mexico, where all the tests were conducted as in a laboratory, the scientists and engineers certainly had a very wonderful opportunity to measure all the forces, temperature, and everything else, so they could not be very much mistaken as to what actually takes place when the bomb explodes. The discrepancy between the two results is due to the fact that the bomb in Japan exploded much higher than it exploded in New Mexico, and apparently as in any explosion the results are dependent on the distance at which the explosion takes place.

Senator MILLIKIN. Just for our information, let's put the thing on a comparable basis, and I will guess some altitudes. Let us suppose that you exploded an atomic bomb of the type we are talking about at 3,000 feet in the air, and you exploded a 10-ton blockbuster at 3,000 feet in the air. What would be the respective effects?

Major DE SEVERSKY. Well, the atomic bomb will be immeasurably more powerful.

Senator MILLIKIN. Let us bring it down to the surface of the earth. Let us suppose you explode a 10-ton blockbuster in the heavier part of lower Manhattan, and at the same point you explode the type of atomic weapon that we are talking about. What would be the proportions of destructive energy released by the two weapons?

Major DE SEVERSKY. Well, the energy would be released exactly as it was calculated, but the effect on the target depends on the nature of the target. It is quite different whether you release this energy within a flimsy half-dry-rotted Japanese village or release the same energy within a steel and concrete city. The difference in one case in actual damage would be perhaps 200 times more or 500 times more; it all depends on how you are going to measure the results—in the number of dwellings or buildings destroyed, in area, in people killed.

Senator MILLIKIN. You have gotten away from my point, Major. I am not talking about two things that are not analogous. I am trying to bring the two bombs to the same spot in lower Manhattan. Would you challenge the statements that have been made as to destructive energy released from the one type of bomb against the other?

Major DE SEVERSKY. Of course not.

Senator MILLIKIN. So that this 200 B-29 statement of yours relates, on the one hand, to destruction of a city of the type of Hiroshima or Nagasaki?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. And you are making a comparison of that with the heavy construction of a city of the type of New York or Chicago. Does that appear to you as a logical basis for making comparisons?

Major DE SEVERSKY. Those are two entirely different statements.

Senator MILLIKIN. I don't want to pursue anything that I have made any mistake about myself. [Reading from Major de Seversky's article in the Reader's Digest:]

I told correspondents in Tokyo, that the effects of the atom bombs—*not of future bombs but of these two*—had been wildly exaggerated. If dropped on New York or Chicago, one of those bombs would have done no more damage than a 10-ton blockbuster—

Major DE SEVERSKY. That is one statement.

Senator MILLIKIN. Then you go on to say:

and the results in Hiroshima and Nagasaki could have been achieved by about 200 B-29's loaded with incendiaries—

Major DE SEVERSKY. No, that is not all—there is something else.

Senator MILLIKIN (continuing to read):

except that fewer Japanese would have been killed.

Major DE SEVERSKY. In other words, the atomic bomb, as far as the loss of life is concerned, is infinitely more destructive than the ordinary bomb.

Senator MILLIKIN. Now we have got two things we are talking about. We are talking about the incendiary effect of the type of bomb at Hiroshima and Nagasaki. That is one thing. We are talking about the effect of two types of bombs dropped on Chicago or New York.

Major DE SEVERSKY. In other words, one is demolition action—that is one statement; and then I compare it with Chicago and New York. But the incendiary action, I compare with 200 B-29's in Nagasaki and Hiroshima. Those are two different statements.

Senator MILLIKIN. Let us put our minds solely on the heavy structures such as we find in Chicago or lower Manhattan. What is the basis of your calculation, assuming that the atomic bomb and the 10-ton blockbuster are dropped at the same place and from the same elevation? What is the basis for your statement that one bomb would produce as much damage, one blockbuster would produce as much damage as the atomic bomb?

Major DE SEVERSKY. I didn't say it produces more.

Senator MILLIKIN. I quote:

If dropped on New York or Chicago, one of those bombs would have done no more damage than a 10-ton blockbuster.

Major DE SEVERSKY. I just simply want to be accurate. I didn't say more; I said "no more." It means about the same; it doesn't mean more.

Senator MILLIKIN. Well, it says very clearly—

If dropped on New York or Chicago, one of those bombs—that is one atomic bomb?

Major DE SEVERSKY. That is right.

Senator MILLIKIN (continuing to read).

would have done no more damage than a 10-ton blockbuster.

Major DE SEVERSKY. That is right. It doesn't mean the 10-ton blockbuster produces any more, but "no more" means about the same, doesn't it?

Senator MILLIKIN. Would you tell us the relative amount of damage that would happen if you dropped an atomic bomb on New York or Chicago, or if you dropped a 10-ton blockbuster?

Major DE SEVERSKY. Do you want me to speculate? In the article I was comparing the damage results of the atomic bomb as it was dropped, to the damage results of a TNT blockbuster's direct hit. But I am perfectly willing to speculate because I don't think I will be too far off. It again depends upon what part of New York it will be dropped—whether it will be dropped in the midst of steel and concrete buildings, or not.

In view of what I saw in Hiroshima and Nagasaki, and particularly in Hiroshima where whole buildings were standing perfectly upright and had very little structural damage, and provided both bombs exploded down below, scoring direct hits, so to speak, I think that the damage from the atomic bomb will be only slightly more than that of a blockbuster. It probably will shatter glass and will bring down some of the brick buildings within a greater distance than the TNT bomb, but I think the blast in that case will be localized by other tall buildings, so the damage will be local and not as widespread as it was in Hiroshima.

Certainly, if the atomic bomb dropped in Hiroshima exploded in the same manner over New York or Chicago, it would not wipe out New York or Chicago. We would have to drop a great many atomic bombs of the same kind in the same manner before we could wipe out New York or Chicago. That is my opinion.

Senator MILLIKIN. When you say "if dropped on New York or Chicago, one of those bombs would have done no more damage than a 10-ton blockbuster," you were assuming that the blockbuster would be exploded at the normal place where a blockbuster is exploded, and you were assuming that for that purpose the atomic bomb would be exploded up in the air as it was at Hiroshima and Nagasaki?

Major DE SEVERSKY. Exactly, because we never explode TNT bombs 2,000 feet in the air.

Senator MILLIKIN. Of course you don't.

Major DE SEVERSKY. Naturally those were ordinary actions that I assumed everybody would take for granted.

Senator MILLIKIN. Let me ask you again whether you consider a statement of this kind going out as a fair analogy when on the one hand you drop a blockbuster at the place it is normally dropped, and on the other hand you are making a comparison with a bomb that is exploded very high up in the air over an entirely different kind of target?

Major DE SEVERSKY. It is not an analysis. That is the whole difference. I have been testifying here that my article was not written to give any detailed analysis. It was to calm down the hysteria that was unwarrantedly spreading all over our land. I tried to counteract that hysteria and to answer the claims and information that did not come from any official sources, but was spread all over our land by

some pseudo-scientists who had not even been within 5,000 miles of Hiroshima and Nagasaki. The statements I made were intended to show by way of illustration that in my candid opinion if that bomb exploded the way it did in Hiroshima and Nagasaki over one of our big cities, it wouldn't have done very much more damage than the damage caused by a direct hit by one of our TNT blockbusters. In other words, it would not wipe out New York or Chicago in the same manner as it wiped out Hiroshima and Nagasaki. That was the purpose. It was not an analysis. It was my personal impression as I saw things, and conclusions I drew from my observations.

Senator MILLIKIN. Let me take you to what perhaps will be an analogous comparison between the effect on a heavy structure area of a large city like Chicago or New York between the explosion of the atomic bomb and the explosion of a 10-ton blockbuster. Let's come back now to my suggestion that we put them both at the same place.

Now, how many blockbusters would you say would be required to achieve the same effect as might be expected from the Hiroshima or Nagasaki bomb?

Major DE SEVERSKY. Well, it is very complicated and an ambiguous subject, because it depends on the kind of target, the disposition of the target, and a great many other conditions which really have to be analyzed and investigated. I think you are going to get a much better answer if you ask some of your specialists, like some of the United States Strategic Bomb Survey people who I think are more capable of giving you a better answer than I could give you offhand.

Senator MILLIKIN. Then may I summarize the effect of your testimony, that you did not intend in your article to make any comparison between a 10-ton blockbuster dropped in a heavy structure city of the type we are talking of and an atomic bomb dropped at the same point?

Major DE SEVERSKY. No, of course not.

Senator HART. Major, your article begins with a statement in which you say that you conveyed your professional findings to the Secretary of War. In view of your answers to Senator Millikin, may I ask you what you consider your profession to be in that regard?

Major DE SEVERSKY. I am an aeronautical engineer, and like any aeronautical engineer, I have a certain amount of understanding of structures. I devoted all my life as a military man to the tactics and strategy of aerial warfare. I deal in the realm of aeronautics and perhaps armament.

As you perhaps know, I designed the first automatic bombsight, and have a basic patent on this device.

Senator HART. May I interrupt you, Major. I do not mean to carry you so far in that. Actually that bombsight was not adopted, was it?

Major DE SEVERSKY. Well, it was adopted by the United States Army. The order was placed.

Senator HART. But not built?

Major DE SEVERSKY. It was built.

Senator HART. But it did not go into production, did it?

Major DE SEVERSKY. No.

Senator HART. Well, I did not wish to go so far afield as that, Major.

Later in your article you said you conveyed to the country that the bomb over Nagasaki was only one-fourth as effective as the one which

was dropped over Hiroshima. Can you tell the committee what it was that you based that statement on?

Major DE SEVERSKY. Simply by measuring the actual area of destruction between the two.

Senator HART. Did you make those observations from the air only?

Major DE SEVERSKY. No; from the ground, too.

Senator HART. Then your statement is that instead of destruction about 2 miles on a side as was the case at Hiroshima, the destruction at Nagasaki was only 1 mile on a side?

Major DE SEVERSKY. Those figures I used were official figures furnished to me by the Air Forces.

Senator HART. Furnished you by the Air Forces?

Major DE SEVERSKY. Yes, sir.

Senator HART. And it was on that alone that you sent this statement out over the country that the bomb at Nagasaki was only one-fourth as effective?

Major DE SEVERSKY. Yes.

Senator HART. You said that measuring by the area of destruction in Nagasaki, the area destroyed in Nagasaki was roughly on the basis of those figures, one-quarter of the area destroyed in Hiroshima. May I ask if you have examined the official reports on the subject and find yourself in concurrence and find they are in concurrence with what you say?

Major DE SEVERSKY. Which reports, Senator?

Senator HART. That comparison as between the area in Hiroshima and in Nagasaki. Do the official reports on the subject bear out your statement?

Major DE SEVERSKY. You didn't see any reports before my statement? Were any reports made before my statement outside of those furnished by the Strategic Air Forces?

Senator HART. Well, before or since, I don't know.

Major DE SEVERSKY. No, I haven't seen anything different as to the size of the devastated area of those towns.

Senator HART. Then what you obtained from the Army Air Forces was not the official figure, you mean?

Major DE SEVERSKY. I don't understand.

Senator HART. You mean to say, Major, you based that statement on data which you obtained from the Army Air Force officers?

Major DE SEVERSKY. It was published in all the papers. It was available.

The CHAIRMAN. Major, you said that you were somewhat surprised at the fact that 15 concrete buildings—I think there were some 15—were still standing in the Nagasaki square mile of main damage. Now, was there any damage done to those buildings?

Major DE SEVERSKY. Yes, there was some damage. As a matter of fact, damage in Nagasaki to concrete buildings was perhaps somewhat greater, I think, than in Hiroshima.

The CHAIRMAN. General Groves has testified before the committee that—

The effects of the explosion in the industrial area were probably more spectacular and startling than Hiroshima; for example, the complete destruction of the huge steel works by blast and fire, and the destruction of the torpedo works by blast alone. Within a radius of 2,000 feet from the point of detonation,

heavy industrial buildings, gas storage tanks, and many reinforced concrete structures were destroyed. The steel frames in all buildings in all cases were pushed away from the point of detonation.¹

Do you agree with that statement?

Major DE SEVERSKY. Well, I wouldn't say that all of them were pushed away in the same direction from the point of the explosion. Some of them, as I remember now, did not follow the same direction. As far as the steel plant is concerned, I didn't see anything remarkable in its appearance. A great many Japanese plants looked exactly like that after they were bombed by high explosives and then consumed by fire.

The CHAIRMEN. Of course, this was one bomb, Major, wasn't it—one atomic bomb?

Major DE SEVERSKY. No; the steel plant was bombed by General Kenny's Air Force 6 days before the atomic bombing with eight direct hits on that plant.

The CHAIRMAN. I see. [Reading:]

For a radius of 8,000 feet, Japanese workers' homes were completely demolished. Up to a radius of 2 miles, workers' homes had collapsed; roofs and walls were smashed, but were left partly standing except in isolated cases where exceptional shielding was given by local topography.²

Do you agree with that statement?

Major DE SEVERSKY. Well, some parts of Nagasaki had wooden houses I think much closer than 2 miles with no damage. That is immediately south of the steel plant. I don't think that distance is 2 miles; I think it is about a mile. There are whole sections of Nagasaki only a mile from the center of the explosion which remained intact; even those flimsy wooden houses were intact.

The CHAIRMAN. Is it your contention that the atomic bomb dropped, we will say, in the Wall Street area would do no more damage than one blockbuster?

Major DE SEVERSKY. It depends on how it is going to be dropped.

The CHAIRMAN. You didn't say that in your article, though, did you?

Major DE SEVERSKY. No; on the contrary, I think it is clear throughout the article that I am comparing the damage that might have been done by the atom bomb, as it exploded in Hiroshima, with a direct hit by a blockbuster. I have repeated it here time and time again, but I couldn't repeat it in every paragraph of my article. If I did, it would not be a good article. No one would read it.

