Subject: Submittal of Safety/Relief Valve In-Plant Testing Results

Pursuant to Section 2.C(4) of the Fermi 2 Operating License, Detroit Edison is hereby submitting the results of a series of in-plant tests of the safety/relief valves (SRVs) which were conducted on March 11-12, 1987. The attached analysis, demonstrated that the acceptance criteria as stated in License Condition 2.C(4) were met. These acceptance criteria, are also contained in Section 2.13.9, "SRV Load Assessment by In-Plant Tests," of NUREG-0661, "NRC Acceptance Criteria for the Mark I Containment Long-Term Program." By copy of this letter, Detroit Edison considers its actions required by Operating License Section 2.C(4) complete.

If you have any questions regarding this submittal, please contact Mr. G. D. Ohlemacher at (313) 586-4275.

Sincerely,

Enclosure

ABSTRACT

A safety relief valve (SRV) test program was conducted at the Enrico Fermi Atomic Power Plant Unit 2 (Fermi 2) on March 11 and 12, 1987. The purpose of the Fermi 2 in-plant SRV discharge test program was to confirm that the measured SRV discharge hydrodynamic loads and their effects on containment structures are bounded by those analytically predicted in the plant unique analysis.

This report describes the test instrumentation, test program, and data reduction, and presents the results of the Fermi 2 in-plant SRV discharge test. Major conclusions drawn from the reduction of the data recorded during the Fermi 2 in-plant SRV discharge test are as follows:

- The measured peak pressures during the cold pipe single valve actuation (SVA) and the hot pipe consecutive valve actuation (CVA) are well below the Fermi 2 values predicted using the plant unique analysis (PUA) methodology, applied at test conditions.
- The measured bubble frequencies were within the limits of the PUA analytical predictions.
- The measured torus shell, support structure, T-Quencher supports and submerged structure strains are considerably less than predicted by the PUA methodology.
- The peak measured accelerations and torus shell membrane stresses are well below the values predicted using the PUA methodology, at test conditions.

Based on the above, it is concluded that the effects of SRV discharge hydrodynamic loads have been adequately addressed in the Fermi 2 PUA and that there are substantial containment design margins for SRV discharge loads.

1.0 INTRODUCTION

1.1 Test Program

The in-plant safety relief valve (SRV) discharge test for the Enrico Fermi Atomic Power Plant, Unit 2 (Fermi 2) was conducted on March 12, 1987. The test was preceded by a shakedown test which was performed on March 11, 1987. The test matrix consisted of two shakedown tests, four single valve actuations (SVA) and four consecutive valve actuations (CVA), as shown in Table 1-1. The Fermi 2 test conforms to the guidelines specified in the U.S. Nuclear Regulatory Commission (USNRC) documents NUREG-0763 (Reference 1) and NUREG-0661 (Reference 2). This report includes an overview of the Fermi 2 in-plant SRV discharge test program objectives, instrumentation, sensor specifications, data reduction, test results, and reconciliation of the remaining plant unique analysis (PUA) licensing commitments. The test plan, NUTECH report DET-01-315 (Reference 3), provides additional details on the Fermi 2 test program.

Prior to beginning the Fermi 2 startup program, the suppression chamber segment corresponding to safety relief valve SRV-2064 was instrumented for the in-plant SRV discharge test program. During the plant startup program, this SRV has demonstrated a history of high tailpipe temperatures. Based on subsequent review of the data it was concluded that any steam weeping past the SRV had a negligible effect on the SRV discharge pressure loads.

1.2 Test Objectives and Scope

The objective of the Fermi 2 in-plant SRV discharge test was to confirm the methodologies used in the PUA and demonstrate that the loads and structural responses, documented in the Fermi 2 Plant Unique Analysis Report (PUAR) (Reference 4), for SRV discharge related loads are conservative, compared to the loadings and structural responses measured during the in-plant test.

The geometric characteristics of the T-Quencher device used at Fermi 2 are similar to those of standard T-Quencher devices used in other Mark I plants, and tested at the Monticello Nuclear Generating Plant. However, the Fermi 2 T-Quencher was specifically designed to more effectively mitigate the SRV discharge air bubble loads than the standard T-Quencher. The Fermi 2 T-Quencher was developed through a series of small scale tests and analytical evaluations to maximize the load reduction benefits. The small scale test results (Reference 6) showed load reductions for the Fermi T-Quencher in the range of 1.5 to 2.5 compared with the standard T-Quencher. The PUA for Fermi 2 was performed using the Mark I program SRV discharge load methodology which is based on the standard T-Quencher. The differences between the Fermi 2 and standard T-Quenchers were modeled as closely as possible within the limitations of the computer programs. The analytical results showed a smaller reduction in loads (about 20%) than the small scale test results.

As part of the Fermi 2 PUA, the suppression chamber structural analysis for the SRV discharge loads was performed using the alternate methodology defined by NUREG-0661, which uses calibration factors to be con-

firmed by plant unique SRV discharge tests. Therefore, the scope of the Fermi 2 in-plant SRV discharge test program includes the confirmation of the calibration factors used in the Fermi 2 PUA.

The Fermi 2 in-plant SRV discharge test program focused on measurement of the following:

1. Peak suppression pool boundary pressures during SRV discharge line (SRVDL) air clearing and steam discharge due to a single SRV actuation (normal water leg, cold and hot pipe).
2. Pressure magnitude and frequency content of the T-Quencher air bubble pressure transients.
3. Water and air clearing reaction loads on the SRVDL and T-Quencher supports
4. Suppression chamber structural response including torus shell membrane stresses due to a single SRV discharge (cold and hot pipe)

The methodology utilized in the Fermi 2 PUA and the remaining NUREG-0661 commitments for Fermi 2 are satisfied by confirmation of these items.

Conservative analytical techniques were utilized in the Fermi 2 PUA to demonstrate that the response of torus attached piping and submerged structures to SRV discharge loads complies with the NUREG-0661 acceptance criteria. Section 2.13.9 of Appendix A of NUREG-0661 stipulates that in cases where conservative analytical techniques are utilized in the analysis, confirmatory test measurements are not needed. Therefore, the Fermi

2 in-plant SRV discharge test program did not include confirmation of submerged structure or torus attached piping response to SRV discharge loads.

The SRV discharge loads methodology used in the Fermi 2 PUA utilizes generically developed conservative methods, as defined by NUREG-0661, for determining line clearing reaction loads on the SRVDL and T-Quencher supports, spatial variations in T-Quencher air bubble loads, load superposition methods for evaluating multiple valve actuations, load changes that accompany consecutive valve actuations, and shifts in bubble frequencies that result from variations in back pressure during air clearing. Therefore, these methods did not require confirmation by in-plant testing. Similarly, suppression pool thermal mixing tests were not conducted since the evaluation of pool temperature response to SRV transients referenced in the PUAR complies with the NRC acceptance criteria.

