NRC COMMENDATION LETTERS

UNITED STATES
NUCLEAR REGULATORY COMMISSION
WASHINGTON, D. C. 20555

JUN 22 1993

Docket Nos. 50-275 & 50-323

Mr. Richard A. Clarke
Chairman of the Board and
Chief Executive Officer
Pacific Gas and Electric Company
77 Beale Street
San Francisco, California 94106

Dear Mr. Clarke:

On June 15-16, 1993, NRC senior managers met to evaluate the nuclear safety performance of operating reactors, fuel facilities, and other materials licensees. The NRC conducts this meeting semiannually to determine if the safety performance of the various licensees exhibits sufficient weaknesses to warrant increased NRC attention. In addition, at this meeting, senior managers identify specific plants that have demonstrated a level of safety performance that deserves formal NRC recognition. At the June 1993 Senior Management Meeting, the Diablo Canyon nuclear power plant (Units 1 and 2) was identified as having achieved a high level of safety performance and as a result met criteria for recognition of its performance. I am pleased to note that Diablo Canyon has again been identified as a good performer.

In identifying such plants, NRC senior managers perform an evaluation of performance in many areas including operational safety, self-assessment, problem resolution, and plant management organization and oversight.

The NRC recognizes that to achieve the level of performance demonstrated by the Diablo Canyon nuclear power plant, there must be management involvement in all phases of plant activities, the staff must be dedicated and knowledgeable and fully supportive of plant activities, and a commitment to safety must exist throughout the organization. We commend you and your staff for achieving this high level of safety performance. Your achievement is a positive example to the industry.

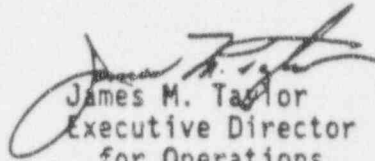

The greatest challenge that you now face is to maintain this level of performance and not to rest on past achievements. Continued management involvement and support, and dedicated efforts from your staff to identify and

Mr. Richard A. Clarke

SALP REPORT

UNITED STATES
NUCLEAR REGULATORY COMMISSION
REGION V

1450 MARIA LANE
WALNUT CREEK, CALIFORNIA 94596-8368

February 12, 1993

Docket Nos. 50-275 and 50-323

Pacific Gas and Electric Company
Nuclear Power Generation, B14A
77 Beale Street, Room 1451
P. O. Box 770000
San Francisco, California 94177

Attention: Mr. G. M. Rueger, Senior Vice President and General Manager
Nuclear Power Generation Business Unit

Subject: Systematic Assessment of Licensee Performance (SALP)
Report Nos. 50-275/92-34 and 50-323/92-34

The NRC's Systematic Assessment of Licensee Performance (SALP) Board has completed its periodic evaluation of the performance of your Diablo Canyon Nuclear Plant for the period July 1, 1991 through December 31, 1992. An Overview is provided as Section II.A of the enclosed Initial SALP Report.

The performance of Diablo Canyon was evaluated in the functional areas of Plant Operations, Radiological Controls, Maintenance/Surveillance, Emergency Preparedness, Security, Engineering/Technical Support, and Safety Assessment/Quality Verification. The criteria used in conducting this assessment and the SALP Board's evaluation of your performance in these functional areas are outlined in NRC Manual Chapter 0516, "Systematic Assessment of Licensee Performance," dated September 28, 1990.

Overall, the SALP Board found the performance of licensed activities at Diablo Canyon to be superior. The Security functional area was assessed by the SALP Board to be Category 2, improving, with all other functional areas evaluated Category 1. Based on the Board's assessment, we wish to recognize the overall performance of your management and staff in exhibiting an attitude clearly directed toward safe facility operation.

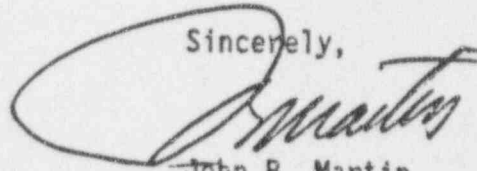

Based upon discussions with your staff, a management meeting to discuss the results of the SALP Board's assessment has been scheduled for February 25, 1993. Arrangements for this meeting will be discussed further with your staff in the near future.

In that no functional area was assessed as Category 3, a written response to the enclosed initial SALP report is not required. However, you may submit comments on the enclosed report, if desired, within 30 days after the February 25 meeting.

In accordance with Section 2.790 of the NRC's "Rules of Practice", Part 2, Title 10, Code of Federal Regulations, a copy of this letter and the enclosed Initial SALP report will be placed in the NRC's Public Document Room.

Should you have any questions concerning the SALP report, we will be pleased to discuss them with you.

Sincerely,

John B. Martin
Regional Administrator

I. INTRODUCTION

The Systematic Assessment of Licensee Performance (SALP) is an integrated NRC staff effort to collect available observations and data on a periodic basis and to evaluate licensee performance based on this information. The program is supplemental to normal regulatory processes used to ensure compliance with NRC rules and regulations. It is intended to be sufficiently diagnostic to provide a rational basis for allocating NRC resources and to provide meaningful feedback to licensee management regarding the NRC's assessment of their facility's performance in each functional area.

An NRC SALP Board, composed of the members listed below, met in the Region V office on January 21, 1993, to review observations and data on the licensee's performance in accordance with NRC Manual Chapter 0516, "Systematic Assessment of Licensee Performance."

This report is the NRC's assessment of the licensee's safety performance at Diablo Canyon Power Plant for the period July 1, 1991 through December 31, 1992.

The SALP Board meeting for Diablo Canyon was attended by:

Voting Members

- K. Perkins, Director, Division of Reactor Safety and Projects, RV (SALP Board Chairman)
- M. Virgilio, Assistant Director for Region IV & V Reactors, Division of Reactor Projects III, IV, V, NRR
- R. Scarano, Director, Division of Radiation Safety and Safeguards, RV
- L. Miller, Chief, Reactor Safety Branch, RV
- P. Johnson, Chief, Reactor Projects Section 1, RV
- S. Peterson, Project Manager, NRR
- M. Miller, Senior Resident Inspector, Diablo Canyon

Other Attendees

- J. Reese, Chief, Facilities Radiological Protection Branch, RV
- R. Pate, Chief, Safeguards, Emergency Preparedness and Non-Power Reactor Branch, RV
- D. Kirsch, Technical Assistant, RV
- P. Morrill, Chief, Operations Section, RV
- W. Ang, Chief, Engineering Section, RV
- P. Narbut, Team Leader, RV
- D. Schuster, Safeguards Inspector, RV
- A. McQueen, Emergency Preparedness Analyst, RV
- L. Norderhaug, Safeguards Inspector, RV
- L. Coblentz, Radiation Specialist, RV
- D. Corporandy, Project Inspector, RV
- C. Myers, Reactor Inspector, RV

II. SUMMARY OF RESULTS

A. Overview

The licensee's overall performance level during this assessment period was good or superior in all areas. Examples of superior performance were demonstrated by relatively event-free operation, low occupational radiation exposure, awareness and training of personnel to minimize safety risks during outages, prompt and aggressive response to indications of cracking in feedwater piping nozzles, and aggressive and well focused insight into performance weaknesses by the Onsite Safety Review Group.

The strengths observed in the Operations, Radiological Controls, Engineering/Technical Support, Emergency Preparedness, and Safety Assessment/Quality Verification functional areas resulted in these areas being rated as Category 1. The board noted in the functional area of Maintenance/Surveillance that early in the SALP period there were a few problems involving prompt problem identification and resolution, and engineering involvement in maintenance issues. The board concluded, however, that the overall performance was superior based on strong corrective actions and very high quality performance throughout the remainder of the period.

While strengths were noted in the security area, security management did not appear to have conducted an adequately broad examination of their activities to assure a high standard of performance throughout the organization. The board discussed NRC-identified problems at length, particularly in comparison with the high level of performance seen in most of the security organization. While corrective actions were taken for specific problems identified by the NRC, it appeared that the requirements of the security organization had not been implemented with a consistent level of assurance of quality. Although management appeared to have corrected weaknesses noted during the previous SALP period, weak management involvement in maintaining high quality in all security program areas detracted from otherwise superior performance in this area.

B. Results of Board Assessment

Overall, the SALP Board found the performance of NRC licensed activities to be very effective and directed toward safe operation of Diablo Canyon. The SALP Board has made specific recommendations in most functional areas for licensee management consideration. The results of the Board's assessment of the licensee's performance in each functional area, along with the results from the previous period, are as follows:

<u>Functional Area</u>	<u>Rating</u>	<u>Trend</u>	<u>Rating</u>	<u>Trend</u>
	<u>Last Period</u>		<u>This Period</u>	
A. Plant Operations	1		1	
B. Radiological Controls	1		1	
C. Maintenance/Surveillance	2		1	
D. Emergency Preparedness	2		1	
E. Security	2	Improving	2	Improving

F. Engineering/Technical Support	1	1
G. Safety Assessment/ Quality Verification	1	1

III. PERFORMANCE ANALYSIS

The following is the Board's assessment of the licensee's performance in each of the functional areas, along with the Board's conclusion for each area and its recommendations with respect to licensee actions and management emphasis.

A. Plant Operations

1. Analysis

During the assessment period, the resident inspectors conducted frequent inspections involving observation of operations activities. Some engineering section and project inspector inspections also evaluated operations activities. Review of operations activities accounted for about 34 percent of the total inspection effort.

The last SALP assessment rated the licensee's performance in this area Category 1. Strengths were noted in relatively event-free operation, and in superior operator response to plant transients. Operations exhibited significant strength in conservative operational decisions. The previous SALP Board also noted weaknesses in occasional lack of timeliness in identifying and resolving problems and in issuing operability determinations.

During this SALP assessment period, the licensee continued to show superior performance in this area. Strengths were observed in the general high quality of the Operations staff's performance, and in relatively event-free and uncomplicated operations. Management involvement has been frequent and probing, assuring timeliness in identifying and resolving problems and in making operability determinations. Operations management has set high performance standards which have usually been met or exceeded.

Recovery from each event, regardless of cause, and the subsequent root cause investigation indicated significant strengths. This was due in part to a high level of skill and sense of ownership among the Operations staff, and to intensive management involvement at all levels of the organization.

During operations at power and during outages, the Operations staff showed strong awareness of overall plant safety system availability and the significance of evolutions relative to the risk to the plant. This appeared to have been a direct result of aggressive management commitment to plant safety and risk reductions. The licensee developed and implemented a comprehensive and effective outage plan that appropriately considered risk associated with plant shutdown evolutions. Operations staffing levels appeared to be appropriate, and operations staff qualifications were strong.

Other examples of significant strengths were as follows:

- Active Operations involvement with maintenance crews near sensitive equipment helped to avert events.
- Documentation of operability determinations was strong, timely and consistent. Also, a very low threshold was established for the level of equipment degradation which required an operability evaluation.
- Operations simulator training was challenging and effective, and critiques appeared to be appropriately critical and probing.
- Toward the end of the SALP period, Operations personnel were progressively more alert to anomalous plant conditions. For example, an operator's observation and followup of a failed fastener resulted in identification and repair of a degraded neutral connector to a main transformer, potentially averting a plant trip.

During this SALP period, two severity Level IV violations occurred in this area. One was a repeat violation, for operation in Modes 2 and 3 with one of two reactor cavity sump wide range level channels inoperable. The other violation involved inadequate instructions to operators for avoiding excessive piping vibration on loss of speed control to the positive displacement charging pump. Neither had an impact on safe plant operation, and each of these instances was promptly corrected.

During the first part of the SALP period, a few Licensee Event Reports (LERs) were issued as a result of personnel errors. Although this was not an unusually high rate, the concern was that it indicated an increasing trend. The personnel error rate was reduced later in the assessment period as a result of strong management involvement.

Four isolated instances of minor weakness were observed, either in following procedures or in coordination with other groups. The most significant involved an inadvertent chemical spill, which generated noxious fumes and prompted declaration of an Unusual Event. Another instance occurred as a result of unclear procedures, which allowed a condenser vacuum pump to be started before its seal water isolation valve was opened. This ultimately resulted in a reactor trip. In each of these cases, root cause evaluation and corrective actions were immediate and appeared appropriate.

In summary, the performance of Operations has been strong, and has continued to improve. Weaknesses have been minor, isolated and infrequent, and have been corrected promptly and appropriately.

2. Performance Rating

Performance Assessment: Category 1

3. Recommendations

None

B. Radiological Controls

1. Analysis

Radiological controls inspections during this SALP period found that the licensee continued to be aggressive in assuring quality. Radioactive effluents continued to decrease, and occupational dose was reduced in 1992 despite a demanding outage schedule. A continued strength was the licensee's innovative approaches to improving measures for personnel radiation protection. Minor weaknesses identified, related to radiological posting and labeling, were solved rapidly and thoroughly. Regional inspectors examining this functional area contributed approximately 5 percent of the total inspection effort during this assessment period.

The licensee's radiological controls performance during the previous SALP period was rated Category 1. The previous SALP Board recommended that management continue to fully support site and corporate initiatives for improving performance. The board also recommended added emphasis toward correcting minor weaknesses in controlling personnel contaminations, reducing the backlog of non-Technical Specification radiation monitoring equipment needing calibration, and training dosimetry clerks and radwaste handlers.

During this assessment period, management continued to be proactive in assuring quality. The ALARA awareness program, established to reward outstanding outage performance, continued to be an effective incentive toward meeting rigorous ALARA goals. The 1991 average occupational dose per reactor was 273 person-rem, and for 1992 was 214 person-rem. Liquid effluents continued to decrease. Gaseous effluents were also maintained at a small fraction of the Technical Specification limits.

Management support was evident in the elaborate remote monitoring capabilities used to support steam generator shot peening and eddy current testing during the 1R5 outage. Use of this equipment significantly reduced both the dose received and the radiological risk involved in conducting several complicated, high-dose tasks at once. In addition, corporate involvement and support was evident in continuing efforts associated with a major upgrade of radiation and effluent monitoring equipment.

The licensee's approach to resolving technical issues was conservative and timely, and demonstrated a clear understanding of the issues involved. In September 1992, the licensee voluntarily made a presentation to members of the NRC Region V staff concerning the status of radiation monitoring system upgrades. Detailed alternate monitoring methods had been analyzed, for use during interim periods while system upgrades were being performed, to ensure proper monitor ranges, efficiencies, and sensitivity to airborne radioactivity. Technical

improvements were observed in licensee programs for radwaste classification, the process control program, and radiological environmental monitoring. Technically sound judgment was also in evidence in the licensee's radiological controls preparations for potential high-dose outage tasks, such as steam generator shot peening, steam generator eddy current inspection, and core barrel inspection.

Licensee management support of training was demonstrated by the extensive efforts made in mock-up training prior to the 1R5 outage. The steam generator mock-up included a fully operational shot-peening apparatus. One weakness was observed involving failure to thoroughly train eddy current testing personnel on the impact that shot peening would have on steam generator airborne radioactivity hazards. A Severity Level IV violation was cited for the resulting hazard. The licensee took prompt corrective action to resolve this weakness.

The licensee's other training practices continued to exhibit excellence. Training and qualification programs made a positive contribution to the understanding of radiological controls issues and adherence to procedures. Staff members were kept abreast of industry knowledge and development through extensive participation in offsite owners' group meetings, Electric Power Research Institute (EPRI) conferences, and other opportunities for offsite involvement. An improvement was noticed in the licensee's training of radwaste handlers. Training on the new 10 CFR 20 requirements also continued for appropriate personnel.

The licensee's site and corporate radiological controls and chemistry groups continued to be well staffed. Key positions were generally filled on a priority basis. Authorities and responsibilities, both in the chemistry and radiation protection organizations, were well defined, and resulted in clear communications both within the groups and with other site organizations.

One voluntary Licensee Event Report (LER) was submitted relevant to radiological controls during this assessment period. The LER dealt with overexposures received by contract radiographers, due to personnel error by the radiographers while performing radiography on the licensee's site. Three Severity Level IV violations were identified in this functional area. Two resulted from inadequate posting and labeling, and one involved the failure to implement procedures to control airborne radioactivity from steam generator work. Neither the violations nor the LER indicated a programmatic breakdown of the radiation protection program. The licensee's root cause analyses and corrective actions were prompt and were effectively implemented.

2. Performance Rating

Performance Assessment: Category 1

3. Board Recommendation

None.

C. Maintenance/Surveillance

1. Analysis

During the assessment period, the resident inspectors conducted frequent inspections which included observation of maintenance and surveillance activities. Engineering inspections also evaluated maintenance and surveillance programs. Review of maintenance and surveillance activities accounted for about 10 percent of the total Diablo Canyon inspection effort.

The last SALP assessment rated the licensee's performance in this area Category 2. Strengths were noted in the initiation of a program for trending safety equipment out-of-service time, and in the use of probabilistic risk assessment to evaluate preventive maintenance programs. Weaknesses were noted in a lack of management aggressiveness in dealing with problem areas; occasional failure to follow procedures, resulting in safety significant events; and a tendency for personnel errors due to lack of self-verification. The licensee was encouraged to involve management in timely problem identification and root cause investigation, and to continue to support industry initiatives.

During this assessment period, the licensee generally displayed improved performance in this area. Virtually trouble-free plant operation evidenced a high quality of maintenance work in that no plant events and almost no equipment failures occurred as a result of improper maintenance. Strengths were observed in the general high quality of maintenance and surveillance work. Additionally, a high level of management involvement in scheduling and planning maintenance and surveillance work maximized safety system availability from a probabilistic risk standpoint, both at power and during outages. This resulted in a considerable benefit to plant safety.

Noteworthy strengths were as follows:

- Outage Management: The management of outages was marked by an overriding understanding and emphasis of the probabilistic risk of each job and evolution. Work crews and planners were trained and aware of the safety significance of the jobs and systems on which they worked at every stage of the outage.
- Qualifications: The training and qualification program for Maintenance personnel was strong. Well maintained training facilities and a dedicated training staff were significant factors in good performance, as was the sense of ownership shown by Maintenance personnel.
- Plant Safety: Maintenance personnel were trained and informed regarding overall plant safety system availability and the significance of their individually assigned work relative to its risk to the plant.

- Prioritization of Work: Outstanding work items were well prioritized, with safety-significant issues given high priority. The backlog of non-outage safety related work items was low.
- Root Cause Investigations: The routine involvement and leadership shown by the Plant Maintenance staff in root cause investigations was a significant strength, as was the routine integration of the Maintenance, Operations, and Engineering staffs in maintenance and surveillance operations.
- Reduction of Personnel Errors: A relatively high number of personnel errors were observed at the beginning of the SALP period. Several of these errors resulted in conditions which prompted a Licensee Event Report or Non-conformance Report. This number was reduced by about half during the remainder of the period due to a high level of management involvement throughout the organization.
- Response to Problems: Overall, the maintenance staff improved their response to problems by identifying, analyzing and correcting maintenance and surveillance problems promptly. This represented an improvement over the last assessment period. Examples of this improvement were the identification and correction of an incorrect reactor coolant system leakage surveillance; prompt, in-depth evaluation and compensatory action for problems with auxiliary feedwater pump steam admission valve FCV-95; and improvement of the clarity of some instrumentation and control surveillances.

Four Level IV violations were cited in this area, involving improper maintenance of containment fan cooler unit (CFCU) backdraft dampers, failure to perform a containment airlock surveillance, failure to identify inconsistencies in a pump vibration measurement procedure by writing an action request, and improper rigging of a cask. In some cases, as illustrated by the inoperable containment fan cooler unit backdraft dampers, Engineering involvement should have been more timely. Improper maintenance of CFCU dampers was significant in that the dampers were not functional, and only after additional analysis did the licensee determine that the CFCUs had been operable despite the improper maintenance. These concerns appear to have been isolated, although the CFCU issue was potentially significant to safety.

Other weaknesses were also observed. One example was the improper tightening of setscrews on some motor operated valve actuators, resulting in a common mode failure vulnerability. Additional, less significant weaknesses were observed. Most were identified by the licensee immediately upon occurrence. Management involvement was effective, and identified problems were promptly and appropriately corrected. Most of these examples occurred early in the SALP period. Since that time, significant improvement has been noted.

2. Performance Rating

Performance Assessment: Category 1

3. Board Recommendations

The Board encourages continued intrusive Engineering involvement in maintenance and surveillance issues, and focused management involvement to ensure continued low levels of personnel errors.

D. Emergency Preparedness

1. Analysis

Two routine emergency preparedness (EP) inspections and two annual emergency exercise team inspections were conducted during this assessment period. Review of the EP program accounted for approximately 6 percent of the Diablo Canyon inspection effort. A strength identified during the current assessment period was in making timely and appropriate classifications during most actual emergency events, exercises and drills. A weakness was noted regarding the making of protective action recommendations (PARs) to offsite agencies during the 1991 annual emergency exercise. Generally, licensee performance in the EP area appears to have improved over the assessment period.

The licensee's EP performance in the last SALP cycle was rated Category 2. The SALP board at that time indicated several recommendations: that management ensure the establishment and implementation of an effective corrective action plan for drill and exercise findings; that licensee management evaluate the adequacy of classroom training provided to emergency response personnel and ensure that personnel are given an adequate number of opportunities to practice their assigned tasks during periodic drills; that the additional dose assessment training provided to Control Room personnel continue; that the need to adhere to radiation protection procedures under simulated emergency conditions also be stressed during classroom training and drills; that administrative procedures be enhanced to ensure that drills and exercises consistently meet emergency plan requirements; and that simulation of sample collection during drills and exercises be avoided to enhance realism and increase the training value.

During the current assessment period, licensee management appeared actively involved in EP activities and demonstrated support by providing the necessary resources to the EP staff. Management took interest in correcting problems and responding to NRC findings which indicated a need for corrective action. During the assessment period, the licensee worked closely with the state, local county governments, and FEMA in resolving issues in offsite preparedness planning. Each of the recommendations from the previous SALP Board was addressed by the licensee during this assessment period. Corrective actions were evaluated by the NRC during routine inspections and observation of the two annual exercises, and improvement was noted in each area. Dose assessment and projection, in particular, were noted as strengths in response facilities during the 1991 and 1992 annual emergency exercises.

Licensee management's approach to the resolution of technical issues appeared generally timely and thorough. During the assessment

period, the licensee significantly upgraded the emergency warning siren system. The new primary system was completed, tested and turned over to the county with 100 percent activation in September 1992. The upgrade provided several new capabilities such as an activation system which allows selective sounding of individual or groups of sirens as opposed to the entire system, and a siren feedback system which provides input to the county when a "runaway siren" sounds without intended activation.

One EP exercise weakness was identified during the 1991 annual emergency exercise. The licensee's system for providing Protective Action Recommendations (PARs) appeared excessively complicated and caused delay in the issuance of PARs. The system was not based solely on plant conditions as would be appropriate, but included coordination of PARs with offsite agencies. This delayed and possibly biased the licensee's decision making. The appropriate emergency plan implementing procedure (EPIP) was revised to insure licensee independence in PAR decision making and was validated through training, drills and exercises. The system appeared to have been effectively implemented during the 1992 annual exercise.

There were no enforcement actions in the EP area during the assessment period. Notifications to the NRC and offsite agencies were consistent with regulatory requirements. The licensee reported nine unusual events to the NRC during the assessment period, including three earthquakes detected at the site. The other events were a reactor coolant system (RCS) leak, a grass and brush fire near the site, a turbine stop valve failure, a sulfuric acid spill, radiation overexposure of two contractor employees, and a temporary loss of communications with the California Office of Emergency Services. All events appear to have been properly identified and analyzed in accordance with regulatory requirements.

EP staffing was an apparent strength, and staff members appeared conscientious toward accomplishment of their assigned duties. No significant changes occurred in the composition of the emergency response organization (ERO) during the assessment period. The licensee had a system to ensure that new ERO personnel were properly trained prior to assignment to emergency organization positions. EP staff and emergency response positions were clearly identified; authorities and responsibilities appeared clearly defined; and key positions were filled as appropriate. Decision-making authority appeared properly delegated to ensure quick identification of and response to problems and changes. Emergency facilities continued to be appropriately maintained and appeared ready for rapid activation. The licensee provided adequate levels of dedicated staff to implement the programs and to interact appropriately with offsite agencies.

During the assessment period, the licensee implemented what appeared to be a substantial change to the EP training program. Previously, the site and corporate headquarters had separate EP training programs and responsibilities. The company-wide responsibility for EP training management and accomplishment was shifted entirely to the site. A system was established to ensure that required training is

conducted and that training due dates are not exceeded, by linking accomplishment of EP training requirements to unescorted access privileges. To supplement and reinforce routine annual training, a program of monthly integrated drills was conducted.

2. Performance Rating

Performance Assessment: Category 1

3. Board Recommendations

The licensee should strive to maintain a consistent level of management oversight to continue and improve on the program quality achieved during this assessment period.

E. Security

1. Analysis

During this SALP period, approximately 4 percent of direct inspection effort was applied to the licensee's physical security and fitness for duty programs. In addition to region based inspections, the resident inspectors also monitored implementation of this program as part of their routine inspection activities.

The previous SALP report rated the licensee's performance Category 2, Improving, for Security. Primary weaknesses identified in that report focused on personnel access control to vital areas and failures of compensatory security measures. These weaknesses were significantly reduced during the current assessment period. In the previous SALP report, the Board encouraged the licensee to resolve a longstanding weakness in the CCTV alarm assessment capability, initially identified during a 1986 Regulatory Effectiveness Review. A significant equipment upgrade to incorporate a video capture system was installed during the current assessment period and has largely eliminated this weakness. Some minor limitations remain with the video capture system and the licensee is actively exploring further equipment and/or procedural improvements.

The licensee's performance in the areas of physical security and fitness for duty appeared, on the basis of inspections conducted, event reports, and other observations and analysis, to be good in all assessment areas. Both program strengths (vital area barriers and armed response) and weaknesses (effectiveness of the audit program and the number of pending requests for security equipment modification or maintenance) have been noted during the assessment period.

Principal strengths in the licensee's security and fitness for duty programs included control of access to vital areas, the use of roving patrols dedicated to armed response (carrying carbines or shotguns, as appropriate, as well as side arms), and the availability of Employee Assistance Programs for contractor employees. A major program upgrade to establish a search train at the intake structure protected area was completed during the assessment period.

A principal program weakness was noted concerning the number of cited and non-cited violations that could have been identified and corrected by a stronger audit program. This indicated a need for increased management attention to upgrade the audit program and make it more effective.

Although the licensee has been aware of a large backlog of action requests for maintenance or modification to security equipment, little progress was seen in addressing this concern. This was also seen as a program weakness. Discounting action requests of an administrative nature or otherwise having no direct effect on security activities, approximately 90 requests were identified as being more than 90 days old, nearly half of which were more than a year old. A more effective audit program could have identified this weakness. This further demonstrated the need for increased management attention.

One Licensee Event Report dealing with safeguards matters (requiring prompt reporting pursuant to 10 CFR 73.71) was issued and adequately resolved during the SALP period. This report dealt with failure of circuit boards in the alarm annunciation system, and prompted a full replacement of the obsolescent components which is scheduled to be completed in the near future. However, technical issues discussed in two reports issued in January and December 1990, and dealing with backup power to communications equipment and vital equipment protected by compensatory measures, respectively, remain to be resolved.

Enforcement actions during the assessment period included four violations, which were resolved by appropriate corrective actions: one each related to access control at the main and intake structure protected areas, one violation related to protection of Safeguards Information, and one violation related to urinalysis testing of fitness for duty program personnel. Two weaknesses related to fitness for duty and four non-cited violations dealing with vital area access control, communications, lighting, and protection of Safeguards Information were promptly corrected by the licensee.

The licensee's loggable safeguards events were promptly and completely reviewed and reported as required. The root cause and trend analyses of these events determined that most of the events were related to aging equipment scheduled for replacement by major hardware upgrades then underway. The frequency of occurrence has exhibited a decreasing trend as those projects have been completed.