The CHAIRMAN. There is only one way to drop a blockbuster, and that is the way it is being dropped now?

Major DE SEVERSKY. That is right.

The CHAIRMAN. Assume one blockbuster dropped in the traditional way were dropped in the Wall Street district in New York. Is it your contention now that it would do no more damage than an atomic bomb dropped as one was at Hiroshima?

Major DE SEVERSKY. The material damage to steel and concrete buildings would not be greater, but the loss of life might be greater due to gamma rays.

The CHAIRMAN. But the property damage would be no greater in your opinion?

¹ See statement of Maj. Gen. L. R. Groves, pt. 1 of the hearings on atomic energy, p. 33.

² Ibid.

Major DE SEVERSKY. Well, roughly not. If I am mistaken, it may be that the atomic bomb would do more damage, but judging from the condition of buildings in Hiroshima, I doubt it.

The CHAIRMAN. There would be no greater blast?

Major DE SEVERSKY. I think I mentioned that the glass, for example, would be blown out over a wide area, because if the blast in Hiroshima was able to knock out panels in the hospital nearly a mile away, there is no reason why the glass in New York would not be blown out 1 mile away, too. That phenomena would take place unless the propagation of the blast is impeded by a series of tall buildings which would probably localize the blast a little bit more. So, if in Hiroshima the glass was blown out 1 mile away, in New York, if the explosion is shielded by tall buildings, the blast effects may be limited to half a mile.

The CHAIRMAN. Now, you stated in your article that if the temperature of an atomic bomb is superhigh, then the heat must have been dissipated in space.

I believe that was the statement you made in the article.

Major DE SEVERSKY. Not, exactly; no. I think I said that apparently they exploded so high that the effect of this heat had been diminished, or something to that effect.

The CHAIRMAN. Do you know Maj. Gen. J. F. C. Fuller, the English general who was supposed to be an expert on ordnance?

Major DE SEVERSKY. Well, I have heard of him.

The CHAIRMAN. Have you, by any chance, read his article, "The Age of Annihilation," in the Army Ordnance magazine for January and February?

Major DE SEVERSKY. No; I did not.

The CHAIRMAN. In it, he makes this statement:

We have also been told: "Theoretically, provided it can be manufactured in sufficient quantity, the atomic bomb has multiplied the destructive power of the American bomber fleets about 3,000 times."³

Do you agree with that?

Major DE SEVERSKY. Providing it can be done?

The CHAIRMAN. Providing you can manufacture enough atomic bombs, the Air Force as it was constituted on VJ-day could have done 3,000 times more damage equipped with atomic bombs than with blockbusters.

Major DE SEVERSKY. Well, of course, I cannot answer precisely his figures. There is no question that the atomic bomb would enhance the power of our Air Forces a great many times.

The CHAIRMAN. He goes on to say:

"Equipped with the new weapon, a fleet of 800 Superfortresses such as recently raided Japan would have the blasting effect of 2,500,000 such airplanes carrying TNT."

Eight hundred equipped with atomic bombs, such as dropped on Nagasaki, could do as much damage as 2,500,000 airplanes loaded with blockbusters.

Major DE SEVERSKY. If he calculated that, probably his figures are correct, provided his assumptions are correct.

³ See the January-February 1946 issue of the magazine entitled "Army Ordnance," the official journal of the Army Ordnance Association, a society of American industrialists and engineers; published in Washington, D. C.

The CHAIRMAN. That would be rather inconsistent with your statement that one blockbuster would do more damage in New York than one atomic bomb.

Major DE SEVERSKY. I don't see any inconsistency. You cannot take those figures and divide and multiply them. You cannot use plain arithmetic. There is a cumulative effect of a raid, too, which ought to be taken into consideration. Very often two bombs, dropped simultaneously on the target, do damage equal to that of three or four dropped separately, one by one. There are a great many factors entering into this business of demolition.

The CHAIRMAN. The blockbuster emits no lethal rays of any kind, does it?

Major DE SEVERSKY. No, it does not.

The CHAIRMAN. Now, the atomic bomb does, doesn't it?

Major DE SEVERSKY. So I understand.

The CHAIRMAN. And many people were killed in Nagasaki and Hiroshima by the rays?

Major DE SEVERSKY. Yes.

The CHAIRMAN. That is true, isn't it?

Major DE SEVERSKY. Apparently. I came evidently too late to see any victims. I couldn't find any but one, I think, but there is no reason for doubting that it does take place, because the experiment in New Mexico certainly proved beyond doubt that there is.

The CHAIRMAN. But in the article you state that the radiation burns were rare. I believe you pointed out that the radioactivity after the blast was not of a dangerous sort, but in any event you stated that the deaths caused by radiation were very rare, in this article.

Now, you have no foundation in fact for that statement, have you?

Major DE SEVERSKY. Well, I would rather you read my unabridged statement to that effect.

The CHAIRMAN. Unfortunately 15,000,000 have read the condensation.

Major DE SEVERSKY. I will stand by what that article states.

The CHAIRMAN. But the testimony before this committee has been, as I recollect it, that thousands of people were killed by burns.

Major DE SEVERSKY. If they were, then apparently the witnesses whom I interrogated did not furnish me with the right information. I personally visited the hospital in Hiroshima. I talked to the Japanese doctors, and they couldn't give me any information that would indicate such fact. Maybe I came too late, but I was looking for the victims, and I couldn't find any.

But, as I say, radioactivity is something that is completely beyond my sphere of specialized knowledge, and I have to abide by the experiment in New Mexico and the findings there as to the actual phenomena that takes place in an atomic explosion, which is good enough for me.

The CHAIRMAN. Now, Major, I think that you did emphasize in your article, and I think it is fortunate that you did, that you were talking about present-type bombs and were not attempting to project into the future any improvements that might possibly be made, if you want to call them improvements, over the atomic bomb.

Major DE SEVERSKY. Of course, this thing is in the same stage that aviation was at Kitty Hawk.

The CHAIRMAN. Do you believe that?

Major DE SEVERSKY. Absolutely.

The CHAIRMAN. It is your belief that the bombs that we have now are to future bombs as the Kitty Hawk plane was to the 700-mile-an-hour plane that we have today?

Major DE SEVERSKY. Well, yes. I would like even to use the words of the group of scientists in Chicago who sort of challenged my statement. They said that Major de Seversky ought to remember that the Hiroshima and Nagasaki atomic bombs are firecrackers in comparison to the future bombs. That is exactly what I intended to show.

The CHAIRMAN. Any further questions?

Senator JOHNSON. I have some questions.

Major, first I want to say this: I am very much interested, and I think this committee will be, in a comparison between the Nagasaki bomb and the Hiroshima bomb. I think that is a very important point, especially in a study of the production of atomic energy.

Did I understand you to say that the Nagasaki bomb's effectiveness was only one-fourth that of the Hiroshima bomb?

Major DE SEVERSKY. Judging by the area of destruction.

Senator JOHNSON. And the Nagasaki bomb's effectiveness was retarded by the physical conditions, was it not—the mountains?

Major DE SEVERSKY. In two directions, yes. In another direction, south, it wasn't particularly impeded.

Senator JOHNSON. Do you think that the Nagasaki bomb was less effective than the Hiroshima bomb?

Major DE SEVERSKY. Judging by the area of destruction, my impression was yes.

Senator JOHNSON. I notice that writers have said that the Nagasaki bomb made the Hiroshima bomb obsolete.

Major DE SEVERSKY. Who said that?

Senator JOHNSON. Well, several writers. I have seen it published several times.

Major DE SEVERSKY. What does it mean?

Senator JOHNSON. Well, it means a great deal to this committee.

Major DE SEVERSKY. What does it mean, "made obsolete"?

Senator JOHNSON. Well, it seems that the Nagasaki bomb was so superior to the Hiroshima bomb that the Hiroshima bomb was already obsolete.

Major DE SEVERSKY. I think that these writers who wrote were interpreting the official information that was supplied to them without realizing what they were saying. I am sure what they were trying to say when they said "superior" is that the design and construction of the bomb itself and the method of explosion and detonation were improved, and therefore the bomb dropped in Nagasaki was a great deal superior to the one that was dropped at Hiroshima, and for these reasons it made the Hiroshima bomb obsolete.

Senator JOHNSON. I think that the opposite is true. I think they meant the effectiveness of the two bombs, and as I understand it, from what little information we have been able to get on the point from witnesses, the Nagasaki is much more difficult to detonate than the Hiroshima bomb. The Hiroshima bomb is much easier to handle than the Nagasaki bomb, but the Nagasaki bomb is so much more effective when it is detonated. That is a very important point to this committee. One reason I might give is that in the tests that are to

be made, the naval tests, the Nagasaki type of bomb is to be used, and then there is a very important point which I don't care to go into now in the production of the two bombs, an extremely important point, and, of course, if we were making atomic bombs, we would want the most effective bomb.

Major DE SEVERSKY. In that case I would recommend that you take the opinion of the scientists and engineers who make the bomb, because they certainly have a better knowledge of which bomb is better. The only thing I have stated about the difference between the two atomic bombs can be read in my statement. Mind you, I am not challenging any official statement: I am challenging the statements of unofficial sources spread around. That is what I am challenging.

Senator JOHNSON. I am not challenging you or anybody else. It was said that the Nagasaki bomb was many times—I read somewhere it was 100 times—more powerful than the Hiroshima. I read it in the paper.

Major DE SEVERSKY. When I got there and got the figures of the square mileage that was destroyed, I found that the actual area of destruction in Nagasaki was about one-fourth that of Hiroshima, and that approximately coincided with the figures supplied by the Air Forces. If the figures I used, on which I based my conclusions, are wrong, my conclusions are obviously wrong.

Senator JOHNSON. Well, from what you say and from what you saw of the effectiveness of the two bombs, comparing the effectiveness of the two bombs, if you were undertaking a naval experiment, which bomb would you use?

Major DE SEVERSKY. I would use the one that is considered to be the more efficient.

Senator JOHNSON. Well, judging the effectiveness only from what you saw there, which one would you use?

Major DE SEVERSKY. Well, if you are asking me the question, I would like to give you my opinion.

Senator JOHNSON. I would like to have your opinion on it because it is an important point.

Major DE SEVERSKY. In the first place my belief is that neither the Nagasaki nor the Hiroshima bombs will sink battleships if they explode in the same manner as they exploded when used at Hiroshima and Nagasaki. Under those conditions I do not think that very much damage will be done to a battleship.

Senator JOHNSON. From either one?

Major DE SEVERSKY. From either one. I mean, as far as material damage is concerned; as far as radioactivity is concerned, speculation on that point I leave to the experts.

No one can accuse me of particular fondness for battleships, but I still think that the battleship, under those circumstances, will survive the atomic bomb.

Of course, if the bomb scores a direct hit, it will probably destroy the battleship, but so will also one of the ordinary bombs of the proper size. It also will destroy a battleship if there is a direct hit. As you know, quite a few battleships were sunk in that manner during the last war.

The only thing, in my opinion, that would be of particular interest is the detonation of the bomb under water. That, of course, might

produce all sorts of effects which are open to speculation. But, as far as dropping the atomic bomb above the fleet—well, I want to repeat that the ordinary bomb, properly designed for that purpose, would produce more positive results, if it scored a direct hit, unless the radiation of the atom bomb will be much greater than it was in Nagasaki, or the gamma ray's effect, which has been referred to in the Hiroshima bombing, will destroy the crew.

As I say, a direct hit will destroy the battleship. Either one of them will.

Senator JOHNSON. In the photographic views of Nagasaki, certain buildings were left standing, tall buildings, which I understand were supposed to be of steel and concrete construction. But we are told that all of them, these buildings, would have to be torn down, that they were so badly damaged that they were not safe, while they looked to be all right from the photographs. We were told they would all have to be demolished, destroyed. Is that your conclusion?

Major DE SEVERSKY. I cannot say that I think so. Of course, some particular buildings may have been damaged, shaken up by the explosion much more than was visible. It is just like using a glass which is cracked: even if I do not see any chips in it, I would not take a drink from that glass, I would take a new glass just as a precaution.

Senator JOHNSON. I am not talking about what we may want to do, but what may have to be done with such buildings. If they were condemned, they wouldn't be condemned simply on a whim, such as if you were to take a highball out of another glass. They would be condemned because of actual damage.

Major DE SEVERSKY. Yes. I think the building has to be inspected and if there is sufficient damage, demolish it.

As I remember, some of those buildings could be rebuilt, and others would have to be taken down.

Senator JOHNSON. You think some of them, however, could remain standing safely?

Major DE SEVERSKY. I think so; particularly in Hiroshima.

Senator JOHNSON. Particular in Hiroshima.

Major DE SEVERSKY. I climbed on top of a great many of them, back and forth, investigating every floor. I wasn't worried that the buildings would fall, when I climbed them.

Senator JOHNSON. Of course, some of them could be standing for several years; although they might not be safe, they could be left standing.

What was the effect on the roofs of these buildings? We were told that there was a blast of wind of 700 miles created by the bomb.

The CHAIRMAN. 1,000 miles an hour.

Senator JOHNSON. Yes; 1,000 miles an hour. And we were told that that wind crushed the roofs of the buildings down into the building. Did you notice that?

Major DE SEVERSKY. I can show you pictures of dozens of buildings where the roofs were not pushed down.

Senator JOHNSON. Where the roofs were intact?

Major DE SEVERSKY. Yes, some of them. A wind of about 700 miles an hour, or 1,000 miles an hour, a wind like that would do terrific damage; therefore, if there were such wind, it must have been very spotty. I can show you in Hiroshima, for example, pic-

tures of towers, poles, such as lamp poles, and all sorts of fragile things, on the roofs of the buildings, that had not been blown away. Such things certainly would have been torn away if a 700-mile-an-hour wind was blowing.