1.3 Quick Look Sensors and Acceptance Criteria

During each of the matrix tests, data from all sensors were recorded on the General Electric Transient Analysis Recording System (GETARS). After each CVA approximately 25% of the recorded sensor time histories were reviewed as quick look sensors. These consisted of:

- Pressure sensors P2 and P3 which measured the peak T-Quencher bubble pressure; P5, P7, P8, and P11 which measured torus shell pressures; P15 which measured internal T-Quencher pressures and P20 which measured SRVDL pressure

- Twenty seven strain gauges located on the torus shell, torus support columns and internal structure supports
- Two temperature sensors at the lower end of the SRVDL

The maximum measured response from each quick look sensor was compared to the associated acceptance criteria for each sensor. For pressure sensors P2 and P3 the mean measured T-Quencher bubble pressure was calculated for the four sets of tests (MT1 to MT8) plus the shakedown tests (SD1 and SD2), and statistically adjusted using a 90-90 confidence band; i.e., 90% confidence that 90% of all pressures will be bounded by the calculated value. The measured 90-90 peak T-Quencher bubble pressures were then compared to the analytically predicted pressures at test conditions (Level 2 acceptance criteria).

The acceptance criteria were developed using the PUAR methodology at test conditions, to ensure that plant safety would not be compromised during the SRV discharge testing. The acceptance criteria were developed for a reactor pressure of 1000 psig. Actual test pressures, Table 1-1, varied from a low of 992 psig to a high of 1023 psig. This variation in pressure produces less than one percent variation in steam flow rate and is within the calculational accuracy of the analytical results presented in Section 5.0. Level 1 acceptance criteria correspond to the ASME Code allowables for the suppression chamber materials while Level 2 acceptance criteria correspond to calculated values expected at actual test conditions. Exceedences of Level 2 acceptance criteria served as a warning threshold, but did not require that testing be halted. Had any of the measured

results exceeded Level 1 acceptance criteria, testing would have been halted until investigation of the measured data ensured that continued testing would not compromise plant safety.

1.4 Summary of Final Test Data Results

The Fermi 2 SRV in-plant test data and the conclusions documented in this report are based on data collected by 124 sensor channels. Representative plots of the data, in engineering units, are presented in Appendices B through D, and the maximum/minimum values for each channel are presented in Appendix E. The test data demonstrates that the Fermi 2 primary containment structures, and piping are adequate for hydrodynamic loads resulting from the actuation of a SRV. The peak suppression pool boundary pressures analytically predicted during SRVDL air clearing and steam discharge for a single SRV actuation conservatively bound the measured results. The measured T-Quencher oscillating air bubble dominant frequency is in good agreement with the analytically predicted frequency. Similarly, measured clearing reaction loads on the SRVDL and T-Quencher supports are conservatively bounded by the analytical predictions.

- NOTES:
1. SRVDL Water Level is the differential pressure between wetwell and drywell in inches of water, as measured on Instrument No. T48-R808 Panel H11-P817.
 2. Torus Water Level is measured by Instrument G51-R402 on Panel H11-P807 as plus or minus from normal water level.
 3. Pool temperature is the average torus water temperature as measured on the Torus Water Temperature Leg.

Abbreviations: CVA - Consecutive Valve Actuation
SVA - Single Valve Actuation

Four types of instrumentation were utilized to obtain the measurements necessary to achieve the test objectives including: pressure transducers, strain gauges, accelerometers, resistance temperature detectors (RTD's) and existing plant system thermocouples. A list of test sensors is provided in Table 2-1. The sensor locations are shown in Figures 2.1 through 2.18. Section 3.0 provides a description of the signal conditioning equipment and the data acquisition system used to process and record data signals from the sensors installed on the containment. Appendix A provides a description of the operational characteristics of the individual pressure transducers, strain gauges, accelerometers, and RTD's used for the Fermi 2 SRV discharge test. The data acquisition system and instrumentation used to record the Fermi 2 SRV discharge test data has been qualified by use in similar SRV test programs. The sensor components that make up the instrumentation scheme have also been qualified individually.

2.1

Instrumentation

Twenty pressure transducers were installed to measure torus shell, SRVDL, and T-Quencher air bubble and internal pressures. The individual pressure transducer locations are shown in Figures 2.1 through 2.3. Pressure transducers P1 through P4 were located on either side of both T-Quencher arms, near the centroid of the T-Quencher arm hole pattern. These sensors were used to measure the SRV discharge loads source pressure from the T-Quencher. Pressure transducers P5 through P14 were located on the inside surface of the torus shell and were used to measure torus shell pressures.

Transducers P5 through P12 were located in the same vertical plane as P1 to P4 and were used to measure circumferential pressure attenuation. The locations of transducers P7, P8, P11, and P12 were based on small scale Fermi 2 T-Quencher test results and were used to measure peak torus shell pressures and the occurrence of any asymmetrical T-Quencher air clearing effects. P13 and P14 provide a check of longitudinal torus shell pressure attenuation. T-Quencher internal pressure was monitored by P15 and P16 mounted on the T-Quencher arms as shown in Figures 2.1 and 2.2.

A SRVDL air bleed system installed inside the drywell, was used to equalize the pressure between the test SRVDL and drywell air space prior to SRV actuation. A schematic of this system is shown in Figure 2.3. Pressure equalization ensures that a constant SRVDL water leg height is maintained between tests and assures repeatability of test conditions. The air bleed system was manually activated from the main control room prior to all SVA and CVA tests. Two low range pressure sensors P17 and P18, were installed in this system, as shown in Figure 2.3, to provide an indication of water level height within the SRVDL following valve closure.

The SRV back-pressures which occur during an SRV discharge were measured by P19 and P20, shown in Figure 2.3. P19 and P20 were located in the longest straight section of the SRVDL (elevation 587'-4") to avoid entrance and exit effects on the measured pressures due to pipe bends.

Ninety-eight strain gauges were installed on the containment, submerged structures and piping to measure representative strain data during the matrix tests. The

strain gauge locations are shown in Figures 2.4 through 2.16. Strain rosettes SR1 through SR12 are shown in Figure 2.4. They were located on the inside and outside surface of the torus shell and provided circumferential and longitudinal normal stress, components, and shear stresses at the extreme fibers of the torus shell. Strain rosettes, SR1 through SR4 and SR7 through SR10, were located at midcylinder of the test bay and measured the circumferential torus shell stress variation. Rosettes SR6 and SR12 were used to measure asymmetrical T-Quencher air clearing effects, should they occur.