Licensee staffing appeared effective in most areas, although the identified long delays in resolving security related action requests may indicate a need for additional senior management support. Key positions have been identified and responsibilities are well defined. Decision making authority appears properly assigned to ensure prompt identification and response to program challenges. During the current assessment period, management implemented team development workshops for all staff. This training showed significant promise in improving staff communications and cohesiveness.

The licensee's guard training and qualification program was well defined and implemented with dedicated resources. During this SALP period, the licensee initiated sophisticated contingency drills incorporating diversionary tactics and covert penetrations.

2. Performance Rating

Performance assessment: Category 2, Improving

3. Board Recommendation

Licensee management is encouraged to more effectively identify and address weak areas. More attention should be given to improving the effectiveness of the audit program and to reducing the number and age of outstanding maintenance requests.

F. Engineering/Technical Support

1. Analysis

During the assessment period, NRC regional and Headquarters inspectors conducted a total of twelve inspections. Two of these inspections were team inspections which addressed motor operated valves and shutdown risk management. The other inspections involved facility modifications, design changes, inservice inspection and testing, erosion/corrosion monitoring, eddy current testing of steam generator tubes, and procurement of a new emergency diesel generator. The resident and project inspectors also conducted inspections in this area. Review of Engineering and Technical Support activities accounted for approximately 15 percent of the total Diablo Canyon inspection effort.

The last SALP assessment rated the licensee's performance in this functional area Category 1. Improvements were recognized in Engineering involvement in plant operations and modification work, design basis reviews, setpoint reverification, vendor interface, personnel qualification and training. A particular strength was found in the commercial grade dedication program. Some weaknesses were noted in incomplete technical work and untimely identification and resolution of problems due to a weak sense of ownership of plant problems. The Board recommended that the licensee provide emphasis on early identification, effective engineering involvement, and timely and thorough correction of plant problems. The licensee was encouraged to continue building a strong interface between corporate and plant engineering groups, with corporate engineering taking a leadership role in the resolution of plant problems. Continuation of innovative corporate engineering training programs was specifically encouraged.

During this SALP assessment period, the licensee showed continued high quality performance in this functional area. Strengths were observed in a generally aggressive and thorough engineering attitude in resolving technical problems, an extensive erosion/corrosion monitoring program, eddy current testing of steam generator tubes, assessment of probabilistic risks to the shutdown plant, and overall

engineering involvement in plant operational activities. The NRR staff observed excellent quality in the technical content and presentation of licensee submittals, which included documents in support of license amendment requests, corrective actions regarding operations and Licensee Event Reports, and responses to NRC bulletins and generic letters. Improvements were observed in timely problem identification, engineering involvement, and problem ownership. Minor weaknesses were noted related to procurement of the new emergency diesel generator (EDG) and certain inservice inspection and testing activities.

Engineering involvement in resolving safety issues was generally timely. The most significant exception was Engineering's assessment of problems with containment fan cooler unit (CFCU) backdraft dampers in early 1992. Additionally, resolution of Regulatory Guide 1.97 issues was delayed by inadequate tracking of engineering actions, but the licensee later identified this weakness and pursued resolution in an aggressive manner. Substantial improvement was displayed later in the SALP period in Engineering's timely resolution of CFCU damper blade cracking.

Strong Engineering performance and initiative were evidenced in Engineering's evaluation of setscrew loosening on motor operated valve (MOV) actuators and the licensee's decision to examine the steam generator feedwater nozzles in response to problems observed at another facility. The feedwater nozzle examinations were extensive and used state-of-the-art techniques. The Engineering staff's assessment of crack indications in both feedwater piping and in a safety injection tank penetration resulted in a conservative decision to replace affected piping segments.

Proactive Engineering involvement was observed in the development of an extensive erosion/corrosion monitoring program. Despite extensive involvement with the industry in the development of predictive analytical computer programs, poor correlation between the quantitative predictions and measured wear rates had been experienced by the licensee. The licensee's program exhibited a defense-in-depth approach to compensate for recognized limitations in the state of the art. Although a program weakness in the measurement of pipe wall thickness was noted, strong engineering ownership of the program compensated for this minor weakness.

Throughout the SALP review period, the licensee demonstrated an aggressive engineering attitude in technical problem resolution. For example, the licensee instituted a supplemental program that is the first surveillance program in a U. S. commercially operated reactor vessel to investigate the effect of annealing and reirradiation on its reactor vessel beltline materials.

Another example of aggressive engineering was resolution of the long-term seismic program. The licensee performed a detailed analysis to demonstrate that adequate seismic margins exist for the structures and equipment which could be affected by increased ground motion in certain frequency ranges at the Diablo Canyon site.

The licensee also developed and implemented an effective outage risk assessment plan which was found superior to other plants which were inspected. The technical support provided for the outage risk assessment plan was excellent.

The engineering program developed for eddy current testing (ECT) of steam generator tubes was observed to be a high quality program incorporating current technology and industry guidance. However, a weakness was noted in that engineering guidelines for ECT data analysis and defect acceptance criteria, although adequate, were not controlled through the use of formal plant procedures.

Specific strengths noted in engineering activities were as follows:

- The motor operated valve (MOV) program was found to be aggressive and conducted in a well integrated manner. A minor weakness was identified in the lack of timely determination of operability following testing, due to the complexity of the engineering evaluation required to evaluate the test data.
- A strong safety perspective was evident in the development of engineering programs to resolve emerging technical issues. The programs were implemented with priority on safety significance.
- Quality assurance involvement was evident in the implementation of engineering programs.
- Design change packages for the installation of a new emergency diesel generator were generally thorough and complete, although minor housekeeping and cleanliness deficiencies were observed.

Four Severity Level IV violations, one Level V violation and one non-cited violation were identified. The violations were minor in nature and did not evidence programmatic breakdowns.

The low number of engineers and lack of clear goals for the plant's System Engineering staff was a concern earlier in the SALP period. The licensee has since increased the staff and clarified the goals for this group, and some improvement has been observed.

The commercial grade dedication of the sixth emergency diesel generator (EDG) presented unique challenges to the licensee's engineering and procurement activities. The Region and NRR Vendor Branch identified weaknesses in the quality of the procurement and commercial grade dedication of the new emergency diesel generator. However, the licensee's root cause investigation was candid and thorough. Also, although most problems encountered during testing of the sixth EDG were found to have been documented and resolved, the test program did not require formal documentation of problems. This weakness was promptly corrected after identification by the NRC.

Inservice inspection and testing activities were found to comply with approved programs. Observed deficiencies in personnel qualifications

and procedural adherence indicated minor weaknesses in the inservice inspection program.

In conclusion, Engineering and Technical Support demonstrated high quality, with continued strong performance. Some weaknesses were observed, but these were minor in that they appeared isolated, of low significance, and were promptly and appropriately corrected.

2. Performance Rating

Performance Assessment: Category 1

3. Board Recommendation

The Board recommends that licensee management provide continued support for the development and long term integration of proactive engineering programs.

G. Safety Assessment/Quality Verification

1. Analysis

Evaluation of this area was based on both region-based and resident inspections. Review of Safety Assessment/Quality Verification activities accounted for about 26 percent of the total Diablo Canyon inspection effort.

The last SALP assessment rated the licensee's performance in this area Category 1. Strengths were noted in the implementation of Event Investigation Teams (EITs). Weaknesses were noted in resolving problems in a timely manner and in occasional lack of management aggressiveness in dealing with problem areas. The licensee was encouraged to provide more management involvement in timely problem identification and root cause investigation, particularly in the area of repeat problems.

During this SALP assessment period, the licensee generally showed improved performance in this area. Management was more aggressive and timely in dealing with problems than during the previous period, and Safety Assessment/Quality Verification performance by line and quality organizations showed continued improvement. A weakness was noted in the identification and correction of precursors of potentially significant problems.

A significant strength was the aggressive implementation of programs to improve control of safety system availability during operating and shutdown modes. These programs were implemented at all levels of the licensee's organization. Plant design changes were also implemented to reduce risk, resulting in improved safety performance and safety system availability.

Audits performed by the Quality Assurance organization were generally good. Lack of intrusive involvement by Quality Assurance in problems such as the improper maintenance of the containment fan cooler back-

draft dampers was a weakness. As discussed in Section III.E, a need for more effective audits was also noted in the Security area. In fact, a factor in several of the problems experienced during this SALP period was insufficient QA involvement. Some improvement was observed in the latter portion of the SALP period. Audits required by Technical Specifications were adequate and appropriate. Additional audits performed as Quality Assurance initiatives showed significant technical depth, and identified weaknesses in complex technical areas not typically reviewed by quality organizations. A noteworthy improvement in QA effectiveness was evidenced in the increased use of surveillances, which are brief audits in specific areas of concern. These audits have allowed rapid focus of QA oversight in problem areas, which resulted in more timely management attention, root cause evaluation, and corrective action.

Safety groups continued to be very strong in safety focus and depth of technical assessment. The Onsite Safety Review Group identified problems consistent with issues of higher safety significance. Management support of this group was adequate. The Nuclear Safety Oversight Committee improved during this assessment period as a result of focus on higher level concerns, and the addition of non- licensee members. The Plant Safety Review Committee continued to be very strong, providing significant safety insight and conservative decision making.

Nuclear Operations Support (NOS), which is not by charter a quality oversight group, performed several reviews and audits during this assessment period which were instrumental in identifying and correcting problems in interfaces between licensee organizations. These NOS reviews and audits resulted in several improvements in the overall implementation of plant safety functions.

During this assessment period the NRR staff reviewed a large number of safety analyses performed by the licensee. The licensee's submittals demonstrated a clear understanding of safety issues and a conservative approach to technical problem resolution. The submittals for license amendment requests were technically adequate and generally complete. Also, several of the licensee's submittals contained probabilistic risk assessment (PRA) analyses which were of high quality (the PRA technique requires considerable effort by the licensee, and when properly used, adds to the basis for approving proposed changes). The licensee's replies to NRC generic letters and bulletins were also timely, responsive and of generally high quality.

Throughout the SALP review period, the licensee consistently and systematically addressed operability concerns in an aggressive manner, and made appropriately conservative decisions until each concern was resolved. Licensee management kept the NRC well informed of initial concerns as well as their followup plans for resolution.

An increased number of personnel errors were observed in several functional areas at the beginning of the SALP period. This number was reduced by about half during the remainder of the period as a

result of an effective human performance enhancement program and aggressive management involvement at all levels of the organization.

The licensee's program for assessing industry events was strong. A few vulnerabilities were identified and corrected promptly. Several programs were enhanced as a result of implementation of lessons learned from the industry.

While the licensee typically has been aggressive in problem resolution, there have been isolated examples of insufficient aggressiveness in pursuing safety issues. For example, based on the review of licensing submittals requesting relief regarding pumps and valves, the licensee's approach to the resolution of inservice testing program issues required amplifying information and in some cases were not technically justified.

Five Severity Level IV violations were cited in this area, one for failure to correct reverse rotation of containment fan cooler units, and the others for failure to correct repeated problems of a lower safety significance in various functional areas.

A few weaknesses were observed. For example, in three cases, precursors of plant problems occurred without being identified as such. An example of one of these three instances was an unplanned turbine speed-up event, corrected by operators, which had two precursors which were not identified and corrected. In each case, the more significant problem occurred because the precursor had not been adequately addressed. Another weakness was that the guidelines used to trend root causes of problems were imprecise, in that root causes of problems could be assigned to more than one area.

In conclusion, the performance of the licensee's line organization is very strong in the assessment of safety and assurance of quality. Independent safety groups, although already strong, showed additional strength during this assessment period. The Quality assurance organization's performance was not as strong as the line organizations, but was above an adequate level.

2. Performance Rating

Performance Assessment: Category 1

3. Board Recommendations

The Board recommends continued management involvement in Safety Assessment/Quality Verification activities, and strongly encourages prompt identification of problems, timely corrective action, effective Quality Assurance audits and prevention of repeat problems.

IV. SUPPORTING DATA AND SUMMARIES

A. Licensee Activities

Unit 1

Diablo Canyon Unit 1 entered the assessment period at full power and operated nominally at full power during the SALP period, with occasional brief power curtailments for maintenance and testing activities, except as follows:

On July 5, 1991 an unplanned start of engineered safety features (ESF) equipment occurred when a licensed operator inadvertently actuated the wrong solid state protection system test switch. The control room operators promptly returned all actuated equipment to normal status.

On March 6, 1992 a plant trip occurred due to the loss of main feedwater pump 1-1. The cause of the trip was traced to a faulty fusible link in an inverter. Unit 1 was restarted on March 9, 1992 after a new inverter was installed for feedwater pump 1-1 and fusible links for feedwater pump 1-2 were inspected. Unit 1 reached 100% power on March 10, 1992.

On April 25, 1992, while conducting maintenance on main feedwater pump 1-1, vacuum in the condenser was lost, causing the main turbine and reactor to trip. The primary cause was attributed to inadequate instructions, which allowed a vacuum pump to be started before its seal water isolation valve was opened. Also, condenser vacuum pump suction line check valve CNC-1-747 was observed to leak excessively when the condenser vacuum pump suction valve was opened. Unit 1 was restarted on April 27, 1992 after evaluation of the event and correction of the cause of the trip. Full power was reached on April 28, 1992.

On July 24, 1992, after observing excessive flow noise from main turbine governor valve number 4, the licensee closed the valve, resulting in Unit 1 operating at 98% power.

On September 17, 1992, Unit 1 shut down for a scheduled 63-day refueling outage. The shutdown was complicated by spurious reopening of a main turbine stop valve and two governor valves, which caused the turbine to accelerate from 1100 RPM to 1870 RPM. A few hours later, during the cooldown, reactor coolant system (RCS) pressure rose above the 350 PSI setpoint. The system responded as expected, with the power operated relief valve opening and relieving pressure.

On November 9, 1992, Unit 1 completed its fifth refueling outage. The unit reached 100% power on November 11, 1992.

On December 23, 1992, an operator observed fragments of a fastening device on the ground. Followup investigation revealed a partially melted neutral line connector on a main transformer. The licensee curtailed power to 10% and separated from the grid, fixed the connector and inspected all similar connectors, and returned to 100% power.

Unit 2

Diablo Canyon Unit 2 entered the assessment period at full power and operated nominally at full power during the SALP period, with occasional brief power curtailments for maintenance and testing activities, except as follows:

On August 31, 1991 Unit 2 shut down for its fourth refueling outage about nine days early because of an unisolable leak in the charging system. The leak had been increasing since its discovery on August 13, 1991. The leak had not yet reached its Technical Specification limit at the time of shutdown. Unit 2's shutdown marked 482 days of continuous operation at power, a new world record.

On October 20, 1991, Unit 2 achieved criticality, marking the shortest refueling outage in Diablo Canyon history. Full power was reached on October 31, 1991.

On February 16, 1992, during a power curtailment to 50% for condenser cleaning, the Unit 2 reactor experienced an exaggerated quadrant power tilt ratio as a result of slightly different efficiencies of the secondary loops. The licensee decreased power below 50%, the level below which the quadrant power tilt action statement does not apply. The licensee also entered the action statement, as a conservative measure. During curtailment operations, the power tilt decreased due to xenon burnup, and did not recur until the following curtailment below 50% power for condenser cleaning on March 14, 1992. During this occurrence, the licensee repeated the earlier process, and entered the action statement. Upon power ascension, the power tilt decreased to normal, and the licensee exited the action statement.

On March 23, 1992, Unit 2 was shut down to investigate a failed turbine stop valve. The licensee disassembled the failed stop valve and found that the nut which secures the valve disk to the swing arm had disengaged, allowing the disk to separate and partially block main steam lead number 2. Unit 2 was returned to power on March 28, 1992 after the failed turbine stop valve was repaired and the other three Unit 2 turbine stop valves were verified to be properly assembled.

B. Inspection Activities

Fifty routine and special inspections were conducted during this assessment period (July 1991 through December 1992), as listed below.

1. Inspection Data

Inspection reports: 91-20, 91-22, 91-24 through 91-27, 91-29, 91-31, 91-32, 91-34 through 91-41, and 92-01 through 92-33. Six of these reports documented management meetings and one documented an enforcement conference.

2. Special Inspection Summary

Special inspections included the following:

- 91-39 October 21 - November 29, 1991: A review of the licensee's Generic Letter 89-10 program for safety related motor operated valves
- 92-09 March 10 - March 17, 1992: Review of the licensee's procurement activities for the 6th emergency diesel generator
- 92-17 March 17 - April 27, 1992: Review of the licensee's maintenance and inspection activities for the containment fan cooler units (CFCUs), as well as licensee operability assessments for the CFCUs
- 92-201 August 24 - October 30, 1992: Shutdown Risk Team Inspection

C. Enforcement Activity

Inspections during this period identified 19 cited violations. Of these, 18 were Severity Level IV and 1 was Severity Level V. No deviations were identified during this period.

D. Confirmatory Action Letters

None.

E. Licensee Event Reports

Unit 1 LERs

Unit 1 issued 40 LERs during this reporting period. The LERs were 83-39, 91-011 through 91-021, and 92-001 through 92-028. LERs 91-021, 92-003, 92-006, 92-010, 92-015, 92-016, and 92-022 were voluntary.

Unit 2 LERs

Unit 2 issued 18 LERs during this reporting period. The LERs were 91-001 through 91-012 and 92-001 through 92-006. LERs 91-002 and 91-008 were voluntary.

TESTIMONY OF PACIFIC GAS AND ELECTRIC COMPANY
ADDRESSING CONTENTION I: MAINTENANCE AND SURVEILLANCE

I. INTRODUCTION

Q1 Please state your name, affiliation, qualifications
and current job responsibilities.

A1 (Giffin) My name is Bryant W. Giffin. I am the
Manager of Maintenance Services for Pacific Gas and
Electric Company ("PG&E") at the Diablo Canyon Power Plant
("DCPP"). I am responsible for all maintenance and outage
activities at DCPP. I have more than 25 years experience
working in the nuclear industry; 12 years with PG&E and
over 13 years as an officer in the United States Navy's
nuclear power program. A summary of my professional
qualifications and experience is provided in Exhibit 1.

(Crockett) My name is William G. Crockett. I am the
Manager of Technical and Support Services for PG&E at
DCPP. I am responsible for Engineering Support, including

1 System Engineering, Plant Engineering, Training, Security,
2 and General Services. I oversee the development and
3 evaluation of the DCPD surveillance testing program. I am
4 the primary site interface with the Design Engineering
5 section of the Nuclear Engineering Services Department,
6 with PG&E's Computer Services Department, and with the
7 Nuclear Regulatory Services Department. I have 16 years
8 of nuclear power experience in operations, maintenance,
9 and engineering, including 14 years at DCPD. I hold a
10 Senior Reactor Operators ("SRO") license (inactive) for
11 both units at DCPD. A summary of my professional
12 qualifications and experience is provided in Exhibit 2.

13 (Vosburg) My name is David A. Vosburg. I am Director
14 of the Work Planning Section in the Maintenance Services
15 Department at DCPD. I am responsible for maintenance
16 planning activities and for scheduling of maintenance,
17 post-maintenance testing, and plant modification
18 activities during normal and outage conditions. I have 16
19 years experience in the nuclear power industry, including
20 13 years at DCPD. In my 13 years at DCPD, I have worked
21 in the Operations, Engineering, and Maintenance
22 Departments. I maintained an SRO license for DCPD from
23 1982 to 1992. A summary of my professional qualifications
24 and experience is provided in Exhibit 3.

25 (Ortore) My name is Steven R. Ortore. I am the
26 Director of the Electrical Maintenance Section in the
27 Maintenance Services Department at DCPD. I am responsible
28 for maintenance of all electrical equipment at the plant.

1 I was formerly the Director of Material Services at DCP, which included responsibility for procurement. I have 19
2 years of experience in the nuclear industry, of which 9
3 years have been at DCP. A summary of my professional
4 qualifications and experience is provided in Exhibit 4.

6 Q2 What contention will the panel address?

7 A2 (All) We will address the San Luis Obispo Mothers for
8 Peace ("MFP") Contention I: Maintenance and Surveillance.
9 MFP in the contention alleges that PG&E lacks a
10 sufficiently effective and comprehensive maintenance and
11 surveillance program to justify the operating license
12 amendment here at issue. That amendment would extend the
13 DCP Unit 1 and Unit 2 operating licenses to the full
14 40-year term that was assumed in the original plant
15 design. A copy of PG&E's license amendment application is
16 provided as Exhibit 5.

17 Q3 What is the purpose of your testimony?

18 A3 (All) The purpose of our testimony is to provide a
19 response to the above contention. This testimony will
20 demonstrate that PG&E has implemented a comprehensive
21 maintenance and surveillance program at DCP.
22 Maintenance and surveillance activities at DCP address
23 degradation of equipment, whether due to equipment aging
24 or service wear, that has been experienced to date or that

1 is expected over a 40-year plant operating lifetime. This
2 specifically includes any pre-operational equipment
3 degradation. Contrary to MFP's claims, PG&E has
4 implemented its maintenance and surveillance programs in
5 an effective, and often outstanding, manner. PG&E
6 recognizes the importance of maintenance and surveillance
7 to efficient, reliable, and safe operation. PG&E has
8 devoted considerable attention to this area and will
9 continue to do so for the full 40 years of operation to be
10 authorized by the proposed license amendment.

11 II. OVERVIEW

12 Q4 What is the definition of "maintenance" as the term is
13 used in your testimony?

14 A4 (All) Maintenance as used in this testimony includes:
15 those activities which are performed to assure that
16 structures, systems and components ("SSCs") will continue
17 to operate as designed, as well as those activities
18 necessary to repair or replace SSCs that are degraded or
19 cannot perform the intended function. Maintenance is
20 considered to be the aggregate of actions at DCPD that (1)
21 minimizes the degradation or failure of SSCs, and (2)
22 promptly restores the intended function of SSCs if they
23 experience operability or functional problems.

1 Q5 What is the definition of "surveillance" as used in
2 your testimony?

3 A5 (All) Surveillance as used in this testimony is the
4 aggregate of periodic tests and/or inspections that verify
5 that SSCs continue to function in accordance with
6 predetermined specifications or are in a state of
7 readiness to perform their particular safety functions.
8 Surveillance activities can trigger maintenance activities
9 based upon the results of the particular tests or
10 inspections.

11 Q6 What is the scope of issues raised in the contention
12 and addressed by your testimony?

13 A6 (All) MFP in Contention I alleges that the maintenance
14 and surveillance programs at DCPD are not comprehensive
15 and effective. Our testimony will demonstrate that the
16 overall maintenance and surveillance programs established
17 at DCPD are comprehensive and effective in assuring the
18 safe and reliable operation of DCPD. The programs meet
19 all established requirements and are effective in
20 identifying and rectifying potential and actual sources of
21 equipment degradation. Moreover, as will be discussed in
22 detail later in this testimony, the individual isolated
23 items cited by MFP as bases for Contention I indicate
24 that, contrary to MFP's claims, our maintenance and

1 surveillance programs are functioning well and as
2 intended, in a comprehensive and effective manner.

3 Q7 How do DCPD maintenance and surveillance programs
4 address "aging" of equipment?

5 A7 (Giffin, Crockett) Equipment aging management is a
6 concept that is integral to the overall philosophy of an
7 effective maintenance and surveillance program. PG&E
8 recognizes that SSCs can deteriorate as service life
9 increases due to "age-related degradation." "Age-related
10 degradation," as defined by the Electric Power Research
11 Institute ("EPRI"), is the gradual deterioration in the
12 physical characteristics of an SSC due to aging mechanisms
13 and which occurs with time or use and could impair the
14 ability of the SSC to perform any of its design functions.
15 An "aging mechanism" is a process that gradually changes
16 the physical characteristics of an SSC with time or use.
17 Some examples of aging mechanisms are fatigue, erosion,
18 corrosion, radiation embrittlement, thermal embrittlement,
19 and service wear.

20 In the case of certain critical components which are
21 subject to complex aging mechanisms (e.g., the reactor
22 vessel and steam generators), or components which may have
23 limited life, special programs have been developed and
24 implemented at DCPD to manage the aging process. These
25 programs are discussed in more detail later in this
26 testimony. For those components where special programs

1 have not been developed, normal maintenance and
2 surveillance activities provide for and facilitate the
3 management of aging mechanisms. DCPD's maintenance and
4 surveillance programs are designed to (1) minimize
5 deterioration through routine maintenance, (2) predict the
6 rate of deterioration, and (3) detect the deterioration of
7 equipment. Specific maintenance tasks respond to
8 unacceptable SSC conditions either by equipment repair or
9 replacement.

10 DCPD, like other nuclear power plants, was designed to
11 operate for at least 40 years. In order to assure safe
12 operation, a defense-in-depth philosophy was incorporated
13 into the plant design, the plant operating programs, and
14 the maintenance and surveillance programs. Specifically,
15 design features have been incorporated to provide the
16 ability to test, inspect, and perform preventive
17 maintenance on SSCs. Furthermore, the plant was designed
18 with redundant trains of safety-related equipment to be
19 able to accommodate equipment failures that are random in
20 time or location. The operators are also trained to
21 recognize and respond to equipment problems, and the
22 maintenance programs are established to assure that
23 equipment problems, which are detected through routine
24 surveillance and operating experience, are corrected.

25 As the NRC has recognized in issuing numerous 40-year
26 operating licenses, and in issuing many license amendments
27 similar to that at issue here, effective and comprehensive
28 maintenance and surveillance programs assure that

1 detectable aging effects are addressed prior to their
2 becoming a safety issue.

3 Q8 What is the relationship between the specific,
4 individual events alleged by MFP in their bases advanced
5 in support of Contention I, and the effectiveness and
6 comprehensiveness of DCP's maintenance and surveillance
7 program?

8 A8 (Giffin) Our testimony will show that the specific
9 examples MFP uses to support its contention that the
10 maintenance and surveillance programs at DCP are not
11 effective or comprehensive do not, in fact, indicate a
12 breakdown in the overall programs. None of the examples
13 resulted in a situation with safety significance. Some
14 are not maintenance-related and those that are do not
15 prove an inadequacy in program scope or its overall
16 implementation. Some of the examples are simply
17 situations in which the maintenance and surveillance
18 program has worked precisely as intended. In all cases,
19 where specific equipment problems were identified or
20 performance weaknesses were observed, corrective actions
21 have been taken. PG&E believes that the examples cited by
22 MFP illustrate a maintenance program that is working and
23 reflect a strong commitment to continuous improvement.

24 MFP speculates that weaknesses in maintenance follow
25 from the DCP rate case settlement and the financial
26 structure for DCP rates. However, none of the examples

1 cited by MFP in the basis for Contention I supports this
2 speculation. None of the examples involved delay in
3 necessary corrective actions or repairs. In fact,
4 necessary repairs were made while the plant was operating.
5 Contrary to MFP, there are times when either unit of DCPD
6 is curtailed at PG&E's discretion in order for prudent
7 repairs or inspections to be performed. These
8 curtailments evidence PG&E's commitment to safe operation
9 as the highest goal for DCPD.

10 Q9 Could you give us a quantitative measure of the
11 magnitude of the maintenance and surveillance program at
12 DCPD?

13 A9 (Giffin, Vosburg) There are approximately 20,000 work
14 activities which require a work order performed each year
15 at DCPD. This includes 6,000 preventive and 7,000
16 corrective maintenance tasks. In addition, there are
17 approximately 10,000 surveillances performed each year,
18 7,000 of which require a work order. Many of these work
19 activities consist of a large number of sequential steps
20 or elements. These are three year averages of the number
21 of work orders performed. It is worth noting that the
22 number of corrective maintenance tasks has decreased
23 steadily for the past three years. In 1990, there were
24 9,000; in 1992, 6,000; and we estimate fewer than 5,000
25 this year.