I do not deny that investigations show that such a wind takes place in an atomic explosion; however, its effect on the target depends on the manner and the conditions under which the explosion takes place.

I don't believe it did take place. I brought with me Kodachrome colored pictures of the points I mentioned. I certainly would like to have an opportunity to show them to substantiate my statement.

In all fairness, instead of just saying, "This is my observation," I should be given a chance to prove it with photographs. I have been more or less interrogated here, and if that is the case, I would like to have the opportunity to show you what I mean with pictures instead of just from "observations." I am sure you gentlemen will certainly agree with my point of view. Common sense will indicate that I am not far off.

Senator JOHNSON. Well, Major, I certainly am not antagonistic to you. I am not trying to badger you or heckle you, or anything of the kind.

You were over there and you saw the effects of these bombs, and I think you are a very important witness and a witness in whom I have had a great deal of confidence throughout the years, and still have.

So, what you are saying and the testimony that you are giving, is taken very seriously by this member of the committee, at least.

Did you visit the New Mexico detonation?

Major DE SEVERSKY. No, I did not.

Senator JOHNSON. You have not seen that?

Major DE SEVERSKY. I only read about that and when I read about it, naturally, until I saw the results of the Hiroshima and Nagasaki bombings, I thought I had a pretty good idea of what took place. I think millions of Americans had the same idea as I did, that everything was completely wiped out, and the sand was fused and the area was covered with a glasslike crust.

I was very much surprised, therefore, when I came there, to find that there were quite a few trees standing, quite a few buildings standing. Some vegetation was still blooming and growing, though not much of it.

I can show you some pictures of it in color, so there will be no doubt about it.

Senator JOHNSON. Trees that were not destroyed and still alive?

Major DE SEVERSKY. All the leaves were gone from the trees but not from some of the low vines on the ground—I have a picture of such a vine, one with six branches, just about 100 feet from the center of the explosion, that looks very pretty.

Senator JOHNSON. Did I understand you to say, Major, a moment ago, that within a mile of the center of the explosion that flimsy Japanese houses were still standing?

Major DE SEVERSKY. Not within a mile.

Senator JOHNSON. Within what radius?

Major DE SEVERSKY. I mean the destruction was within a radius of 1 mile. Beyond that, I found Japanese buildings that stood up—in Nagasaki.

Senator JOHNSON. Still standing?

Major DE SEVERSKY. Yes.

Senator JOHNSON. One mile from the center?

Major DE SEVERSKY. Roughly about 1 mile. I have pictures of them which I would like to show you.

Senator JOHNSON. Was that true in both cases?

Major DE SEVERSKY. It was a 1-mile radius in Nagasaki. I think that is one thing that was different between the two; I think the radius in Hiroshima was a little bit greater than 1 mile, as I remember.

Senator JOHNSON. Did you talk to anyone that had that experience there and was blinded by the light of the bomb?

Major DE SEVERSKY. No, but I talked to some people who were not blinded—you mean blinded forever?

Senator JOHNSON. Just for the moment.

Major DE SEVERSKY. Yes. Well, this fellow [indicating photographer] blinds me all the time, but I am used to that.

However, seriously speaking, that is true. Yes, that was the thing that about everybody who saw the flash agreed on.

I talked to the people in the Press Building, just three or four blocks from the center of the explosion. When I came, there were quite a few people in it. I went there with one of our A-2 officers and some members of the United States Strategic Bombing Survey. I talked to the people in the building. Among them were about three or four Japanese who were in the building when the bomb exploded and they were able to describe to me more or less what happened.

They said that at first they saw a flash, then terrific explosion. All the windows were blown out. The fire started on the fourth floor, where they stored negatives, inflammable negatives. They did not discover the fire, of course, until quite a few minutes later. By that time all the surrounding wooden houses were already on fire.

They argued among themselves as to the cause of the fire. Some of them were sure that the negatives caught fire at the moment of the explosion; and others said, no, they caught fire from the adjacent trees or wooden houses. When the latter became inflamed, sparks started to fly into the building through the broken windows.

Senator MILLIKIN. I would like to ask a couple of questions, Mr. Chairman.

The CHAIRMAN. Senator Millikin.

Senator MILLIKIN. Pursuing the line suggested by Senator Johnson, assume that there were two Hiroshimas, each exactly the same as the other. Suppose you dropped the normal Hiroshima bomb on one, and then you dropped the Nagasaki bomb on the other Hiroshima. Which would have done the most damage?

Major DE SEVERSKY. Well, I have no choice. The difference between them, as far as the damage was concerned, would be so little that I think either one of them would be equally good.

Senator MILLIKIN. You have no preference?

Major DE SEVERSKY. They were perfect jobs at that time.

Senator MILLIKIN. You have no knowledge of the respective potency of the two bombs?

Major DE SEVERSKY. No.

Senator MILLIKIN. On page 124 of the Reader's Digest to which I refer, it says:

The more painstakingly I analyze my observations, indeed, the more convinced I am that the same bombs dropped on New York or Chicago, Pittsburgh or Detroit—

you are referring there to the Nagasaki and Hiroshima bombs—

would have exacted no more toll in life than one of our big blockbusters, and the property damage might have been limited to broken window glass over a wide area. True, the atom bombs apparently were released too high for maximum effect. Exploded closer to the ground, the result of intense heat might have been impressive. But in that case the blast might have been localized, sharply reducing the area of destruction.

Do your observations which you have made to the effect that you were comparing an atomic bomb exploded in the air as against a blockbuster exploded on the ground, apply also to what I have read?

Major DE SEVERSKY. Yes.

Senator MILLIKIN. And on page 125, you say:

It seems to me completely misleading to say that the atomic bomb used on Japan was "20,000 times more powerful" than a TNT blockbuster. From the view of total energy generated, this may be correct. But we are not concerned with the energy released into space. What concerns us is the portion which achieves effective demolition. From that point of view, the 20,000 figure is reduced immediately to 200 for a target like Hiroshima. For a target like New York, the figure of 20,000 drops to one or less.

May I ask you again, did you have in mind when you wrote the things I have cited here, an atomic bomb exploded in the air, as against a blockbuster exploded on the ground?

Major DE SEVERSKY. The same.

Senator MILLIKIN. That runs all through your testimony?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. And when you say that you reduce the effectiveness of the atom bomb dropped on a target like New York from a figure of 20,000 to 1 or less, that rests on the assumption that you have discussed; and it also rests on your judgment as distinguished from actual calculation?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. Thank you.

Senator AUSTIN. I would like to ask a question.

The CHAIRMAN. Senator Austin.

Senator AUSTIN. Is it correct or not that the explosive effect of a detonation of TNT or of atomic energy includes the eccentricity of swirls or waves of energy going in incalculable directions so that you may have one spot in the area uninjured by the wave and right beside it a spot is destroyed by the wave? Is that characteristic of such an explosion?

Major DE SEVERSKY. As far as the atom bomb is concerned, I have observed the same thing.

Senator AUSTIN. Yes.

Major DE SEVERSKY. I have observed, for example, in Nagasaki, instances where, say, for a mile everything is destroyed; in another mile in the same direction there was no destruction. Then, all of a sudden, at the end of the 2 miles, we find some destruction again.

Also, in Hiroshima, I found isolated districts where there was destruction by blasts beyond the radius of the general destruction.

So, apparently, there is a phenomenon of rebound or a certain irregularity in the distribution of blast, the primary cause of which might be the terrain. It is for this particular type of phenomenon.

As I said, my observation was that it is true that there was no definite regularity in the propagation of the blast. I mean, that is the deduction that I made from my observations in those two cities.

Senator AUSTIN. Historically, we have many examples of that characteristic of explosives. I recall one of an explosion in a laboratory, where one side of the laboratory was completely blown out and yet people in the other side of the same room were wholly uninjured and unaffected by the explosive wave.

Major DE SEVERSKY. That is why, Senator, I am so reluctant to tell exactly what is going to happen when two bombs are exploded within, say, Wall Street in New York, on contact. It is very difficult to predict exactly what is going to take place.

It depends upon the conditions, the character of the target, and the interrelationship between the components of the targets or the places.

But, one thing I do know. It is not going to do what people believe through so many stories; that is, that for 2 miles in radius New York would be completely wiped out. That is what I tell people about those two bombs, so that they will really calm down a bit.

Senator AUSTIN. It comes down to the general principle, does it not, that where an explosion takes place in an area where there is destructible material, the extent of the explosion must be related to the power of the explosive; isn't that about it?

Major DE SEVERSKY. We have to have some basis to start with.

Senator MILLIKIN. Mr. Chairman.

The CHAIRMAN. Yes, sir.

Senator MILLIKIN. I think everyone would agree that the area of demolition that was achieved in either Nagasaki or Hiroshima would not be duplicated in lower Manhattan with either one of the two bombs. But would that destruction, in terms of units of destruction, be the same?

Major DE SEVERSKY. No. Units of destruction are not necessarily in direct proportion to the energy released. In the latter area, the units will be smaller. It all depends on the yardstick used to measure the destruction.

Senator MILLIKIN. Units of energy will be calculated on the theoretical proportions, will they not?

Major DE SEVERSKY. They will be there, they cannot disappear.

Senator MILLIKIN. And the effect will be lessened in the case of either the blockbuster or the atomic bomb?

Major DE SEVERSKY. In other words, you have to consider the limiting factors which are inherent in the target itself. In the latter case, the target, with its tall steel and concrete buildings, will impede the propagation of the blast and even the propagation of the gamma rays; it will protect some of the people.

Senator MILLIKIN. But it is not a fair comparison to take an area of destruction and then erect a sort of strawman to make the argument on the theory that someone claims that there may be the same destruction in the lower part of Manhattan?

Major DE SEVERSKY. What is this?

Senator MILLIKIN. In Hiroshima you had a definite area of destruction, right?

Major DE SEVERSKY. That is right.

Senator MILLIKIN. No one would expect the same area of destruction in Manhattan, would they?

Major DE SEVERSKY. Oh, would they not? I can show you illustrations from all over the world, in Europe and American newspapers. To show you the pictures is not just the same as telling you; you'll see what I mean if you let me show you these pictures, because, you see, visual education and visual demonstration are more powerful than words.

When people see a red circle drawn around New York and the caption says that this is what will happen if an atom bomb is dropped, that everything within that red circle will be destroyed, such a picture will remain in their memories much longer than the oral descriptions of people who know.

One of the purposes of my article was to offset such incredible claims for the bomb. I think wild exaggeration is only going to hamper your work and becloud a clear understanding of what is taking place.

As I said, before I went to Hiroshima and Nagasaki myself, I was, like other people, oversold. I was lucky I didn't write anything about it.

But I remember telling a friend that if an atom bomb were dropped on the Navy, it would blow the Navy out of the water, it would evaporate the water around the fleet and leave ships suspended in space; then the battleship would plump back into the water and would be swallowed by the ocean.

That is what I was telling some of my friends that the Hiroshima bomb would do to the Navy—under the impact of hysterical propaganda.

So, you can readily understand my feelings when I come to Hiroshima and Nagasaki and I realized what a fool I would have been if I had made those statements public—in writing. I was mad.

Senator MILLIKIN. Would it not be equally misleading, Major, to depreciate the explosive effects, the destructive force of the atomic bomb if it landed in the same place as the blockbuster? Would not the enormous energies released produce somewhat the same amount of damage, even though the area might be less than at Hiroshima or Nagasaki?

Major DE SEVERSKY. No, I don't think this is a fair question, sir. There is nothing misleading in the things I have said. I do not say that the bomb is almost a human being and can think; I do not say that if it were dropped from this altitude there is going to be so much energy, and if it were dropped somewhere else the released energy would be different. It releases the same energy, naturally, no matter where it is dropped.

I still believe that I am nearer to the truth by saying that if the bomb were dropped over Chicago as it was over Nagasaki, the same bomb, at the same altitude, it will do no more damage than one blockbuster.

Those people who say that the entire city of Chicago would be blown up are way off the beam. From a tactical point of view, I think I am certainly much nearer to the truth. You see, I am speaking in terms of tactical considerations. I am talking as an airman.

If I have an air force and I have to do a job of destruction of Hiroshima, I could do the same job with 200 B-29's that the atomic bomb did from one B-29.

From a purely tactical point of view, therefore, that atom bomb was only 200 times more powerful, because, for all practical purposes, the city would have been wiped out in both cases.

To say that it was 20,000 times more powerful—because a lot of people felt that in order to destroy Hiroshima we had to exert 20,000 times more effort—just isn't so.

Measured in the tactical effort of the Air Force, we could do the same thing with 200 B-29's. We also must not forget another condition, a condition which I notice is overlooked when atomic discussion begins to apply atomic energy to the future war possibilities. It assumes that the enemy is going to take it sitting down.

People go on the assumption that we are going to be on the delivering end and that the enemy is going to be solely on the receiving end. Because we had control of the air over Japan, we were able to send one atomic bomb in one airplane. If we hadn't had control over Japan's air, we probably would have had to send 200 airplanes to be able to deliver 1 atomic bomb. In the future, of course, that ratio might be changed.

And again, I feel it my duty as a citizen who was there and who saw the results of atomic bombings to tell people exactly what it means in military effort. Because I am particularly interested in our national defense, I try to measure the military effort exerted under single atomic bomb conditions, with ordinary methods of bombing. But I would like to qualify that the loss of life would not have been as large, if ordinary incendiaries had been used.

Senator MILLIKIN. And as to these remarks that you just made, your comparison is again assuming the explosion of the atomic bomb in the air?

Major DE SEVERSKY. That is the premise of my article. I only discussed those bombs as they were dropped and how they were dropped.

The CHAIRMAN. Well, what do you think would happen to human beings in the area of the atomic bomb explosion, as compared to people in the area of one 10-ton blockbuster? The loss of life, of course, has been proven to be measurably greater.