Strain gauges SG1 through SG30 were located on the torus support saddles and columns in the test bay and the two adjacent bays, as shown in Figure 2.5 through 2.7. These strain gauges measured suppression chamber support loads, basemat reaction loads, and provided a means of obtaining longitudinal load attenuation. As shown by Figures 2.8 through 2.12, strain gauges SG31 through SG45 were located on submerged structures in the vicinity of the test bay. SG31 through SG34 were located on the pinned-end horizontal T-Quencher support members, and SG35 and SG36 on a vertical T-Quencher support member. SG37 through SG39 were located on the vent header vertical support column and SG40 through SG43 on the T-Quencher pedestal support. SG44 and SG45 were located on the RCIC exhaust line support in the suppression pool.

SG46 through SG50, SG52, and SG53 were located on the RCIC turbine exhaust line, inside and outside the torus shell, near the penetration as shown in Figures 2.12 and 2.13. SG51 was omitted due to the penetration configuration. Measurements from these strain gauges were used to determine the hydrodynamic load effects acting on the

submerged portion of the torus attached piping as well as suppression chamber motions at the penetration locations. SG54 and SG55 were located on a downcomer bracing rod to measure downcomer lateral load effects. SG56 through SG59 were located on the SRVDL near the vent line penetration, as shown in Figures 2.14 and 2.15, to determine the effects of SRVDL water clearing thrust loads on the wetwell portion of the SRV piping. SG60 through SG63 were located on the inside downcomer at midbay of the non-vent test bay to measure SRV discharge submerged structure loads on the downcomers, and the dynamic characteristics of the downcomers and vent system.

Four accelerometers were installed to measure torus shell and torus attached piping response to SRV discharge loads. Accelerometers A1 and A2 (Figure 2.13) measured accelerations of the RCIC turbine exhaust line valve located outside the torus. Accelerometer A3 (Figure 2.17) measured the coupled torus/piping system radial accelerations of the suppression chamber at the RCIC turbine exhaust torus penetration locations. Accelerometer A4 (Figure 2.17) was located symmetrically to accelerometer A3 on the opposite side of the mitered joint in the test bay, and measured the "clean shell" radial acceleration of the suppression chamber.

Seventeen temperature sensors were originally installed in the suppression chamber to provide thermal mixing data during an extended SRV discharge. Prior to the test, the NRC approved the PUAR pool thermal mixing methodology and hence these sensors were not utilized. Temperature sensors T5 and T6 (Figure 2.18) were used to monitor the SRVDL vent line penetration and wetwell SRVDL temperature. The outer surface temperature of the

penetration reinforcement sleeve was monitored by sensor T5. The outer surface temperature of the SRVDL near the vent line penetration was monitored by sensor T6.

2.2 Data Acquisition System

The General Electric Transient Analysis Recording System (GETARS) was used for data acquisition during the shakedown and each test in the SRV discharge test matrix. Figure 2.19 provides a schematic of the data acquisition system. GETARS sampled a total of 274 channels of which 124 were utilized for SRV discharge test instrumentation, plus the four additional channels used for the SRV initiation signal. The remaining 146 channels provided plant operational data for uses other than the SRV test. A sampling rate of 1000 samples per second per channel was used. Data was originally recorded using pulse code modulation (PCM) tape and later transferred onto magnetic tapes for subsequent data reduction and analysis. Data from approximately 25% of the 124 SRV discharge test sensors were reviewed immediately following each test to confirm that the acceptance criteria were not exceeded. A total of five magnetic tapes were needed to accommodate data from the two shakedown and eight matrix tests (four SVA and four CVA tests). These magnetic tapes were used for subsequent off-line data processing.

2.3 Accuracy of Instrumentation

The total end-to-end accuracy (from the sensing element to data recorder) of each sensor group used in the Fermi 2 in-plant SRV discharge test was analyzed to confirm that the instrumentation system was compatible with the range of expected test results. As described in

Appendix A, the following sensor types were used to measure data:

- 1) Bell & Howell pressure transducers
- 2) Endevco Accelerometers
- 3) Ailtech and Micro-Measurements strain gauges
- 4) Medtherm resistance temperature detectors

Data from these sensors were recorded by GETARS on magnetic tapes. Table 2-3 lists the accuracy of the recording system for each sensor. Table 2-4 summarizes the results of the data accuracy analysis.

An estimate of the sensor accuracy can be determined if the following characteristics are known for the data and the data acquisition system:

- 1) The individual accuracies of the data acquisition system components, from sensing element to recording of the data, and the appropriate conditions with which to apply these accuracies.
- 2) The characteristics of the data recorded, such as magnitude and frequency.
- 3) The test conditions which influence the data. These can include noise, vibration, and temperature effects.

The resolution of the data acquisition system, including multiplexers and computers, is 5 mV. Using this resolution and instrument calibration factors, the data

system accuracies for pressure transducers, strain gauges, accelerometers and resistance temperature detectors were calculated as shown in Table 2-3.

The Validyne Signal Conditioner Model CD-173 accuracy is estimated to be 2.8% of the peak measured value.

The Validyne Signal Conditioner Model PA-375 accuracy for accelerometer signal conditioning is estimated to be 0.1% of the peak measured value.

In determining the accuracy of the Fermi 2 in-plant SRV discharge test data, the maximum recorded values were chosen for each sensor group. The following sections discuss the accuracy of data obtained for each sensor group.

2.3.1 Pressure Transducers

Pressure transducers used in the Fermi 2 in-plant SRV discharge test were the normal operating temperature Bell & Howell/CEC-1000-0207 (0 to 100 psia), and the high temperature Bell & Howell/CEC-1000-0208 (0 to 1000 psia). The CEC-1000-0207 transducers were used to measure suppression pool pressures, while the CEC-1000-0208 transducers were used to measure SRVDL and internal T-Quencher pressures.

As shown in Table 2-4, the total accuracies for the pressure data are influenced by three components in the data gathering system:

- 1) Bell & Howell pressure transducer
- 2) Validyne Model CD173 signal conditioner
- 3) Data Acquisition System (GETARS)

The Bell & Howell pressure transducers have a maximum error of $\pm 0.20\%$ of full range output (FRO) for the 0 to 100 psia transducers, and $\pm 0.22\%$ for the 0 to 1000 psia transducers. These errors are primarily affected by non-linearity, hysteresis, non-repeatability, and thermal effects.

The accuracy of data acquisition system and Validyne Signal Conditioner Model (CD-173) is discussed in Section 2.3.