1 In the context of these numbers, it must be recognized
2 that the design of the plant; the checks and balances
3 inherent in the maintenance and surveillance programs;
4 state of the art tools, test equipment, and facilities;
5 and the training and qualifications of the maintenance
6 personnel all provide assurance that there will be a
7 minimal number of errors made and that when errors are
8 made or equipment degrades, there will be no safety
9 significance.

10 III. DESCRIPTION OF DCPD MAINTENANCE AND SURVEILLANCE PROGRAMS

11 Q10 What programs at DCPD are included within the umbrella
12 of "maintenance and surveillance" programs?

13 A10 (Giffin, Crockett) At DCPD, PG&E has established
14 several programs or activities that addressing topic of
15 maintenance and surveillance of safety-related equipment.

16 These include:

- 17 • Technical Specification required surveillances;
- 18 • Numerous equipment surveillances not required by the
19 operating license;
- 20 • Inservice Inspection ("ISI")/Inservice Testing ("IST")
21 Programs;
- 22 • The Environmental Qualification ("EQ") Program; and
- 23 • The Maintenance Program.

24 These activities and programs collectively assure that any
25 significant degradation of plant equipment will be

promptly identified and addressed throughout the proposed 40-year operating license terms.

Technical Specification Surveillances

Q11 Please describe the role of Technical Specification surveillances?

A11 (Crockett, Giffin) DCPD Technical Specifications are part of the plant NRC operating license and include numerous requirements for testing and/or assessment of safety-related SSCs. PG&E has adopted a surveillance and testing program in accordance with the industry standard ANSI N18.7-1976/ANS 3.2, "Administrative Controls and Quality Assurance for the Operation Phase of Nuclear Power Plants." In accordance with PG&E procedure NPAP-C3, "Conduct of Plant and Equipment Tests," the DCPD surveillance and testing program administratively controls the surveillance testing required by the Technical Specifications. A computerized master schedule is used to schedule and track the status of Technical Specification surveillance tests and to ensure that these tests are performed at the required intervals.

Over 10,000 Technical Specification-required surveillance tests are performed at DCPD each year. The actual number of SSCs tested is much higher because many surveillances actually test multiple components. If the results of a surveillance test are not within specific operability limits, the SSC is declared inoperable and the

1 Technical Specifications provisions are invoked. In these
2 cases, PG&E initiates problem investigations and necessary
3 maintenance activities to restore the SSC to its design
4 condition in a timely fashion. Technical Specification
5 surveillance testing provides assurance that
6 safety-related equipment failures or substandard equipment
7 performance will not remain undetected and that the
8 required reliability and state of readiness of SSCs to
9 function in accordance with predetermined specifications
10 is maintained for the life of the plant.

11 Other Surveillances

12 Q12 Are there routine surveillances of SSCs at DCPD other
13 than Technical Specification surveillances?

14 A12 (Crockett, Giffin) Yes. In a broad sense, there are
15 many plant activities in addition to Technical
16 Specification-required surveillance test procedures which
17 result in surveillance information about equipment
18 condition and performance. Examples of these activities
19 are:

- 20 • Routine operator plant equipment inspections as
21 required by Administrative Procedure DLAP
22 OP1.DC3, "Auxiliary Operator Routine Plant
23 Equipment Inspections;"
- 24 • Predictive maintenance program testing (e.g.,
25 vibration monitoring, oil analysis, and thermography)

1 as specified in Administrative Procedure C-751,
2 "Predictive Maintenance Program;"

- 3 • Preventive maintenance program inspections (e.g.,
4 routine inspections of check valves) as required by
5 Administrative Procedures C-750, "Maintenance
6 Department Preventive Maintenance Program," and C-450,
7 "Instrument and Controls Preventive Maintenance;"
- 8 • Procedure functional checks (e.g., turbine trip
9 testing during startup);
- 10 • Performance tests of important equipment not
11 controlled by the Technical Specifications (e.g.,
12 equipment controlled by Equipment Control Guidelines),
13 as described in Administrative Procedure DLAP
14 OP1.DC16, "Control of Plant Equipment Not Required by
15 the Technical Specifications;"
- 16 • Inspections performed as part of the erosion/corrosion
17 monitoring program required by Administrative
18 Procedure D-300, "Monitoring of Erosion/Corrosion
19 Induced Pipe Wall Thinning;"
- 20 • Testing performed after maintenance to verify that
21 equipment performance has been restored to the
22 required level as specified in Administrative
23 Procedure C-6S3, "Post Maintenance Testing;" and
- 24 • System engineer quarterly equipment walkdowns in
25 accordance with Administrative Procedure TS5.ID1,
26 "System Engineering Program."

27 All of these different tests and inspections provide
28 detailed, specific, on-going information about the current

condition of plant SSCs. These tests also provide thousands of data points on the performance of plant equipment, which are included and reviewed in the preventive and predictive maintenance programs. Based on this information, maintenance is scheduled and performed in a manner that maintains equipment performance at the required level for the life of the plant.

ISI/IST Programs

Q13 You listed in A10 above the ISI/IST Program. Please briefly describe this category of surveillance testing.

A13 (Crockett) The ISI and IST Programs were initiated in 1985 for Unit 1 and in 1986 for Unit 2, corresponding to the start of commercial operation of each unit. The ISI and IST Programs comply with the requirements of 10 CFR 50.55a(b)(2) and 50.55a(g), as well as the requirements in the Technical Specifications. The ISI and IST Programs include inspection, testing, and maintenance of pressure-retaining components (including their support structures) as required by the American Society of Mechanical Engineers Boiler and Pressure Vessel ("ASME B&PV") Code.

Components that are within the scope of the IST Program are designated pumps and valves that are required to perform a specific function in shutting down the reactor or mitigating the consequences of an accident. Periodic pump tests are performed in accordance with ASME Section XI, subsection IWP. Such tests measure

1 operational pump performance by observing, measuring and
2 recording specific data such as pump/motor vibration,
3 flow, and bearing temperatures. Also, periodic valve
4 tests are performed in accordance with subsection IWV of
5 Section XI. These tests measure the performance of
6 power-operated valves, safety valves, and check valves.
7 As applicable, depending on the valve type, these tests
8 check stroke, stroke time, seat leakage, and relief
9 setpoints. For both pump and valve tests, data are
10 analyzed and compared to specific criteria for
11 operability.

12 The ISI Program specifically includes nondestructive
13 examinations such as visual, surface, and volumetric
14 examinations. The surface examinations are done with
15 liquid penetrant or magnetic particle methods. The
16 volumetric examinations are done using ultrasonic or
17 radiographic examination methods. The objective of these
18 examinations is to:

- 19 • Identify any unexpected service-induced component
20 degradation, which would be evidenced by surface
21 cracks, wear, corrosion, or erosion;
- 22 • Locate any evidence of component leakage during system
23 pressure or functional tests; and
- 24 • Verify operability of components and integrity of
25 component supports.

26 10 CFR 50.55a(g) requires revision of the ISI and IST
27 Programs as necessary to comply (to the extent practical
28 within the limitations of design, geometry, and materials

1 for construction of components) with the edition of the
2 ASME B&PV Code and Addenda in effect and adopted by the
3 NRC twelve months prior to the start of each 10-year
4 inspection interval. These programs ensure that pressure-
5 retaining components will be adequately inspected, tested,
6 and maintained throughout the proposed 40-year operating
7 license terms.

8 EQ Program

9 Q14 How does the EQ Program relate to maintaining plant
10 material condition through the proposed 40-year operating
11 term?

12 A14 (Ortore) EQ is a rigorous program to confirm that
13 electrical equipment which would be relied on in the event
14 of an accident will be capable of performing its design
15 safety function to assure safe shutdown of the reactor,
16 despite exposure to the harsh environment postulated to
17 result from an accident. The process of environmental
18 qualification includes:

- 19 • determining which plant components are required to be
20 operable in a harsh environment;
- 21 • defining the environmental conditions which each
22 component may be exposed to, and for how long;
- 23 • using appropriate testing and/or analysis to
24 demonstrate the component will operate in the harsh
25 environment for the period of time;

- 1 • determining a "qualified life" based on the expected
- 2 service conditions;
- 3 • identifying and implementing appropriate surveillance,
- 4 maintenance and procurement requirements to assure the
- 5 environmental qualification of the component is
- 6 maintained;
- 7 • documenting all of the above.

8 The EQ Program for DCPD complies with the requirements
9 of 10 CFR 50.49. As applied to DCPD, 10 CFR 50.49
10 requires that electric equipment important to safety and
11 located in a harsh post-accident environment be
12 environmentally qualified, at a minimum, in accordance
13 with IEEE 323-1971 and the Category II positions in
14 NUREG-0588, dated December 1979. In accordance with 10
15 CFR 50.49(1), replacement equipment (for equipment that is
16 required to be environmentally qualified) is required to
17 be qualified in accordance with IEEE Standard 323-1974 and
18 the Category I positions in NUREG-0588, unless there are
19 sound reasons to the contrary. The DCPD EQ program was
20 evaluated and found by the NRC to be in conformance with
21 applicable requirements in 1981 and 1985.

22 As described in detail later in this testimony,
23 maintenance of EQ equipment is a formal program at DCPD.
24 The master list of equipment required to be
25 environmentally qualified is maintained as a controlled
26 engineering drawing and is revised as plant design changes
27 are implemented. Surveillance activities are performed to
28 detect adverse trends in equipment performance or the

1 normal operating environment. Maintenance procedures
2 assure that the qualified configuration of equipment is
3 restored after maintenance and that appropriate
4 maintenance activities are conducted to preserve the
5 qualified status. Equipment that is not qualified for the
6 entire 40-year operating license term is refurbished or
7 replaced prior to exceeding its "qualified life."

8 Maintenance Program

9 Q15 The major element relevant to MFP's contention under
10 the maintenance and surveillance umbrella referenced in
11 A10 is the Maintenance Program. Please describe this
12 program generally.

13 A15 (Giffin) As noted above, maintenance is the integrated
14 means of maintaining the plant material condition
15 throughout the plant's operating life by managing the
16 effects of degradation and service wear on SSCs. The DCP
17 Maintenance Program was developed with the basic
18 philosophy that it is necessary to have the requisite
19 administrative and technical controls to ensure that
20 maintenance is performed in a timely, controlled, and safe
21 manner, consistent with applicable requirements, the
22 license, and quality control criteria.

23 The DCP Maintenance Program has been implemented
24 through procedures which incorporate relevant information
25 from the Technical Specifications, design basis criteria,
26 industry standards, equipment vendor and manufacturer

1 recommendations, NRC Safety Evaluation Reports and PG&E
2 maintenance experience at both nuclear and fossil plants.
3 They provide the means to monitor, inspect, maintain, and
4 test plant SSCs in a programmatic manner. The program
5 includes maintenance tasks on both safety and
6 non-safety-related SSCs.

7 As will be described further in this testimony,
8 maintenance tasks are categorized as either preventive or
9 corrective maintenance. Preventive and corrective
10 maintenance tasks were initially identified and initiated
11 during the plant construction phase. Maintenance
12 activities have been conducted throughout the construction
13 phase, the system turnover to plant staff, the period from
14 operational testing through the start of commercial
15 operation, and during commercial operation. This helps to
16 assure that SSCs were not adversely affected during the
17 period of plant construction. Additionally, Westinghouse
18 was present onsite during the construction phase and has
19 provided preventive maintenance information and guidelines
20 for the Nuclear Steam Supply System ("NSSS") equipment it
21 supplied. The Westinghouse guidelines also include
22 recommended chemistry controls and system layup
23 conditions.

24 In addition to procedural guidance on specific
25 maintenance activities, maintenance procedures also
26 provide for scheduling, implementing, and documenting
27 activities covered by the Maintenance Program. PG&E
28 installed a computer-based Plant Information Management

1 System ("PIMS") in 1985 to assist plant maintenance and
2 engineering personnel in these activities. PG&E also
3 committed additional resources to develop state-of-the-art
4 machine shops, maintenance training facilities, spare
5 parts inventories, and management systems. Staff
6 resources and personnel training are provided to fully
7 implement and use these support resources. All of these
8 program elements are described in more detail later in
9 this testimony.

10 Q16 You mentioned PIMS. What is PIMS?

11 A16 (Crockett) PIMS is a computer-based system that
12 utilizes a mainframe computer system at DCPD. PIMS runs
13 on a local area network and is available 24 hours a day to
14 over 3,000 users. It functions to improve information
15 flow, work planning, and productivity. It is regarded as
16 one of the most comprehensive information systems in the
17 nuclear industry.

18 PIMS specifically provides users with the ability to
19 manage and obtain up-to-date information directly related
20 to:

- 21 • Problem reporting and tracking
- 22 • Regulatory commitment management
- 23 • Plant component information and history
- 24 • Maintenance task instructions and history
- 25 • Measuring and test equipment calibration tracking
- 26 • Materials purchasing and processing

- 1 • Inventory control
- 2 • Radiation exposure tracking
- 3 • Personnel and training records
- 4 • Plant access management

5 A typical day will result in over 200,000 completed
6 PIMS electronic transactions.

7 Q17 What are the regulatory requirements for maintenance
8 and surveillance programs?

9 A17 (Giffin) The requirements for the implementation of
10 maintenance and surveillance programs are found or
11 referenced in several places. The DCPD Technical
12 Specifications provide surveillance requirements for
13 safety-related equipment and specify the requirements for
14 the ISI/IST program as described above. The Code of
15 Federal Regulations, 10 CFR Part 50, also provides certain
16 specific requirements, such as the EQ requirements. These
17 provisions, however, contain no explicit requirements for
18 a maintenance program. PG&E has committed in the DCPD
19 Final Safety Analysis Report Update ("FSAR") to follow the
20 standards of ANSI 18.7-1976/ANS-3.2, "Administrative
21 Controls and Quality Assurance for the Operational Phase
22 of Nuclear Power Plants," as endorsed and modified by the
23 NRC, in Regulatory Guide 1.33, "Quality Assurance Program
24 Requirements (Operation)." PG&E also has long been
25 actively involved with establishing maintenance guidance
26 for the nuclear industry. In 1971, a PG&E manager was the

1 chairman of the committee that authored ANSI 18.7/ANS 3.2.
2 In 1976, one of our present executive officers coauthored
3 the 1976 version which we committed to follow. This
4 continuous involvement by PG&E demonstrates our management
5 commitment to fostering comprehensive maintenance programs
6 in the nuclear industry. These documents provide guidance
7 concerning the maintenance and testing of safety-related
8 SSCs. Accordingly, the maintenance program PG&E has
9 established at DCPD is much broader in scope than required
10 by any of these documents. For example, our program
11 includes many maintenance activities for nonsafety-related
12 and balance-of-plant ("BOP") equipment.

13 The NRC is implementing a new maintenance rule
14 (10 CFR 50.65) which will become effective in 1996. Our
15 preliminary assessment is that our existing programs meet
16 the requirements of this new rule and that few changes to
17 our programs will be required.

18 IV. ELEMENTS OF AN EFFECTIVE AND COMPREHENSIVE
19 MAINTENANCE PROGRAM

20 Q18 Focusing now on the DCPD Maintenance Program, is there
21 any objective standard by which to judge the proper scope
22 of such a program?

23 A18 (Giffin) Yes. Maintenance is a very complex and
24 interrelated program which includes (1) the identification
25 of an equipment problem or potential equipment problem,

1 (2) the planning of the work activity intended to prevent
2 a problem from occurring or to return the equipment to its
3 design condition, (3) the preparation of a detailed
4 procedure or work order defining the steps necessary to
5 perform the work, (4) scheduling the work activity,
6 (5) obtaining the parts which are necessary to complete
7 the task, (6) assigning qualified personnel to actually
8 perform the work, (7) performing the work, and (8)
9 performing necessary testing at the completion of the work
10 to ensure that the equipment is in operable condition.

11 With this scope in mind, the nuclear industry and the NRC
12 have generally agreed that the Institute of Nuclear Power
13 Operations ("INPO") document 90-008, "Maintenance Programs
14 in the Nuclear Power Industry," (Revision 1, March 1990),
15 identifies the requisite elements for a comprehensive
16 maintenance program. INPO 90-008 was recognized by the
17 NRC in its Statement of Considerations for the Maintenance
18 Rule, and the NRC expressly found that detailed
19 recommendations for the conduct of maintenance, such as
20 INPO 90-008, should be developed by the licensee, not the
21 NRC. (See 56 Federal Register 31,313, July 10, 1991.)

22 These elements are:

- 23 • A well-staffed and qualified organization that is
24 provided with the tools and facilities necessary to
25 perform tasks effectively and efficiently;
- 26 • A proper mix of corrective and preventive maintenance
27 to provide assurance that equipment degradation is
28 identified and corrected prior to failure;

- 1 • Accurate procedures or work instructions for craftsmen
2 so that the work activities can be performed in a
3 quality manner;
- 4 • Maintenance planning and scheduling to assure that all
5 involved plant departments are aware of the activities
6 and interferences are minimized;
- 7 • Post-maintenance testing to verify that the
8 maintenance task was performed correctly and the
9 equipment is ready to be returned to service;
- 10 • Availability of correct and qualified parts and
11 material to support the repair and return to service
12 of the component;
- 13 • Control of measuring and test equipment to ensure the
14 accurate performance of instrumentation and equipment
15 used for calibrations, testing, and repairs;
- 16 • A detailed root cause analysis program to understand
17 the cause of equipment failures; and
- 18 • A maintenance history program to provide historical
19 data for maintenance planning and to support trending
20 analyses of equipment performance.

21 Similar but less-detailed elements are identified in
22 ANSI 18.7-1976/ANS-3.2. The elements of INPO 90-008 have
23 been addressed in the DCPM Maintenance Program and are
24 explained in our Program Directive MA1 "Maintenance." The
25 Program Directive is included with this testimony as
26 Exhibit 6.

1 Maintenance Organization

2 Q19 The first element of a maintenance program is a well-
3 staffed and qualified organization with necessary tools
4 and facilities. Let us break this element into three sub-
5 topics and address each: the maintenance organization,
6 the training and qualifications of maintenance personnel,
7 and maintenance facilities. First, please describe the
8 maintenance organization for DCPD?

9 A19 (Giffin) The DCPD maintenance organization is clearly
10 identified and has been communicated to personnel so that
11 responsibilities, lines of communication, performance
12 objectives, and mission are clearly understood. The DCPD
13 Maintenance Services Department organization chart is
14 included as Exhibit 7 to this testimony.

15 About four years ago, the DCPD maintenance functions
16 were part of three different departments. A decision was
17 made to arrange the plant organization along functional
18 areas. Accordingly, the Maintenance Services Department
19 was established and the sections having maintenance
20 responsibilities were assigned to that department. The
21 Maintenance Services Department now consists of six
22 sections: Electrical Maintenance, Mechanical Maintenance,
23 Instrumentation and Controls ("I&C"), Work Planning and
24 Scheduling, Materials, and Outage Management. There are
25 approximately 598 employees in the Maintenance Services
26 Department, 300 union employees, 298 professionals. This

1 organization is well-staffed and well-suited to its
2 purpose.

3 Q20 Please describe each organization within the
4 Maintenance Services Department individually, with the
5 section responsibilities and the staffing.

6 A20 (Giffin) The Mechanical Maintenance Section is
7 responsible for maintaining and servicing all mechanical
8 components at DCPD. This includes the supervision and
9 programmatic controls needed to ensure that all components
10 are monitored and maintained in reliable working
11 condition. Engineering support within the section
12 provides procedural guidance, troubleshooting, and
13 technical direction. The Mechanical Maintenance Section
14 consists of 157 employees.

15 The I&C Section is responsible for the maintenance and
16 periodic testing of all plant instrumentation. Duties
17 include the supervision and administration of the
18 preventive and corrective maintenance programs for that
19 equipment, and the implementation of the Technical
20 Specification instrumentation surveillance program.
21 Engineering support within the section is provided in the
22 areas of problem troubleshooting, test reviews and
23 direction, tracking and trending of component failures,
24 design change scoping and installation sponsorship, plant
25 computer systems maintenance and programming expertise,
26 integrated communication interfaces, design engineering

1 support, and quality problem evaluations and reviews. The
2 I&C Section consists of 123 employees.

3 The Electrical Maintenance Section is responsible for
4 maintenance of all electrical plant equipment, including
5 main generator and exciter, all motors, generators,
6 switchgear, batteries, chargers, inverters and motor
7 operated valves ("MOVs"). Engineering support is provided
8 within the section. The Electrical Maintenance Section
9 consists of 88 employees.

10 The Work Planning Center is comprised of two main
11 functional groups: Work Planning and Work Scheduling. The
12 overall responsibility of the Work Planning Section is to
13 provide the plant maintenance sections with detailed
14 working documents that reflect a safe, efficient work plan
15 that is in compliance with all plant procedures, programs
16 and regulatory requirements. The Work Scheduling Section
17 is responsible for the coordination and scheduling of all
18 plant work activities in a manner that maximizes efficient
19 utilization of plant resources and enhances the safe and
20 reliable operation of the plant. The Work Planning Center
21 consists of 105 full time personnel.

22 The Outage Management Section is responsible for the
23 planning, scheduling and direction of all activities
24 associated with refueling outages and unscheduled outages
25 of sufficient duration or complexity. The outages are
26 directed from the Outage Control Center, utilizing a
27 representative from each of the major disciplines on a
28 seven day a week, 24 hour a day basis. Outage Management

1 is also responsible for the Lessons Learned program which
2 captures items that worked well or things that need to be
3 improved during outages. During non-outage periods, there
4 are 6 people assigned to the outage management team.
5 These people coordinate the efforts of schedulers and
6 planners. During an outage, the maintenance services
7 organization is augmented by about 400 engineers and
8 craftsmen.

9 The Material Services Section has about 118 full time
10 employees and is responsible for the procurement of
11 material (equipment and parts), warehousing, issuance and
12 repair of tools, and the calibration of measuring and test
13 equipment. Procurement, within this section, also has
14 responsibility for defining the technical and quality
15 requirement of material requests.

16 Q21 Are there examples of organizational methods utilized
17 at DCP, beyond what you have just described, to foster
18 continued improvement?

19 A21 (Giffin) Yes. As part of our commitment to continuous
20 improvement in the maintenance organization, we have
21 instituted the High Impact Team ("HIT") concept. A HIT is
22 a multi-discipline team with members from a vertical slice
23 of the organization who are selected based upon the
24 particular maintenance issue or project involved. HITs
25 are formed for complex outage tasks, to facilitate
26 teamwork for new projects, or for other complicated multi-

1 discipline tasks. HITs are given the resources,
2 abilities, and authority to implement actions and
3 improvements so that tasks are accomplished in an
4 excellent and improving manner. Industry and PG&E
5 management have recognized the efficiency, quality, and
6 productivity benefits of employee teams. The DCPH HIT
7 teams have proven to be a very successful example. By
8 having a management team which supports continuous
9 improvement and employee involvement, coupled with HITs to
10 look for and implement improvements, a working environment
11 exists at DCPH where change for the better is expected.

12 Training and Qualifications

13 Q22 Please describe the qualifications of the personnel
14 involved in maintenance activities.

15 A22 (Giffin, Crockett) PG&E has committed to the
16 requirements of ANSI/ANS 3.1-1976³, "For Selection and
17 Training of Nuclear Power Plant Personnel." The
18 qualifications of the DCPH maintenance staff are quite
19 high, and exceed the ANSI/ANS 3.1-1976² requirements. Five
20 of the seven section directors in the Maintenance Services
21 Department have been either licensed or certified SROs,
22 three have advanced technical degrees, and they all have
23 over 15 years experience in the nuclear industry. The
24 maintenance foremen and general foremen have, on average,
25 15 years of nuclear experience. The qualification of
26 maintenance craftsmen who perform specific maintenance

1 tasks are ensured by a rigorous training program. In the
2 NRC's last Systematic Assessment of Licensee Performance
3 ("SALP") report on the Maintenance area at DCPD (February
4 12, 1993), the NRC listed as a noteworthy strength:

5 "Qualifications: The training and qualification
6 program for Maintenance personnel was strong.
7 Well maintained training facilities and a
8 dedicated training staff were significant factors
9 in good performance, as was the sense of ownership
10 shown by Maintenance personnel."

11 Maintenance training programs at DCPD have been
12 accredited by INPO. These accredited training programs
13 include Mechanical Maintenance, Electrical Maintenance,
14 I&C, and Maintenance Supervisory Training. INPO
15 accreditation is an ongoing process that is re-evaluated
16 every four years. The maintenance training programs at
17 DCPD were first accredited in 1988 and accreditation was
18 renewed in 1992. As a result of obtaining and maintaining
19 accreditation for all of the INPO identified programs,
20 DCPD has been designated as a full member of the "National
21 Academy for Nuclear Training."

22 In recognition of DCPD's commitment to training and
23 the quality of its programs, DCPD's training director was
24 selected to participate with INPO and the Department of
25 Energy in a project to assist the Russian nuclear
26 organizations with their training programs.

27 Q23

How are maintenance personnel trained?

1 A23 (Crockett, Giffin) DCPP training programs are designed
2 to provide journeymen and foremen who will perform
3 specific maintenance tasks with the skills and knowledge
4 needed to successfully and safely complete their work. The
5 training programs meet the requirements of ANSI/ANS 3.1,
6 the state-approved apprenticeship program, and the INPO
7 accreditation criteria.

8 The maintenance training programs are comprised of
9 distinct components:

- 10 • Apprenticeship
- 11 • Basic (or Fundamental) Qualification for Journeyman
- 12 • Advanced (or Select) Qualification for Journeyman
- 13 • Supervisor Training
- 14 • Continuing Training

15 The apprenticeship program is State of California
16 approved and is a negotiated contractual agreement with
17 the International Brotherhood of Electrical Workers. Once
18 in an apprenticeship, individuals are given two or three
19 years of training and guidance in their chosen field.

20 Examples are:

- 21 • Machinist (3 years)
- 22 • Electrician (3 years)
- 23 • Welder (3 years)
- 24 • Instrument Repairman (2 years)
- 25 • Control Technician (2 years - must have already
26 completed either electrical or instrument repairman
27 requirements).

1 When job vacancies for craftsmen occur, they are
2 filled by graduates of the apprentice program. However,
3 sometimes these vacancies are filled by journeymen from
4 outside of the DCPD maintenance organization. These
5 journeymen may come with a variety of backgrounds.
6 Although they are considered to be journeymen, their
7 specific skills, knowledge, and experience may be
8 different than that specifically required for basic
9 qualification at DCPD. Thus, all such personnel are
10 tested upon entry into the Maintenance Services
11 Department. The test results, along with interviews by
12 supervision and review of previous work documentation,
13 determine the initial training needed to meet the
14 requirements for Basic (or Fundamental) Qualification for
15 Journeyman.

16 The topics of the Basic qualification training
17 program, and the amount of training available, are shown
18 in Exhibit 8. Once an incoming journeyman satisfies the
19 Basic (or Fundamental) qualifications, further advanced
20 training on selected plant components is given based on
21 need. Examples of advanced or plant-specific training,
22 and the time available, are shown in Exhibit 9.

23 In addition to plant-specific training on components
24 and equipment, all maintenance workers attend continuing
25 training seminars on a quarterly basis, except during
26 outage periods. These seminars are used to address plant
27 and industry issues, changes recently made to the
28 facilities or equipment, and recent "lessons learned."