Major DE SEVERSKY. Well, the gamma rays will be a factor in the latter case, but, as I said before, by the time I got there I couldn't collect any authoritative information on radioactivity.

The CHAIRMAN. But the people were dead, were they not; over 100,000 were killed at one stroke.

Major DE SEVERSKY. But there won't be so many killed in the future, because, you see, what will happen in the future is that people won't be taken by surprise. They will be prepared for the ordeal. Now, in the case of Hiroshima; the whole city collapsed instantaneously; there were no open streets left, since they were blocked by debris.

For example, if an incendiary bomb were to be dropped in this room, we still could run out through the doors. But there were no doors, no windows, in Hiroshima, everybody was pinned underneath the rubble. The wood was scattered and spread all over the streets. No one could go through them. Everybody lay exactly where they were.

So, regardless of the effectiveness of the gamma rays, there was a terrific loss of life.

The CHAIRMAN. All that would not have been done by one 10-ton blockbuster?

Major DE SEVERSKY. Of course not. I think it is clear in my article, there is no question about it.

The CHAIRMAN. General Groves has testified before this committee—

Senator JOHNSON. First, before you go on to that, Senator, may I read one paragraph of the major's statement; it is short, on that point?

The CHAIRMAN. Surely.

Senator JOHNSON. In describing what happened at Hiroshima, the major said:

It was like a great flyswatter 2 miles broad, slapped down on a city of flimsy, half-rotted wooden houses and rickety brick buildings. It flattened them out in one blow, burying perhaps 200,000 people in the debris. One must see it to believe the flimsiness of such Japanese structures. For the most part they are built of two-by-four boards, termite eaten and dry-rotted through generations. To make things worse, they are top-heavy with thick tile roofs. Often they tumble down without apparent reason.⁴

That figure of 200,000 people, that is the estimate of the number of people that were buried in the debris in Hiroshima?

Major DE SEVERSKY. Some probably escaped. I mean, they were knocked down but some were able to crawl out.

Senator JOHNSON. Further on, you say that 60,000 were burned to death.

Major DE SEVERSKY. That was information that was given me when I was over there.

Senator JOHNSON. Further on, you say:

Thousands of them must have been killed outright by falling walls and roofs; the rest were crippled and immobilized in a burning hell and some 60,000, it is estimated, were burned to death.⁵

The CHAIRMAN. Major, I just have one final question.

When we were talking to General Groves here about the possible future results of a bomb being dropped—let us leave New York and Chicago and come to Washington—the question was directed to General Groves:

General, relating the bomb to approximately the same size that was sent over Hiroshima, suppose one dropped upon Washington. Could you estimate the amount of damage and relate it to Washington?⁶

General Groves answered:

Related to Washington, if that bomb had been dropped, say, in the center of the Pentagon, there wouldn't be any Pentagon left.

Do you concur in that opinion?

Major DE SEVERSKY. I do.

The CHAIRMAN (continuing to read):

General GROVES. * * * If it were dropped in what would probably be the goal of any enemy dropping it in Washington, so that it hit on the Federal triangle

⁴ See Major de Seversky's Supplementary Report on Atomic Bombings of Hiroshima and Nagasaki, which follows his statement in this part of the hearings.

⁵ Ibid.

⁶ See pt. 1 of the hearings on atomic energy, p. 42.

and destroyed the offices of the Government, it would have destroyed an area maybe 2 miles in diameter so there wouldn't be much left there.

Of these big Federal buildings that are well built, many would have their walls standing. All of the limestone and marble on the facing would have been blown off. There is not much question of that, but the concrete and steel structure might still be standing.

All interior partitions would be gone; all the windows and window frames would be gone, and in general you would have a number of buildings standing just as you see them in the picture of Hiroshima, everything flat in between, and maybe 2 feet deep in rubble of all varieties with these walls standing there but absolutely unusable.

Do you concur in that statement?

Major DE SEVERSKY. Not in its entirety, sir. I think it is very pessimistic.

The CHAIRMAN. "The normal house"—this is still quoting General Groves—

that most Washingtonians live in would be completely destroyed in that area. It wouldn't be findable.

Major DE SEVERSKY. Yes; with regard to the wooden buildings, probably they would suffer the same fate that they did in Hiroshima.

The CHAIRMAN (continuing to read):

The area of real damage, where there wouldn't be much left, would have extended from the Capitol to the National Cathedral on Massachusetts and Wisconsin, or something of that general order.

It would have gone over across the river into the Pentagon area, and have blown out all the windows and window frames of the Pentagon, and probably blown out most of the interior partitions. It would not have destroyed the Pentagon, but it would probably have done a tremendous amount of damage.

You think that is too pessimistic a conclusion?

Major DE SEVERSKY. Naturally, the damage that would be done here would be much greater than in New York or Chicago, because in Washington you have big concrete buildings with little wooden houses alongside, and those wooden houses would catch fire. Perhaps the damage here would be much greater than in Chicago or New York.

The CHAIRMAN. Well, at least, as far as Washington is concerned, you do not say that one blockbuster would be as effective as one atomic bomb?

Major DE SEVERSKY. No; that is why my comparison was with Chicago and New York.

The CHAIRMAN. Well, we are kind of interested in Washington, too.

Major DE SEVERSKY. So am I. As I said in my article, it all depends on the character of the target itself. The target Washington is certainly more susceptible to destruction by atomic bombs than a target like New York or Chicago.

The CHAIRMAN. How many blockbusters do you think it would take, here in Washington, to do the same amount of damage as one atomic bomb?

Major DE SEVERSKY. Well, it is very difficult to say; but, with the terrifically excellent precision of our Air Force, I don't think it would take very many to destroy the same number of buildings.

The CHAIRMAN. What do you mean by "very many"?

Major DE SEVERSKY. Well, I imagine—I saw some destruction by our raids, particularly by the B-29's, where the B-29's dropped 1,000-pound or 2,000-pound bombs, 2,000 G. P. bombs in average—200 of

them probably would exceed the damage, the actual physical damage, in Washington, of one atomic bomb.

Senator HART. Major, I understand your objective in producing this article was to offset considerable overstatement, in your judgment, as to the power demonstrated by the two explosions over those two Japanese cities.

Now, in your comparison of one 10-ton blockbuster with one atomic bomb, were you really attempting to offset those overstatements by one of your own? Do you feel now that you were overstating, in that comparison?

Major DE SEVERSKY. No; I don't think so. I think, now, as I stated before—and as far as my own conscience is concerned it is clear—I think that if the same atomic bomb were dropped over the steel and concrete section of New York or Chicago, the same atomic bomb, at the same altitude as in Hiroshima, the demolition would not have been greater than the destruction created by one 10-ton blockbuster.

You may find me wrong; maybe I went too far—I don't know; but it is the result of my careful judgment, within certain limits of accuracy, of course based upon my visual appraisal of what had taken place in Japan.

But, I know one thing; it would not have destroyed Chicago completely, the same way it did Hiroshima and Nagasaki.

Senator HART. You do not dispute General Groves' statement to the effect that the interiors of the buildings which were left standing because of their strength would have been entirely ruined, and so on?

Major DE SEVERSKY. Some would, some would not.

Senator HART. And that was done over an area that could not be possibly done by one 10-ton blockbuster, could it?

Major DE SEVERSKY. No; of course not, because the blast of the atomic bomb is certainly more extensive than the blast of a blockbuster.

Senator HART. I rather fear, Major, that you were combating what you thought was one overstatement by one of your own.

Major DE SEVERSKY. If I only equalize it, I am very happy. I think overexaggeration is a great danger to our country.

As I say, it is dangerous. The other day, a very well-known commentator gets up and says, "It is all a lot of bunk to talk about reorganization of our military institutions; we must dispense completely with all our present forms of national defense; the atomic bomb has replaced them; we do not need an army or a navy or an air force."

Senator HART. Particularly the Navy?

Major DE SEVERSKY. Well, he said it was even foolish to think of the reorganization of these departments, the Army and the Navy and the Air Force; he said that you must abolish them, because the next war is going to be fought entirely by a push-button from a scientific laboratory.

I certainly feel that it is very dangerous to our national security, the propagation of such stories. Such thoughts, I think, are very dangerous.

Senator MILLIKIN. Mr. Chairman, may I ask a question?

The CHAIRMAN. Yes.

Senator MILLIKIN. In your comparison, Major, you were comparing the case of the explosion in the air of an atomic bomb as against a blockbuster exploding on the ground.

Assuming that an atomic bomb were exploded on the ground in lower Manhattan, how many blockbusters would you have to have to do the same effect? It would require probably more than one?

Major DE SEVERSKY. If the bomb hits on the ground, the atomic bomb, then the effect of the heat is going to be tremendous.

Senator MILLIKIN. Yes.

Major DE SEVERSKY. And, of course, the radiation will be much greater in the explosion of the atomic bomb. I have conceded from the beginning that the atomic bomb is certainly a great step forward in the science of demolition.

I feel that while atomic energy may not yet perform useful work such as running washing machines, flatirons, toasters, and jet airplanes, I still feel that we are dealing with a very efficient explosive which enhances the power of our military forces.

Senator MILLIKIN. How many blockbusters would you guess would be required to do the same effect as the atomic bomb in the instance I have given you?

Major DE SEVERSKY. Why do you want my guess? If you are so interested, we may furnish you later on with more substantial statements.

Senator MILLIKIN. Well, your guess, your judgment, was what you based these other figures on.

Major DE SEVERSKY. Well, frankly, all right, if you want my guess—it is going to stand as a guess.

Looking again at what happened at Hiroshima—and I still want to show these pictures so that you can see the same thing as I did—my guess is—

Senator MILLIKIN (interposing). I want to see them.

Major DE SEVERSKY (continuing). If it were dropped right on the ground, amongst very high, tall buildings, I imagine that it probably—I have figured out that inasmuch as one 10-ton blockbuster probably will destroy a block, each blockbuster one block apiece completely, and it will also damage the surrounding buildings to a certain extent, blow the windows out, and the partitions, and so on, the atomic bomb probably will destroy not only the block it hit but probably the next one in every direction. So, in reality, it will probably require 10 blockbusters to cause the same demolition that will be done by 1 atom bomb, if both of them scored direct hits.

Senator MILLIKIN. And at the same point.

Major DE SEVERSKY. And at the same point.

Senator MILLIKIN. Thank you, sir.

The CHAIRMAN. So that makes you 10 percent right, if you take the figure of one given in the Reader's Digest.

Major DE SEVERSKY. No. Again, you are measuring different things. You cannot measure yards with minutes. When it comes to the Reader's Digest, when it comes to the explosion of an atomic bomb exploded above the ground, I am going to stick to what I said, just the same.

That is my impression; I made the statement, and I do not intend to deviate.

The CHAIRMAN. Have you taken into account the damage that would result in the case of skyscrapers?

Major DE SEVERSKY. No fire damage resulted to the top, the roofs, of the Hiroshima skyscrapers.

The CHAIRMAN. So, you don't think there will be any fire damage in New York?

Major DE SEVERSKY. Of course, in the case of very small buildings—as in Hiroshima, some of them not more than 10 stories high—the decrease in distance from the bomb exploded high in the air would be about 100 feet, or roughly 5 percent; the heat effect is not much greater.

But, if you take on the Empire State Building, which is 1,200 feet high, then you have reduced that distance considerably. You cut it in half. In that case, I would not be surprised but that the top of the Empire State Building would sizzle a bit. Yet the Public Library might remain fairly cool, though practically all its windows would be blown out.

It all depends on the target. Scientific destruction isn't such a simple thing. That is why our Air Force has such an elaborate institution for operational research.

We had such operational research in the Eighth Air Force. Most of those people in it were scientists; they tried to estimate actually the amount of explosives required to destroy a given target. Imponderables came into the picture; they studied the problem thoroughly so that they could tell almost exactly what to use against a given target, and how much of it was required. It was a big job.

The CHAIRMAN. Major, I want to ask you a very simple question.

Major DE SEVERSKY. Yes.

The CHAIRMAN. Would this fire damage that you would anticipate from an atomic bomb exploded in New York be not greater than the one 10-ton bomb, the blockbuster?

Major DE SEVERSKY. If it drops 2,000, 3,000 feet up?

The CHAIRMAN. If it drops 3,000 feet up and the blockbuster drops on the ground, what would be the difference in the damage or the danger from fire by the explosion?

Major DE SEVERSKY. Judging from the appearance of the Hiroshima buildings, I do not think that widespread fire would be the case.

The CHAIRMAN. Thank you.

Major DE SEVERSKY. But, I do not know what might happen if it exploded 500 feet or 600 feet or 200 feet.

The CHAIRMAN. If it exploded at 500 feet, you might expect greater fires?

Major DE SEVERSKY. Naturally, because there is no question in my mind, judging by the experiments in New Mexico, that considerable heat was generated.

Therefore, it is quite obvious that the nearer to the buildings that the bomb will explode, the greater will be the effect of the heat generated by the explosion, which heat there is no question occurs.

The CHAIRMAN. Now, you gentlemen—

Major DE SEVERSKY. I would like to say something more.

The CHAIRMAN. Pardon me.

Major DE SEVERSKY. I would just like to make this concluding statement. As to the value of the atomic bomb. I am not depreciating the

value of the atomic bomb. As a matter of fact, I think it is a great thing, and I think it is a great thing that it was used.

I only want to make one thing clear. I worked since early days with our Air Force. I felt that there was a great apathy in recognizing the air power as a new, decisive military force. I think it is very gratifying to see that now, in the case of atomic energy, we are going in advance of the scientific phenomena. We are talking about and planning the regulations for the use of atomic energy, when nobody even knows how to harness and use it commercially. Scientists writing in the newspapers are from 10 to 50 years apart as to the actual time when such energy will be harnessed to do useful work.