As shown in Table 2-4, the overall accuracy of the pressure transducers is 5% of the peak measured pressures for all pressure transducers except P17 and P18 which have an overall accuracy of 11%.

2.3.2 Accelerometers

The accelerometers utilized for the Fermi 2 in-plant SRV discharge test were Endevco 7717-200 isoshear piezoelectric devices. The 7717-200 accelerometers (0.003 to 500 g's) were installed on the torus shell and the RCIC turbine exhaust valve operator.

As shown in Table 2-4, the total error for the accelerometer data is affected by relative errors of the three components in the data recording system:

- 1) Endevco accelerometer
- 2) Validyne Signal Conditioner - Model PA-375
- 3) Data Acquisition System (GETARS)

The maximum error of the Endevco accelerometers is based on a linear deviation of $\pm 5\%$ from 1 Hz to 4 kHz and a transverse sensitivity of $\pm 3\%$.

As stated previously, the accuracy of Validyne Signal Conditioning Model PA-375 is 0.1% of the peak measured value, and the accuracy of data acquisition system is 5 mV.

As shown in Table 2-4, the overall accuracy of the accelerometer data is 5% of the peak measured accelerations.

2.3.3 Strain Gauges

Ailtech Model MG125 weldable gauges were used to measure strain data on the internal torus shell, SRV piping, internal and external torus attached piping, and piping support struts. Micro-Measurements Model EA06-125RS-350 (Rosettes) and Model 125AC-350 (uniaxial) strain gauges were used to measure strain data on torus external shell and supports. These gauges have rated strain levels of $\pm 20,000$ $\mu\text{in}/\text{in}$.

The Ailtech and Micro-Measurements gauge factor maximum error is $\pm 3\%$. The accuracy of the data acquisition system and the Validyne Signal Conditioner Model CD173 has been previously discussed in Section 2.3.

As shown by Table 2-4, the overall strain gauge data accuracy is 5% of the peak measured strains for all strain gauges except SG10 through SG16 which have an overall accuracy of 11%.

2.3.4 Resistance Temperature Detector (RTD)

Medtherm Model PRT-50-250-10387 RTD's were used to measure SRVDL and vent line penetration temperatures. The operating range for these RTD's is 50°F to 600°F.

The accuracy of these RTD's specified by the manufacturer is $\pm 0.5^\circ\text{F}$. The accuracy of Validyne Signal Conditioner Model CD173 has been previously discussed in Section 2.3.

As shown in Table 2-4, the overall accuracy of the temperature measurements is 0.4%.

2.3.5 Summary

Many of the readings taken during the SRV discharge tests were of small magnitude compared to the capabilities of the measuring devices. The instrumentation provided data accurate to within 5% for all sensors except pressure transducers P17 and P18 and strain gauges SG10 through SG16 which have accuracies of 11%. This is well within acceptable accuracy limits.

2.4 Failed or Suspect Sensors

Failure or erratic performance of some instrumentation is inherent when conducting in-plant tests. Upon reviewing the reduced data, sensors which failed or behaved erratically were identified. Table 2-5 lists these sensors and includes remarks on the effect of their failure with respect to the overall objectives of the test program. Results from all sensors listed in Table 2-5 were ignored in this test report for each test in which they failed or were suspect. The failure of

strain gauges SR2B and SG58 was known prior to the test. Even though data from these gauges were recorded during the tests, it was not transferred to magnetic tape for subsequent data processing. Some strain gauges measured strains comparable to the noise levels (2 to 4 μ in/in). These strain gauge results were used for subsequent data processing because the recorded signals produced readable data.

SCHEMATIC OF DATA ACQUISITION SYSTEM

3.0 DATA REDUCTION

3.1 Introduction

The measured time-histories for each of the 124 instrumentation channels were recorded by GETARS on magnetic tape for off-line processing. On completion of each test, real time data were compared against the test acceptance criteria.

The data processing and reduction of raw data was performed using the software package, REDUCE, Version 1.4.0. REDUCE is a compilation of NUTECH proprietary codes developed for this purpose. The data reduction was performed on a CYBER-730 system.

3.2 Data Tape Information

As detailed in Table 3-1, a total of five magnetic tapes were used to store the data recorded during the in-plant SRV discharge test program. Each data sample is represented by a 16-bit word, and the data acquisition was performed with a sampling rate of 1000 samples per second per channel.

3.3 Standard Processing Approach

The following processing and data reduction steps were performed on all sensors:

- Convert the binary digit stream on the data tape to decimal voltage values.

- Demultiplex the data for each channel and convert the signal to engineering units by dividing the voltage values by the sensor's calibration factor.
- Remove unwanted D.C. offset, transducer bias or thermal drift from the data to obtain the dynamic portion by the transient.
- Low pass filter the data at 100 Hz to remove unwanted high frequency noise.
- Perform frequency analysis and calculate the power spectral densities (PSD).

3.4 Pressure Transducer Analysis

The maximum and minimum values of the filtered pressure time-histories were tabulated for each pressure transducer. A frequency analysis was performed, and PSDs developed for each pressure transducer.

3.5 Strain Gauge Analysis

The maximum and minimum peak values and the time at which the peak occurred was calculated for each strain gauge. A frequency analysis was performed and the PSDs were computed for each strain gauge. Principal stress, shear stress and stress intensity time histories were calculated for each rosette. Axial and bending stress components were calculated for each group of uniaxial gauges. A combined total force time history was calculated for the two groups of ten strain gauges installed on the miter joint saddle supports.

3.6 Accelerometer Analysis

In addition to tabulation of maximum and minimum values, PSD's and acceleration response spectra were developed for each sensor from the filtered time-histories. Envelope response spectra were computed at one percent of critical damping for the torus shell mounted accelerometers (A3 and A4).

3.7 Channels Analyzed

Data reduction analyses were performed for the following sensor channels as part of the Fermi 2 in-plant SRV discharge test program:

<u>Type</u>	<u>Number</u>
Strain	98
Pressure	20
Accelerometers	4
Temperature	2

In addition, four channels were monitored to provide SRV actuation signals for a total of 128 sampled data channels related to the SRV discharge test. Additionally, 146 channels providing plant operational data for other uses not related to the SRV test were sampled by GETARS. These data channels were not transferred to magnetic tape and do not form part of this report.

Table 3-1

DISCUSSION OF RESULTS

This section provides a review of the data recorded during the test, and tabulated in Tables 4-1 through 4-6 and Appendix E. Typical time histories and PSD's for each group of sensors are provided in Appendices B through D. Each discussion highlights the major observations derived from data, with comparisons of the measured results with analytically predicted values for single and consecutive valve actuations.