1 These seminars also afford management an opportunity to
2 stress areas of concern.

3 Q24 How do you utilize "hands-on" training at DCPD?

4 A24 (Crockett, Giffin) All aspects of DCPD maintenance
5 training programs stress "hands-on" training activities.
6 The majority of the classes are taught in a lab or shop
7 facility and take advantage of plant-specific training
8 aids. The classes consist of lectures with examples,
9 coupled with actual hands-on experience on equipment
10 utilizing actual plant procedures and work packages
11 similar to those used to perform maintenance in the plant.
12 Examples of plant specific equipment available in the
13 training facilities are:

- 14 • Reactor Coolant Pump (seal and motor alignment
- 15 portions)
- 16 • Steam Generator Channel Head and Tubesheet
- 17 • 10% Steam Dump Valve
- 18 • Limitorque Valves and Operators
- 19 • Reactor Trip Breaker
- 20 • Digital Feedwater Controls
- 21 • Nuclear Instrumentation and Protection Systems
- 22 • Diesel Engine

23 With the extensive training aids available in our
24 training program, the majority of tasks requiring
25 qualification can be fully accomplished in the training
26 facilities. However, in some instances additional "on the

1 job" training in the plant is required prior to
2 qualification. An individual's qualifications are tracked
3 by a qualification matrix that identifies the tasks an
4 individual is qualified to perform. The foremen makes use
5 of this matrix when assigning work to assure that only
6 qualified personnel are assigned to a job. When possible,
7 workers are also given the opportunity to train on new
8 equipment prior to its installation in the plant.

9 This extensive training program demonstrates a strong
10 commitment to the development of the skills and knowledge
11 of maintenance personnel. In the 1993 SALP report, the
12 NRC recognized the strength of PG&E's training in the
13 maintenance area noting:

14 "Plant Safety: Maintenance personnel were trained
15 and informed regarding overall plant safety system
16 availability and the significance of their
17 individually assigned work relative to its risk to
18 the plant."

19 Maintenance Facilities

20 Q25 What are the facilities that support the maintenance
21 programs at DCPFP?

22 A25 (Giffin, Crockett) PG&E has provided excellent
23 facilities for the performance of maintenance activities.
24 State of the art training facilities, machine shops,
25 calibration facilities, and warehouse storage areas are
26 available to support the maintenance program and specific
27 maintenance tasks. These facilities include:

- 28 • Maintenance Shops Building

- 1 • Warehouses
- 2 • Computer Center and Associated Equipment
- 3 • Machine Shops
- 4 • I&C Shop
- 5 • M&TE Lab

6 The Maintenance Shops Building is a \$10 million
7 facility, located adjacent to the plant protected area.
8 In this building are laboratories, shops, and classrooms
9 totaling 70,000 square feet of space devoted to the
10 training of plant personnel. Within the mechanical,
11 electrical, and instrumentation shops and laboratories are
12 many of the same components and equipment installed and
13 operating within the actual plant. These are used for the
14 troubleshooting and repair training described above. When
15 infrequent maintenance activities are planned, the
16 equipment in this facility is also used to rehearse the
17 activity and refresh the skill of the craftsmen before the
18 activity is performed in the plant.

19 The main Warehouse is a \$18 million facility with over
20 100,000 square feet of storage area with a material
21 testing laboratory, a Quality Control inspection area, and
22 an environmentally controlled storage room. In addition
23 to the main Warehouse, there are several satellite
24 warehouses to store specialized equipment, e.g., the spare
25 generator storage building that houses one complete spare
26 main generator, the spare rotor storage building that
27 contains three low pressure turbine rotors, Warehouse A
28 that is used to store components and materials that may be

radioactive, and Warehouse B that is used to store other large equipment and material to be surplusd.

The Computer Center and associated facilities are located in the Administration Building at DCPD and occupy 25,000 square feet. The Center includes:

- A fully automated mainframe computer facility housing an IBM 3090 400J series machine.
- A network operating center housing over 30 network servers.
- A computer support and help desk facility.
- An information systems prototype and testing facility.
- The data communications hub internal to the plant and the gateway to external PG&E facilities.
- Applications maintenance, development, and administrative areas.
- A support staff of full time personnel

The cost to staff and operate the facility is approximately \$12.5 million per year. This cost provides us with the capability to execute business transactions at the rate of 700-800 transactions per minute and to maintain over 130 gigabytes of plant information available for rapid on-line retrieval. Collectively, the staff and the facilities provide DCPD with state of the art information technology services.

There are four machine shops at DCPD. The first is the Cold Machine Shop Building located south of the Unit 2 Turbine Building. It is an \$8 million facility consisting of 35,700 square feet and is shared by the Electrical and

1 Mechanical Maintenance Sections. The second is
2 strategically located between both units in the Turbine
3 Building. A third facility is located at the intake
4 structure and consists of 2760 square feet at a cost of
5 \$720,000. These three "cold" machine shops are used to
6 work on equipment that is not radiologically contaminated.
7 Radiologically contaminated equipment is brought to a
8 fourth facility, the "hot" machine shop, where special
9 controls are in place to clean the equipment, prevent the
10 spread of contamination, and protect the workers. All
11 four machine shops have proper equipment, such as lathes
12 and drill presses, with appropriate environmental
13 conditions conducive to ensuring maintenance quality and
14 work efficiency.

15 The I&C Shop is an \$8 million facility with over
16 25,000 square feet of I&C repair shops (for repairs and
17 instrument calibrations), telecommunication shops, a
18 medical facility, and office area. The I&C shop was
19 constructed to consolidate all I&C functions in one
20 location to enhance communication and overall work
21 efficiency.

22 Part of the I&C Shop is the Measuring and Test
23 Equipment ("M&TE") calibration lab. Here, high accuracy
24 calibration is performed on equipment that, in turn, is
25 used to calibrate plant equipment. Over 700 pieces of
26 M&TE are calibrated monthly during non-outage periods, and
27 about 5,000 per month during outage periods.

1 In addition to these facilities, DCPD has various
2 laydown areas, tool storage, repair and issue stations,
3 and temporary facilities that are used during outages.
4 Together, all of these facilities ensure the effective and
5 efficient performance of maintenance activities.

6 Preventive and Corrective Maintenance

7 Q26 The next element is achieving a "proper mix" of
8 preventive and corrective maintenance. How is this
9 element satisfied at DCPD?

10 A26 (Ortore) Maintenance is generally defined as falling
11 into two categories, preventive and corrective.

12 Preventive maintenance tasks are periodic, planned, or
13 predictive actions taken to ensure that equipment
14 continues to maintain its design function. Preventive
15 maintenance tasks are normally performed on a
16 predetermined scheduled basis prior to any equipment
17 failure or degradation. Annually we perform about 14,000
18 preventive maintenance tasks at DCPD. These activities
19 range from simple equipment inspections, replacement of
20 limited life items such as lubricants, filters, wear
21 rings, bearings, and diaphragms, to major equipment
22 overhauls. Preventive maintenance tasks are selected so
23 as to maintain equipment in a condition which will
24 increase reliability and extend the life of equipment.

25 A Master Equipment List ("MEL") identifies and tracks
26 the majority of plant equipment, both safety-related and

1 nonsafety-related. Starting with the MEL, the following
2 equipment is selected to be included in the preventive
3 maintenance program: (1) any installed equipment, either
4 NSSS or BOP equipment, needed for safe and reliable plant
5 operation, (2) any equipment requiring preventive
6 maintenance based on PG&E commitments, (3) any equipment
7 whose malfunction can cause direct personnel injury, and
8 (4) any equipment where the implementation of preventive
9 maintenance may cause a reduction in operating costs.
10 There are about 17,500 components included in the DCP
11 preventive maintenance program.

12 A program of predictive maintenance has also been
13 incorporated into our maintenance program at DCP as a
14 part of preventive maintenance. Predictive maintenance is
15 the continuous or periodic monitoring and diagnosis of
16 selected equipment parameters to provide early detection
17 of equipment degradation prior to equipment failure. This
18 is accomplished by gathering and analyzing information,
19 predicting future degradation, and then taking action to
20 limit the degradation before partial or complete failure
21 occurs. For example, this could involve taking a
22 lubricating oil sample from a piece of rotating equipment
23 such as a pump or motor (which is a standard task),
24 analyzing the sample for metal wear products and other
25 particulates to determine the amount and type of wear
26 occurring, and trending these findings to determine the
27 degree of degradation that may have taken place. If
28 necessary, we will then recommend specific maintenance

1 actions for equipment. Generally, DCPD utilizes a variety
2 of nonintrusive equipment monitoring techniques including:

- 3 • Lubrication analysis (as just discussed)
- 4 • Vibration monitoring and diagnostics
- 5 • Air and motor operated valve diagnostic testing
- 6 • Acoustic analysis
- 7 • Infrared thermography
- 8 • Bearing temperature analysis
- 9 • Insulation resistance
- 10 • Non-destructive analysis
- 11 • Monitoring and trending of equipment data

12 The predictive maintenance program is described in
13 procedure, AP C-751, "Predictive Maintenance Program."

14 Corrective maintenance consists of the repair and/or
15 restoration of equipment. As discussed above, this is a
16 normal and expected part of the maintenance program.
17 Corrective maintenance is performed when equipment is not
18 able to perform its intended function or is outside
19 operating limits. The maintenance action will return the
20 equipment to a specified performance level. For example,
21 if a valve packing is leaking and needs to be tightened,
22 that task would be listed as corrective maintenance. We
23 perform on the average 7,000 corrective maintenance tasks
24 at DCPD each year.

25 Q27 How do we know that at DCPD we have achieved a "proper
26 mix" of preventive and corrective maintenance?

1 A27 (Giffin, Ortore) Within the nuclear industry, a high
2 ratio of preventive maintenance (including surveillances)
3 to total maintenance is indicative of an efficiently
4 managed maintenance program which is effective in
5 maintaining the plant in a safe and reliable condition.
6 Obviously this is a very subjective assessment. It is in
7 our interest to minimize corrective maintenance, to the
8 extent practical, through preventive maintenance.
9 However, preventive maintenance cannot avoid all
10 corrective maintenance, nor would such a goal be practical
11 from an operating perspective. INPO formerly monitored
12 this parameter and had established 60 percent as the
13 objective.

14 At DCP, we monitor preventive maintenance tasks as a
15 percentage of all maintenance tasks and strive to maintain
16 the ratio above 60 percent. Over the past three years the
17 number of corrective maintenances performed have decreased
18 which can be attributed to the effectiveness of the
19 preventive maintenance program. Based on this performance
20 and the experience gained since we began monitoring this
21 percentage, we believe that we are maintaining a proper
22 mix. We believe also that the overall reliability of the
23 plant to date, as measured by the plant availability and
24 plant capacity factors, is a good indicator of a proper
25 mix.

1 Maintenance Procedures

2 Q28 The next element of a maintenance program includes the
3 procedures and/or work instructions. Please describe how
4 this works at DCPD.

5 A28 (Vosburg) In order for maintenance activities to be
6 performed in a consistently safe and efficient manner by
7 the craftsmen, accurate procedures providing technical
8 guidance and direction have to be in place. We have
9 expended considerable effort at DCPD over the last several
10 years in the preparation of state of the art maintenance
11 procedures. There are currently about 6,000 written
12 procedures which are used to conduct specific maintenance
13 activities. Exhibit 10 to this testimony is a list of
14 these maintenance and surveillance test procedures. These
15 procedures are periodically reviewed and updated, as
16 necessary. The procedures that the craftsmen use have
17 been prepared with input from the workers and provide the
18 necessary graphics and check lists. The relevant
19 procedures for specific tasks are incorporated, as
20 appropriate, into task-specific work packages described
21 below.

22 Planning and Scheduling

23 Q29 The next element concerns planning and scheduling of
24 maintenance tasks. How is this accomplished at DCPD?

1 A29 (Vosburg) With approximately 20,000 maintenance and
2 surveillance work orders performed each year, it is
3 extremely important to plan and schedule the activities
4 correctly. This is one of the important functions of the
5 Work Planning Section of the Maintenance Services
6 Department and is part of a detailed, comprehensive work
7 control process. The work control process provides the
8 integrated mechanism under which plant maintenance
9 activities and equipment problems (including both
10 preventive and corrective maintenance tasks) are
11 identified, reviewed, prioritized, planned, scheduled,
12 performed, tested and closed out. The process ensures
13 that plant maintenance activities are planned and
14 performed in a safe, timely, efficient and controlled
15 manner. The process is specifically designed to
16 coordinate maintenance activities to minimize the time
17 that safety-related equipment is out of service.

18 Q30 How are corrective maintenance activities identified
19 for incorporation into the work control process?

20 A30 (Vosburg) A key objective in the overall maintenance
21 program is to ensure that actual or potential plant
22 equipment problems will be identified and documented in a
23 timely manner. One facet of the surveillance testing and
24 preventive maintenance programs is directed towards early
25 identification of discrepant equipment conditions, with
26 the desired goal of repairing/replacing equipment before

1 failure. Device calibrations also play a part in flagging
2 trends which aid in early detection and repair.

3 Maintenance tasks identified by these programs are
4 scheduled and tracked through the work control process.

5 Any individual who discovers a problem in the plant is
6 responsible for initiating an Action Request ("AR") or
7 reporting the problem to a supervisor who must then
8 initiate an AR in a timely manner. A significant factor
9 which contributes to the effectiveness of the problem
10 reporting system at DCPD is that all personnel working at
11 the plant have access to the system, either directly or
12 through their immediate supervisor. At the plant site
13 alone, there are more than 1,800 computer terminals
14 available where ARs may be initiated and at least as many
15 plant personnel with direct access to the system. Since
16 the AR system is used not only for documenting plant
17 equipment problems but also for documenting administrative
18 tasks, requesting design changes, requesting
19 interdepartmental support, etc., there is a high level of
20 familiarity with the problem reporting process throughout
21 the plant staff.

22 Q31 Once maintenance tasks are identified, what means
23 exist to track the scheduling, planning, and completion of
24 those tasks?

25 A31 (Vosburg) The administrative controls for the work
26 control process at DCPD are integrated into PIMS. Using

1 this system, all data entered at any one computer terminal
2 during the process is immediately available at other
3 computer terminals throughout the plant. This attribute
4 makes the entire system highly responsive to plant
5 maintenance needs. One advantage of PIMS is that the
6 system itself assigns unique task numbers to new
7 documents, thereby ensuring that none are inadvertently
8 misplaced. Once an AR is created, it cannot be
9 destroyed - even if it is taken to "rejected" status.

10 The ARs module within PIMS ensures that problems
11 receive appropriate levels of review and are tracked
12 through resolution. The AR is the key which
13 electronically ties together all other modules which make
14 up the maintenance process (equipment clearances, work
15 orders, quality evaluations, post-maintenance test
16 requirements, etc).

17 An overview of the DCPD work control process as it
18 relates to a plant equipment problem is illustrated in
19 Exhibit 11. In the sequencing of a typical maintenance
20 work request, the key elements of the process are
21 described below:

- 22 • Upon identification of a maintenance problem, the
23 person who discovers it will initiate an AR at a
24 convenient terminal. After filling in as much
25 information as is available at that time, the AR is
26 left in the "initiated" status and the individual's
27 supervisor is notified.

- 1 • The supervisor reviews the AR for accuracy and assigns
2 a priority to the AR in accordance with the plant work
3 prioritization system. The supervisor is also
4 responsible to ensure that Operations is immediately
5 notified of any problem that is believed to have an
6 impact on plant safety or equipment operability. This
7 notification is documented on the AR. The AR is then
8 taken to the "reviewed" status. This effectively
9 makes the AR available to the Work Planning Center.
- 10 • The Work Planning Center routes the AR to the
11 appropriate planner, who is then able to begin
12 preparation of a work order, another electronic module
13 document which is linked to the AR.
- 14 • As part of the work order preparation, the planner
15 reviews the problem as documented on the AR and begins
16 collecting information necessary to plan the
17 maintenance activities. This may include (but is not
18 limited to): a walkdown of the jobsite; identification
19 of relevant procedures, drawings and vendor manuals;
20 identification of special processes (such as welding);
21 interviews with foreman and craft; identification of
22 administrative limitations on the job sequence; and
23 investigation of any salient information contained in
24 the PIMS Component or Maintenance History Databases.
- 25 • The planner may use other specialized modules within
26 PIMS to electronically research and order spare parts,
27 flag quality-related aspects to the Quality Control
28 group, request Radiation Work Permits for radiological

1 work, request any clearance (equipment
2 isolation/tagout) which will be required in order to
3 commence work, and notify other disciplines of the
4 need for technical assistance.

- 5 • When the planner has all necessary information
6 collected, he/she writes the work flow description
7 directly into the electronic work order. Quality
8 related work orders are reviewed by the Quality
9 Control organization for the incorporation of needed
10 inspection hold points which are inserted into the
11 work order. The work package is then created which
12 includes a copy of the work order, copies of
13 maintenance procedures referenced by the work order,
14 and other supporting documentation such as vendor
15 manuals and applicable plant drawings. The work
16 package is then assigned to the appropriate
17 maintenance foreman.
- 18 • Another electronic link ties the work order to the
19 on-site scheduling software. The job is integrated by
20 the scheduling staff into the overall maintenance
21 picture to ensure that it is performed in a time frame
22 commensurate with its priority. It must be merged
23 into the work stream along with other tasks to be
24 scheduled, such as corrective or preventive
25 maintenance activities and surveillance testing.
- 26 • The maintenance task is performed by the appropriate
27 discipline, following which the work order is reviewed
28 by the foreman. The package is then returned to the

1 Work Planning Center for closure. The planner
2 transcribes the results of the maintenance action into
3 the Component Maintenance History (another PIMS module
4 which provides a running history of maintenance to aid
5 in future planning efforts and/or research) and then
6 forwards the completed work order to Document Control
7 for archiving.

8 Q32 What considerations go into planning the scope of work
9 for specific maintenance tasks?

10 A32 (Vosburg) Work planning creates the integrated work
11 package based on the following considerations:
12 • Consistency and conformance to standards and
13 requirements;
14 • Safety, reliability and effect on generation
15 capability;
16 • The quality classification of the work, to assure that
17 the plant quality organizations are integrated into
18 the work planning process;
19 • Integration with work scheduling to maximize the
20 efficiency of all work performed; and
21 • The safety and radiation protection of plant workers.

22 Q33 Explain how maintenance tasks are scheduled.

23 A33 (Vosburg) The overall objective of the work scheduling
24 function is to coordinate and schedule plant work

1 activities in a manner that maximizes efficient
2 utilization of plant resources and enhances the safe and
3 reliable operation of the plant. To accomplish this we
4 developed a computerized scheduling program which
5 interfaces with PIMS. Periodic schedules identify when
6 equipment maintenance, testing or inspection is required.
7 These computer schedules are routed to appropriate
8 sections for planning and performance of the work. The
9 scheduling program allows for integration of all work
10 activities into the schedule.

11 The framework for the scheduling of plant maintenance
12 and surveillance activities is built around a process
13 known as the Mode One Integrated Daily Schedule ("MOIDS").
14 This process uses a 12-week rolling matrix which
15 identifies the required Technical Specification
16 surveillance tests for plant equipment and reserves blocks
17 of time within the base schedule for the performance of
18 these tests. All other maintenance activities related to
19 the equipment are then identified and incorporated into
20 these maintenance windows. Typical activities to be
21 included would be the routinely scheduled preventive
22 maintenance activities and any necessary corrective
23 maintenance activities. Using this method, both the
24 number of times that equipment is removed from service and
25 the amount of time that the equipment is unavailable are
26 minimized. Using the MOIDS concept, plant schedulers
27 along with senior licensed personnel from Operations meet
28 twice a week to develop the schedule for the upcoming

1 week. All activities to be performed on safety-related
2 equipment are reviewed by the group for plant safety
3 impact. All preventive maintenance activities to be
4 included are reviewed to assure that work necessary to
5 enhance the reliability of the equipment is performed
6 within the normal maintenance window and is not
7 unnecessarily deferred.

8 An additional enhancement to the scheduling process
9 has been the assignment of a licensed Operations
10 representative to the scheduling group. This innovation
11 has proven instrumental in the improvement of
12 communication between the Planning, Scheduling, and
13 Operations organizations. The Operations representative
14 provides guidance to ensure that work is scheduled in a
15 way that optimizes use of Operations and Maintenance
16 manpower. He or she also provides input to the schedule
17 from a risk assessment standpoint and reviews scheduled
18 work to identify potential safety system interactions.
19 This aids in the early identification and resolution of
20 schedule conflicts and improves the overall efficiency and
21 safety of the final schedules.

22 Q34 How do you monitor work to control the backlog of
23 maintenance activities?

24 A34 (Vosburg) The work control system at DCPD provides the
25 means for identifying, tracking, and controlling the
26 maintenance backlog. The backlog of corrective and

1 preventive maintenance is tracked separately with specific
2 goals for each as established by management at the
3 beginning of each year, with the general intention of
4 reducing each as low as practicable. Since all
5 maintenance items at DCPD are individually tracked through
6 PIMS, status reports can be generated quite readily and
7 are available for management review.

8 Post-Maintenance Testing

9 Q35 Please describe the DCPD post-maintenance and post-
10 modification testing program.

11 A35 (Crockett, Vosburg) Post-maintenance and
12 post-modification testing ("PMT") is a key component to
13 implementation of the plant maintenance program. The
14 primary objective of PMT is to ensure that all plant
15 equipment which has undergone maintenance or modification
16 activities has been demonstrated to be fully functional or
17 operable prior to return to service.

18 Technical Specifications specifically require that
19 safety-related equipment be properly tested and any
20 associated problems resolved following maintenance or
21 modification prior to declaring the equipment operable.
22 However, PMT at DCPD is not limited to Technical
23 Specification equipment. From an overall plant safety and
24 reliability standpoint, it is a good practice to perform
25 PMT following maintenance or modification of plant
26 equipment not required by the plant Technical

1 Specifications to ensure that the equipment will fulfill
2 its design function prior to returning the equipment to
3 service.

4 Generally, PMT requirements are specified in the work
5 order and in each case will be commensurate with the
6 maintenance or modification work completed and the
7 importance of the equipment to plant safety and
8 reliability. At DCP, PMT consists of two different types
9 of testing: Maintenance or Modification Verification
10 Tests ("MVT") and Operability Verification Tests ("OVT").
11 MVTs are typically those tests, inspections, or
12 verifications which are performed by the implementing
13 organization without actually operating the equipment.
14 For example, typical MVTs would include cleanliness
15 checks, electrical continuity and megger checks, and
16 instrument loop tests. OVTs are those tests specifically
17 designed to prove Technical Specification operability.
18 OVTs usually consist of performing the appropriate
19 Technical Specification surveillance test.

20 Q36 How is PMT planned, controlled, and tracked?

21 A36 (Crockett, Vosburg) Identification and tracking of the
22 necessary testing begins with the work planner during the
23 development of the work package. Based on the scope of
24 the work, the planner must decide prior to issuing the
25 package to the field whether PMT is required and who is

1 responsible for identifying the required MVTs. Normally,
2 to determine the MVTs, the planner routes the work package
3 to the appropriate review group to identify any necessary
4 in-process inspections, parts dedication tests, and static
5 and dynamic tests specified in applicable industry codes,
6 standards and vendor manuals. These tests and inspections
7 are normally included in the work order created on PIMS.
8 OVTs are also identified and tracked by the PMT module
9 within PIMS.

10 Documented completion of the required PMT is an
11 essential component of the equipment control process used
12 by Operations when returning equipment to service. Prior
13 to returning equipment to service, Operations will verify
14 that all the work is completed and that the PMT has been
15 successfully performed.

16 In total, the process for identification and tracking
17 PMT is tied directly to the work performed and includes
18 multiple cross-checks to ensure that adequate testing is
19 accomplished.

20 Procurement of Parts

21 Q37 The next element requires that correct and qualified
22 parts be readily available to support maintenance. How is
23 this achieved at DCPD?

24 A37 (Ortore) In order to assure high reliability of
25 operation, equipment downtime must be minimized.
26 Accordingly, when a component is removed from service for

1 maintenance, it is important that any parts necessary to
2 restore or repair the component be readily available. The
3 DCPD Warehouse and parts ordering system provide a
4 comprehensive and reliable means for accomplishing this
5 goal.

6 When a work order is produced, any parts that are
7 required for the work are identified and that information
8 is electronically transmitted to the Warehouse. The parts
9 are staged for the craft foreman prior to the start of the
10 work so they are verified and ready for installation
11 before removing a system from service. The computer
12 system also orders any parts which have dropped below a
13 preset limit. The onsite warehouses together have more
14 than 200,000 square feet of storage space and contain
15 about 59,600 different items (worth about \$100 million) in
16 spare parts inventory.

17 Q38 How do you assure that replacement components and
18 parts are procured in accordance with original design
19 requirements so as to maintain the design basis?

20 A38 (Ortore) To assure that replacement parts meet
21 original design requirements, a quality assurance program,
22 together with a careful engineering review of replacement
23 parts is used. Many American manufacturers and suppliers
24 of items to the nuclear industry have 10 CFR 50, Appendix
25 B, quality assurance programs that are audited by PG&E.
26 These manufacturers become our "qualified suppliers."

1 Safety-related components or parts purchased from
2 qualified suppliers must be procured: (1) as the identical
3 item, which is an exact duplicate of the original item
4 with identical quality assurance, quality control,
5 technical and documentation requirements, and purchased
6 from the original supplier, or (2) a documented
7 engineering evaluation (called a replacement part
8 evaluation) must be performed to ensure the replacement
9 part meets or exceeds the design requirements of the
10 original component. In total, PG&E devotes considerable
11 resources -- both in engineering time and money -- to
12 assure that replacement components and parts are
13 equivalent to or better than the original.

14 Q39 How do you assure the item you ordered is the one
15 received?

16 A39 (Ortore) Receipt inspection is performed on all items
17 delivered to DCPD from the supplier. Receipt inspections
18 range from checking the model number and supplier
19 documentation against the purchase order to a more
20 detailed inspection by the Quality Control organization
21 for safety-related and graded quality items. Any item not
22 fully meeting the criteria established in the purchase
23 documents is placed on hold, thus preventing its use in
24 the plant until the discrepancy is resolved.

1 To assist in receipt inspection, DCPD has a material
2 testing lab onsite that is used to test items. Equipment
3 in the lab includes:

- 4 • a portable X-ray fluorescent spectrometer for metallic
5 material identification;
- 6 • an optical emission spectrometer for metallic material
7 identification;
- 8 • an infrared spectrometer for elastomer identification
- 9 • Rockwell hardness tester for determining metallic
10 hardness tests; and
- 11 • Other equipment, including durometers, system
12 scientific alloy analyzers, and normal lab facilities.

13 This lab is staffed with qualified quality control
14 inspectors.

15 Q40 How do you assure that the effects of age and
16 environment on stored items do not adversely affect the
17 quality of the item?

18 A40 (Ortore) All items with shelf-life considerations have
19 the shelf-life determined based on criteria from the
20 manufacturer, industry standards [EPRI NP-6408,
21 "Guidelines for Establishing, Maintaining and Extending
22 the Shelf Life Capability of Limited Life Items"
23 (NCIG-13)], or other sound engineering criteria. Material
24 that has an expired shelf life is segregated and not
25 released for issue without further documented evaluation.
26 When a new part or item is installed in the plant,

1 preventive maintenance is appropriately scheduled to take
2 into account any impact of shelf life on the design life
3 of the part or item.

4 To reduce the effects of the environment on stored
5 equipment, storage levels are established that correspond
6 to the specifications in ANSI N45.2.2, "Packaging,
7 Shipping, Receiving, Storage and Handling of Items for
8 Nuclear Power Plants." Four storage levels are
9 established, from level A through D, with the most
10 stringent controls placed on Level A. For materials that
11 are highly sensitive to environmental conditions such as
12 electrical components, the material is stored in Level A
13 storage. Level A storage provides temperature control
14 between 60 and 90 degrees and humidity control between 30
15 and 60 percent. The ventilation system is filtered to
16 provide an atmosphere free of dust. The main Warehouse at
17 DCPD has an environmental room that meets or exceeds the
18 Level A storage requirements. The remainder of the
19 Warehouse is storage level B, which is indoors with
20 temperature controls. (Storage level C is inside with no
21 temperature controls and level D is outdoors. For shelf
22 life consideration, a minimum of storage level B is used.)

23 To further reduce the effects of age and environment
24 on stored items, in-storage maintenance is performed.
25 In-storage maintenance is based on manufacturer
26 recommendations, past experience, and the significance of
27 the item to plant safety. In-storage maintenance can

1 involve visual examinations, cleanings, rotation of
2 shafts, and application of preservatives.