But I still think it is wonderful that in this particular case we were on time, which means to be ahead of time. But I do feel that great harm was done to the atomic cause by overexaggeration of what actually took place in those two cities. I don't attribute that hysteria to any official information because there was no official information, so far as I saw, that would inspire such wild predictions.

The CHAIRMAN. I have read to you, Major, from General Groves' testimony before this committee. Of course, it is in great disagreement with what you say.

Major DE SEVERSKY. Well, it is not in disagreement with me alone. I might be wrong, but I vaguely remember that there was disagreement between General Groves and Dr. Bush. I think General Groves said that the bomb could destroy 40,000,000 men in an instant; and Dr. Bush said that it would be 30 years before we could approximate anything like that figure.

There is another source of confusion in the minds of the people, because the scientists themselves cannot agree on what the bomb itself can do and I think that they ought to get into line and give us one story, because I think it is very confusing, not only to me, who am not a specialist but have a smattering of knowledge, but even more so to the people, when one scientist tells us that we are going to use atomic energy for practical purposes in 5 years, and another in 50 years. There is something wrong in Denmark.

If one of my engineers told me that he had designed such and such an airplane but he was not sure whether it would work in 1 year or 2 years or 30 years, I would fire him.

There is too much basis for speculation. I think the atomic boys ought to line themselves up, so that people would have a true, uniform picture, so that they would know where they stand as far as the use of atomic energy is concerned.

In the particular case of its use over Japan, I thought it was a very well-chosen weapon, and I would like to read you the concluding statement which I made to the Secretary of War, which is going to be made public, on the use of the atomic bomb.

Psychological effect of the atomic bomb: Even before the atomic explosion, Japan, with its industries destroyed, and all the major cities but Kyoto reduced to ashes, was a thoroughly defeated and beaten nation. It was desperate to terminate hostilities—and it was searching for a face-saving device to protect the prestige of the Government in order to avoid internal collapse. The atomic bomb provided a perfect excuse for surrender. They could now pretend that they were not to blame for the defeat—an almost supernatural element had intervened to force their hand.

Emperor Hirohito placed the responsibility for defeat on the Japanese people themselves. He pointed out that the scientific backwardness of Japan made the struggle hopeless, and urged the Japanese people to endeavor to improve their scientific knowledge in the years of peace to come.

But it should also be remembered that the atom bomb provided a providential face-saver for our military leadership. Having failed to understand the strategic action of air power, or to visualize its decisive function, we were committed to colossal invasion plans. The so-called Olympic and Coronet invasion operations were ready, dates were set, immense resources deployed. Our leadership was deeply committed to invasion, because it had so often and so vigorously insisted that there could be no victory without coming to grips with the Japanese armies in the traditional fashion. No doubt many of them were heartsick about the necessity, but they felt that there were no alternatives. Although it was already evident to all airmen and many in the other services that in Japan we were winning a victory through air power, I am personally convinced that we would have gone through with the invasion and paid the tragic and unnecessary cost in life. The momentum of the old assumptions was too great to be arrested.

Came the atom bomb. Instantly it released everybody from all past commitments. The nightmare of an invasion about which there was so much doubt was canceled out. Now victory without the preliminary of invasion and mile-by-mile surface struggle—with seven million Japanese still under arms—became possible, without loss of prestige. It was a face-saving miracle which saved perhaps half a million American lives and several million Japanese lives. Though the Hiroshima and Nagasaki episodes added only less than 3 percent to the material devastation already visited on Japan, its psychological value was beyond calculation—for both the defeated and the victors.

Those who made the decision to use the atom bomb, therefore, should be highly commended, because never in the history of human conflict was there a better demonstration of applying the right force in the right place at the right time.

This is, I feel, exactly what happened at Hiroshima and Nagasaki. The atom bomb was used, the targets were chosen perfectly, because there we were able to exact the maximum effect, both material and psychological.

It is also important that in all our dealings with this explosive, as long as we have explosives, we ought to continue to treat it as one of our greatest military advancements. I personally feel that until atomic energy becomes a utility—in other words, something like electric power, for light and power—it primarily will constitute a weapon, or, rather, a major explosive weapon. I think we ought to continue to develop it in comparative secrecy, until such time as the world will decide to disarm.

I think, in this proposed commission, that the military should be represented, at least until such time as the energy of nuclear fission becomes a utility and releases power which can be harnessed to do useful work. So long as it is only an explosive, I think it is very important for us to treat it as a military subject.

The CHAIRMAN. Thank you very much, Major. Can you get your pictures out?

Major DE SEVERSKY. Right here?

The CHAIRMAN. Yes.

Senator JOHNSON. Major de Seversky, do you want to place in the record your full statement?

Major DE SEVERSKY. Yes, please.

Senator JOHNSON. Mr. Chairman, may we have Major de Seversky's full statement for the record?

The CHAIRMAN. Yes, I think it should be put in the record.

Major DE SEVERSKY. All right, fine. It is a part of my report to the Secretary of War, also.

(The prepared statement submitted by Major de Seversky is as follows:)

FEBRUARY 11, 1946.

The Honorable ROBERT P. PATTERSON,
Secretary of War, War Department, Washington, D. C.

DEAR MR. SECRETARY: As special consultant to the Secretary of War, and in line with your instructions, I left for the Pacific theaters of war on September 26, 1945, and returned to the United States on November 15, 1945. My mission was to observe and appraise the role of air power in the attainment of victory over Japan; to study the magnitude and character of aerial destruction; to study the air-power strategy, tactics, and equipment of the Japanese. I was interested, among other things, in appraising the nature and effects of aerial warfare in the Pacific in the light of my observations during a similar mission in the European and Mediterranean theaters of operation.

In pursuance of these purposes, I traveled extensively through the entire area, and especially the main Japanese home islands. I discussed all pertinent questions with key leaders in our own and allied commands; interrogated enemy military and civilian leaders; and talked to people in all walks of life in the defeated country. I made several flights in a B-29 and went through the B-29 tactical procedures in visual and instrument bombing. Opportunities were ample for observing our own as well as enemy equipment, air bases, installations, supply and logistic stations.

In Japan proper, I made observations in the leading cities, including Tokyo, Yokohama, Yokosuka, Fuchu, Karawa, Konosu, Kumagaya, Oshi, Fukaya, Sano, Ishibashim Nikko, Nagoya, Kyoto, Toyonaka, Kobe, Kure, Amura, Sasebo, as well as dozens of smaller towns and villages. I circled and observed scores of other cities from the plane. I made a particularly intensive study—from the air and on the ground—of Hiroshima and Nagasaki, the two cities on which atom bombs were dropped.

I visited Guam, Saipan, Tinian, and Iwo Jima, and in all these places conferred with commanding officers and toured our installations. I also stopped at Shanghai, Manila, and Corregidor, making flights of observation over Manila, Corregidor, Fort Drum, and Subic Bay. During a day's stop at Calcutta, I conferred with Rt. Hon. Richard G. Casey, at that time Governor General of the Bengal Province, and with Sir Alan Brooke, new Chief of Staff of the British Army. Also, I visited all U. S. Army Air Forces installations and Air Transport Command installations at Kurachi, Cairo, Tripoli, Casablanca, the Azores, and Stevensville.

Among the American commanders with whom I conferred in line with my mission were Gen. Douglas MacArthur, General of the Army; Gen. Walter Krueger, Maj. Gen. Ira P. Swift, and their respective staffs; Maj. Gen. F. C. Sibert in command at Kure; Maj. Gen. Harry Schmidt, USMC, at Sasebo; Maj. Gen. LeRoy P. Hunt, USMC, at Nagasaki; Gen. Barney Giles and his staff; Lt. Gen. Nathan B. Twining and his staff; and Lt. Gen. Albert C. Wedemeyer. I had occasion to talk to Mr. Franklin D'Olier, chairman of the United States Strategic Bomb Survey, and his assistant, Mr. Paul H. Nitze. They and their staff gave me the fullest cooperation. I spent considerable time with Maj. Gen. O. A. Anderson and his staff and with General Fellers, personal aide to General MacArthur.

Among the Japanese, I interviewed Emperor Hirohito and high-ranking members of his household; Rear Admiral Takata of the Imperial Japanese Navy; Lieutenant General Kawabe, commanding at Kokosoguan; Major General Miwa; Lt. Gen. Saburo Endo, who was in charge of aircraft and engine production for the entire Japanese Empire; Lieutenant General Samo, commandant of the Osaka Arsenal; and many others. I interrogated key leaders of industry, among them Mr. Matoro, former chairman of the board of the Mitsubishi enterprises. In addition, I talked to average Japanese of all classes. Especially in the atom-bombed cities, with a view to a more accurate understanding of what actually took place there, I questioned doctors, nurses, fire fighters, eyewitnesses.

On the basis of these varied observations and discussions, I am in a position to transmit to you my personal judgments on a variety of aspects of the war in the Pacific theaters.

* * * * *

11. *The two atom bombs.*—I come now to my observations on the atom bombing of Hiroshima and Nagasaki. Because of the importance of this subject, I have dealt with it more comprehensively in a supplementary report which I

am attaching to this report. Here I shall merely summarize my observations: After spending 2 days in each of the atom-bombed cities, examining the destruction areas and questioning all types of local observers, I gave an interview to American correspondents in Tokyo. My statements at that time were in such striking contrast to the misconceptions about the character and effects of the atom bombing that they evoked a storm of controversy. I am obliged, however, to report to you the facts as I saw them and the conclusions I drew from these facts.

I did not "underrate" the atom bomb, nor raise doubts about its significance for the future of warfare. My interview dealt solely with the actual bombs dropped on the two Japanese cities and the actual results obtained. The loss of life and property was as large and as tragic as reported. But the character of the destruction did not even resemble the popular notions generally held on the subject.

The common belief, based on erroneous lay reports and pseudoscientific assumptions, is that scores of thousands of people died "instantaneously" in a kind of vaporizing process; that solid matter evaporated instantly in unprecedented superheats; that in huge areas "bald spots" were created by total combustion of all organic and inorganic matter. All of these assumptions are wholly unfounded.

The destruction was entirely incendiary in character, and the deaths were due almost entirely to fire and to falling structures. The atom-bomb blast collapsed the flimsy, half-rotted and top-heavy wooden houses, causing thousands of fires which immediately combined into one huge bonfire. The victims were caught and pinned in the debris where most of them perished in the many hours that the conflagration raged.

Most important, concrete buildings, even in the very heart of the bomb explosions, remained erect, though most of them were gutted by the spreading fire. More than that, even flagpoles, siren devices, and other fragile objects on such buildings remained intact. There were no traces of unusual heat effects even on the tallest of the surviving buildings. Neither in Hiroshima nor in Nagasaki was there any such "bald spot" as we were led to expect by the New Mexico experiments. Everywhere, including the immediate area of explosion, there were charred and leafless trees, poles, half-burned and unburned chunks of wood—the typical debris of a fire. In short, there were no visible effects different in nature from those caused by ordinary incendiary bombing and the physical picture presented by the two cities was precisely the same as in Japanese cities destroyed by ordinary bombs.

Another item which needs noting is that the damage in Nagasaki was only about one-fourth as large as in Hiroshima, despite the fact that the bomb dropped on Nagasaki was said to have been more powerful. It suggests that the relation between mass and destructive results is not necessarily in direct proportion. Of course, it is quite possible that the heights at which the bombs were exploded had much to do with the extent of the damage and the absence of any of specific "atomic" effects.

As to the deaths from radioactivity—by the time I had arrived at Hiroshima and Nagasaki, I could not find any victims, nor could I get any first-hand information from doctors, nurses, or hospital attendants to whom I talked. Since the New Mexico experiment proved beyond any doubt the presence of radioactivity in atomic explosion, such cases should have taken place in the two Japanese cities unless the bomb exploded so high that its effect was greatly reduced.

I made the statement in Tokyo, and feel justified in repeating it here, that the same bombs dropped in exactly the same way on a steel-and-concrete city like New York or Chicago would have done no more damage than a 10-ton block-buster. Had Hiroshima and Nagasaki been modern concrete and steel cities, there would have been no wholesale collapse of houses, no bonfire and no such tremendous loss of life.

Another statement, which I do not hesitate to reiterate, is that two hundred Superforts loaded with incendiaries would have done as much damage to Hiroshima as the atom bomb, except that the loss of life would most likely have been smaller.

It seems to me of the greatest importance that these facts about the atom bombing be made known to the American people. Enlightened democratic public opinion has been the prime factor in guaranteeing our victory in this war. The maintenance of such an opinion requires that our people be taken fully into confidence on all the facts.

SUPPLEMENTARY REPORT ON ATOMIC BOMBINGS OF HIROSHIMA AND NAGASAKI

Because of the importance of the above subject, I felt warranted in submitting to you a more detailed and descriptive report in connection with the use of atomic bombs on Hiroshima and Nagasaki.

I made five separate observation flights over each city, and spent 2 days in each city examining the sites and the character of the damage. I observed the ruins and the rubble, visited structures which had survived the bombing, interrogated eyewitnesses, and took hundreds of pictures. This effort, moreover, was the climax of nearly 8 months of intensive study of destruction in all its aspects. I had become thoroughly familiar with every variety of damage—from high explosives, incendiaries, liquid fire, artillery shells, dynamite, and combinations of several of these.

Having completed my inspection of the atom-bombed cities, I therefore felt justified in giving my impressions to American correspondents in Tokyo, who transmitted them, on the whole accurately, to the American people. It was my considered opinion, I told them, that the effects of the atom bombs—not of future bombs but of the two specific specimens unloosed on Japan—had been wildly exaggerated and that the nature of the destruction had been fantastically distorted. The same bombs, I told them, if dropped in the same manner on a modern city like New York or Chicago, would have done no more damage than a 10-ton blockbuster; and the results obtained in Hiroshima and Nagasaki could have been accomplished by about 200 B-29's loaded with incendiaries, though the loss of life in that case would have been much smaller.