The measured tailpipe temperature prior to shakedown test SD1 was 213°F, which is indicative of a weeping valve. An elevated SRVDL temperature is sometimes accompanied by an increase in SRVDL pressure, which leads to a depressed water leg. Temperatures measured by sensors T5 and T6, located on the SRVDL within the torus air space, were reviewed and showed torus ambient temperature. It was judged that the leak was small and the airbleed system would equalize the water leg, and the pressure buildup was slow enough so that test results would not be significantly affected. The shakedown test was performed with a tailpipe temperature of 213°F. The SRV reseated following SD2 and the tailpipe temperature reduced to 167°F for MT1. For all subsequent tests, the tailpipe temperatures were approximately 212°F and the SRV was assumed to be weeping.

4.1

Pressure Data

The pressure sensor data indicates that the Fermi 2 T-Quencher design performs better than anticipated, with measured peak T-Quencher bubble pressures less than 50% of predicted values. The data substantiates the Fermi 2

small scale T-Quencher test load reductions (Reference 6) and implies that the Mark I methodology for predicting SRV discharge related loads is conservative for the Fermi 2 T-Quencher design. Similarly, measured torus shell pressures are less than half of the predicted pressures.

Data were recorded for twenty pressure sensors for each test. Off-line data for eight of the twenty pressure sensors were reviewed following each test to assure that the test predictions were not exceeded. The preliminary results for these eight pressure sensors were reported in the quick look report (Reference 5). This section of the report presents the final reduced pressure data for eighteen pressure sensors. As discussed in Section 2.3, two sensors (P1 and P12) did not provide usable data.

As noted above, all SVA discharge tests, except MT1, were performed with an elevated (212°F) SRV tailpipe temperature. Review of the measured pressure data shown in Tables 4-1 through 4-4 shows only minor differences in pressure amplitudes between test SD1, MT1 and the other SVA tests. The only measurable difference between MT1 and the other SVA tests is a shift in T-Quencher dominant bubble frequency ranging from 7 Hz up to 11 Hz. This frequency shift tends to move the dominant bubble frequency closer to the fundamental frequencies of the suppression chamber and results in a more conservative comparison of measured results with analytical values. Because of these facts, it was concluded that any steam weeping past the SRV had a negligible effect on the results. Therefore, tests SD1 and MT1 were included in the statistical sample to calculate the 90-90 pressure amplitudes; i.e., 90% confidence that 90% of measured results will be less than this pressure.

Appendix B provides typical pressure time histories and PSD's from each test.

4.1.1 SRVDL and T-Quencher Internal Pressure Data

As described in Section 2.1, sensors P19 and P20 were located in a straight section of the SRVDL, sensors P15 and P16 were located inside the T-Quencher arms, and sensors P17 and P18 between the air bleed valves to provide pressure time histories for the SRVDL and T-Quencher.

As shown in Table 4-1, the measured SRVDL peak SVA internal pressure was 220 psig, and 216 psig for a CVA. The calculated line losses, at test conditions, from the SRV to sensors P19 and P20 is 25 psig resulting in a peak SRV back pressure of 245 psig. This is less than the analytically predicted SVA and CVA back pressures of 322 and 381 psig, respectively.

As shown in Table 4-1, the peak measured T-Quencher internal pressure was 216 psig for a SVA and 139 psig for a CVA. These values compare to pretest analytically predicted values of 231 and 287 psig for the SVA and CVA, respectively. Table 4-1 also shows that the T-Quencher water clearing from the two T-Quencher arms was symmetrical, as the difference in internal arm pressures was typically less than 3 psid with a maximum of 15 psid.

Following closure of the SRV, steam pressure in the SRVDL decreases rapidly as the steam flows out into the suppression pool. At a sufficiently low steam pressure, pool water will re-enter the SRVDL, causing rapid depressurization as the steam in the line is condensed

by the inflowing water which causes the SRVDL vacuum breakers to open, and drywell air to fill the line. The T-Quencher discharge tests conducted at the Monticello Nuclear Generating Plant showed that the SRVDL waterleg stabilized to a position below that of the normal water leg, usually within ten seconds of SRV closure. Pressure transducers P17 and P18, between the air bleed valves, were used to determine the approximate water leg height. The inner air bleed valve was opened ten seconds after SRV closure. The test results indicated that the residual SRVDL pressure had stabilized at 2 to 2.5 psid. This is equivalent to a depressed water leg of about 5.8 feet. The outboard air bleed valve was opened ten seconds later and the SRVDL pressure immediately dropped to drywell ambient. The pressure remained steady until both air bleed valves were closed ten seconds prior to the consecutive valve actuation.

4.1.2 T-Quencher Bubble Pressure Data

As shown in Figures 2.1 and 2.2, sensors P1 through P4 were installed on the center line of the T-Quencher arms to record the peak T-Quencher air bubble pressures. As discussed in Section 2.4, sensor P1 failed prior to conducting the test program and, therefore, the evaluations and conclusions are based on the measured data for P2 to P4. The peak measured T-Quencher bubble pressure for each sensor is presented in Table 4-2. P3 consistently recorded the highest T-Quencher bubble pressures, while data from P2 and P4 were significantly less. As discussed in Section 4.1.3, the higher T-Quencher bubble pressures, measured by P3, do not appear to have a significant affect on the corresponding suppression pool boundary pressures.

The peak measured T-Quencher bubble pressures for the SVA tests, adjusted to provide a 90-90 confidence band, are +5.3 psid, -5.7 psid compared with the predicted values at test conditions of +12.04 psid, -10.38 psid. For the CVA test series the measured pressure including the 90-90 confidence band are +2.9 psid, -3.5 psid compared with predicted values of +13.35 psid, -10.15 psid. The measured SVA T-Quencher dominant bubble frequencies varied from 7.0 Hz for MT1 to 11.0 Hz for MT5 with an average of 8.6 Hz, compared to the predicted frequency of 6.4 Hz. The higher T-Quencher dominant bubble frequencies measured for MT5 and MT7 are indicative of steam in the SRVDL, and it is possible that valve leakage was somewhat larger for these tests than SD1 (8.7 Hz) and MT~ (8.2 Hz). There are no significant differences in torus shell pressures for the SVA tests. The CVA T-Quencher dominant bubble frequencies varied from 9 Hz to 11 Hz, with an average value of 9.5 Hz compared to the predicted frequency of 6.8 Hz.