3 Control of Measuring and Test Equipment

4 Q41 Another aspect of maintenance is control of Measuring
5 and Test Equipment ("M&TE"). How is this addressed at
6 DCPD?

7 A41 (Giffin) A program for the control and calibration of
8 M&TE has been implemented to ensure that equipment, such
9 as test meters and torque wrenches, is functional and
10 accurate to support maintenance activities. The DCPD M&TE
11 program is described in Administrative Procedure D-5,
12 "Control of Mechanical, Electrical and Instrument &
13 Controls Measurement, Test and Performance Monitoring
14 Equipment." The DCPD M&TE program has been enhanced
15 significantly over the past several years. We have
16 invested in state of the art equipment and facilities for
17 the calibration of this special equipment. PIMS is used
18 to track and control M&TE. A highly trained and qualified
19 staff is in place to manage and support the M&TE program.
20 These elements have improved our performance in the M&TE
21 area.

22 Root Cause Analysis Program

23 Q42 Another element of maintenance is a detailed root
24 cause analysis program. How does PG&E address this
25 element especially in regard to equipment failure rates?

1 A42 (Giffin) One of the very important components of an
2 effective and comprehensive maintenance program is a
3 program which provides for a systematic analysis of
4 unplanned occurrences pertaining to maintenance. This
5 analysis is designed to identify the root cause of an
6 event. With a root cause, corrective actions can be
7 implemented so that occurrences of the same type can be
8 prevented. Root cause analysis at DCPD is controlled
9 by Procedure NPAP C-26 "Root Cause Analysis." This
10 procedure provides guidance in several analysis techniques
11 such as cause and effect analysis, event and causal
12 factors analysis, change analysis, barrier analysis, task
13 analysis, and human factors surveys. The procedure is
14 supplemented by training provided by both PG&E's Training
15 Department and outside industry experts. We have made
16 major investments in training our engineers and managers
17 in effective root cause analysis techniques as part of our
18 commitment to avoid repetitive problems.

19 Q43 How are root cause determinations made for DCPD?

20 A43 (Giffin) PG&E's root cause determinations have
21 different levels depending on the occurrence being
22 investigated. A root cause determination is required for
23 all quality problems. These are classified as either
24 Nonconformance Reports ("NCRs" - most significant) or
25 Quality Evaluation ("QEs" - less significant

1 A Technical Review Group ("TRG") performs a root cause
2 analysis for each NCR. A TRG is a multi-disciplined group
3 established for each NCR and chaired by the DCPD
4 department with the most responsibility for the issue.
5 The TRG includes representatives from Quality Assurance,
6 Quality Control, and all involved departments. Agreement
7 on the root cause must be unanimous among the TRG members.
8 Effective corrective actions are developed by the TRG only
9 after the root cause of the event is determined and agreed
10 upon. The Plant Staff Review Committee ("PSRC") reviews
11 the root cause analysis for all NCRs. If the PSRC does
12 not agree, the TRG reconvenes to resolve the differences.
13 The PSRC also reviews the corrective actions recommended
14 to ensure they are adequate to prevent recurrence.

15 A root cause determination is performed for all QEs by
16 the responsible department. Corrective actions are
17 established after the root cause is determined. Root
18 cause determinations for all QEs are reviewed by the
19 Quality Control Department.

20 Maintenance History/Failure Trending

21 Q44 What does PG&E do in the area of component maintenance
22 history and failure trending?

23 A44 (Crockett) A major component of root cause analysis
24 and component failure trending is the history of the
25 components. Currently there are approximately 187,000
26 individual components in the DCPD Component Data Base,

1 each with its own maintenance history available in PIMS.
2 The information is readily available on PIMS when a
3 problem occurs with a particular component. For example,
4 it is possible to determine the maintenance history of an
5 individual valve, or all valves with the same
6 model/manufacturer, or all valves in a system. Component
7 experience is also available from an industry wide
8 database, the Nuclear Plant Reliability Data System
9 ("NPRDS"), maintained by INPO.

10 PG&E uses component history data for two systematic
11 failure trending in several respects. First, all failures
12 of components necessary for accident mitigation or whose
13 loss of function could initiate significant plant
14 transients are reported and included in NPRDS. The
15 failure report contains extensive detail, including
16 manufacturer, model number, serial number, supplier ,
17 application, failure mode, detection method, corrective
18 actions, symptoms of failure, systems affected, narrative
19 of the failure, and cause.

20 DCPD examines every component failure report in the
21 NPRDS database that results in a major transient. If the
22 same component is used at DCPD in a similar application,
23 PG&E investigates the failure to determine if our
24 application, maintenance practices, or surveillance
25 testing assure we will not have the same transient. When
26 corrective actions are required, the normal processes are
27 used.

1 Second, DCPD design and maintenance departments
2 routinely research failure rates in components as part of
3 the design or parts replacement process. Any DCPD
4 components failing at a rate higher rate than the industry
5 average are evaluated and an appropriate evaluation is
6 initiated.

7 Third, Nuclear Safety Engineering researches component
8 failure rates using the DCPD component history. Failure
9 rates are initially screened by computer using
10 continuously upgraded evaluation techniques. Components
11 that are identified in this process are then screened by
12 engineers. This methodical evaluation process will detect
13 failure trends occurring within systems by component type,
14 manufacturer/model, and by other groupings. This is an
15 approach designed to detect any aging failure mechanisms.

*

16 V. MAINTENANCE AND EQUIPMENT AGING MANAGEMENT AT DCPD

17 Maintenance and Surveillance Programs and Activities

18 Q45 How does maintenance and surveillance at DCPD address
19 equipment aging?

20 A45 (Giffin) As described above, equipment aging
21 management is inherent in maintenance and surveillance.
22 PG&E has long recognized the benefits to be gained from
23 initiatives to identify and address the effects of
24 age-related degradation of SSCs. A commitment to aging
25 management has existed since construction at DCPD began.

1 As a result, PG&E has many mature maintenance and
2 surveillance programs and practices in place at DCPD that
3 address equipment aging.

4 Some of the more significant programs and activities
5 that assist in mitigating the effects of age-related
6 degradation include:

- 7 • The preventive maintenance program provides the
8 necessary inspection, testing, and monitoring
9 activities and periodic equipment servicing and
10 refurbishment to maintain the reliability of the
11 equipment.
- 12 • The predictive maintenance program seeks to forecast
13 the functional ability and necessary maintenance of
14 SSCs.
- 15 • The corrective maintenance program addresses the
16 repair of plant SSCs. Corrective maintenance can
17 provide valuable input to the aging management program
18 regarding potential aging effects.
- 19 • Surveillance test programs, including ISI/IST, help to
20 detect any degradation that might affect SSC
21 operability or reliability.
- 22 • Fatigue monitoring provides on-line fatigue cycle
23 monitoring of sensitive components.
- 24 • The EQ program defines qualified life and service
25 criteria for certain electrical equipment.
- 26 • A reactor vessel embrittlement management plan
27 outlines PG&E's long term strategy to assure the

1 integrity and operational life of DCP's reactor
2 vessels.

- 3 • A Motor Operated Valve ("MOV") testing and evaluation
4 program identifies and mitigates performance problems
5 with safety-related MOVs through design reviews and
6 testing activities.
- 7 • A steam generator Strategic Management Plan employs
8 inspection results, industry experience, and
9 engineering analyses to predict steam generator
10 degradation trends and recommend aging mitigation
11 strategies.
- 12 • Structural monitoring addresses the condition and
13 integrity of important plant structures.
- 14 • An erosion/corrosion program addresses the aging
15 effects of erosion/corrosion mechanisms in piping
16 systems.

17 Each of these programs or activities produce specific
18 results and corrective actions to maintain and/or restore
19 equipment to its required performance level. These
20 measures address aging effects regardless of whether the
21 aging occurred prior to or during plant operation. In
22 addition, results from these programs are used to develop
23 new or enhanced strategies to improve maintenance and
24 monitoring activities, highlight strategic issues, and
25 increase understanding of aging mechanisms to insure that
26 necessary actions are taken for mitigation.

1 Plant/Equipment Improvements to Date

2 Q46 Since plant startup, has PG&E made or planned plant
3 equipment modifications or replacements at DCPD which
4 improve reliability or reduce the likelihood of future
5 age-related degradation?

6 A46 (Giffin) Yes. A number of major plant modifications
7 designed to improve reliability or upgrade safety-related
8 equipment have been made during the eight years since DCPD
9 began operation. Several others are planned in the near
10 future. Some of the more significant modifications
11 include:

- 12 • *Copper Removal* - This project involved replacement of
13 all feedwater heaters and retubing of all moisture
14 separator reheaters. These changes resulted in the
15 removal of essentially all copper from the secondary
16 side of the plant to increase the life of the steam
17 generators.
- 18 • *Condensate Polisher Addition* - To increase the life of
19 the steam generators, a Condensate Polisher System was
20 added to process secondary water by ion-exchange.
- 21 • *Ammonium Hydroxide Storage* - To regenerate condensate
22 polisher resin, a 6,000 gallon bulk storage tank for
23 ammonium hydroxide was added.
- 24 • *SG Blowdown Rate Increase* - To improve secondary water
25 chemistry and thus increase the expected life of the
26 steam generators, the blowdown rate has been
27 increased.

- 1 • *Control Room Upgrade* - A detailed control room design
2 review ("DCRDR") was performed in accordance with the
3 requirements specified in Supplement 1 to NUREG-0737.
4 Weaknesses in the man-machine interface between
5 control room operators and equipment were identified
6 in the DCRDR. Following review and approval by the
7 NRC, control room equipment upgrades have been
8 implemented.
- 9 • *High Density Spent Fuel Pool Racks* - The original fuel
10 racks in each unit's spent fuel pool were replaced
11 with high density racks, increasing the capacity in
12 each spent fuel pool from 270 to 1324 fuel assemblies.
- 13 • *Improved Fuel Design* - The reactor fuel used in each
14 unit is being replaced with an improved VANTAGE 5
15 Westinghouse design.
- 16 • *Boron Injection Tank ("BIT") Removal* - In response to
17 industry experience and NRC recommendations, the BITs
18 in both Diablo Canyon units were removed from service
19 to reduce the potential for boric acid crystallization
20 in the Emergency Core Cooling System ("ECCS") piping
21 and valves which could potentially have degraded
22 safety-related equipment operability.
- 23 • *Reduced Boric Acid Concentration* - The boron
24 concentration in the Boric Acid System has been
25 reduced from 12 to 4 weight percent to reduce the
26 potential for boric acid crystallization in safety-
27 related components.

- 1 • *Digital Feedwater Control System* - A digital feedwater
2 control system was installed to improve feedwater
3 control performance and reliability. The enhanced
4 feedwater control features provided by this system
5 reduces the likelihood of steam generator level-
6 related reactor trips.
- 7 • *Computer Replacement* - The original plant process
8 computer was replaced with one having improved
9 man-machine interface, greater capacity, faster
10 response time, improved print and report capability,
11 improved retrieval of historical data, and complete
12 redundancy to prevent loss of information due to
13 single failure.
- 14 • *ATWS Mitigation System Actuation Circuitry ("AMSAC")* -
15 The AMSAC System was installed in both Diablo Canyon
16 units to ensure reactor protection during an
17 anticipated transient without scram ("ATWS") event
18 that results in the loss of the secondary side heat
19 sink. AMSAC is designed to trip the main turbine,
20 initiate auxiliary feedwater flow, and isolate steam
21 generator blowdown and sample lines during an ATWS
22 with a low steam generator level condition.
- 23 • *Chlorination System Modifications* - Modifications to
24 the Chlorination System include (1) the use of liquid
25 hypochlorite to control microbiofouling instead of
26 gaseous chlorine, (2) implementation of continuous
27 chlorination of the auxiliary saltwater system to
28 control macrobiofouling (invertebrate marine life),

1 and (3) possible use of intermittent injection of a
2 chlorine/bromine mixture to prevent macrofouling in
3 the Circulating Water System.

- 4 • *Fatigue Monitoring* - PG&E has installed an on-line
5 fatigue monitoring system at Diablo Canyon that will
6 continuously analyze plant operational data to track
7 fatigue usage of critical reactor coolant system
8 components.

- 9 • *Additional Diesel Generator* - Addition of a sixth
10 diesel generator will provide each unit with three
11 dedicated diesel generators. This will enhance
12 reliability of the onsite power distribution system by
13 eliminating dependence on a swing diesel generator and
14 the associated procedural complexities. Installation,
15 testing, and tie-in of the sixth diesel was completed
16 in April 1993.

- 17 • *Plant Process Protection System Upgrade* - This project
18 will upgrade the Process Protection System by
19 replacing the existing HAGEN 7100 equipment with a
20 Westinghouse Eagle 21 system. New steamline break
21 logic and steam generator low-low level trip time
22 delay options will be included in the upgrade. These
23 changes will improve the reliability and availability
24 of the Process Protection System. The digital
25 microprocessor-based system with computer-enhanced
26 testing will also minimize the likelihood of personnel
27 error during surveillance testing. System

1 installation is scheduled for the spring of 1994 for
2 Unit 1 and the fall of 1994 for Unit 2.

- 3 • *RTD Bypass Elimination* - This project will replace the
4 resistance temperature detector ("RTD") bypass loop
5 piping with fast response RTDs installed in the hot
6 and cold legs of the Reactor Coolant System. Plant
7 downtime and radiation exposures will be reduced and
8 numerous snubbers can be eliminated. Installation is
9 scheduled for the spring of 1994 for Unit 1 and the
10 fall of 1994 for Unit 2.

- 11 • *Radiation Monitoring System ("RMS") Upgrade* - This
12 project will upgrade the present RMS to improve
13 performance and reliability, and reduce required
14 maintenance. Most of the work is scheduled to be
15 completed by 1995.

16 Many of these major modifications, made subsequent to
17 the issuance of the operating licenses for DCP, P,
18 constitute upgrades in plant equipment or operating
19 systems which will help minimize the effects of
20 age-related degradation on the plant over the remainder of
21 the 40-year operating life contemplated by the license
22 amendment request.

23 Aging Management Program Directive

24 Q47 Has PG&E formalized its aging management efforts?

1 A47 (Giffin, Crockett) Yes. The overall aging management
2 program for DCPD was recently established pursuant to
3 Program Directive TS1, "Plant Aging Management." This
4 program encompasses and augments the many existing
5 programs (listed in A45 above) that address age-related
6 degradation over a 40-year operating life.

7 The DCPD aging management program collects data and
8 utilizes input from many resources to insure that PG&E
9 stays on the "cutting edge" of new developments and
10 technologies for detecting and responding to age-related
11 degradation. New research findings, industry operating
12 experience, and information from the NRC, EPRI,
13 Westinghouse, and other sources are considered for
14 inclusion in appropriate programs. A process is also
15 defined to integrate PG&E and industry experience into the
16 existing DCPD maintenance and surveillance programs.

17 A major element of this enhanced aging management
18 program involves increased emphasis on aggressive
19 participation in activities that capture new technological
20 advances and tools developed to improve nuclear plant life
21 cycle management/aging management capabilities. As a
22 result, during the first half of 1993 PG&E pursued this
23 objective through the following initiatives:

- 24 • In January 1993, PG&E joined the EPRI Life Cycle
25 Management ("LCM") subcommittee. EPRI is a recognized
26 leader in research and development activities
27 involving all aspects of the power industry. The LCM
28 subcommittee has been established as a forum to

1 develop and/or assemble state of the art technical
2 information , tools, and methodologies to assist
3 nuclear power plant licensees in optimizing plant
4 performance by identifying, evaluating, and mitigating
5 the effects of plant aging to support continued safe,
6 reliable long term nuclear plant operation.

- 7 • Acting on a PG&E initiative, the Region V Engineering
8 Manager's Forum ("EMF"), consisting of representatives
9 from Region V licensees, recently authorized the
10 establishment of an aging management subcommittee.
11 One of the primary objectives of this subcommittee is
12 to share, collaborate, and disseminate information
13 regarding issues and developments involving aging
14 management.

- 15 • In February 1993, utility owners who are members of
16 the Westinghouse Owners Group authorized an \$8
17 million, five year project to manage nuclear plant
18 life cycle management/license renewal issues facing
19 the industry. One of the primary objectives of this
20 program is to develop technical reports (based upon
21 ongoing research, technical evaluations and plant
22 experience) and other tools that guide member
23 utilities in their efforts at managing aging in
24 important plant components. PG&E has taken a
25 leadership role in this effort by serving on a core
26 project management team.

1 The above initiatives enhance the existing, ongoing
2 PG&E efforts to identify, evaluate, and implement evolving
3 aging technologies, tools, and methodologies.

4 **Q48** Are there other programs at DCPD to address
5 aging/maintenance of specific equipment?

6 **A48** (Giffin) Yes. As we stated at the outset of this
7 testimony in A7, for certain critical components subject
8 to complex aging mechanisms, or for certain components
9 with a limited life (e.g., some EQ equipment), special
10 maintenance programs have been implemented at DCPD. Some
11 of these mature programs are also listed in our response
12 A45 listing existing programs that effectively address
13 equipment aging. We will now describe a few in greater
14 detail.

15 Steam Generator Tube Degradation

16 **Q49** How does PG&E address steam generator tube
17 degradation?

18 **A49** (Giffin) At DCPD, steam generator tube degradation is
19 monitored and managed by careful chemistry control during
20 operation and by an extensive cleaning and inspection
21 program during each refueling outage.

22 During plant operation, chemistry conditions in the
23 condensate, feedwater, steam generators, makeup water, and
24 other systems are monitored and controlled in accordance

1 with the chemistry guidelines published by EPRI (PWR
2 Secondary Water Chemistry guidelines - Revision 3, May
3 1993). These guidelines reflect state-of-the-art industry
4 thinking with respect to measures for reducing corrosion
5 and for enhancing steam generator reliability.

6 During refueling outages the following techniques are
7 used for tube cleaning and inspection:

- 8 • "Sludge lancing" to remove sludge accumulated during
9 operation;
- 10 • "Pressure pulse cleaning" to aid in sludge removal in
11 the upper area of the tube bundle; and
- 12 • Eddy current inspection to assess the condition of
13 tubing (PG&E is actually inspecting by this technique
14 a much larger scope than required by applicable
15 guidelines to proactively assure detection of trends).

16 PG&E is also an active member of the EPRI Steam
17 Generator Reliability Project. Participation in this and
18 other industry groups helps keep PG&E aware of new
19 developments related to steam generators. As new
20 understanding of steam generator tube degradation emerges
21 and new processes and recommendations for mitigation of
22 age-related degradation are developed, PG&E has actively
23 pursued prompt implementation of such initiatives.

24 Examples of steam generator maintenance initiatives at
25 DCPD are heat treatment of row 1 and 2 tube U-bends and
26 "shotpeening" of all hot leg tube ends.

27 PG&E has also prepared a comprehensive Steam Generator
28 Strategic Management Plan which compares the status of

DCPP steam generator tube degradation with that of other steam generators throughout the industry and predicts performance over time. Based on the current number of so-called "defective" tubes, DCPD compares well with the industry. Tubes are defined as "defective" with degradation equal to or greater than 40 percent through wall. Defective tubes are required to be repaired by either plugging or sleeving. Unit 1, with 43 tubes (0.3 percent of total tubes) plugged, is in the 20th percentile of the industry (i.e., 80 percent of plants have higher steam generator tube degradation rates); Unit 2, with 76 tubes (0.6 percent) plugged, falls just above the 50th percentile. If this level of performance continues, we predict that less than 10 percent of the tubes in each unit would require repair before the end of life based on license recapture (i.e., 2021 for Unit 1 and 2025 for Unit 2). It is also estimated that most of these tubes could be repaired by sleeving so that the overall effect on steam generation and plant performance would be minimal.

Reactor Pressure Vessel Aging Management

Q50 How does PG&E address reactor pressure vessel embrittlement?

A50 (Giffin) PG&E has and will continue to comply with NRC regulations governing Reactor Pressure Vessel ("RPV") surveillance and integrity codified at 10 CFR 50.61 and

1 Part 50, Appendix H. The DCPD Reactor Vessel Radiation
2 Surveillance Program is designed to monitor changes in
3 material/mechanical properties of the DCPD RPVs over the
4 operating life of the plant to assure safe continued
5 operation of the vessel. DCPD's surveillance program was
6 designed to meet the requirements of ASTM E-185, "Standard
7 Practice For Conducting Surveillance Tests For Light Water
8 Cooled Nuclear Power Reactor Vessels."

9 Reactor vessel integrity is also evaluated through
10 periodic 10-year in-service inspections which are required
11 by ASME Section XI. The in-service inspections require
12 volumetric inspection of all pressure retaining welds, and
13 all full penetration nozzle welds; volumetric and surface
14 inspection of all pressure retaining dissimilar metal
15 welds and visual inspection of 25 percent of the partial
16 penetration nozzle welds external surface. The first
17 in-service inspection was successfully conducted on both
18 units during the most recent outages, with no adverse
19 findings.

20 Alternative fuel management strategies are also
21 continually being evaluated to determine the most
22 effective way to reduce reactor vessel exposure to neutron
23 irradiation. To date these strategies have resulted in two
24 fuel arrangement changes. DCPD implemented Phase 1 of the
25 fuel management strategy in the first reload of each unit
26 by incorporating a "low leakage" fuel loading pattern
27 which yielded approximately a 30 percent flux reduction
28 compared to standard loading patterns. A low leakage

1 loading pattern is achieved by loading relatively low
2 enrichment fuel assemblies which have been previously
3 burned in the preceding cycle in the core periphery to
4 reduce the number of neutrons produced near the vessel
5 wall. Phase 2 of the fuel management strategy was
6 incorporated into the cycle 3 design which targets flux
7 reduction measures in specific areas (i.e., the welds
8 adjacent to the corner baffle locations).

9 PG&E has also recently implemented a comprehensive,
10 state of the art Embrittlement Management Program which is
11 designed to manage all of the issues relating to reactor
12 vessel embrittlement.

13 Q51 Has PG&E's regulatory compliance in this area been
14 documented?

15 A51 (Giffin, Crockett) Yes. Compliance with all NRC
16 regulations governing vessel integrity has been documented
17 in PG&E's response to Generic Letter 92-01 (PG&E Letter
18 No. DCL-92-150, dated June 30, 1992). In addition, PG&E
19 has calculated the Reference Temperature for Pressurized
20 Thermal Shock ("PTS") for each weld metal and base metal
21 in the DCPD beltline region for neutron fluences
22 corresponding to 40 operating years. Since all materials
23 meet the screening criterion in 10 CFR 50.61, neither
24 additional flux reduction nor plant specific PTS analyses
25 are required to comply with the PTS rule. Details of the

PTS evaluation were submitted to the NRC in 1992 (PG&E Letter No. DCL-92-056, dated March 6, 1992).

Erosion/Corrosion

Q52 How does PG&E address piping erosion/corrosion concerns?

A52 (Crockett) The term Erosion/Corrosion ("E/C") in the context of nuclear power plants refers to the process of wall thinning in susceptible piping or other pressure boundary components caused by the flow of water or wet steam. E/C is a normal part of the plant aging process; consequently, its management is an integral part of normal maintenance at DCP. All DCP secondary-side piping systems operating above 212°F, containing single or two-phase water (but not dry steam), are susceptible to the effects of E/C and are therefore included in a DCP E/C Monitoring Program. Notably, safety-related piping which is fabricated of stainless steel is not susceptible to E/C degradation.

The rudiments of the DCP E/C Monitoring Program were established in 1983, well before commercial operation was achieved. Later, in early 1987, PG&E formed a multi-discipline E/C Task Force. The Task Force is charged with developing and maintaining a broad-based perspective on E/C monitoring at DCP. Rather than relying upon any single methodology for the prediction of E/C-susceptible locations, the Task Force has maintained a

1 defense-in-depth approach to address E/C at DCP. PG&E's
2 defense-in-depth philosophy includes monitoring E/C
3 experience through a number of industry and NRC sources.

4 The DCP E/C inspection scope incorporates
5 approximately 160 components per unit in the most recent
6 outage inspections. The most severe examples of E/C
7 degradation found at DCP are highly localized, and
8 typically occur downstream of control valves and at
9 reducing orifices in areas of extremely high fluid
10 turbulence. Piping at all such locations has been or is
11 in the process of being replaced with E/C-resistant
12 material such as stainless steel or chrome-moly steel.
13 These replacements are a permanent solution to the
14 degradation problem, as proven by continued monitoring.

15 The next-fastest wearing piping occurs in the high
16 pressure extraction steam piping exiting the high pressure
17 turbine. The majority of this piping has already been
18 replaced at DCP with stainless or chrome-moly steel as a
19 permanent solution, as proven by continued monitoring.
20 The replacement of the remainder of this piping at DCP is
21 scheduled to be completed within the next several fuel
22 cycles.

23 The DCP E/C Monitoring Program was identified as an
24 engineering strength in the 1992 NRC SALP Report. We
25 believe the E/C program is an integral part of the PG&E
26 corporate commitment to the safe, reliable operation of
27 DCP.

1 EQ Equipment

2 Q53 How does PG&E maintain the continuing qualification of
3 electrical equipment within the scope of the EQ program?

4 A53 (Ortore) As discussed earlier, each item of EQ
5 equipment has a calculated qualified life corresponding to
6 the time the equipment can operate under its normal,
7 installed operating conditions and still be considered
8 qualified for the postulated post-accident harsh
9 environment. For equipment whose qualified life is less
10 than 40 years, replacements are scheduled and made before
11 the end of the qualified life (in accordance with
12 procedure AP D-756, "Maintenance and Surveillance of
13 Electrical and I&C Environmentally Qualified (EQ)
14 Equipment").

15 PG&E considers the anticipated effects of normal
16 operating environmental conditions, including temperature,
17 corrosion, dynamic interactions and radiation exposure, in
18 the overall design of equipment utilized for
19 safety-related service at DCPD. EQ equipment in
20 particular is specified, designed, and fabricated for the
21 anticipated service conditions. Required periodic
22 inspections, tests, and surveillances provide assurance of
23 continued equipment performance within these operating
24 environments. To the extent EQ requirements dictate
25 particular maintenance requirements (e.g., to preserve
26 qualified life under normal conditions, or to simply
27 preserve qualification such as by maintaining equipment

1 seals), these requirements are incorporated into the
2 maintenance practices for the specific equipment. This
3 process is also established by AP D-756.

4 Equipment qualified lives are specifically calculated
5 based on the anticipated service environment.
6 Environmental conditions which might have adverse effects
7 on of these components are monitored by normal
8 surveillance test procedures ("STPs") and periodic
9 functional checks during routine operations and preventive
10 maintenance. For example, DCPD procedures STP I-1A,
11 "Routine Shift Checks Required by Licenses" and STP I-1B,
12 "Routine Daily Checks Required by Licenses," specifically
13 provide for the monitoring of outside and inside
14 containment temperatures, respectively. These temperature
15 measurements assure that Technical Specifications are met
16 during plant operation for containment average air
17 temperature monitoring (Technical Specification 3/4.6.1.5)
18 and for important outside containment area temperature
19 monitoring (Technical Specification 3/4.7.11). If the
20 temperature recorded during these surveillances exceeds
21 the limitations in the Technical Specifications,
22 corrective measures are taken to restore the temperature
23 within limits and an evaluation is performed by
24 engineering to identify any necessary reduction to the
25 qualified life of EQ equipment.

26 PG&E also has established a program for temperature
27 monitoring in connection with maintenance of EQ equipment.
28 Two maintenance procedures provide guidance:

1 • MP E-57.4, "Environmental Qualification Maintenance
2 and Survey of Containment Penetrations, Cable and
3 Splices": and

4 • MP E-57.8A, "Temperature Monitoring".