I did not "underrate" atom bombs or dispute their future potential. Certainly I did not dismiss lightly the hellish horror of the two stricken cities. I merely conveyed my professional findings on the physical results of the two bombs—and they happened to be in startling contrast to some of the hysterically imaginative versions spread through the world.

My statements at that time were in such striking contrast to the misconceptions about the character and effects of the atom bombing that they evoked a storm of controversy. The dissenting faction pounced upon my findings in outraged anger. I was attacked by all sorts of people. Scientists who had not been within 5,000 miles of Hiroshima issued round robins denouncing my views. These critics behaved, indeed, as if they had a vested interest in the fanciful misrepresentation of the facts. Almost for the first time in my career, I found myself in the position of a "conservative" under attack by "extremists."

The violence of the opposition, however, cannot alter the facts on view in the two Japanese cities. Many of these facts which the most honest and best-intentioned observers may be unable to interpret correctly unless they have the necessary training and experience. Because I believe that the truth is more useful than pseudoscientific fairy tales, I must repeat that the events of Hiroshima and Nagasaki have been seriously misreported and misunderstood, with the result that confusion prevails on a subject which calls for accuracy, clarity, and calm appraisal.

I was in England testing British jet planes when the atomic bombs were dropped. Naturally, I was as excited as everyone else by the new development and the horizons opened up by atomic power. My whole life had predisposed me to credit the miracles of science. From the teeming newspaper and radio accounts, I visualized the total devastation of Hiroshima and Nagasaki in one-millionth of a second. With my mind's eye I saw the instantaneous dissolution of the cities and their people, not a building left standing in the stricken areas, sand and earth fused to glass, steel evaporated, tens of thousands of human beings "pulverized" in the twinkling of an eye. Because they were so often and so unanimously repeated, I credited the reports of heat of incalculable intensity, instant extinction of life and destruction of matter. I agreed, as a matter of course, with those who said that if such a bomb were dropped over a battleship, the heat would melt the vessel or evaporate the surrounding ocean, or both, in a flash.

In short, I accepted the popular picture of a new kind of total destruction, different not only in extent but in quality from the destruction by explosives and fire I had seen elsewhere. One curious item did stir my doubts. It was a photograph of a devastated Hiroshima in which a concrete building stood upright in the midst of the bombed area. It set me wondering how that structure had evaded the phenomenal new force. All the same, if I had not journeyed to Japan and investigated for myself, I probably would still be laboring under the illusions so common on the subject.

After visiting the major war areas scattered through the Pacific, I arrived in Japan. I began the study to which you had assigned me, by making an aerial tour of the islands of Honshu and Kyushu, which compass the main portion of industrial Japan. Taking off from Tokyo, I flew over Yokohama, Yakuska, Nagoya, Osaka, Kobe, Akashi, and dozens of other cities and towns subjected to air attack. Some of the towns are so close together that they seem almost continuous industrial areas.

All these areas of annihilation presented approximately the same visual pattern. The smaller towns were completely burned out. Viewed from above, the consumed sections looked pinkish—an effect produced by the piles of ashes and rubble mixed with rusted metal. That color, in fact, is the prevailing one in devastated Japan seen from overhead. Similar pinkish carpets were spread out in the larger cities, but among them stood big and small modern buildings and factory structures, unscathed bridges and other objects. Many of the buildings, of course, were gutted by fire but this was not apparent from the air.

The center of Yokohama, for instance, seemed almost intact when viewed from the vantage point of an airplane. Osaka, the Chicago of Japan, was a vast expanse of pink crisscrossed with white lines, except in the more modern center of town, where the concrete buildings had survived the ordeal. The long industrial belt stretching from Osaka to Kobe had been laid waste by fire, but the factories and other concrete structures with few exceptions were still standing. On the whole, it was a picture quite different from what I had seen in German cities subjected to demolition bombardment; quite different, too, from the picture presented by the Osaka arsenal—the most devastated high-explosive target I have seen. The difference lay in the fact that Japanese destruction was overwhelmingly incendiary, with comparatively little structural damage to noninflammable targets.

Finally, we flew over Kure, where so many Japanese battleships litter the ocean floor—and then to Hiroshima.

I was keyed up for my first view of an atom-bombed city. I was prepared for radically different sights: the kind of sights suggested by the excited descriptions I had heard and read. But, to my surprise, Hiroshima looked exactly like all the other burned-out cities I had observed in the 8 hours of aerial cruising.

Within an area defined by a ring of black undestroyed houses, there was the familiar pink blot, about 2 miles in diameter. What is more, it was dotted with buildings still standing erect, with charred trees, poles and other things. Only 1 of the city's 20 bridges was down. The concrete heart of Hiroshima, its clusters of modern buildings in the downtown section, stood upright and seemingly undamaged—how strange, I thought, that in all the hundreds of Hiroshima pictures published after the bombing, I did not happen to see a single "shot" of this section.

I had viewed numerous targets destroyed by every conceivable method and had confidently expected to find something novel here. What I found was simply another and quite typical burned-out Japanese city. I know what the blast of a 5- or 6-ton bomb can do to nearby buildings. It was obvious to me at once from the appearance of Hiroshima's concrete buildings that the blast could not have been as powerful as we had been led to expect. It was extensive blast, as evident in the size of the area effected, rather than intensive. Closer inspection of the buildings later would show, of course, terrific damage by fire, just as in Tokyo or Osaka.

I had heard about buildings instantly consumed by unprecedented heat. Yet here under my eyes were buildings, structurally intact, and what is more, topped by undamaged flagpoles, lightning rods, painted railings, penthouses with wooden-framed doors, air-raid precaution sirens bright in their silver paint, and other fragile objects; clearly they had withstood the blast and somehow escaped the phenomenal heat. None of this jibed with my preconceptions based on the generally accepted reports.

We landed. For 2 days I examined Hiroshima. I drove to the T-bridge which was the aiming point for the atomic bomb. In its environs I looked for the "bald spot" where everything presumably had been vaporized and "boiled into dust" in the twinkling of an eye. It wasn't there or anywhere else in the city. I looked for other traces of phenomena that could reasonably be tagged as unusual, as "atomic" in character. I could not find them.

What I did see was in substance a replica of Yokohama or Osaka, or the Tokyo suburbs—the familiar residue of an area of wood and brick houses razed

by uncontrollable fire. Everywhere I saw the trunks of charred and leafless trees, burned and unburned chunks of wood, the rubbish heaps left by unchecked fire. Obviously it was a fire, here as in other Japanese cities, intense enough to bend and twist steel girders and to melt glass until it ran like lava.

I examined with particular attention the concrete buildings nearest to the center of explosion, some of them only a block from the heart of the atom blast. They showed no structural damage—only the typical effects of fire. Even cornices, canopies, and delicate exterior decorations were intact. Window glass was shattered, of course, but single-panel frames held firm; only window-frames of two or more panels were bent and buckled. The blast impact, therefore, could not have been very intensive. Nor was there any trace of heat beyond what was normally generated by inflamed Japanese cities without the benefit of atom bombs.

Then I questioned a great many people who were inside such buildings when the bomb exploded. Their descriptions matched the scores of accounts I had heard from people caught in concrete buildings in areas hit by blockbusters and incendiaries. They indicated no special effects that could be attributed to the new kind of explosive.

Hiroshima's 10-story press building is located about 3 blocks from the center of the explosion. It is badly gutted by fire but otherwise unhurt structurally. I was told that the people caught in the building did not suffer any unusual effects. They saw a flash. Fire broke out on the fourth floor, where inflammable negatives and films were stored, and thence spread to other floors. Some of the tenants asserted that the fire started simultaneously with the bomb flash; others insisted that it was set off by sparks from the nearby cinema theater, which had caved in and burst into flame.

The Hiroshima hospital, about a mile from the heart of the explosion, had most of its window panels blown out. Because there were no wooden structures in its immediate vicinity, however, it escaped fire. In general, the effects here were analogous to those produced by the blast of a distant TNT bomb.

The more I looked and questioned, the more convinced I was that the world had obtained a totally erroneous impression of what had taken place in Hiroshima. The total death and destruction were as large as reported. The horror was as profound as reported. But the character of the damage was in no sense unique; neither the blast nor the heat was as tremendous as generally assumed; and most important, there was clear proof that the same bomb applied in the same manner on a different type of target would have had totally different results.

From Hiroshima I flew to Nagasaki. I repeated the process of investigation and cross-examination. It added little to what I had learned in the other city. The pink blot was much smaller. It was also studded with concrete buildings, gutted by fire, but standing upright. Fewer of these buildings were in evidence, only because there were fewer modern structures in Nagasaki.

In contrast with Hiroshima, all of downtown Nagasaki, though chiefly wooden in construction, survived practically undamaged. Part of this unaffected section, it was explained, had apparently been shielded from the explosion and its consequences by the intervening hills. But another part, west of the river, lies down the river in a straight and quite unimpeded line from the explosion center. It is not protected by the hills. Yet it escaped serious damage, with only a few of its houses caved in. The Nagasaki blast had virtually dissipated itself by the time it reached this area. Few houses collapsed and none caught fire.

Some of the mistaken reports about Nagasaki derive from the fact that all destruction is credited to the atom bomb. It must be remembered, however, that the city had undergone an effective raid by General George Kenney's bombers on August 1, 6 days before the atom bomb was released. The famous Mitsubishi plant in the heart of Nagasaki had received its share of the 20 high-explosive bombs dropped in that raid, 8 of them scoring direct hits on machinery. That plant, which I inspected in detail, presented the typical appearance of an industrial objective which had suffered high-explosive attacks and fire.

On the basis of my observations, this is what I visualize as actually having happened in Hiroshima and in essence it holds good for Nagasaki as well.

If there had been any primary fire, that is to say fire kindled by the heat of the explosive itself, my personal observation could not justify such a conclusion. The bomb presumably exploded too far above ground for that. If the temperature within the exploding area is superhigh (and the effects in New Mexico tend to indicate that) then it must have been dissipated in space. The

presence of unscorched paint and fragile objects on the top of the concrete buildings would tend to encourage such an assumption. What struck Hiroshima was the extensive blast.

It was like a great fly swatter 2 miles broad, slapped down on a city of flimsy, half-rotted wooden houses and rickety brick buildings. It flattened them out in one blow, burying perhaps 200,000 people in the debris. One must see it to believe the flimsiness of such Japanese structures. For the most part they are built of 2-by-4 boards, termite-eaten and dry-rotted through generations. To make things worse, they are top-heavy with thick tile roofs. Often they tumble down without apparent reason.

The wooden slats of the collapsed houses were piled like so much kindling wood in a fireplace. Fires flared simultaneously in thousands of places, from short circuits, overturned stoves, kerosene lamps and broken gas mains. The whole area exploded into one fantastic bonfire, as normally happens after a major incendiary attack. The concrete buildings naturally were also enveloped in flames.

In normal incendiary fires, people have a chance of escape. Parts of the houses burn before other parts; the inmates run from room to room, then into the streets, to open places, to the rivers. In Hiroshima the majority had no such chance. They were hopelessly pinned and trapped in the burning debris. Thousands of them must have been killed outright by falling walls and roofs; the rest were crippled and immobilized in a burning hell and some 60,000, it is estimated, were burned to death.

Those who managed to extricate themselves rushed for the bridges and the rivers. There is reason to deduce that the one collapsed bridge broke under the weight of the frenzied mobs, although some maintain that it was brought down by the bomb blast. On the other bridges, the crush of hysterical humanity pushed out all the railings, catapulting thousands to death by drowning. The missing railings were not wrenched out by the bomb blast as nearly all reports have had it.

On a vast and horrifying scale it was fire, pure and simple, that took such a high toll of life and property in Hiroshima, and in Nagasaki as well. There was no evaporation of human beings or steel or wood, no melting and boiling of matter other than the usual kind in great conflagrations. All these claims are pure invention, the product of imaginations inflamed by atomic publicity.

The victims did not die instantaneously in a sort of atomic dissolution. They died slowly, horribly, in the long hours that the fire raged in the stricken cities. Quite possibly the blast was strong enough to cause internal injuries to many of those caught in the center of explosion, particularly lung injuries. But that, too, is an effect quite familiar among victims of ordinary high-explosive bombing.

As to death from gamma rays—by the time I had arrived at Hiroshima and Nagasaki, I could not find any victims, nor could I get any first-hand information from doctors, nurses or hospital attendants to whom I talked. Since the New Mexico experiment proved beyond any doubt the presence of radioactivity in atomic explosion, such cases should have taken place in the two Japanese cities unless, again, the bomb exploded so high that its effect was greatly reduced; nor could I find anyone who had personal knowledge of any lingering radioactivity phenomena.

Such are the facts as I found them—and they seem to me tragic enough without imaginative pseudoscientific trimmings. I might add that I am not alone in my impressions. Scientific observers on the spot to whom I talked in general shared my point of view. Nothing official came from the War Department to justify the wild exaggeration. The blasts were powerful enough to collapse miles of flimsy wood and brick houses, but too weak to damage the concrete buildings even at the focal centers of the explosions. It is simply untrue that 60,000 people in Hiroshima and 40,000 in Nagasaki were snuffed out in one-millionth of a second. It simply is not true that matter was vaporized in the intense heat—if steel had evaporated, certainly wood would have done the same, and undamaged wood abounds everywhere in the rubble. In neither of the bombed cities was there a bald spot—a spot denuded of all inflammables such as was created in the New Mexico experiment—and both atom-bombed areas have plenty of tree trunks, walls with growing vines, half-burned wood, to disprove the claims of superheat.