4.1.3 Suppression Pool Boundary Pressure Data

The peak torus shell pressures measured during the Fermi 2 in-plant SRV discharge test series were recorded for sensor P8 at 12° above bottom dead center. This is consistent with the test measurements observed at the Monticello Nuclear Generating Plant. Pressure sensors P5 through P14 were utilized to provide longitudinal pressure attenuation with distance along the torus shell. Sensor P12 failed to provide consistent data and was not included in the analysis.

The peak measured torus shell pressures are presented in Tables 4-3 and 4-4, with typical pressure time histories

presented in Appendix B. The SVA measured torus shell peak pressures, with a 90-90 confidence band, were +1.8 psid, -2.2 psid compared with the predicted values of +7.84 psid, -8.82 psid respectively. The measured peak CVA torus shell pressures, with a 90-90 confidence band, were +1.9 psid, -2.4 psid compared to the predicted values of +6.87 psid, -7.99 psid, respectively. A review of the data presented in Tables 4-3 shows that the peak measured suppression pool boundary pressures for MT1 are similar to those for all other tests. And, as discussed in Section 4.1.2, the only discernable difference between MT1 and the other SVA tests is a shift in measured T-Quencher dominant bubble frequency from 7 Hz to 11 Hz. The measured torus shell bubble frequencies are similar to those reported in Section 4.1.2, 8.6 Hz average for the SVA tests and 9.5 Hz for the CVA tests.

Figures 4-1 through 4-3 show the T-Quencher bubble pressure attenuation. The torus shell pressure distribution is similar to that predicted by the Fermi 2 PUAR methodology, with measured pressure about 30% of the predicted pressure magnitudes. There is no evidence of asymmetric loads resulting from oscillating T-Quencher air bubbles.

The measured torus shell pressures are less than 30% of the predicted values and demonstrate that the T-Quencher design is performing better than predicted by the NUREG-0661 analytical models. The T-Quencher behavior is similar to that predicted by the 1/12th scale Fermi 2 T-Quencher tests performed in 1978 and 1982 (Reference 6).

4.2 Strain Data

As described in Section 2.1, twelve strain rosettes and sixty-three uniaxial strain gauges were installed on the torus shell, torus support structures, internal structures, and piping to measure the SRV discharge load structural response. Table 4-5 provides the maximum measured torus mitered joint support loads at azimuth 326.25°. Appendix C provides typical strain and load response time histories. Appendix E provides the maximum and minimum strains recorded for each gauge by test.

4.2.1 Torus Support Saddle and Column Loads

Twenty-four strain gauges were located on the columns (two each) and saddles (ten each) supporting the torus at the miter joint of the test bay (azimuth 326.25°). The measured saddle strain data were processed to provide the total force time history for both saddle base plates for each test. The maximum measured upward and downward saddle and column loads are provided in Table 4-5. The total miter joint vertical load was calculated by summing the maximum measured saddle and column reactions regardless of time of occurrence.

The maximum mitered joint SVA vertical load, adjusted to include a 90-90 confidence band, is 116 kips upward and 126 kips downwards, compared to the analytically predicted values of 422 kips upward and 481 kips downward. For the CVA test, the total adjusted 90-90 confidence band vertical load for the mitered joint was 137 kips upward and 125 kips downward, compared to analytically predicted CVA values of 343 kips upward and 417 kips downward. The dominant frequency of the column

and saddle loads was similar to those of the torus shell and T-Quencher bubble at 8.6 Hz and 9.5 Hz for SVA and CVA, respectively.

The five torus support columns, instrumented with strain gauges, include columns at azimuths 281.25°, 303.75° and 326.25°. The recorded strains for these columns were very small typically 1 μ in/in, with no obvious attenuation of the load. The maximum strain measurements for each gauge are given in Appendix E. As shown by Table 4-5, over 90% of the total support reaction load induced by an SRV discharge is carried by the saddles.

4.2.2 Torus Shell Membrane Stress Intensities

The maximum extreme fiber stress intensities were calculated from time-phased torus shell strain data using the rosette strain components, and are tabulated in Appendix E for SVA and CVA load cases. Membrane stress intensities were calculated as the average of the inner and outer extreme fiber values. As described in Section 2.4, the diagonal leg of rosette SR2 failed prior to the test and could not be replaced due to its location. Therefore, the membrane stress intensities at 12° inboard of bottom dead center (BDC) were calculated using the measured data from the other two gauges in the rosette and SR8 located on the exterior surface.

The peak membrane SVA stress intensity was estimated to be 0.7 ksi located 12° inboard of BDC. The maximum extreme fiber stress intensity was 0.7 ksi, also located 12° inboard of BDC. The peak stresses 12° outboard of BDC were approximately 0.4 ksi, reducing to 0.2 ksi at

60° above BDC. These values compare to the analytically predicted stresses of 2.25 ksi at 12° and 1.13 ksi at 60° above BDC.

The measured CVA stresses show a similar pattern, with the maximum calculated membrane stress intensity of 0.5 ksi at 12° and 0.4 ksi at 60° above BDC compared to the analytically predicted results of 2.0 ksi and 1.0 ksi, respectively.

The dominant frequency of the torus shell strains is similar to the torus shell pressures, with average values of 8.6 Hz for the SVA and 9.5 Hz for CVA tests.

4.2.3 Internal Structures and Piping

Thirty three strain gauges were installed in eleven groups on internal structures and piping. The measured strain data for each group of gauges was processed to develop an axial and a bending stress time history for the component. The maximum measured strains for each strain gauge, and the maximum axial, bending and extreme fibre stresses for each group of strain gauges are presented in Appendix E.

The maximum measured stress for the internal structures, including the 90-90 confidence band limits, occurred on the quencher support, and was 0.46 ksi for the SVA and 0.45 ksi for the CVA. These values are much less than the analytically predicted stresses of 2.2 ksi for SVA and 2.4 ksi for CVA. The measured stresses for other internal structures and components were much smaller, varying from 0.03 ksi to 0.17 ksi. Table 5-2 shows comparisons of the maximum measured stresses, including

the 90-90 confidence band limits, with analytically predicted results for each group of strain gauges.

4.3 Accelerometer Data

As described in Section 2.1, accelerometers were installed on the torus shell and the RCIC turbine exhaust valve operator as a check on the affects of SRV discharge loads. The peak measured values for each accelerometer are given in Table 4-6. The torus shell envelope response spectra for the SVA and CVA tests are shown in Figures 4.4 and 4.5.