5 Procedure MP E-57.4 provides the necessary guidance for
6 the visual inspection and insulation resistance testing of
7 cable penetrations and splices in accordance with EQ
8 requirements. MP E-57.8A provides guidance for the
9 methods of specific device temperature monitoring to
10 obtain qualitative temperature information. In accordance
11 with these procedures, temperature indicating stickers are
12 placed on various EQ devices to identify any equipment
13 that may be exposed to temperature extremes higher than
14 previously considered for qualified life purposes. These
15 stickers identify momentary peaks and are sometimes
16 augmented by continuous temperature recording devices.
17 This program allows engineering to again consider whether
18 local conditions cause any impact on the qualified life of
19 equipment.

20 Structures

21 Q54 How does PG&E maintain plant structures?

22 A54 (Giffin) Maintenance of structures at DCPD has been
23 based upon experience and proven practices that PG&E has
24 employed over decades of operation at its generating
25 facilities. Aging of passive, long-lived structural
26 concrete and steel in particular is caused by processes

1 that are well understood and readily detected. Conditions
2 such as spalling or cracking of concrete, corrosive or
3 caustic attacks from leaks, spills or exposure to the
4 environment, mechanical damage, and rust are routinely
5 identified and reported by plant personnel (e.g.,
6 operators, firewatches, and security personnel) as they
7 move about the plant. They are investigated and
8 appropriate action taken. In addition, as noted
9 previously, at DCPD system engineers conduct periodic
10 walkdowns of their systems. During their inspections,
11 they can observe signs of structural degradation.

12 For safety-related structures, functional surveillance
13 requirements are specified in the Technical
14 Specifications. This periodic surveillance testing
15 verifies operability of these structures. For example,
16 functional integrity of the DCPD containment structures
17 must be routinely tested and documented by local and
18 integrated leak rate surveillance test procedures.
19 Containment coatings are also inspected under a special
20 program.

21 VI. ISSUES RAISED BY MOTHERS FOR PEACE

22 Q55 Are you familiar with the Supplement to Petition to
23 Intervene filed by the MFP on October 26, 1992 alleging
24 certain problems with PG&E's maintenance and surveillance
25 program for DCPD as specified in the bases for proposed
26 Contentions I and IV?

1 A55 (All) Yes.

2 Q56 Are you also familiar with MFPs Supplemental Response
3 to First and Second Sets of Interrogatories and Request
4 for Production of Documents Filed by PG&E which the MFP
5 filed on June 21, 1993, and in particular Attachment C,
6 which was MFPs unfiled "Reply to NRC and PG&E Responses to
7 Petitioner's Supplement to Petition to Intervene dated
8 December 10, 1992," relating to Contentions I and IV
9 regarding alleged deficiencies in PG&E's maintenance and
10 surveillance programs?

11 A56 (All) Yes.

12 Q57 In the original contention bases and the unfiled reply
13 of December 10, 1992, MFP has identified a number of
14 examples which they allege support their contention that
15 the DCPD maintenance and surveillance programs are not
16 sufficiently effective and comprehensive. Could you
17 comment on these assertions?

18 A57 (All) MFP in these documents has identified a number
19 of specific events at DCPD which they allege demonstrate
20 that DCPD's maintenance and surveillance programs are not
21 sufficiently effective and comprehensive. Many of these
22 events have been reported and documented in our extensive
23 process of identifying problems, thoroughly investigating
24 them, taking corrective action, and improving our

1 operations to prevent recurrence. Specific problems which
2 have been identified and discussed by MFP in support of
3 their contention which will be discussed in greater detail
4 later in this testimony, involve containment fan cooler
5 unit backdraft dampers, the positive displacement pumps
6 operating procedures, steam generator feedwater nozzle
7 indications, reactor cavity sump level indication, the
8 motor operated valve program, debris found in the
9 containment building, diesel generator turbo charger
10 bellows bolting, diesel generator fuel oil piping
11 corrosion, chemical volume and control system leakage,
12 measuring and test equipment control deficiencies,
13 emergency diesel generator surveillance test issues, fuel
14 handling building ventilation leakage, residual heat
15 removal ("RHR") recirculation sump screen deficiencies and
16 turbine governor and stop valve malfunction.

17 Q58 Can you characterize these examples in a general sense
18 and put in perspective their nature, significance and
19 relationship to the overall maintenance and surveillance
20 program?

21 A58 (All) The alleged problems are in some cases examples
22 where something has fallen short of our expectations.
23 However, these identified problems have been relatively
24 minor, had no safety significance, have been thoroughly
25 investigated and pursued, and have resulted in
26 improvements to our maintenance and operations practices.

1 In most cases, the problems are examples of how effective
2 and thorough PG&E's maintenance program has been in
3 addressing isolated errors or omissions and aggressively
4 following up to assure that we are continuously improving
5 our performance.

6 It is also important to note at the outset that the
7 number of problems identified by MFP is very small when
8 compared to the very large number of tasks and individual
9 actions which comprise our overall maintenance and
10 surveillance programs. Over the past three years, PG&E
11 estimates that there have been more than one million
12 individual tasks and activities conducted during an
13 operating cycle per unit in our maintenance and
14 surveillance program. The relatively low rate of problem
15 occurrence (e.g., reportable events, missed surveillances,
16 nonconformances) indicates a well-functioning program,
17 with an active and aggressive problem identification and
18 resolution effort. Nonetheless, it is important that even
19 a relatively small number of problems be properly
20 identified, documented, resolved, and used to improve the
21 overall effectiveness of the DCPD maintenance and
22 surveillance program. These identified problems have been
23 extensively reviewed, in accordance with DCPD's problem
24 resolution program described earlier in this testimony.
25 Root causes have been determined and measures taken to
26 prevent recurrence.

1 Q59 Can you draw any additional conclusions about the
2 specific events discussed by MFP (in the documents
3 referenced in Q56) relative to any pervasive patterns or
4 recurring events?

5 A59 (All) As we review these specific events, as well as
6 the events characterized in the problem report documents
7 referenced by the MFP, we see no pervasive or systematic
8 problems that would indicate a programmatic weakness in
9 our maintenance and surveillance programs. Rather, we see
10 random occurrences or omissions that are typical of human
11 shortcomings when engaged in a complex array of human
12 activities. In some cases, a procedure was not
13 sufficiently explicit. Other occurrences involved
14 individual inattention to detail; while still others
15 involved the exercise of judgment by an individual that
16 some activity is acceptable, when a later, more thorough,
17 review determines it to be unacceptable. We conclude that
18 these are random problems of the type that one might
19 normally anticipate to occur in the implementation of a
20 nuclear plant maintenance and surveillance program. In
21 addition, a defense-in-depth philosophy was incorporated
22 into the plant design, the plant operating program, and
23 the maintenance and surveillance programs at DCPD. This
24 includes redundant trains of safety equipment, operator
25 training to recognize and respond to problems, and
26 surveillance and maintenance to identify and correct
27 problems and potential problems. This defense-in -depth

1 assures that individual random equipment failures and
2 personnel errors will have no effect on safe operation of
3 the plant.

4 On the other hand, as we have previously stated, it is
5 extremely important that we learn from these problems,
6 investigate them and understand them fully, and
7 continuously improve our maintenance and surveillance
8 programs based on what we have learned. Each identified
9 problem has its associated corrective action, which often
10 includes improvements to procedures, training, work
11 implementation, or work control. During this evaluation
12 process, PG&E critically assesses how it conducts its
13 activities. Thus, it should not be surprising that we
14 identify mistakes and errors and use this information to
15 formulate new and/or better ways to conduct our
16 maintenance and surveillance activities.

17 Additionally, PG&E engages in a variety of
18 self-critical evaluations and assessments which are
19 designed to provide insight into and improve maintenance
20 and surveillance at DCP. This constant search for ways
21 to improve is a hallmark of PG&E's and has contributed to
22 the NRC placing DCP on the "best plants" list for the
23 past two years. Far from being an indication of
24 programmatic weakness, PG&E's documented investigation and
25 self-critical evaluation of the items cited by MFP,
26 indicates that the overall maintenance and surveillance
27 program is strong, effective and comprehensive.

1 Containment Fan Cooler Units Backdraft Dampers

2 Q60 For each of the specific events discussed by the MFP,
3 please provide a very brief description of what went wrong
4 and what was done about it. Let's begin with the
5 Containment Fan Cooler Units Backdraft Dampers.

6 A60 (Giffin) Each of the DCPD units has five Containment
7 Fan Cooler Units ("CFCUs") within the containment to
8 provide ventilation and cooling during normal operation as
9 well as postulated accident conditions. Each CFCU has a
10 backdraft damper downstream of the fan. The backdraft
11 damper is designed to close on reverse air flow and
12 prevent the fans from rotating in a reverse direction.
13 The design basis accident reverse flow could be caused by
14 higher pressure in the discharge duct resulting from a
15 postulated pipe rupture in the lower portion of the
16 containment structure.

17 The problems with the backdraft dampers discussed,
18 among other places, in NRC Inspection Report ("IR") 92-17,
19 involved loose counterweights on the dampers and the
20 incorrect assembly of certain linkages connecting the
21 damper vanes caused by inadequate maintenance practices.

22 PG&E identified and evaluated these problems and
23 determined that the CFCUs were operable in the as-found
24 condition. Accordingly, there was no safety significance
25 to the issue. The NRC found no programmatic deficiency or
26 breakdown in PG&E's maintenance program and did not take
27 any escalated enforcement action.

1 Nonetheless, because the inadequate maintenance
2 practices fell short of our expectations PG&E formed a HIT
3 team to assure adequate planning and coordination of
4 maintenance on CFCUs. Our investigations revealed several
5 areas for improvement in the maintenance and surveillance
6 of the CFCUs, including improved procedures for damper
7 linkage servicing and tightening of damper counterweights,
8 improved procedures for post-maintenance inspection and
9 testing, improved training, and additional emphasis on
10 attention to detail when working on the plant ventilation
11 systems.

12 In addition, we increased system engineering support
13 for this type of ventilation system and improved our
14 efforts in performing thorough and probing investigations
15 of problems in ventilation systems. Later, as part of our
16 increased inspection efforts on this system, small cracks
17 were found in some of the damper vanes. By the end of the
18 recent Unit 2 refueling outage, all of the damper vanes in
19 both units had been replaced with material which is less
20 susceptible to initiation of fatigue cracks.

21 Positive Displacement Pump Operating Procedures

22 Q61 Please discuss the issues raised by MFP concerning the
23 positive displacement pump operating procedures in the
24 1990-1992 period?

25 A61 (Giffin) Each of the Diablo Canyon Units has one
26 Positive Displacement (Charging) Pump (PDP) and two

1 full-capacity Centrifugal Charging Pumps ("CCPs") to
2 maintain water level in the reactor coolant system
3 pressurizer during normal operation. The CCPs have higher
4 flow capacity and are also used to inject water into the
5 primary system under certain postulated accident
6 conditions. During normal operation, it is preferable to
7 use the low flow PDP for charging. However, the industry
8 has experienced hydraulic/mechanical vibration problems
9 with this type of high pressure, low flow reciprocating
10 pump for many years. At DCP, the PDPs have required
11 relatively high maintenance, and vibrations under certain
12 operating conditions have caused pipe cracking in some of
13 the associated small diameter piping system.

14 In August 1990, the PDPs for both units were placed in
15 standby service status pending installation of in-line
16 vibration dampening devices. In the interim, the CCPs are
17 being used for this normal charging function in accordance
18 with plant operating procedures.

19 In August 1992, PG&E received two notices of violation
20 concerning the lack of appropriate procedures for
21 operation of the PDPs as a backup to the CCPs in the
22 unlikely event of a fire in the centrifugal charging pump
23 room. Our own investigation concluded that there was a
24 weakness in our procedures for using the PDPs as a backup
25 under this postulated fire situation. However, neither
26 the NOV nor our own evaluation found any deficiency in
27 maintenance or surveillance of the PDPs. In fact, the
28 problems related to a lack of clear procedural guidance

1 provided by engineering and operations to the operating
2 staff on use of the PDPs in response to a postulated fire
3 involving both centrifugal charging pumps. Simply stated,
4 this deficiency was not a maintenance-related issue.

5 The operators' procedures and instructions were
6 clarified to better define the standby status of the PDPs
7 pending the installation of the in-line vibration
8 dampening equipment.

9 There was no safety significance due to placing the
10 PDP in the backup mode while the vibration problem was
11 investigated because the combustible loading in the area
12 was limited, smoke detection and the wet-pipe sprinkler
13 system were available, and an hourly fire watch was in
14 place in the CCP rooms.

15 Steam Generator Feedwater Nozzle Indications

16 Q62 Could you address the MFP reference to indications of
17 steam generator feedwater nozzle cracks in Unit 1 in 1992?

18 A62 (Crockett) The steam generator feedwater nozzle is a
19 20-inch diameter piping connection through which feedwater
20 flows into each steam generator. These nozzles and the
21 immediate upstream piping are susceptible to interior
22 surface cracking as found at other nuclear power plants.
23 This surface cracking results from nozzle metal
24 temperature difference caused by certain relatively
25 infrequent operating flow conditions during which cold
26 water is flowing into the steam generator through a hot

1 nozzle. During a visit to another nuclear plant, a PG&E
2 engineer observed a problem the plant had with feedwater
3 nozzle cracking. When the engineer returned to DCP, he
4 recommended that as a prudent measure, inspections for
5 similar cracking be performed at DCP at the next
6 scheduled refueling outage. As a result, during the fifth
7 refueling outage for Unit 1, in September 1992, an
8 ultrasonic inspection was performed which indicated some
9 surface cracking indications in the steam generator
10 feedwater nozzle connection welds at DCP.

11 Based on these findings, a short piping section and
12 the pipe-to-nozzle weld were replaced on all four steam
13 generators in DCP Unit 1. Later metallurgical
14 investigations of the removed pipe and weld material,
15 using sophisticated detection techniques, determined that
16 the actual interior surface cracking was significantly
17 smaller than indicated by the original ultrasonic
18 evaluation. The ASME code allows such small surface
19 cracking and, thus, we could have actually continued
20 operation without repair. Our crack growth projection
21 calculations demonstrated that crack growth would not have
22 exceeded code allowables for at least another full cycle
23 of operation.

24 Surface crack depth was determined to have been
25 acceptable during the previous cycle operation, and
26 repairs were not required for safety or code compliance
27 reasons. Thus, there was no safety significance to this
28 issue.

1 Nonetheless, to minimize future potential problems in
2 this area, a design change is being developed to install a
3 thermal sleeve device inside the pipe and nozzle
4 connection to prevent contact between cold feedwater and
5 the hot nozzle connection at this location during the
6 relatively infrequent operating conditions of high
7 temperature differential. In retrospect, this is an
8 excellent example of the proper functioning of the DCPD
9 maintenance and surveillance program, especially in
10 assimilating industry experience and proactively
11 initiating repairs even where existing standards do not
12 require such repairs.

13 Reactor Cavity Sump Level Indication

14 Q63 MFP has raised a question regarding alleged inadequate
15 corrective action involving the Reactor Cavity Sump Pump
16 Level Indication system. Could you address this question?

17 A63 (Vosburg, Crockett) On November 6, 1990, it was
18 discovered that both Wide Range Reactor Cavity Sump Level
19 instrumentation channels were inoperable. Investigative
20 actions subsequently determined that the instruments had
21 been inoperable since August 21st of that year. The cause
22 for the failure of one of the indicators was due to a
23 blown fuse. However, due to the intermittent nature of
24 the failure, our extensive investigation could not
25 determine the exact cause for the failure of the other

1 channel. A suspect component was replaced and the
2 instrument was tested and returned to service.

3 The delay in recognizing these failures was due to the
4 fact that the instrumentation normally indicates zero
5 percent sump level and the indicators had "failed low",
6 thus giving approximately the same indication. Sump level
7 is also displayed on the Safety Parameter Display System
8 ("SPDS") which provides the plant operators with certain
9 safety-related information. The SPDS provides an
10 indication when questionable input values are detected.
11 As a corrective action for this event, training was given
12 to operations and maintenance personnel on interpreting
13 the SPDS displays with respect to failed channel
14 indications.

15 On October 22, 1991, another intermittent failure
16 occurred in one of the two sump level indicators and
17 investigation determined that the indicator had been out
18 of service for approximately eight days. Again, the root
19 cause for the instrument failure could not be found. After
20 replacing the instrument and much of the interconnecting
21 cable, the problem was resolved. The sump level
22 instrumentation has operated normally since that time.

23 Since the failed instrument had been inoperable for
24 approximately eight days prior to discovery, the
25 effectiveness of the initial corrective action was
26 reexamined. Additional corrective measures were taken to
27 revise STP I-1B, "Routine Daily Checks Required By
28 Licenses", to include a step for a member of the

1 Operations staff to check the SPDS display each ^{day} shift.
2 The STP now includes specific guidance with respect to
3 SPDS indications of a questionable instrument channel and
4 actions to be taken when channel problems are identified.
5 As further corrective action, PG&E has reviewed all SPDS
6 and control room indicators where a similar instrument
7 failure might be difficult to detect from the control room
8 and improved the procedure to cover these additional
9 control room indicators.

10 This event is not indicative of a programmatic
11 breakdown in the maintenance program. In each case,
12 extensive investigative effort was expended to determine
13 the specific cause of the instrument failures. However,
14 in some cases involving intermittent failures it can be
15 extremely difficult to pinpoint the exact cause for an
16 equipment failure. The most likely causes of the problem
17 are addressed, the equipment tested and/or replaced, and
18 returned to service under increased surveillance. In this
19 case, the initial actions taken to improve the capability
20 to identify a degraded channel were not effective. When
21 this was recognized, more comprehensive actions were taken
22 to replace the faulty equipment and assure that any
23 possible failures in the future would be promptly
24 detected.

1 Motor Operated Valves

2 Q64 MFP has identified DCP's response to Generic Letter
3 89-10, regarding motor operated valves, as being
4 deficient. Could you discuss this issue and DCP's
5 response?

6 A64 (Ortore) An extensive MOV testing program is being
7 implemented throughout the industry in response to NRC
8 Generic Letter 89-10. In their Supplemental Petition, MFP
9 refers to NRC Inspection Report 91-39, dated January 24,
10 1992, which identified certain weaknesses in PG&E's MOV
11 testing program involving calculation methodology,
12 selection criteria, verification parameters and trending.

13 MFP's reading of the inspection report is out of
14 context. Notably, the NRC inspection report in fact
15 concluded that PG&E appeared to be developing an
16 "aggressive" and comprehensive Generic Letter 89-10
17 program. No deviations or violations of NRC requirements
18 were found. The NRC inspection report comments regarding
19 "weaknesses" are typical of NRC inspection activities in
20 areas of development and improvement. The inspection
21 report also commented that our MOV program was proceeding
22 satisfactorily. Their comments and concerns were
23 evaluated by PG&E and our program has been adjusted in
24 specific areas to make further improvements.

25 PG&E believes that it has a good MOV program. PG&E is
26 monitoring the development of the industry's response

1 through its participation on industry groups and
2 committees. Again, nothing in the NRC IR cited by MFP
3 supports the conclusion that this aspect of DCP's
4 maintenance and surveillance program is deficient.

5 Debris Found in Containment Building

6 Q65 MFP has stated that DCP had a problem with debris in
7 the containment building. Could you discuss this issue?

8 A65 (Crockett) The RHR recirculation sump in each
9 containment building provides a collection point for water
10 during a postulated accident, so that the water can be
11 recirculated, cooled and returned to the system for
12 accident mitigation. Housekeeping inside the containment
13 building should assure that no loose debris (rags, papers,
14 clothing, plastics, etc.) can be transported to the
15 containment sump.

16 In October 1991, near the end of the Unit 2 fourth
17 refueling outage, certain debris was found in the
18 containment building during a PG&E Quality Control
19 surveillance. The debris included a small plastic bag,
20 some wipealls, a tool bag, a water jug and a tool bin. An
21 engineering evaluation demonstrated that this small amount
22 of debris would not have impacted the operability of the
23 safety systems and, therefore, it did not represent a
24 safety concern. Later, during the Unit 1 fifth refueling
25 outage, although there was overall improvement, some
26 further problems with control of debris were noted.

1 These problems with control of debris in the
2 containment building caused PG&E to recognize that the
3 program in effect to control material and housekeeping in
4 containment during outages needed to be reorganized and
5 strengthened to clarify responsibility for housekeeping
6 and control of loose debris.

7 Corrective action has included the logging of
8 all personnel in and out of containment at key times,
9 logging and inspection of all jobs in progress every
10 shift, periodic containment walkdowns, and a
11 documented tailboard explaining the importance of
12 housekeeping rules for all workers allowed in containment.
13 The containment coordinator is now responsible for
14 performing a housekeeping inspection of the accessible
15 work areas of the containment during each shift to verify
16 maintenance of housekeeping standards. PG&E believes that
17 these corrective actions will prevent recurrence.

18 Diesel Generator Turbo Charger Bellows Bolting

19 Q66 Could you discuss the problem with DCP's expansion
20 bellows during pre-operational installation of the new
21 sixth emergency diesel generator?

22 A66 (Vosburg) An expansion bellows is used on the turbo
23 charger for each emergency diesel generator to connect the
24 turbo charger to the exhaust piping. The issue cited by
25 MFP and addressed in NRC IR 92-14 (June 5, 1992) involved
26 insufficient written instructions for installing the lower

1 flange connecting the expansion bellows to the turbo
2 charger during pre-startup installation of the new sixth
3 diesel generator. The installation engineer verified the
4 correct bolting and gasket material to be used, and the
5 installation was completed. However, this action was not
6 documented in accordance with DCPD procedures. Because
7 the work was completed properly, the documentation
8 deficiency had no safety significance.

9 This issue was not a maintenance or surveillance
10 problem. It occurred during the installation of the new
11 sixth diesel generator during the construction phase. At
12 the time, the sixth diesel generator had not been turned
13 over to the plant, and was not yet part of the plant's
14 safety systems. The deficiency in documentation was
15 corrected and the level of attention to such documentation
16 was improved on the sixth diesel generator project.

17 Diesel Generator Fuel Oil Piping Corrosion

18 Q67 Could you discuss the corrosion problem discovered by
19 PG&E involving the diesel generator fuel piping?

20 A67 (Crockett) The diesel generator fuel oil system is
21 used to transfer fuel oil from underground storage tanks
22 to the emergency diesel generators. This small diameter
23 piping runs below ground in concrete trenches, on the
24 seaward side of the turbine building and within the
25 turbine building buttress area. The piping was installed
26 in the 1970s and has experienced corrosion on its external

1 surfaces from the salt air environment. Over time, this
2 environment corroded the piping's exterior surface in
3 areas where the external coating on the piping had not
4 been fully effective in preventing corrosion.

5 This problem, identified by PG&E in voluntary Licensee
6 Event Report 1-92-006, was discovered during a PG&E
7 inspection. Certain local repairs were made in the highly
8 corroded areas. PG&E determined that the system's
9 operability was not compromised even in the degraded
10 condition. However, based on the general conditions of
11 the piping and the environment in the trench area, it has
12 been decided to replace the entire length of piping and to
13 use improved coating techniques in the new installation.

14 Accordingly, this issue - identified and corrected by
15 PG&E - does nothing to support MFP's contention. This
16 type of problem and its resolution illustrates how the
17 DCPM maintenance and surveillance program functioned
18 properly to find the deteriorating piping and then to
19 replace the piping with upgraded design materials or
20 construction techniques.

21 Chemical and Volume Control System Leakage

22 Q68 Describe the chemical and volume control system
23 leakage issue raised by MFP regarding valve diaphragm
24 degradation.

25 A68 (Giffin) During normal plant operation, the primary
26 function of the Chemical and Volume Control System

1 ("CVCS") is to maintain reactor coolant system inventory.
2 Parts of the system are heat-traced to keep concentrated
3 boric acid in solution. During a postulated accident,
4 portions of the system are used to recirculate and supply
5 water to mitigate the accident.

6 In June 1992, during a routine radiation survey,
7 leakage was noted from a CVCS valve bonnet in a
8 heat-traced portion of the system. This leakage was
9 determined to be outside the design basis for CVCS
10 leakage. The leak was immediately stopped by tightening
11 the valve body-to-bonnet nuts. The issue was identified
12 by PG&E and reported in LER 1-92-009, Revision 1, dated
13 January 11, 1993.

14 Our investigation revealed that the cause of the
15 leakage was thermal degradation of the valve diaphragm due
16 to a malfunctioning heat trace thermostat causing leakage
17 through the body-to-bonnet joint. Corrective actions
18 included lowering the heat trace temperature for the
19 valve, reviewing every other valve in similar service in
20 Units 1 and 2 to verify there were no other potential
21 problems, reviewing the entire heat trace system for
22 proper setpoints and installation, and improving our
23 surveillance monitoring program.

24 A similar leak occurred in September 1991 due to a
25 different root cause. In that instance, valve
26 body-to-bonnet leakage was caused by an isolated case of
27 the valve vendor recommendations (concerning bonnet nut
28 torque and diaphragm replacement) not being adequately

1 included in the preventive maintenance program. The
2 preventive maintenance program was reviewed and upgraded
3 to address this issue. No similar problems were found.

4 The analysis of the as-found leakage in both events
5 determined these events were not safety significant or
6 programmatic.

7 Measuring and Test Equipment Control Deficiencies

8 Q69 Describe DCP's response to measurement and test
9 equipment control deficiencies identified in 1991.

10 (Giffin) An NRC inspection during February 1991 found
11 deficiencies in the control of Measuring and Test
12 Equipment ("M&TE") administered by the Mechanical
13 Maintenance ("MM") Department at DCP. This inspection
14 also found that PG&E's own Quality Control ("QC") and
15 Quality Assurance ("QA") Departments had previously
16 audited the MM M&TE program and found similar deficiencies
17 which had not been aggressively corrected.

18 The identified deficiencies were reviewed in detail to
19 determine the potential impact on plant equipment. The
20 deficiencies involved calibration or use of torque
21 wrenches and mechanical gauging devices. The application
22 of the torque wrenches and gauging devices was found to
23 have no effect on the plant equipment. The overall
24 maintenance program controls for safety-related work
25 (e.g., detailed work orders, post-maintenance operability

1 testing, etc.) were found to be adequate. Therefore,
2 there was no safety significance to these deficiencies.

3 The corrective action for the deficiencies in the MM
4 M&TE program included accelerating a previous management
5 decision to transfer and consolidate all responsibility
6 for MM M&TE equipment to the Instrument and Controls (I&C)
7 Department M&TE program -- a program which was, and is,
8 working effectively. Prior to the NRC inspection, PG&E
9 had initiated a QA audit to verify and supplement
10 information on the deficiencies found by PG&E's QC
11 organization, but had not yet implemented improvement in a
12 timely manner. Additional corrective action included
13 improvement in the quality resolution process, better
14 definition of management expectations concerning the
15 resolution of quality audits, and improved training on
16 M&TE requirements.

17 Emergency Diesel Generator Surveillance Test Issues

18 Q70 In their reply to PG&E's response to the proposed
19 contention, MFP supplements the original basis of the
20 proposed contention by citing "weaknesses" stated by the
21 NRC in IR 92-01. The MFP state that these "weaknesses"
22 challenge the maintenance and surveillance program. What
23 is your reaction to this issue.

24 A70 (Crockett) During 1991, the NRC performed an extensive
25 functional inspection on Diablo Canyon's electrical
26 distribution system. The NRC issued IR 92-01 as a result

of this inspection. The specific "weaknesses" which were described on page 1 of this NRC report and discussed by MFP were attributed by the NRC to the Engineering Department. These weaknesses were not relevant to DCP's maintenance and surveillance programs. Two Severity Level IV NOVs were issued but they were separate and apart from the NRC "weaknesses" discussed by MFP. Both NOVs related to specific surveillance procedures which have been corrected. The overall conclusion of the inspection was that DCP's electrical systems were acceptable, no immediate safety or operability concerns were identified, and no broad scope programmatic breakdowns were noted.

Fuel Handling Building Ventilation Leakage

Q71 Describe the DCP fuel handling building ventilation leakage issue raised by MFP's Contention IV (age-related degradation).