I come now to those of my statements at the Tokyo conference which have drawn the most passionate retorts: (1) That the Hiroshima and Nagasaki bombs, if dropped on a large American city, would have done little if any more damage than a 10-ton blockbuster; and (2) that 200 B-29's loaded with incendiaries

would have visited the same amount of damage on Hiroshima—or on Nagasaki—as the atom bombs.

In connection with the first statement, the essential fact is that all but one of the concrete buildings in the center of Hiroshima, where the bomb exploded, show neither signs of structural damage nor traces of intense heat from above. It is an inescapable deduction, therefore, that if all of Hiroshima had been a city of steel and concrete like the average American or European city, the results would have been comparatively light. In that event, only the buildings directly hit—only those at the actual point of contact—would have suffered seriously. There would have been no collapsed houses, no instantaneous bonfire, no such colossal loss of life.

The more painstakingly I analyze my observations, indeed, the more convinced I am that the same bombs dropped on New York or Chicago, Pittsburgh or Detroit, would have exacted no more toll in life than one of our big blockbusters, and the property damage might only have been confined to shattered window glass over a wide area. True, the atom bombs apparently were released too high for maximum effects. Exploded closer to the ground, the results of intense heat might have been evident and impressive. But in that case the blast might have been localized, sharply reducing the area of destruction.

The same logic, incidentally, applies to a bomb of the Hiroshima or Nagasaki type dropped over a battleship. Unless a direct hit (or perhaps a near miss) were scored, the battleship would have sailed serenely on its course, I believe; and the crew, if it did not remain on the open deck, would have survived as well. A direct hit is another matter; but we know that when an 11-ton bomb hits a battleship it rolls over and sinks in 22 seconds, as the mighty *Tirpitz* did when struck by a British bomb.

I must add, of course, that whether or not battleships can be wiped out by atomic bombs has not the slightest strategic importance. The battleship is obsolete not because it can be "atomized" but because it has lost its military functions.

On my second statement, three scientists at the University of Chicago were among those who took me severely to task. They pointed out, according to a radio broadcast, "that if 200 Superforts with ordinary bombs could wipe out Hiroshima as a single atomic bomb did, the same number of planes could wipe out 200 cities with atomic bombs."

These experts meant well. Their elementary arithmetic was faultless. They merely forgot to mention one detail—that the 200 cities should be as flimsy and dry-rotted as Hiroshima. The crux of the matter is the target. Potential destruction on one type of objective does not necessarily apply to another type. On a steel-and-concrete city high explosives would have to be added to do the job. One atomic bomb hurled at Hiroshima was equal to 200 Superforts; but in New York or Chicago a different kind of atomic bomb exploding in different fashion, would be needed before it could equal one Superfort loaded with high explosives.

In the frantic journalism immediately after the Japanese were atom-bombed, a newspaper published a picture of Manhattan Island with an area roughly 2 miles in diameter in the heart of the city blacked out. This was intended to dramatize what the bomb dropped on Hiroshima would have done if dropped on New York. Such a falsification of the facts is obviously too gigantic to have been intentional. It merely attests the hysterical credulity with which absurd claims and senseless deductions are being swallowed.

It seems to me completely misleading to say that the atomic bomb used on Japan was "20,000 times more powerful" than a TNT blockbuster. From the view of total energy generated, this may be correct. But we are not concerned with the energy released into space. What concerns us is the portion which achieves effective demolition. From that point of view, the 20,000 figure is reduced immediately to 200—and that only for a target susceptible to the kind of results obtained in Hiroshima. For a target like New York, the figure of 20,000 drops to one or less.

In any case, the comparison of the atom bomb with TNT is not helpful, since the two are not commensurable at this stage of development. It is like comparing a pneumatic drill and a flaming torch—everything depends on whether you're trying to burn a wooden fence or demolish a concrete wall. All we can say with certainty is that the atomic bomb proved supremely effective in destroying a highly flimsy and inflammable city. It is one of those cases when the right force was used against the right target at the right time to produce the maximum effect. Those who made the tactical decision to use it in these cases should be highly complimented.

The United States Strategic Bomb Survey, which did such a splendid job in assessing the bomb damage in Europe, and which is now studying the ruins of Japan, unquestionably will furnish us with an equally authoritative report in the latter case. It will leave little doubt as to the true causes and effects of the atomic-bomb demolition.

The bomb dropped on Nagasaki was said to be a great many times more powerful than the one dropped on Hiroshima. Yet the damage in Nagasaki was much smaller. Hiroshima is twice as big as Nagasaki and 60 percent of it was destroyed, whereas only 30 percent of Nagasaki was wiped out by a much bigger and better bomb. In Hiroshima, 4.7 square miles were razed; in Nagasaki, only 1.45 square miles. The improved atom bomb, in other words, was only about one-fourth as effective!

Why? There are various theories, but no one known for certain. It underlines the fact that something besides additional mass will be needed to produce greater results on the target. The fact that a bomb contains 100 or 1,000 times as much uranium or plutonium is no guarantee that it will be more destructive in direct proportion to the mass. Eventually, of course, the science of demolition will solve the problem of obtaining maximum results from atom missiles. Methods will surely be found for dissipating less of the released energy in space and directing more of it to destruction. The aforementioned Chicago scientists reminded me in their statement that "the bombs dropped on Japan were the first atomic bombs ever made. They are firecrackers compared to what will be developed in 10 or 20 years."

That is exactly the point I am trying to make: That we are as yet in the primitive stage of the atomic weapon—a stage equivalent, in some respects, to that of aviation when the Wright brothers made their first successful flight at Kitty Hawk. Imaginative scientists and journalists at that time could have stirred up a panicky excitement by behaving as if superplanes were already a reality and all other forms of transportation had to be scrapped at once.

Something of this sort of behavior has served to stampede humankind into a state of near hysteria by the first exhibit of atomic destruction. Fantasy is running wild. There are those who think we ought, willy-nilly, to dispense with all other forms of national defense. They talk of a dozen professional suicides who will take compact atomic bombs in suitcases, put on false whiskers, deploy themselves through an enemy country—or in our own country—and blow it to bits in a few seconds. Such hyperbole makes exciting Sunday-feature stories, but it is a dangerous basis for national thinking.

On the size of the bombs, incidentally, there had been much uninformed speculation. How do so many experts know that the atomic bomb weighed only "a few ounces" or "a few pounds"? After all, our biggest bomber, not a pursuit plane, was chosen to carry it. How do they know that there were no operational difficulties and other complications which affect the effectiveness of the new explosive?

Some of the confusion that exists in relation to the actual results of the atomic explosion over Hiroshima and Nagasaki could be explained by the fact that a great many people automatically transplanted the results obtained in New Mexico to those towns. They took for granted that the phenomenon of New Mexico repeated itself in Japan in all details. Most of them apparently did not realize the paramount effect of the altitude at which atomic explosion takes place. As a matter of fact, unless one has a broad knowledge of demolition in all its various forms, the first-hand observation obtained in New Mexico might prove a handicap to those who later on visited Hiroshima and Nagasaki. Impressed by the original explosion, they took for granted that the entire destruction was caused by the direct and primary action of the bomb.

To the eye accustomed to the bomb damage, Hiroshima does not represent any more remarkable a sight than hundreds of other bombed cities anywhere on the face of the earth. The only remarkable thing about it is that one single bomb did it, but I must repeat that the credit for the result must be equally divided between the unusual efficiency of the bomb and the unusual flimsiness of the town. The enormous loss of life should also be credited to the element of surprise. The population was not prepared for the ordeal and no precautions of safety were taken. If a city of this size had been unexpectedly attacked by poison gas, the loss of life might have been even greater, yet the use of a simple gas mask might preclude any loss of life. Even thus,

death from radioactivity in the future may be prevented by appropriate defensive measures.

There seems to be almost a conspiracy of circumstances to whip up atomic hysteria. Emperor Hirohito, his court, their press and their radio, had every reason to propagate extreme versions. It gave them the perfect face-saving excuse for surrender. They could not pretend that they were not to blame for the defeat—an almost supernatural element had intervened to force their hand.

But it should be acknowledged that the atomic bomb provided a providential face-saver for our military leadership as well. Having failed to understand the strategic action of air power, or to visualize its decisive function, we were committed to colossal invasion plans. The so-called Olympic and Coronet invasion operations were ready, dates were set, immense resources deployed. Our leadership was deeply committed to invasion, because it had so often and so vigorously insisted that there could be no victory without coming to grips with the Japanese armies in the traditional fashion. No doubt many of them were heartsick about the necessity, but they felt that there were no alternatives. Although it was already evident to all airmen and many in the other services that in Japan we were winning a victory through air power, I am personally convinced that we would have gone through with the invasion and paid the tragic and unnecessary cost in life. The momentum of the old assumptions was too great to be arrested.

Came the atom bomb. Instantly it released everybody from all past commitments. The nightmare of an invasion about which there was so much doubt was canceled out. Now victory without the preliminary of invasion and mile-by-mile surface struggle—with 7,000,000 Japanese still under arms—became possible without loss of prestige. It was a face-saving miracle which saved perhaps half a million American lives and several million Japanese lives. Though the Hiroshima and Nagasaki episodes added only less than 3 percent to the material devastation already visited on Japan, its psychological value was beyond calculation—for both the defeated and the victors.

Other circumstances conspired to skyrocket the dramatization of the atom bomb. Somehow it fitted into nearly everybody's propaganda purposes. To isolationists it seemed final proof that we could let the rest of the world stew in its own juices—with our head-start in atomic energy and our superior know-how, we were safe against the rest of the world. The internationalists, on the other hand, tried to intimidate us by reminding us that we had no monopoly on science. Everyone could manufacture the atomic bomb, they said, and if we didn't play ball we would be destroyed.

And thus the exaggerations and frantic forecasts flourished in our land. Thus public opinion was fed on fantasy to the pitch of fever. The process is still under way. Even an attempt to report sanely what actually did occur in the atom-bombed Japanese cities is resisted as a species of treason.

I am one of those who fought against inertia and apathy in the domain of air power. Consequently I am gratified that in relation to the emergence of atomic energy the public is alert, that we are planning well ahead. But there is no call for the kind of frenzy that paralyzes understanding. Our only safety is in a calm confrontation of the truth.

I earnestly urge a cooling-off period on atomic speculation. In my study of the war—and especially of the reasons for our victory—I have been convinced that our chief advantage lay in the fact that, as a democracy, our people had access to the truth. This made it possible for an enlightened public opinion to act as a decisive corrective on the blunders and prejudices of military leadership. Where the strategic ideas of a dictated Germany were frozen, ours were kept under constant public scrutiny and pressure. It was that which kept our leaders on their toes, made them responsible to the people and gave our war effort a flexibility that guaranteed success.

It is in the interest of that crucial enlightened public opinion that I have considered it necessary to cut through fantasy about the bombing of Hiroshima and Nagasaki in an effort to get closer to the truth. I am the last one to deny that atomic energy injects a vital and perhaps revolutionary new factor into military science and world relations. But I do not believe that the revolution has already taken place and that we should surrender all our normal faculties to a kind of atomic frenzy. Whatever we decide to do, let us do it calmly, logically and above all without doing violence to ascertainable facts.

ALEXANDER P. DE SEVERSKY.

FEBRUARY 11, 1946.

The CHAIRMAN. Major, I understand that your demonstration might take as much as an hour. Is that correct?

Major DE SEVERSKY. Well, I can limit it to half an hour.

The CHAIRMAN. General Farrell is anxious to get away, and I suggest that we could do these pictures after lunch and also hear the other gentlemen. I suggest that we project the pictures after lunch. General Farrell is anxious to get away, and I understand that you are not ready anyway; you have no extension cord.

We will proceed with General Farrell.

STATEMENT OF GEN. THOMAS F. FARRELL

The CHAIRMAN. General Farrell, I believe you were General Groves' deputy in charge of the exploding of the two bombs.

General FARRELL. I was in charge of the operations in the Marianas; yes sir.

The CHAIRMAN. You have read Major de Seversky's article and you have heard his testimony today?

General FARRELL. Yes, sir.

The CHAIRMAN. Would you please go ahead, General, and comment on it?

General FARRELL. Well, I will have to disagree definitely with some of the conclusions, most of which have been discussed by the committee. The principal conclusion in there is that one 10-ton blockbuster exploded in New York or Chicago would do as much damage as an atomic bomb which was exploded as high in the air as the one which was exploded over Nagasaki and Hiroshima.

Secondly, there was the conclusion that B-29's loaded with incendiaries would have done the same or as much damage in Hiroshima as was done by the atomic bomb. There were some minor statements about how there was no damage to lighting poles, flagpoles, and no structural damage to the concrete buildings. Then, the statements that the people in the hospital, the Red Cross hospital in Hiroshima, were not seriously affected.

Let me see, there are one or two more: That in New York, property damage through an atomic bomb would be limited to broken window glass scattered over a wide area; that the damage in Nagasaki was confined to one square mile; that in Hiroshima it was 4.1 square miles. Those are the principal points that I disagree with.

Now, taking them in order: The atomic bomb does release the energy equivalent of 20,000 tons of TNT. That has been measured and computed by distinguished scientists. The 10-ton bomb has the TNT equivalency of about 5 tons.

On its very face, the energy of one is not equivalent to the energy of the other, under any circumstances. The energy released from a 10-ton blockbuster, if you dropped it at an intersection of downtown New York, speaking very liberally it might be conceived to destroy four blocks, and I doubt if that would be total destruction. That would be an area of 16 acres, or one-fortieth of a square mile.

In Hiroshima the absolute total destruction, the total area of absolute damage ran up to 4 square miles; and the area of substantial damage, serious damage, was a couple of more square miles, totaling something like 7.

At Nagasaki the total damage to the buildings was about 2.4 in the built-up area. The 2.4 was the area of very serious damage. The secondary, but still serious, damage was 1.2 more, or 3.6 in total.