The peak SVA acceleration (A4) for the "clean torus shell" measured was 0.65g, compared to 0.38g for the coupled torus shell/piping system acceleration (A3). The analytically predicted accelerations, at test conditions, were 1.9g and 1.3g for A4 and A3, respectively. The coupling affects of the RCIC turbine exhaust piping with the torus compared with the clean torus shell acceleration is shown by the envelope response spectra in Figures 4.4 and 4.5. It is evident that the coupled shell/piping system acts as a filter to reduce the torus attached piping response. The calculated response at 24 Hz is the same for A3 and A4, however, at all other frequencies the clean shell spectra envelopes that of the coupled shell/ piping system. This difference is most obvious in the higher frequencies where the clean shell response is as much as six times that of the coupled shell/ piping system.

The measured CVA response is similar to that described above for the SVA case. The peak measured clean torus shell response (A4) was 0.91g compared to 0.26g for the coupled shell/piping response (A3). The analytically

predicted accelerations were 2.0g and 1.4g for A4 and A3, respectively. The CVA clean shell (A4) response spectra are typically much greater than the coupled shell/piping spectra (A3), except at a frequency of 24 Hz where both have the same value.

The peak measured SRV discharge load accelerations for the RCIC turbine exhaust valve operator were all less than 1.0g, with an amplification factor of about two to four between the measured coupled shell/piping system response (A3) and the valve operator (A1). These low levels of acceleration are much less than the analytically predicted response of 1.7 g.

The confirmation of the Fermi 2 PUAR SRV discharge methodology discussed in Section 1.2, has been performed by selecting key parameters which can be reliably measured and analytically predicted. The measured values of these parameters, described in Section 4.0, were compared to the analytically predicted values of the same parameters, obtained by applying the Fermi 2 PUA SRV discharge methodology at test conditions. The conclusions presented in this section demonstrate that the Fermi 2 PUA methodology predicts conservative analytical results for SRV discharge loads.

The data presented in Tables 5-1 and 5-2 demonstrates that the Fermi 2 T-Quencher design, which is similar to the standard Mark I T-Quencher design, is very effective at mitigating loads; with measured peak bubble pressures less than 50% of the analytically predicted values. The data substantiates the additional load reduction capability of the Fermi 2 T-Quencher compared with the standard Mark I T-Quencher, and indicates that the NUREG-0661 methodology for predicting SRV loads is more conservative for Fermi 2. The measured T-Quencher bubble frequency content indicates good correlation with the analytically predicted frequency. Measured torus shell pressures are less than half of the pressures analytically predicted using the PUA methodology. The measured shell and torus support column strains are consistent with the measured pressure data, and range from 10% to 40% of the analytically predicted values. The measured accelerations range from 25% to 65% of analytically predicted values. These results confirm that the calibration factors used in the Fermi 2 PUAR for SRV discharge analysis have been conservatively applied.

Volume 2 of the Fermi 2 PUAR (Reference 4) describes the individual design basis loads considered in the analysis of the torus shell and support structures. These loads are combined into a series of controlling design load combinations, reported in Tables 2-2.2-11 through 2-2.2-13 of Reference 4, with the stresses for critical components reported in Tables 2-2.5-1 through 2-2.5-8. The PUAR SRV discharge loads are reported for single valve, ADS and fifteen valve load cases. As described in Reference 4, the SRV discharge loads at design conditions represent a major portion of the total response in most of the load combinations. Reductions in the analytically derived SRV discharge loads would result in a corresponding increase in the calculated design margins documented in the PUAR.

An assessment to determine the estimated reduction in the analytically predicted SRV discharge loads in the PUAR was made using the test data reported in Section 4.0 and Tables 5-1 and 5-2 of this report. The SRV discharge loads and stresses for the torus shell and support structures given in Tables 2-2.5-1 and 2-2.5-2 of the PUAR (Reference 4) were conservatively reduced using the minimum analysis/test ratios developed in Table 5-2. The suppression chamber stresses for the controlling load combinations reported in Table 2-2.5-3 were reduced in accordance with the estimated decrease in the design basis SRV discharge load stresses included in the load combination. A proportional reduction in the SRV discharge loads increases the design margins (calculated/allowable) values reported in Table 2-2.5-3 (Reference 4) from 0.99 to approximately 0.9 for the torus shell, and from 0.76 to approximately 0.4 for the torus support components. Reducing the SRV discharge

loads will also increase the weld stress design margins reported in the PUAR.

The maximum vertical support reaction design margins, provided in Table 2-2.5-4 of the PUAR (Reference 4), will increase from the reported value of 0.82 to approximately 0.4. Similarly, the reported torus shell design margin for lateral loads, given in Table 2-2.5-7, would show a small increase from 0.99 to 0.93. The effect of reducing the calculated design basis SRV discharge load induced stresses will be most pronounced in the fatigue evaluation reported in Table 2-2.5-8 of the PUAR (Reference 4). Reducing the primary plus secondary stress range induced by design basis SRV discharge loads from the 39.54 ksi reported in Table 2-2.5-1 to an estimated 16 ksi reduces the torus shell maximum cumulative fatigue usage factor from 0.87 to approximately 0.5.

Based on the conservative estimates discussed above, reductions in the design basis SRV discharge load induced stresses would increase in the torus shell design margins by about 10%. Similarly, the maximum cumulative fatigue usage factor for the torus shell is estimated to decrease by a factor of 2. It should be noted that a more detailed re-examination of the Fermi 2 PUA calculation packages would be required in order to confirm the estimated increases in the containment design margins discussed above. That is, each containment component, piping system, support member, or attachment weld would require re-examination on a case-by-case basis. It is judged that a more detailed re-examination of the PUA calculations would result in even greater containment design margins.

Note: (1) Measured values are statistically adjusted 90-90 values for all test in the test matrix.

CONCLUSIONS

The evaluation of the data collected during the Fermi 2 SRV tests demonstrates that the objectives of the test program have been met. The major conclusions drawn from the test data review are:

- The measured peak pressures for SVA and CVA are much lower than the analytically predicted values using PUA methodology, and very much lower than the Fermi 2 PUAR design review values.
- The measured SVA T-Quencher bubble frequencies ranged from 7.0 to 11.0 Hz, with a average value of 8.6 Hz. The 7.0 Hz frequency was measured for the non-weeping test (MT1) and shows good correlation with the predicted value of 6.4 Hz. Other SVA tests had a small amount of steam in the line which affected the frequency content resulting in increase amplification. The measured CVA T-Quencher average bubble frequency was 9.5 Hz, compared with the predicted frequency of 6.8 Hz.
- The clearing reactions loads on the SRV discharge line and T-Quencher supports were typically less than 20% of the analytically predicted values at test conditions.
- The measured strains on the torus shell, torus support structures, internal structures and piping typically range from 10% to 40% of analytically predicted values.
- The peak measured zero period accelerations (zpa) are well below the analytically predicted response

at each location. The coupled torus shell/piping systems accelerations are less than half of the clean shell response.