A71 (Crockett) The Fuel Handling Building ("FHB") ventilation system for each unit is designed to maintain a slight negative pressure inside the building. This design is accomplished by removing more air (with the exhaust fans) than what is supplied to the FHB (by the supply fan). Thus, air leakages will be inward and all potential releases from the spent fuel pool are exhausted through filters. This functional capability is required to be verified by a surveillance test procedure every 18 months. On September 1989, this surveillance was performed and

1 fully met the specific requirements for negative
2 pressures. The next required test was performed on
3 January 18, 1992. Although the measured pressure was
4 negative, it did not meet the specific operability
5 requirement. PG&E conservatively assumed that the FHB
6 ventilation system was inoperable at the time of fuel
7 movement during the Unit 1 third refueling outage in
8 October 1989. Prompt action was initiated in accordance
9 with our problem resolution procedure to investigate the
10 situation, determine a root cause and implement corrective
11 action.

12 Our investigation determined that the cause of system
13 inoperability was the existence of small leakage paths
14 into the building due to building and seal degradation.
15 Corrective action included sealing the leaks. Both FHBs
16 have also been re-sided. The new siding is the best
17 available on the market with an expected life of greater
18 than 25 years.

19 Analysis of the event showed that because of
20 conservatism in the ventilation system design, sufficient
21 negative pressure was maintained at the surface of the
22 spent fuel pool throughout the event and there was no
23 safety significance.

24 RHR Recirculation Sump Screens

25 Q72 MFP has stated that DCPD had a problem with gaps in
26 the containment building recirculation sump screens and
27 debris inside the sumps. Could you discuss these issues?

1 A72 (Crockett) Yes. RHR recirculation sumps are
2 surrounded by debris screens. In February 1990, the NRC
3 issued Enforcement Action 89-241 citing PG&E for three
4 violations related to the RHR recirculation sump screens.
5 One of the violations involved inadequate engineering and
6 construction completion, which resulted in unacceptable
7 gaps in the screen structure. The second involved
8 operational control that allowed an unattended open access
9 hatch in the screens. Neither of these two violations
10 bears any relation to maintenance or surveillance. Both
11 were corrected. The third violation included a reference
12 to poor performance of a visual surveillance of the sumps,
13 which resulted in unidentified debris remaining in the
14 sumps. This deficiency was an isolated personnel error --
15 an individual failed to implement an otherwise clear
16 procedure. This does not indicate a program problem. As
17 a corrective action, PG&E clarified requirements for
18 inspection of the sumps.

19 Turbine Governor and Stop Valve Malfunction

20 Q73 Describe the DCPD turbine governor and stop valve
21 malfunction cited by MFP.

22 A73 (Vosburg) The main turbine speed is controlled by four
23 governor valves ("GVs") during startup, operation and
24 shutdown. Four additional stop valves ("SVs"), located in
25 line with the GV's, are used to trip and isolate the
26 turbine during overspeed and other conditions. All eight

1 valves are controlled by an electro-hydraulic ("EH")
2 system.

3 In September 1992 during a Unit 1 shutdown,
4 simultaneous circumstances occurred which resulted in a
5 steam flow path being created through the SVs and GVs
6 after the turbine had been tripped, thereby causing the
7 turbine to accelerate. The operators controlling the
8 evolution immediately tripped the turbine. No reactor or
9 turbine limits were exceeded.

10 Our investigation into this event found the cause to
11 be a combination of factors, including a sticking pressure
12 switch, low EH system pressure and steam leakage.
13 Corrective actions included replacing and upgrading the
14 pressure switch, correcting several conditions in the EH
15 system and revising our shutdown procedures to add
16 additional verification of EH system control parameters
17 during turbine shutdown.

18 Two other previous related events merit discussion.
19 In August 1991, a problem with the Unit 2 turbine control
20 system resulted in a spurious GV opening. Rigorous
21 investigative testing could not determine the root cause.
22 The problem was intermittent and could not be reproduced.
23 The most likely cause was thought to be a sticking
24 pressure switch, similar to the switch which contributed
25 to the September 1992 Unit 1 event. The switch was
26 replaced. In March 1992, a spurious SV opening occurred
27 on Unit 1 due to suspected steam leakage. The SVs were

1 operable and, therefore, no corrective action was
2 necessary.

3 PG&E believes that its investigation and corrective
4 actions for these two events were comprehensive and
5 thorough. In retrospect, operations personnel should have
6 implemented more positive interim compensatory action
7 (such as changes to the operating procedure or additional
8 training) which may have prevented the third, September
9 1992, event. As part of our corrective action for the
10 third event we upgraded our use of interim compensatory
11 measures.

12 No operating limits were exceeded during any of the
13 three events. This equipment is not safety-related. None
14 of the events was safety significant.

15 4kV/12kV Cable Problems

16 Q74 MFP has raised an issue regarding maintenance of the
17 4kV and 12kV underground cables between the turbine
18 building and the intake structure. Please discuss the
19 recent problems experienced by DCPD involving these
20 cables.

21 A74 (Ortore) DCPD has experienced three failures of 4kV
22 cables -- two safety-related and one nonsafety-related.
23 Two of these failures were random in nature and time of
24 occurrence. One of the failures was detected by PG&E
25 during post-maintenance High-Potential ("Hi-Pot") testing.
26 Additionally, there were two area-specific failures of

1 non-safety 12kV cables. Both types of cable are contained
2 in conduits located in underground duct banks routed
3 between the turbine building and the intake structure.
4 The safety-related and non-safety related 4kV cables
5 supply electrical power to safety related cooling water
6 pumps and a non-safety related load center transformer,
7 respectively. The nonsafety-related 12kV cables supply
8 electrical power to the main circulating water pumps.

9 The failures which occurred in the 12kV
10 nonsafety-related cables were caused by exposure to a
11 contaminant which was present in the underground conduits
12 in a localized area between the turbine building and the
13 intake structure and which caused severe cable jacket and
14 insulation degradation. Both of these failures were
15 detected with the ground detection system, allowing
16 operator action to isolate the cable before complete
17 failure of the cable.

18 Neither of the two safety-related 4kV cable problems
19 involved actual in-service failures. One involved a
20 momentary alarm indication signaling a potential ground
21 fault. When this occurred, the redundant cooling water
22 pump was started and the cable with the potential fault
23 was isolated. The second case occurred during routine
24 "Hi-Pot" testing while the cable was out of service during
25 a refueling outage. One of the two safety-related 4kV
26 cables was in a location remote from the more recent 12kV
27 cable failures. Moreover, the 4kV cable jackets did not
28 exhibit any physical degradation as did the 12kV cable

1 jacket. These differences would suggest that there was no
2 imminent common-mode cable failure mechanism involved with
3 these occurrences .

4 After failures occurred to the 4kV and 12kV cables,
5 the failed cable sections were replaced. Reviews of the
6 original design, installation, quality assurance and/or
7 quality control audits for the failed cables were
8 conducted. These reviews have concluded that the installed
9 cables are of acceptable quality and design for their
10 specific applications and service conditions (wet or dry).
11 However, as a prudent measure, additional sections of
12 unfailed 4kV and 12kV cables have been replaced.

13 A contributory cause of the 12kV failures was believed
14 to be water carrying contaminants into the cable conduits.
15 While sump pumps are provided in the vaults, they were not
16 at that time part of the formal maintenance program and,
17 accordingly, were not maintained in an adequate manner.
18 After rains, the vaults would fill with water and flood
19 the conduits. The sump pumps have been repaired and are
20 now included in our preventive maintenance program.

21 PG&E believes that the maintenance activities with
22 regard to these underground cables are adequate,
23 particularly given the installations involved. To the
24 extent our continuing analysis of these issues suggests
25 the need for further maintenance activities, they will be
26 included in our program.

1 Q75 Are there other issues raised by the MFP in their
2 supplemental filing of December 10, 1992 regarding
3 Contention I, that were not maintenance and surveillance
4 issues? If yes, would you please comment on them.

5 A75 (Giffin) Yes, there are several issues raised by the
6 MFP in the document that are not maintenance issues. The
7 major issues are as follows:

- 8 • CCW, AFW, and Fuel Oil Transfer Pump Vault Drain (NRC
9 Enforcement Action 89-85, May 5, 1989)
 - 10 - These problems involved design or design basis
11 issues, not the maintenance and surveillance
12 programs. They were corrected by revisions to
13 operating procedures, reclassification of
14 equipment, or upgrading design basis
15 documentation.
- 16 • Feedwater Pump - Control System Power Supply Failure
17 (Management Meeting of April 2, 1992).
 - 18 - This problem was a design issue involving a
19 particular electrical circuit design for redundant
20 power supplies, and it was not a maintenance or
21 surveillance issue. A complete reassessment of
22 this design to enhance the capability to withstand
23 local component failures was performed and
24 modifications to the electrical circuit were
25 implemented.

1 • Residual Heat Removal ("RHR") System Operational
2 Problems (NRC Enforcement Action 87-131, dated
3 August 7, 1987 and NRC NUREG 1269, "Loss of
4 Residual Heat Removal System, Diablo Canyon Unit
5 2")

6 - The loss of RHR occurred during mid-loop
7 operating conditions. The causes of this
8 event were related to inadequate control of
9 system operation during this infrequent and
10 abnormal operating condition. The event
11 resulted in extensive investigative and
12 corrective action. The enforcement action
13 cited deficiencies in the operating procedure
14 control, the quality control inspection, and a
15 safety evaluation. These were not maintenance
16 or surveillance issues. Corrective actions
17 included several operating procedure changes,
18 upgrading of operator training, and
19 improvement of the temporary level indicating
20 systems used during refueling outages.

21 In summary, none of these matters related to any
22 programmatic deficiency or breakdown in DCCP's maintenance
23 or surveillance programs.

24 VII. CONCLUSION

25 Q76 Do any of the problems cited by MFP and described
26 above indicate a pervasive concern relative to lack of

1 timeliness in resolution of problems or a lack of proper
2 attention?

3 A76 (Giffin) No. In the vast majority of cases we
4 consider our response to have been timely. In applying
5 resources to address issues, we consider safety
6 significance, operational necessity, and the time it takes
7 to perform a comprehensive assessment of the issue. For
8 the kinds of issues identified by MFP, we believe that
9 thorough investigation and thoughtful corrective action
10 are very important aspects. We also believe that we have
11 emphasized the need for thorough responses, and that the
12 extensiveness of our corrective actions reflects our
13 desire to promote significant improvements to our
14 maintenance and surveillance program.

15 Q77 Do these issues of events indicate a programmatic
16 deficiency or breakdown in PG&E's maintenance and
17 surveillance programs at DCPD? Why or why not?

18 A77 (Giffin) No. The issues or events described above do
19 not in any way represent a programmatic deficiency or
20 programmatic breakdown in PG&E's maintenance and
21 surveillance programs at DCPD. These issues or events
22 represent a relatively few random and isolated occurrences
23 that are inevitable in any large and complex program of
24 human activities. They are not concentrated in any one
25 aspect of the program. Rather, they have involved

1 different equipment, systems, procedures, locations, or
2 operating conditions. Furthermore, they have occurred at
3 random times and in a random manner, without a particular
4 pattern relating to organization staffing or supervision.

5 Moreover, I want to re-emphasize that the
6 maintenance-related problems that have occurred at DCPD
7 represent only a small number of occurrences relative to
8 the very large number of maintenance activities,
9 surveillances, and individual steps in maintenance work
10 orders. We perform more than a million individual
11 maintenance and surveillance tasks and activities at each
12 unit during each refueling cycle. These problems and
13 issues have been aggressively handled and thoroughly
14 documented in a clear, self-critical manner.

15 Q78 Are you aware of events or documents, other than those
16 cited by MFP as a basis for Contention I and discussed
17 above, that relate to maintenance and surveillance at
18 DCPD?

19 A78 (Giffin) Yes. Based on information provided to MFP by
20 PG&E during discovery in this case, MFP has identified
21 other documents which it intends to rely upon in this
22 proceeding. Some of these relate to plant maintenance and
23 surveillance activities.

24 Q79 How would you characterize these documents?

1 A79 (Giffin) These documents generally are part of our normal
2 processes. As we have discussed elsewhere in this
3 testimony, when issues or problems are identified at the
4 plant, they are documented and thoroughly investigated to
5 prevent recurrence. A process is in place to track these
6 matters to resolution. We believe that a program of
7 aggressively finding and documenting problems, thoroughly
8 investigating them, and continually improving our
9 operations is essential to a complete and comprehensive
10 approach to plant maintenance.

11 In addition, as a means to foster continuous
12 improvement, we do perform from time to time candid self
13 assessments of our programs. In this context, the
14 existence of deficiency reports, critical
15 self-assessments, and the like are not evidence of a
16 faulty maintenance program. Rather, they evidence a
17 properly functioning program.

18 Q80 Does this conclude your testimony?

19 A80 (Crockett, Ortore, Vosburg) Yes.

NUCLEAR REGULATORY COMMISSION

BEFORE THE ATOMIC SAFETY AND LICENSING BOARD

In the Matter of:)	Docket Nos. 50-275-OLA
)	50-323-OLA
Pacific Gas and Electric Company)	
)	(Construction Period
(Diablo Canyon Nuclear Power)	Recovery)
Plant, Units 1 and 2))	

TESTIMONY OF TEDD A. DILLARD ON BEHALF OF
PACIFIC GAS AND ELECTRIC COMPANY
ADDRESSING CONTENTION I: MAINTENANCE AND SURVEILLANCE

Q1 Please state your name, affiliation, and current
job responsibilities.

A1 My name is Tedd Dillard. I am the Supervisor of
Component Programs for the Nuclear Division of Florida
Power & Light Company ("FPL"). I was the Manager of
Maintenance at the St. Lucie Nuclear Power Plant from
May 1983 until November 1988. Prior to that, I was the
Mechanical Maintenance department head at St. Lucie for
eight years. My current responsibilities include
supervising the efforts of a group of engineers
responsible for the FPL Nuclear Division's technical
expertise for major plant components at both FPL
nuclear facilities. I am also responsible for
developing FPL's implementation plan for the
Maintenance Rule, 10 CFR 50.65.

1 Q2 What other qualifications do you have in the area
2 of nuclear power plant maintenance?

3 A2 In addition to my maintenance experience at FPL, I
4 have had an opportunity during the past six years to
5 visit a number of nuclear power plants and participate
6 in several industry maintenance assessment efforts. I
7 was corporate evaluator on an Institute of Nuclear
8 Power Operations ("INPO") maintenance assistance review
9 team evaluation of our Turkey Point Plant. I was a
10 peer evaluator on an INPO maintenance assistance review
11 team at the Ft. Calhoun Nuclear Plant. I was a member
12 of one of several teams who visited the Mihama Nuclear
13 Plant of Kansai Electric Company in Japan in
14 conjunction with our quality improvement efforts. I
15 served on the Nuclear Management and Resources Council
16 ("NUMARC") Ad Hoc Committee that developed the industry
17 response to the proposed Nuclear Regulatory Commission
18 ("NRC") Maintenance Rule. I also served on one of four
19 committees that developed the implementation guidance
20 document for NUMARC that the NRC has endorsed with the
21 regulatory guide for the NRC Maintenance Rule.

22 I have more than 23 years of experience in United
23 States commercial nuclear power plants, the last 20 of
24 which has been with FPL.

25 A copy of my professional qualifications is
26 provided in Exhibit 12.

1 Q3 What contention will you address?

2 A3 I will address San Luis Obispo Mothers for Peace
3 ("MFP") Contention I, which is:

4 "The San Luis Obispo Mothers for Peace contends
5 that Pacific Gas & Electric Company's (PG&E)
6 proposal to extend the life of the Diablo Canyon
7 Nuclear Power Plant for more than 13 years (Unit
8 1) and almost 15 years (Unit 2) should be denied
9 because PG&E lacks a sufficiently effective and
10 comprehensive surveillance and maintenance
11 program."

12 Q4 What is the purpose of your testimony?

13 A4 The purpose of my testimony is to provide my
14 opinion as to whether PG&E has implemented a
15 comprehensive and effective maintenance program at the
16 Diablo Canyon Nuclear Power Plant ("Diablo Canyon").
17 PG&E specifically requested that I visit Diablo Canyon
18 and review the maintenance program, procedures, and
19 program implementation at the plant in light of my
20 experience with maintenance at St. Lucie and in
21 observing and evaluating other nuclear power plants.
22 It is my understanding that PG&E solicited my views, in
23 part, based on the fact that St. Lucie has been given
24 Category 1 ratings by the NRC in the maintenance area
25 in Systematic Assessment of Licensee Performance
26 ("SALP") evaluations. St. Lucie is also one of the
27 plants singled out by the NRC for distinction on its
28 "Best Plants" list.

1 Q5 What were your overall impressions of the Diablo
2 Canyon maintenance program?

3 A5 Based on my review of the program and procedures,
4 my interviews with maintenance personnel, and my visit
5 to the plant, it appears to me that PG&E has
6 implemented a comprehensive and effective program. I
7 observed no significant weaknesses. In the time
8 available to me, I did not, of course, review all
9 details of the program. However, I should add also --
10 and I will spell this out in more detail below -- that
11 based on my experience, I believe I can spot quite
12 readily a well-maintained plant or a poorly-maintained
13 plant based on some important indicators. Diablo
14 Canyon appeared to me to be very well maintained by a
15 very professional and knowledgeable staff.

16 Q6 In general, explain the criteria you applied in
17 evaluating Diablo Canyon.

18 A6 I will use as a guide the elements contained in
19 INPO Document 90-008, Maintenance Programs in the
20 Nuclear Power Industry. This document is a compilation
21 of the performance objectives and criteria used by INPO
22 in evaluating nuclear power plants. I believe that the
23 objectives and criteria are comprehensive and that if
24 an organization effectively implements them the
25 resulting performance will be good, and more

1 importantly, will continue to improve over time. Like
2 many plants, Diablo Canyon has a maintenance program
3 that meets the elements contained in INPO 90-008. I
4 would like to point out that INPO 90-008 is not an
5 organization chart or structure, but is a list, in no
6 particular order, of elements or functions of
7 maintenance that have been shown to be important to the
8 effective operation of a nuclear power plant.

9 I note also that in one of the prehearing
10 conference orders in this case, the Licensing Board
11 observed that the existence of adequate programs on
12 paper does not constitute proof of effectiveness, but
13 that "the implementation of these programs is the only
14 real gauge of their effectiveness." Given my operating
15 background, I could not agree more. When I look at a
16 plant, Diablo Canyon included, I specifically look at
17 how paper programs are implemented.

18 In addition to an overview of the programs in
19 place at Diablo Canyon, I have, therefore, tried to
20 make specific personal observations at the plant. It
21 is not the purpose of my testimony to respond in detail
22 to any of the specific examples cited by MFP in the
23 bases for their contention. However, I have tried to
24 use observations closely related to their examples.
25 There are thirty INPO elements, but I am addressing the
26 eighteen that I believe are most relevant to the
27 contention.

1 Q7 Please address your criteria one-by-one and
2 provide your observations regarding Diablo Canyon. The
3 first concerns Management Assessment.

4 A7 • Management Assessment

5 Performance Objective: Management and
6 supervisory personnel should monitor and
7 assess station activities to improve all
8 aspects of station performance.

9 Criteria: Line managers and supervisors are
10 responsible for and personally take part in
11 monitoring and assessing station activities.
12 Assessments by other independent groups, such
13 as Quality Assurance, are used by line
14 managers and supervisors as a management tool
15 to assist them in assessing station
16 performance.

17 It is my observation that this element of the
18 program is in place. Specific examples are:

- 19 • The housekeeping throughout the plant was
20 excellent.
- 21 • There were only about twenty action tags hanging
22 on equipment in the secondary part of the plant.
- 23 • The condition of both operating and standby
24 equipment was very good.
- 25 • Compliance with industrial safety work practices
26 was excellent. Everywhere I went people wore
27 their hard hats, eye glasses, and hearing
28 protectors.
- 29 • People were careful to ensure that fire and
30 security doors locked properly behind them.
- 31 • Supervisors and managers that I talked to were
32 readily able to discuss the condition of

1 equipment, and were very responsive to questions
2 about the trends in performance and condition in
3 their area.

4 It is my conclusion that the conditions that I
5 have listed (and there are many more) would not be true
6 unless the managers and supervisors are doing an
7 excellent job in assessing plant conditions.

8 Q8 The next criterion is Quality Programs. Please
9 describe your observations in this area.

10 A8 • Quality Programs

11 Performance Objective: Quality programs
12 should effectively monitor activities that
13 affect safe and reliable plant operation,
14 provide feedback to line management on
15 quality of performance, and contribute to
16 improved performance.

17 Criteria: Quality programs reinforce and
18 support the line functions of managers and
19 supervisors. Line managers and supervisors
20 are responsible for and held accountable for
21 the quality of work performed within their
22 area of responsibility.

23 There were a number of indications that quality
24 programs are healthy at Diablo Canyon. Some examples
25 follow:

26 • One of the best examples that the attitude toward
27 quality programs is good is the comprehensive
28 plant aging management document, "Aging Management
29 Program," dated June 30, 1992, generated at a very
30 high level in the organization. This shows a
31 strong commitment to the issue. This is being

1 addressed as a high level business objective. It
2 is a very comprehensive document and includes all
3 aspects of plant aging. It addresses how to
4 define terms and how to apply the programs. It
5 discusses different age-related degradations and
6 mechanisms. But most importantly, it outlines the
7 relationship of the many activities,
8 organizations, and outside factors that bear on
9 the issue. It also assigns responsibility for the
10 implementation. I believe this document indicates
11 that PG&E is clearly aware of the importance of
12 managing this issue and has taken action to do so.

- 13 • Examples of quality programs in place that I
14 observed are:

- 15 - Hot work permits
- 16 - Equipment clearance tagging
- 17 - Scaffold tagging

18 These examples demonstrate that quality programs
19 are in place and are working.

20 Q9 The next criterion is Maintenance Organization and
21 Administration. Please address this.

- 22 A9 • Maintenance Organization and Administration

23 *Performance Objective:* The maintenance
24 organization and administration should ensure
25 effective implementation and control of
26 maintenance activities.

27 *Criteria:* Administrative controls are
28 employed in the conduct of maintenance

1 activities that affect safe and reliable
2 plant operation. Examples of such activities
3 include scheduling of preventive maintenance,
4 use of special tools and lifting equipment,
5 and use of measuring and test equipment.

6 In my tour of the plant and discussions with plant
7 staff, it was clear that the maintenance organization
8 and administration are being effectively implemented.
9 Observations are:

- 10 • In all discussions with plant staff, they had a
11 ready answer for who was responsible for various
12 aspects of what was being discussed. For example,
13 when talking to technical support people about the
14 Inservice Testing ("IST") program, they had a
15 clear understanding of how the check valve
16 inspection program in maintenance fits in.
- 17 • The Work Planning Department plans and coordinates
18 the work of all three maintenance disciplines with
19 the Operations Department. This is a free-
20 standing organization that must effectively
21 coordinate the activities of many different
22 departments. They are responsible for daily work
23 and outage activities, too. The efficient outages
24 that Diablo Canyon has had show how effective PG&E
25 has been, as this is a major effort coordinating
26 several thousand activities in a sixty-day period.
- 27 • Significant work has been done at the intake
28 structure over the past couple years. The scope
29 and volume of this work was substantial and
30 required a coordinated effort from many groups to

1 be successful. The success of the improvements in
2 the intake structure is an excellent example of
3 organizational effectiveness.

- 4 • An interdepartmental administrative procedure was
5 developed to improve the implementation of the
6 plant's response to Generic Letter ("GL") 89-10
7 regarding motor-operated valves ("MOV"). This
8 document outlines the actions and accountabilities
9 of eight different plant organizations that play a
10 role in effectively responding to the requirements
11 of GL 89-10. The NRC noted in their inspection of
12 this area that "the inspection findings indicated
13 that you appear to be developing an aggressive,
14 well-integrated program for assuring MOV
15 reliability. Program strengths were found in the
16 area of program scope and your high impact team
17 (HIT) approach to integrating the
18 multi-disciplined activities required for the
19 89-10 program."

20 These examples show, in my opinion, that the
21 maintenance organization is properly defined and that
22 proper administrative controls are in place. From what
23 I have seen, the organization appears to be effective.

24 Q10 Next, please address the Plant Material Condition
25 at Diablo Canyon.

- 26 A10 • Plant Material Condition

1 Performance Objective: The material
2 condition of the plant is maintained to
3 support safe and reliable plant operation.

4 Criteria:

- 5 - Systems and equipment are in good
6 working order; examples of this include
7 the following:
- 8 a. Fluid system leaks are minimized.
9 b. Equipment is appropriately
10 protected from adverse
11 environmental conditions.
12 c. Instruments, controls, and
13 associated indicators are
14 calibrated, as required.
15 d. Good lubrication practices are
16 evident.
17 e. Fasteners and supports are properly
18 installed.
19 f. Equipment, structures, and systems
20 are properly preserved and
21 insulated.
- 22 - Material deficiencies are identified and
23 are in the work control system.
24 - Temporary repairs are minimized and
25 permanent requires are made when
26 conditions permit.
27 - Temporary environmental protection
28 (e.g., dust, humidity, freeze, shock) is
29 provided for plant equipment when needed
30 to support construction, outage, or
31 maintenance activities.
32 - Newly installed or modified
33 systems/equipment are verified to be in
34 good working order prior to operational
35 acceptance by the plant staff.

36 Plant material condition is one of most visible
37 examples of maintenance effectiveness. The condition
38 of the equipment is the end to which all programs and
39 efforts point. While visual appearance alone is not a
40 guarantee of reliability, it is a very good indicator
41 of equipment condition. Diablo Canyon has an excellent

1 plant material condition. Some of the many examples
2 are noted below:

- 3 • I toured two of the six emergency diesel generator
4 rooms. The rooms were very clean with no dust or
5 trash anywhere. There were no equipment or tools
6 left anywhere in either of the rooms. There were
7 only two action request tags hanging in both
8 spaces. The air start air supply system was very
9 leak-tight as the compressors never cycled in the
10 ten minutes we were in the rooms.
- 11 • The 4kV switch gear rooms were in excellent
12 condition. There were no cross-under pipe manway
13 cover leaks. It has been my experience that they
14 are next to impossible to consistently make up
15 leak tight.
- 16 • The piping rack area, which includes the auxiliary
17 feedwater ("AFW") piping, was in very good
18 condition. The valves, pipe hangers and pipe
19 snubbers were all in good condition.
- 20 • The feedwater heater level control stations were
21 in excellent shape. They were leak-free, clean,
22 the lights behind the level site glasses were lit
23 and were in about as good a condition as any I
24 have ever seen. It has been my experience that the
25 level site glasses are difficult to prevent from
26 leaking. The insulation on the feedwater heaters
27 was very clean and neat.

- 1 • The main feedwater pump and drive turbines were in
2 very good shape. These types of turbines have a
3 low pressure control oil system and usually have a
4 number of small leaks on the reservoir and bearing
5 pedestals, in my experience. These particular
6 ones were very clean and dry. The turbine
7 platforms were clean and free of any debris.
- 8 • The condensate pumps, the condensate booster
9 pumps, and the heater drain pumps were all clean
10 and leak-free.
- 11 • Diablo Canyon uses a large vacuum pump to draw
12 vacuum and a steam jet to maintain vacuum, so the
13 pump is in standby mode most of the time. It was
14 in excellent condition.
- 15 • The condenser wells were in very good condition
16 with no evidence of leaks down in the well area.
17 The wells were very clean. There were no
18 materials or tools stored down in the wells.
- 19 • The intake area, both top-side where the screen
20 drives are and below where the pumps and motors
21 are, was in excellent condition. This area has
22 had a large effort directed at improving its
23 condition in the last year. Large areas of
24 concrete have been chipped out and replaced. They
25 are about complete with this effort and the
26 results are outstanding.
- 27 • The intake screens are being replaced with new
28 stainless steel all welded units.