In New York, we have only a small percentage of heavy structures, certainly not exceeding 10 percent. The greater part of New York is brick and stone buildings and an even greater area of wooden buildings.

The damage to New York there would be somewhat lower than at Hiroshima or Nagasaki. As compared to the 6 or 4 square miles, there, to be conservative, the damage in New York would be 3 to $3\frac{1}{2}$ square miles. That would still be 120 or 140 times the damage created from the explosion of a blockbuster.

The damages resulting from this atomic bomb are, speaking generally, three—flame, blast, and radiation. In addition, there is another one, I think that we must add, which is the psychological damage, fear. This weapon is a saturation weapon, in that the damage is instantaneous and total and complete and there is no defense. People lose what courage and ability they may have had to defend themselves and cope with the situation. Therefore, that is a most potent factor.

To substantiate that: From eyewitnesses we hear stories of great streams of people leaving Hiroshima and Nagasaki immediately after the bombing; and that is one of the most potent effects from the use of this bomb, this psychological impact.

I do not know that we could create the same damage with 200 planes.

Major de Seversky compared the 1 plane with the 200 planes. We were attached to the Three Hundred and Thirteenth Wing at Tinian. We saw the reports of the B-29 raids with incendiary planes. Since then, we have gotten the factual information from the Twentieth Air Force. The figures are as follows:

The total number of incendiary-carrying airplanes was 15,964. The total number actually dropping incendiaries was 14,462. The total square miles destroyed was 172. It took 84 B-29's to destroy 1 square mile by incendiary raid.

Applying that factor to the Hiroshima situation, you would come out with 378 planes for the very heavily damaged section. Taking into consideration the secondary area of serious damage, it would be 352 more, or a total of about 730 B-29's to do the same total damage and the same secondary damage as that of one atomic bomb. It would take 730 B-29's to do what one atomic bomb did to Hiroshima.

Nagasaki was a bad target, from the point of view of the bomb. It was surrounded and shielded by hills, the width of the area was only about a mile and a half, and more than half of the total effect of the bomb was wasted against the hillsides.

Taking only the built-up area, the total destruction in Nagasaki was 2.4 square miles, which gives us, from the same figuring, 202 airplanes; if we take the secondary damage, we would have to add to that 101 airplanes, or a total of 303.

So, combining those figures, we would have used 730 planes at Hiroshima and 303 for the damage at Nagasaki. So, I would have to say that 200, as stated by Major de Seversky, was a very low average. A more comparable figure might be 500 B-29's.

Also, as we measure the actual damage against the potential damage, we must keep in mind the fact that at Nagasaki a great portion of the

effective power of that bomb was wasted, because Nagasaki was not a suitable target.

The CHAIRMAN. General Farrell, 11 men were carrying the atomic bomb. How many men would there be in 500 Super-Fortresses carrying incendiaries?

General FARRELL. Some 5,000, sir. There are 10 or 11 in a crew; 5,000 is the answer.

The CHAIRMAN. Thank you.

General FARRELL. So, on those two points, I would have to disagree with the conclusions of Major de Seversky.

Now, then, comparing the destruction as between Hiroshima and Nagasaki, there is a distinction, because there was a considerable difference in the character of the two cities.

Hiroshima was a weak Japanese city; it was built, the houses, mostly of bamboo and tile and small 2-by-4 framing.

I must say that situation was thoroughly well known to the War Department and to the scientists working on the problem. We had a distinguished target committee sitting for weeks deciding upon the selection of targets. All that data were before them, they knew what was to be expected. The target was selected so as to utilize to the maximum the power of that bomb. And, gentlemen, the results came out exactly as predicted and as expected in Hiroshima.

In estimating the damage over a place like upper New York, it would be, somewhat, a problem differing only in degree. The damage would be somewhat less. I would cut the area of primary damage from 6 miles. In my judgment it would be 4 square miles, although that may be conservative. It would still be 150 or 160 times the power of the one 10-ton blockbuster.

In places where there were high skyscrapers, they would cut that down lower, to maybe 2 square miles. That would still be 80 times the blockbuster.

I do not want to exaggerate, but I want to get across the fact that the public is coming to think that this bomb hasn't the power it actually has. It does have that power.

On the other hand, I do protest against exaggerations, particularly the lurid exaggerations, the statements that the atomic bomb is like a volcano or an earthquake.

The atomic bomb is probably the greatest man-made demonstration of power, but it does not compare with nature. I think it is awful enough and potent enough as it stands, without exaggeration and certainly without belittlement.

The atomic bomb certainly can be made bigger. Certainly, you can make more. Certainly you could deliver more. I do not think you would drop one bomb over New York.

I don't want to say what eight bombs might do to New York, properly placed, or what three bombs could do to Washington, or six in Chicago. Those cities would not be functioning, if proper locations for bombs were selected, with proper fuzing, taking into consideration the character of the buildings below them.

In the atomic bomb we have a terribly powerful force and it must be regulated.

There was a statement that the ground was not seared. Of course it wasn't seared. Our intention was not to get total destruction but

to get the maximum area of destruction. As I say, the predictions were exactly as indicated.

The bomb, exploded high in the air, does release a tremendous percentage of its energy into the open. It is only the part of the energy which strikes the ground that does the damage. But you could not do anything else unless there were some way of getting it into the ground rapidly before it exploded.

But there is no question about its might. If two bombs will do to cities what was done to Hiroshima and Nagasaki, put two cities out of commission and stop a war, I think it is a fairly effective weapon.

Those are my views with respect to the conclusions in the article. We have very detailed statistical reports and photographs of the thirty-odd reinforced concrete buildings in Hiroshima. Seven of them did suffer serious structural damage.

At Nagasaki there was much more damage to reinforced concrete structures. The buildings directly in the area were either totally destroyed or destroyed except for a few walls.

There was a school building where one whole side was crushed in. There was a church with 12- and 18-inch brick walls blown completely to pieces. So it does, even at a great height, have a tremendous effect on masonry work.

And remember, all you have to do to increase that destructiveness is to bring it down a little bit. We should not belittle it, and we must keep the public aware of the fact that this thing has tremendous power.

If two atomic bombs can do that, 200 could do more, and 2,000 could do more. I am sure you gentlemen are aware of the seriousness of this, and I think it is terribly important to keep the public aware of the seriousness.

Senator JOHNSON. What about the naval experiment that is under way?

General FARRELL. I think that has rather a great deal of value for the Navy, Senator, because they will learn many things about the designing of ships, about tactics and organization.

I think also it will have a tremendous effect upon the American public and the world, to teach them again that this bomb is something of tremendous power. For that reason alone, even if the Navy learned nothing, I think the experiment will be worth the effort and cost put into it.

Senator JOHNSON. Do you concur in the judgment, the selection of the Nagasaki bomb rather than the Hiroshima bomb for the naval experiment?

General FARRELL. Yes, sir. That bomb is more efficiently designed, and it is considerably improved.

Senator JOHNSON. What about the effectiveness, more than the design?

General FARRELL. I think our statistics show that the effectiveness is greater or certainly equal to the other.

I think the impression that the Nagasaki bomb is capable of doing less damage was brought about by the fact that more than half of the area in Nagasaki where this bomb was exploded was surrounded and shielded by wooded hillsides, where the bomb simply blasted the hillsides. The unit destruction was certainly equal to the other.

I may say, however, that the Hiroshima bomb caused greater fire damage, the fires were more widespread, because it landed over an area largely built up of ramshackle structures; whereas at Nagasaki there were more steel buildings and masonry, and the fire was not so damaging. The blast effect was greater than in a similar region in Hiroshima. The fire damage was greater at Hiroshima also because there were secondary fires caused from overturned stoves and short circuits, which set fire to great areas.

Senator MILLIKIN. Is it possible to compare the effects of an atomic bomb exploded in the air with the effects of a blockbuster exploded on the ground?

General FARRELL. They certainly are not the same. However, I will be fair about it. Those are the proper places to set those two off for their respective jobs.

Senator MILLIKIN. For their particular purposes?

General FARRELL. The blockbuster bombs should be exploded on the ground, and the atomic bombs in the air.

Of course, you could detonate the atomic bomb in the ground or at the ground. While it would be a guess, I think it would certainly totally destroy at least 1 square mile, which again is more than 40 times the power of the blockbuster.

The area, compared to a 10-ton blockbuster, would be not less than 1 square mile which would be totally destroyed by the atomic bomb.

Senator MILLIKIN. Thank you.

The CHAIRMAN. Major de Seversky wants permission to ask the General a couple of questions, if that is agreeable to the committee.

Major DE SEVERSKY. In the first place, I want the general to feel that I do not criticize the fact that the bomb was exploded 2,000 feet in the air. On the contrary, I will repeat what I said, that I thought it was the right force to use, that it was used in the right place at the right target.

In other words, I know it was calculated to be exploded at that altitude in order to produce the maximum blast effect.

But, at the same time, the General—when making comparisons, he said that in New York it would destroy—what was it?

General FARRELL. About four city blocks.

Major DE SEVERSKY. And he said in Hiroshima it destroyed 4 square miles.

Mr. MORRISON. A 10-ton blockbuster would destroy four city blocks.

Major DE SEVERSKY. These I consider not comparable. You cannot compare one blockbuster destroying four blocks in New York and an atomic bomb destroying 4 square miles in Hiroshima, because the targets themselves are so utterly different. There is no use in comparing two different forces, used on entirely different targets.

Then, a further thing. There is the question of preparedness. The Japanese certainly were not prepared for the atom bomb, but it does not mean that the world is going to be unprepared in the future. The important fact is that the Japanese were not prepared. Any weapon used with the element of surprise can produce abnormally high results, no matter what it is, even a penknife.

For example, if we take Hiroshima and drop on Hiroshima, without any suspicion on their part, poison gas, we would probably kill everybody in Hiroshima. However, if they were prepared, if they expected

it, by using a rather simple measure such as a gas mask, they may reduce this loss to only a few people.

Therefore, the fact that a terrific result was gained through surprise is not so remarkable. I think it would be much more remarkable if the people were prepared and, in spite of it, terrific damage were inflicted. Then I think you would have something to brag about.

But the Japanese were caught by surprise. It was in our favor; it was our advantage. Let us not consider surprise an inherent part of the weapon. In the future, the world will find means of defense. Of necessity, there will be provided some sort of shield against radioactivity. There will be bomb shelters for people, lined with the proper insulation.

So, while it is true that the terrific loss of life and damage was due to the element of surprise, I want to point out that the element of surprise is not going to be with you forever.

Now, the General said something which in a way substantiates my statement. He said if we had to bomb a concrete city, he would use the bomb differently and a different fuze. That is exactly what I said in my article. In order to produce maximum damage in New York, "a different kind of atomic bomb exploding in a different fashion would be needed." In other words, if it exploded away up in the sky, it would not be the most efficient way of using the bomb against a city like Chicago or New York. Also, you would have to have quite a few more atomic bombs to destroy them than you did in Hiroshima and Nagasaki.

As to the number of airplanes used to produce the same damage, I disagree with General Farrell. I am willing to stand on my experience.

I think his number of 700 is exaggeration. I have studied bombing a great deal. I have studied not only the actual destruction on the ground but I have also led bombing forces in attack in World War I. I am convinced that I could have knocked out these two cities so that they would have been absolutely no good for any useful purpose, with all their industries blown out, with the number of planes I have stated.

The CHAIRMAN. Do you wish to make any comment, General?

General FARRELL. The only thing I will say is that the figures I gave are based on the actual records of all the incendiary bombs dropped by the B-29's in the Pacific area. The data are from the official records of the Twentieth Air Force, and it comes out to 84 aircraft actually over the target; you must use 84 per square mile.

Mr. NITZE. May I comment?

The CHAIRMAN. Certainly.

Mr. NITZE. I think part of the difference in the computations comes from the fact that a good part of the B-29 raids against cities were conducted against areas partially burned out, so that actually it decreased the effectiveness.

These cities where the atomic bombs were dropped were undamaged, virgin targets. Our calculations, I think, would come closer to 300 planes.

The same results could be accomplished with fire bombs, but the point is that you still have to consider the matter of blast; you would

not get the same blast effect or anywhere near the same casualty effect, nor anywhere near the same psychological effect.

So, there was only a partial effect which could have been achieved with something in the order of 300 B-29's, dropping incendiaries.

General FARRELL. I would like to give you a few factual data as to the physical damage.

At Nagasaki, the window damage was complete, at 12,000 feet, or $2\frac{1}{2}$ miles. The plaster damage was very heavy up to 9,000 feet. The roof damage was heavy up to 2 miles; light up to 3 miles. Window frames and doors, heavy up to 8,000; light up to 12,000. Nine-inch brick walls, heavy up to 5,000 feet; some damage at 6,000. That is, these brick walls were cracked.

Heavy reinforced concrete buildings, 10-inch walls or 6-inch walls, were destroyed up to 2,000 feet. Churches built of brick, 18-inch brick, completely destroyed at 3,500 feet.

That gives a damage radii of total and secondary damage of different types of structures—those were all from blast.

Major DE SEVERSKY. If the general states that the concrete buildings were destroyed up to 10,000 feet, I can also state that concrete buildings were not destroyed as close as 200 feet.

General FARRELL. There were exceptions; yes, sir. There was destruction up to 2,000 feet, however.

Major DE SEVERSKY. Did you say that at Nagasaki the total destruction was 12,000 feet?

General FARRELL. For glass.

Major DE SEVERSKY. Oh, windows.

The CHAIRMAN. Thank you very much.

Senator JOHNSON. Does the general have something else to put in the record?

General FARRELL. No, sir.

The CHAIRMAN. Now, we can go ahead for a short period of time.

If there is no objection from any member of the committee, we will go ahead with the next witness.

Who would like to be next?

Off the record.

(Discussion off the record.)

STATEMENT OF COL. STAFFORD WARREN