It is concluded that the PUA methodology used for Fermi 2 and documented in Reference 4, is conservative and that considerable additional primary containment system design margin exists for SRV discharge loads.

APPENDIX A

SENSOR SPECIFICATIONS

SENSOR SPECIFICATION

Type of Sensor: Pressure Transducer

Sensor Identification(s): P1 to P14, P17 and P18

Location: Suppression Pool and Air Bleed System

Expected Response: 10-35 psia

Frequency Range: 0 Hz to 200 Hz

Environmental Conditions:

Atmosphere: Water, Air, Steam

Temperature: 50°F to 270°F

Pressure (psia): 50

Manufacturer/Model: Bell & Howell/CEC-1000-0207

Operating Range/Accuracy: 0 to 100/ +2% of Full Range Output
(F.R.O.)

Additional Information:

Sensors were supplied with special 1/2" thread and six electrical brazed terminal cups to replace standard electrical connector. Sensors had 100' of steel sheath cabling. Extension cabling was P/N 6XFT 24-1936-XTF, Tefzel wire, overall stranded shield with Tefzel tape jacket. All wires met the fire protection guidelines of NFPA-803 and IEEE 383-1974. Signal conditioning was supplied via Validyne Model CD173.

SENSOR SPECIFICATION

Type of Sensor: Pressure Transducer

Sensor Identification(s): P15, P16, P19 and P20

Location: SRV Discharge Line and Quencher

Expected Response: 0 to 700 psia

Frequency Range: 0 Hz to 200 Hz

Environmental Conditions:

Atmosphere: Water, Air, Steam

Temperature: 400°F

Pressure (psia): 700

Manufacturer/Model: Bell & Howell/CEC-1000-208

Operating Range/Accuracy: 0 to 1000 psia/+0.22% of F.R.O.

Additional Information:

Sensors were supplied with special 1/2" thread and six electrical brazed terminal cups to replace standard electrical connector. Sensors had 100' of steel sheath cabling. Extension cabling was P/N 6XFT 24-1936-XTF, Tefzel wire, overall stranded shield with Tefzel tape jacket. All wires met the fire protection guidelines of NFPA-803 and IEEE 383-1974. Signal conditioning was supplied via Validyne Model CD173.

SENSOR SPECIFICATION

Type of Sensor: Strain Gauge

Sensor Identification(s): SR1 to SR6
SG31 to SG63

Location: Internal Torus Shell, SRV Piping, Support Struts,
Internal and External Torus Attached Piping

Expected Response: Varies from 0 to 200)in/in

Frequency Range: 0 Hz to 200 Hz

Environmental Conditions:

Atmosphere: Water, Air, Steam

Temperature: 50°F to 270°F

Pressure (psia): 50

Manufacturer/Model: Ailtech/MG125/31-01HV-50*

Operating Range/Accuracy: .020 in/in/+3%

Additional Information:

Sensors had 50 feet of 1/16" O.D. steel sheath cable with three open leads. Sensors were hydrostatically tested to 2500 psig and 500°F prior to shipment by the vendor.

Extension wire was P/N 3XFT 24-1936-XTF Tefzel wire with stranded shield and Tefzel jacket. All wires met the fire protection guidelines NFPA803 and IEEE 383-1974. Signal conditioning was supplied via Validyne Model CD173.

* Temperature compensation was based on the material type to which the sensor was attached.

SR1 - SR6	SA516, Gr. 70
SG31 - SG34	SA106, Gr C
SG35 - SG36	SA240, Ty. 304L
SG37 - SG43	SA106, Gr. B
SG44 - G49	SA53
SG54, SG55	SA36
SG56 - SG59	SA106, Gr. B
SG60 - SG63	SA56, Gr. 70

SENSOR SPECIFICATION

Type of Sensor: Strain Gauge

Sensor Identification(s): SR7 to SR12
SG1 to SG30

Location: Torus external shell and supports

Expected Response: 0 to 200)in/in

Frequency Range: 0 Hz to 200 Hz

Environmental Conditions:

Atmosphere: Air

Temperature: 50°F to 100°F

Pressure (psia): 14.7

Manufacturer/Model: Micro-Measurements/EA06-125RS-350 (SR7 to
SR12)

EA06-125AC-350 (SG1 to SG30)

Operating Range/Accuracy: .020 in/in/±3%

Additional Information:

Extension wire was P/N 3XFT 24-1936-XTF Tefzel wire with stranded shield and Tefzel jacket. All wires met the fire protection guidelines NFPA803 and IEEE 383-1974. Signal conditioning shall be supplied via Validyne Model CD173.

SENSOR SPECIFICATION

Type of Sensor: Accelerometer

Sensor Identification(s): A1 to A4

Location: RCIC Isolation Valve and Torus Shell

Expected Response: .005 to 2g

Frequency Range: 1 Hz to 200 Hz

Environmental Conditions:

Atmosphere: Air, 50% R. H.

Temperature: 80°F

Pressure (psia) 14.7

Manufacturer/Model: Endevco/7717-200 or equivalent

Operating Range/Accuracy: .003 to 500g*/+5% full scale

Additional Information:

Extension wire was P/N 2XFT 24-1936-XTF Tefzel wire with stranded shield and Tefzel jacket. Wire met fire protection guidelines NFPA803 and IEEE 383-1974. Additional equipment to be used in conjunction with the above accelerometers will be an Endevco remote charge converter Model 2652M11 and Validyne signal conditioning.

* The accelerometer full scale ranges were set for the test by adjusting the gain of the Validyne signal conditioning to values appropriate for the expected peak accelerations.

SENSCR SPECIFICATION

Type of Sensor: Resistance Temperature Detector

Sensor Identification(s): T5 and T6

Location: SRV Discharge Line and Vent Line Penetration

Expected Response: 50°F to 400°F

Frequency Range: 0 Hz to 1 Hz

Environmental Conditions:

Atmosphere: Water, Air, Steam

Temperature: 50°F to 200°F

Pressure (psia) 30

Manufacturer/Model: Medtherm/PRT-50-250-10387

Operating Range/Accuracy: 50°F to 600°F/±0.5°F

Additional Information:

Sensors were platinum thin film resistance thermometer detector (RTD) with 10 feet of steel sheath cable. Extension cable was P/N 4 XFT 24-1936-XTF Tefzel wire, stranded shield with Tefzel jacket. Wire met fire protection guidelines NFPA-803 and IEEE 383-1974. Signal conditioning shall be supplied via AGM Validyne Model CD173.