1 There are many other specific observations I could
2 make but I believe the examples provided demonstrate
3 that the equipment at Diablo Canyon is in very good
4 condition. This is one of the very best plants that I
5 have seen. There is no doubt in my mind that a plant
6 could not be kept in this condition and not have an
7 effective maintenance program.

8 Q11 What were your observations regarding the Work
9 Control System?

10 A11 • Work Control System

11 Performance Objective: The control of
12 maintenance work should support the
13 completion of tasks in a safe, timely, and
14 efficient manner such that safe and reliable
15 plant operation is optimized.

16 Criteria:

- 17 - The work control system provides
18 management with an accurate status of
19 maintenance planning and outstanding
20 maintenance work.
- 21 - Work planning includes considerations
22 such as material, tool, and manpower
23 requirements; interdepartmental
24 coordination; safety considerations;
25 radiological protection requirements;
26 and quality control requirements.
27 Maintenance history records and NPRDS
28 information are considered where
29 appropriate.
- 30 - Advance planning is performed and
31 routinely updated for scheduled outages.
32 Considerations such as work priority,
33 work procedures and instructions,
34 plant/system conditions, length of
35 outage required, prestaging of documents
36 and material, and coordination of
37 support activities are included.

1 Some of my observations follow:

- 2 • Diablo Canyon has a work planning department that
3 has the responsibility of planning all of the work
4 done by the Maintenance Department and scheduling
5 all of the work performed on site. They do this
6 on a daily basis as well as for outages. Every
7 morning they meet with the representatives of all
8 operating departments to go over the schedule for
9 the next few days. They meet on Friday afternoon
10 to review the plan for the weekend and again on
11 Tuesday to factor in what happened over the
12 weekend. This process is very tightly controlled
13 as a great effort is given to coordinate all the
14 activities necessary to accomplish a given job.
15 Jobs brought in late to this process must be
16 important in order to be included. The effort put
17 into the efficient planning and scheduling pays
18 off in reduced manhours and equipment out of
19 service time. To do it well is the mark of a
20 strong organization, in my opinion, as it is
21 difficult to bring all different groups and
22 activities together on the dozens of jobs that are
23 done on any given day.
- 24 • The maintenance action requests ("ARs") are part
25 of the maintenance equipment history, and the
26 number and age of action requests are tracked by
27 department. The division directors are

1 responsible for the control of the backlog and age
2 of the action request in their areas.

3 • The excellent overall housekeeping condition of
4 the plant is an indicator of an effective work
5 control system.

6 • The posting of hot work permits, equipment
7 clearances, and scaffold tags are also indications
8 of an effective work control system.

9 I believe that these examples show that the work
10 control system at Diablo Canyon is well conceived.

11 Q12 Please address the Conduct of Maintenance at
12 Diablo Canyon.

13 A12 • Conduct of Maintenance

14 Performance Objective: Maintenance should be
15 conducted in a safe and efficient manner to
16 support plant operation.

17 Criteria:

- 18 - Personnel exhibit professionalism and
19 competency in performing assigned tasks that
20 results in quality workmanship.
- 21 - Maintenance personnel are attentive to
22 identifying and are responsive to correcting
23 plant deficiencies with a goal of maintaining
24 equipment/systems in an optimum material
25 condition.
- 26 - Managers and supervisors routinely observe
27 maintenance activities to identify and
28 correct problems and to ensure adherence to
29 station policies and procedures including
30 industrial safety and radiation protection.

31 This is an important aspect of maintenance
32 performance. The conduct of maintenance is not as

1 visible as the plant material condition, but is an
2 important indicator of the way that the results are
3 obtained. Some examples of my observations on the
4 conduct of maintenance at Diablo Canyon follow:

- 5 • Everyone that I observed out in the plant was very
6 conscious of industrial safety work practices.
7 They all wore their safety equipment and were
8 careful that all security and fire doors were
9 secured behind them. This showed me that the
10 habit of doing things right is a part of their
11 daily work. It has been my experience that it is
12 very difficult to get hundreds of people to do all
13 these small daily activities consistently well.
- 14 • During my tours of the plant, I noted many times
15 that supervisors were out in the field. In two
16 cases, I saw the mechanical department head
17 inspecting equipment in the plant at different
18 locations and times. In my discussions with him
19 he displayed a good knowledge of the plant and the
20 equipment in it.
- 21 • During my tour of the intake area, I was impressed
22 with the area foreman's knowledge of and
23 commitment to the intake area. He was obviously
24 very enthusiastic about his work. He readily
25 answered all of my questions, and in many cases
26 anticipated where I was leading to and volunteered
27 much more information. An example of this was on
28 a question I had about the intake crane. He not

1 only answered my questions, but told me what the
2 plans were for future work on the crane. He
3 discussed experience they had on the cables, the
4 plans to replace the cables with stainless, and
5 the schedule for non-destructive examination of
6 the hook. The crane had recently been included in
7 a plant-wide crane inspection program. Such
8 knowledge and enthusiasm is a clear example, in my
9 mind, of a very healthy commitment to the
10 effective conduct of maintenance. Such
11 outstanding examples would not exist, I believe,
12 unless a strong culture exists at the plant to
13 support it.

14 • During my tour of the high voltage switchgear
15 rooms, I noted a significant work activity where
16 large steel beams were being added to stiffen the
17 walls. This was in response to a seismic upgrade.
18 This work involved cutting, welding, grinding,
19 painting, and chipping in the relatively small
20 space between the switchgear cabinets and the
21 walls. The area had been very effectively
22 controlled by the manner in which the scaffolding
23 had been erected, and clear, yellow plastic was
24 draped to prevent arc flashes from harming people
25 and dust from escaping from the work area. This
26 is a good example of effective conduct of
27 maintenance.

1 I believe these are examples wherein the
2 maintenance program is being implemented very well at
3 Diablo Canyon.

4 Q13 Did you observe a Preventive Maintenance Program
5 at Diablo Canyon?

6 A13 • Preventive Maintenance

7 Performance Objective: Preventive maintenance
8 should contribute to optimum performance and
9 reliability of plant systems and equipment.

10 Criteria:

- 11 - A preventive maintenance program is
12 effectively implemented and includes systems
13 and equipment that affect safe and reliable
14 plant operation.
- 15 - Preventive maintenance, including predictive
16 maintenance activities, are performed at
17 appropriate intervals. These intervals
18 maximize equipment availability.
19 Considerations such as operational
20 experience, vendor recommendations,
21 engineering analysis, and cost/benefit
22 analysis are used as a basis to establish
23 preventive maintenance tasks and intervals.
- 24 - Preventive and maintenance activities are
25 scheduled and performed within established
26 intervals. Preventive maintenance is waived
27 or deferred only with management approval.

28 Yes. Some observations related to preventive
29 maintenance made during my plant tour follow:

- 30 • The implementation of activities for preventive
31 maintenance are done by the respective maintenance
32 organizations. The development and coordination
33 of specific preventive maintenance activities is
34 the responsibility of the Preventive Maintenance

1 Engineering Group. They are responsible for the
2 technical aspect of preventive maintenance
3 activities and for determining the proper
4 frequency of the activities. The Group includes
5 representatives from the maintenance disciplines.
6 The Group reviews vendor recommendations,
7 technical manuals, data provided by Reliability
8 Engineering, and equipment history files which
9 include all action requests for that piece of
10 equipment. This appeared to be a comprehensive
11 and effective process and the overall plant
12 equipment condition reinforces this view.

13 • Diablo Canyon is implementing a reliability
14 centered maintenance ("RCM") project. This is an
15 ongoing effort, the results of which are available
16 plant-wide on their computer-based information
17 management system (known as "PIMS"). The basis of
18 why an activity is or is not recommended is
19 documented and can be referred to in the future to
20 support why a certain activity is recommended.

21 Factors included are:

- 22 - why it is a critical component
- 23 - what the RCM analysis results are
- 24 - what the system engineer analysis was
- 25 - what the vendor recommendations are

26 This RCM project is an effort by the maintenance
27 organization to improve the performance of the
28 plant equipment. This project appears to receive

1 high levels of commitment from management as it
2 was mentioned by several management-level people
3 in discussions with them. This is an example, in
4 my view, of an organization that is looking for
5 ways to constantly improve its performance.

- 6 • The preventive maintenance program also ties in
7 with the Inservice Inspection/Inservice Testing
8 and performance monitoring activities at the
9 plant.

10 It is my conclusion that the preventive
11 maintenance program at Diablo Canyon is in place to
12 improve equipment performance.

13 Q14 Please address your next criterion, Maintenance
14 Procedures and Documentation.

15 A14 • Maintenance Procedures and Documentation

16 Performance Objective: Maintenance
17 procedures and other work-related documents
18 should provide appropriate directions for
19 work and should be used to ensure that
20 maintenance is performed safely and
21 efficiently.

22 Criteria:

- 23 - The preparation, review, approval, and
24 revision of procedures and other
25 work-related documents are properly
26 controlled.
- 27 - Documents used in lieu of procedures
28 (such as excerpts from vendor manuals)
29 receive the same review and approval as
30 procedures.
- 31 - Procedures and other work-related
32 documents such as vendor manuals,

1 drawings, reference materials, and
2 posted job performance aids used in
3 support of maintenance are technically
4 accurate and up-to-date.

5 Specific examples I observed wherein this element
6 is being effectively implemented at Diablo Canyon are:

7 • My review of selected procedures satisfied me that
8 procedures are in place for effective control of
9 maintenance activities. I did not review all
10 procedures. However, the procedures I did review
11 were comprehensive, clear, and in general what
12 would be expected of effective procedures.

13 • Specific procedures examined include:

- 14 - MA1, Maintenance (which is a program overview
15 document and shows how all of the maintenance
16 elements within the plant work together)
- 17 - OM7, Problem Resolution
18 OM7 ID1, Problem Identification and
19 Resolution Action Request
- 20 - AP C-250, Preventive Maintenance Program
21 (electrical)
- 22 - AP C-450, Preventive Maintenance Program
23 (I&C)
- 24 - NPAP C-3, Conduct of Plant and Equipment
25 Tests
- 26 - AP C-62, Preventive Maintenance Living
27 Program
- 28 - AP C-352, Surveillance Testing and Inspection

1 Q15 Does PG&E compile and evaluate Maintenance
2 Histories?

3 A15 • Maintenance History

4 Performance Objective: Maintenance history should
5 be used to support maintenance activities, upgrade
6 maintenance programs, optimize equipment
7 performance, and improve equipment reliability.

8 Criteria: Maintenance history records are
9 maintained for systems, equipment, and components
10 that affect safe and reliable plant operations.

11 Yes. Based on my discussion with maintenance
12 personnel, reliability engineering personnel,
13 preventive maintenance engineering, as well as some
14 system engineering personnel, and upon my procedure
15 review, I believe it is reasonable to conclude that
16 Diablo Canyon has an effective maintenance history
17 program. Some of my observations are:

18 • All of the action requests for a piece of
19 equipment are permanently added to the
20 computerized history file. This aids in the
21 determination of equipment performance and
22 evaluation of the effectiveness of preventive
23 maintenance activities.

24 • The reliability centered maintenance project
25 information is entered into equipment history.

26 • The trending of equipment performance by the
27 reliability engineering group is an effective use
28 of equipment history.

- 1 • Outage management utilizes historical performance
2 as a base for current outage planning.

3 Q16 Please address your next criterion, Maintenance
4 Facilities and Equipment.

5 A16 • Maintenance Facilities and Equipment

6 Performance Objective: Facilities and
7 equipment should effectively support the
8 performance of maintenance activities.

9 Criteria:

- 10 - Maintenance facilities size and
11 arrangement promote the safe and
12 effective completion of work.
- 13 - Measuring and test equipment (M&TE) is
14 calibrated and controlled to provide
15 accuracy and traceability. Out-of-
16 tolerance test equipment is removed from
17 service. Plant equipment calibrated
18 with out-of-tolerance test equipment is
19 evaluated in a timely manner for
20 operability, and is recalibrated as
21 necessary.

22 Diablo Canyon has excellent facilities. The plant
23 as a whole has excellent facilities and the maintenance
24 facilities are outstanding. During my tour of the
25 plant, I had an opportunity to see most of the
26 maintenance facilities, as well as the training
27 facilities. Some specific examples follow:

- 28 • There is a very good light machine shop and
29 mechanical facility between the units in the
30 turbine building. This shop was very spacious and
31 very well equipped. There were four lathes, two
32 milling machines, and several smaller power tools

such as drill presses and grinders. It was also equipped with a nice overhead crane.

- The intake structure has its own free-standing workshop area that is almost as large and well-equipped as the maintenance shop described above. They also have an office and break/lunch building. They have many special tools used in the repair of intake equipment.

- The I&C shop was very spacious and well-equipped for a large number of I&C workers (I think I counted about 80 benches).

- The M&TE calibration shop was the best I have ever seen. PG&E has the capability at Diablo Canyon to calibrate most equipment used in the plant; the shop acts as a common calibration shop for all M&TE equipment on site including health physics. The calibration equipment was all in excellent shape and the storage of calibrated equipment was also excellent. PG&E separates the uncalibrated instruments from the calibrated instruments, and the history of individual calibrations is kept in a computer history program. All jobs that an instrument was used on are kept in this history, so if an instrument is found out of calibration the work that was done with it is immediately known. The individual that took me through the shop was quick to point out the many strengths in this shop and demonstrated them to me. This is

1 another example of a very knowledgeable person
2 readily able to demonstrate the effectiveness of
3 the work they do. Highlights pointed out to me
4 included the optical scanner used to identify both
5 the M&TE equipment as well as the individual who
6 checks it out.

- 7 • The training facilities were also very good. I
8 will discuss them more in the element on training.

9 In summary, I believe that Diablo Canyon's
10 facilities would compare favorably to any nuclear
11 facility in the United States.

12 Q17 Please address Maintenance Personnel Knowledge and
13 Performance.

14 A17 • Maintenance Personnel Knowledge and Performance

15 Performance Objective: Maintenance personnel
16 knowledge and performance should support safe
17 and reliable plant operations.

18 Criteria:

19 - Maintenance is performed by or under the
20 direct supervision of personnel who have
21 completed applicable formal
22 qualification associated with the tasks
23 to be performed.

24 - Maintenance personnel knowledge is
25 evidenced by an appropriate
26 understanding of areas such as the
27 following:

- 28 a. maintenance policies and procedures
- 29 b. general plant layout
- 30 c. purpose and importance of
- 31 plant/systems and equipment
- 32 d. effect of work on plant systems

- e. industrial safety, including hazards associated with work on specific equipment/systems
- f. radiological protection and as low as reasonably achievable ("ALARA") principles
- g. job-specific work practice
- h. cleanliness and housekeeping practices

During my inspection of the plant, and in discussions with plant personnel as part of my review of the maintenance program, I had many opportunities to observe the knowledge and performance of maintenance personnel. Some of my observations are as follows:

- My discussion and tour with the Mechanical Department head revealed that he was very knowledgeable about the plant equipment and the programs and processes used to maintain the equipment.
- The Electrical Department supervisor, who discussed Generic Letter 89-10 activities with me, was very knowledgeable about the program and equipment related to motor operated valves.
- As I indicated in my comments on the M&TE shop, the people who were associated with M&TE were extremely knowledgeable of that program and how it fits in with the rest of the plant activities.
- I will discuss this more later, but the training supervisor for Maintenance demonstrated a strong knowledge of the training aspect of maintenance, as well as knowledge of how some of the training

1 facilities are used to do maintenance on equipment
2 from the plant.

3 • The area foreman for the intake area was extremely
4 knowledgeable about this area. I covered this in
5 the element on plant material condition, but it is
6 a very good example of personnel knowledge and
7 bears repeating.

8 • I observed discussions between the foreman and
9 some of the crew members related to work at the
10 intake structure. Based on the comments and
11 detail of the discussions, I would say that the
12 journeymen were very knowledgeable about the work
13 being performed.

14 I conclude that this element is being effectively
15 implemented at Diablo Canyon.

16 Q18 Please describe what you observed regarding the
17 Technical Support Organization and Administration
18 Performance Objective.

19 A18 • Technical Support Organization and Administration
20 *Performance Objective:* Technical support
21 organization and administration should ensure
22 effective implementation and control of
23 technical support.

24 *Criteria:*

- 25 - The organizational structure is clearly
26 defined.
27 - Staffing and resources are sufficient to
28 accomplish assigned tasks.
29 - Responsibilities and authority for each
30 management, supervisory, and

1 professional position are clearly
2 defined and understood.

- 3 - Interfaces with support groups,
4 including corporate groups and contract
5 services, are clearly defined and
6 understood.
- 7 - Technical support personnel have
8 sufficient expertise regarding plant
9 systems, components, and operations to
10 effectively investigate and resolve
11 plant problems.

12 My discussions with plant staff and my review of
13 plant and corporate procedures show that the technical
14 support function is well established at Diablo Canyon.
15 Some specific observations follow:

- 16 • The data trending of equipment performance done by
17 the Reliability Engineering group is analyzed and
18 the results forwarded to preventive maintenance
19 engineering. This is a good example of technical
20 support.
- 21 • The tie between the several department
22 organizations needed to implement ISI, IST, and
23 equipment qualification is generally clear and
24 well understood by the individuals involved.
- 25 • The motor operated valve activities are covered by
26 a program plan document that formalizes the plant
27 efforts to comply with GL 89-10.
- 28 • The corporate level aging document mentioned
29 earlier is also an example of effective technical
30 support.

31 I believe these examples show that this element is
32 clearly in place and is being implemented well.

1 Q19

Please address the Surveillance Testing Programs

2 A19

• Surveillance Testing Programs

3 Performance Objective: Surveillance
4 inspection and testing activities should
5 provide assurance that equipment needed for
6 safe and reliable plant operation will
7 perform within required limits.

8 Criteria:

- 9 - Administrative systems and controls
10 ensure timely completion and review of
11 required surveillances.
- 12 - Surveillance testing programs result in
13 a high degree of reliability of
14 equipment needed for safe and reliable
15 plant operations.
- 16 - Procedures used for surveillance testing
17 contain sufficient detail to ensure safe
18 plant operation during testing and
19 provide for consistent test performance
20 and accurate results. Procedures
21 simulate, as near as practical, the
22 actual conditions under which the system
23 must operate on demand.

24 In assessing the effectiveness of this element, I
25 interviewed a number of plant personnel and made
26 specific observations of equipment and work being
27 performed:

- 28 • The IST program appears to be well-defined. The
29 supervisor of this program was very knowledgeable
30 about the requirements of IST. He pointed out to
31 me that they have a program document that clearly
32 states the relationships of the many activities
33 involved in completing the IST program
34 requirements. We discussed in detail how this
35 program relates to check valve inspections
36 performed by Mechanical Maintenance. This area is

1 often one that is not well integrated and leaves
2 room for some problems. I believe that Diablo
3 Canyon has done an adequate job of ensuring good
4 compliance of these two programs.

- 5 • The implementation of the ISI program appears to
6 be very good.
- 7 • The implementation of environmental qualification
8 by the different maintenance departments is also
9 very good.
- 10 • The implementation of the motor-operated valve
11 program is very strong. As I mentioned earlier,
12 PG&E has a program plan document that shows the
13 relationship of the different organizations that
14 must coordinate well in the compliance to
15 GL 89-10.

16 Q20

Does PG&E address Performance Monitoring?

17 A20

• Plant Performance Monitoring

18 *Performance Objective:* Performance
19 monitoring activities should optimize
20 plant reliability and efficiency.

21 *Criteria:*

- 22 - Programs are implemented to
23 routinely monitor, collect, trend,
24 and analyze performance data
25 (including thermal, hydraulic,
26 electrical, acoustical, and
27 mechanical data) for equipment,
28 systems and components important to
29 plant reliability and efficiency.
- 30 - Approved procedures or guidelines
31 and knowledgeable personnel are
32 used to conduct performance

1 monitoring functions. Tests are
2 conducted consistently to aid in
3 analyzing results.

4 Discussions with plant staff and inspection of
5 equipment provided me with the following examples for
6 this element:

- 7 • The gathering, trending, and analyzing of data
8 done by Reliability Engineering is a good example
9 of this element.
- 10 • The RCM/preventive maintenance activities also
11 support plant performance monitoring.
- 12 • The IST and ISI programs contribute to plant
13 performance monitoring very well.
- 14 • The actual valve testing of motor operated valves
15 is a part of performance monitoring.
- 16 • I believe that NRC SALP assessments, while not a
17 direct measure of plant performance, are a very
18 good indication of the plant performance. A
19 review of the most recent SALP for Diablo Canyon
20 satisfied me that PG&E is performing its licensed
21 responsibilities very well.

22 Q21 What were your observations regarding Maintenance
23 Personnel Training and Qualification?

- 24 A21 • Maintenance Personnel Training and Qualification

25 Performance Objective: The maintenance
26 personnel training and qualification program
27 should develop and improve the knowledge and
28 skills necessary to perform assigned job
29 functions.

1 Criteria: Programs are established and
2 implemented for initial and continuing
3 training.

4 A significant contributor to maintenance strength
5 is training. A key indicator to the health of this
6 relationship is the attitude that maintenance has for
7 training and that training has for maintenance. I
8 observed a number of things that show me Diablo Canyon
9 has a very healthy relationship:

- 10 • I got very clear feedback from the maintenance
11 manager that he is a strong supporter of training.
12 I also heard from at least two of his division
13 directors that he is a strong supporter of
14 training.
- 15 • The maintenance training supervisor attends the
16 Maintenance Department's morning meeting each day
17 instead of his own training division morning
18 meeting.
- 19 • On a tour of the maintenance training facilities,
20 it was clear that training was well supported with
21 equipment and mock-ups. Some specific examples
22 are:
 - 23 - The reactor coolant pump/seal mock-up was
24 about as realistic as it could be. It is
25 full-scale and is made of the actual
26 materials. This provides for a very
27 realistic training aid. Reactor coolant pump
28 seal performance and change out of seals is a

1 very important part of plant reliability,
2 outage activities, and radiation exposure.
3 - They have a full-sized, real emergency diesel
4 engine in training.
5 - The electrical training area has a wide
6 variety of motor operated valve operators.
7 This would provide very important training in
8 the proper maintenance of MOVs.
9 - The I&C Lab was exceptional in my experience.
10 They have one channel of the reactor
11 protection system with all of the components,
12 including actual control rod drive motors and
13 drive shafts and rod position indication.
14 This facility is so realistic that they bring
15 electronic circuit boards from the plant and
16 troubleshoot them on the training aid.
17 - There were classes going on in all three
18 disciplines during my tour.
19 - About one-third of the training staff go to
20 other plant departments during refuelings to
21 perform outage-related work. This is an
22 excellent way to keep the training staff up-
23 to-date on plant activities and to strengthen
24 the personal ties.

25 Q22

Does PG&E effectively use industry reliability
26 data?

1 A22 • Nuclear Plant Reliability Data System ("NPRDS")

2 Performance Objective: The NPRDS should be
3 effectively used to improve equipment
4 reliability and to report component failure
5 information to the industry.

6 Criteria: NPRDS engineering data is
7 maintained up-to-date and in accordance with
8 program guidance.

9 Discussions with plant personnel indicated that
10 the use of the NRPDS is effective. The RCM project
11 utilizes this information. The system engineers seem to
12 be using it as well. The Preventive Maintenance
13 Engineering group utilizes NPRDS data in determining
14 the recommendations on preventive maintenance
15 activities.

16 Q23 How does PG&E address the element of maintenance
17 related to operating experience reviews?

18 A23 • In-House Operating Experience Review

19 Performance Objective: In-house operating
20 experience should be evaluated, and
21 appropriate actions should be undertaken to
22 improve safety and reliability.

23 Criteria:

- 24 - In-house events are screened for
25 significance and prioritized for
26 evaluation.
- 27 - Rigorous investigation is performed on
28 significant in-house events to determine
29 root causes, generic implications, and
30 necessary corrective actions to prevent
31 recurrence.

32 Several examples of effective use of in-house
33 operating experience were evident to me:

- 1 • The plant-wide use of computerized action request
2 ("AR") forms seems to strengthen the availability
3 of in-house information. All AR forms are
4 trackable via computer, so any issue can be
5 tracked to see if it is being responded to
6 properly.
- 7 • The AR is a permanent part of equipment
8 maintenance history and figures in on the schedule
9 of work to be done and the tracking and trending
10 of repetitive failures.
- 11 • An interesting aspect to ARs for me is that they
12 can be for any type of problem. They do not have
13 to be for equipment deficiencies, but can be for
14 program and process problems. This allows for a
15 very wide range of issues to be identified. This
16 seems to me to be an indication of an organization
17 that is not afraid of criticism and change for the
18 better.
- 19 • While it is not clear who has accountability for
20 root cause analysis (a situation also true at
21 other facilities), it seems to be because
22 everybody has accountability for it. Every time I
23 asked, "Who had accountability for root cause?,"
24 the answer was, "I do," or "we do," or "here's how
25 it works," with a ready explanation. Significant
26 problems are addressed with an officially formed
27 team dedicated to whatever the problem is.

1 I believe that Diablo Canyon has a very effective
2 use of in-house experience.

3 Q24 Did you observe any system for Industry Operating
4 Experience review?

5 A24 • Industry Operating Experience Review

6 Performance Objective: Significant industry
7 operating experiences should be evaluated,
8 and appropriate actions should be undertaken
9 to improve safety and reliability.

10 Criteria:

- 11 - A comprehensive evaluation is performed
12 on applicable, significant industry
13 operating experience, and appropriate
14 corrective action is completed in a
15 timely manner.
- 16 - Sources of significant industry
17 experience information reviewed for
18 applicability include the following:
 - 19 a. INPO Significant Operating
 - 20 Experiences Reports ("SOERs")
 - 21 b. Significant Event Reports ("SERs")
 - 22 c. Significant by Others ("SO")
 - 23 notifications
 - 24 d. INPO Significant Event
 - 25 Notifications ("SENS")
 - 26 e. NRC letters, bulletins, and
 - 27 information notices
 - 28 f. Supplier and architect/engineer
 - 29 reports

30 Most of the examples I provided for in-house
31 operating experience also apply to industry experience.
32 However, several additional observations are warranted:

- 33 • The success that Diablo Canyon has had with
34 respect to the MOV/GL 89-10 issue is an indication
35 that they are effectively in touch with the rest
36 of the industry.

1 • Changes to the IST program reflect a strong tie
2 with industry issues.
3 • The check valve program is one that has
4 effectively responded to industry activities.
5 • Diablo Canyon performs a self-evaluation prior to
6 their INPO evaluation. They utilize the help of
7 peer evaluators from other plants to do this.
8 This evaluation appears to be more rigorous to me
9 than the actual INPO evaluation. They have about
10 28 people working for three weeks looking at all
11 areas. From the number of findings and the detail
12 involved, it is clear to me that the intent is to
13 find the weaknesses themselves and to strengthen
14 the performance from self-identified issues. This
15 is an indication of a very healthy organization.

16 Q25 What do you conclude overall from your review?

17 A25 Based upon my review, I am satisfied that Diablo
18 Canyon does in fact have a comprehensive and effective
19 maintenance program. While there may be individual
20 deficiencies in the implementation of the programs, the
21 overall strength of the programs provides for
22 corrective action and continued improvement.

1 Q26 In raising Contention I, MFP cited a number of
2 incidents and reports that they believe show the Diablo
3 Canyon maintenance program to be less than adequate, or
4 at least less than adequately implemented. Do these
5 citations affect your view of the Diablo Canyon
6 program?

7 A26 I have not reviewed all of these incidents and
8 citations in detail. However, I am familiar with the
9 types of incidents and reports referenced. These do
10 not change my overall conclusions.

11 From my experience, it is unreasonable to expect,
12 given the complexity of a commercial nuclear power
13 plant, that there will not occasionally arise a
14 confluence of events that creates an unsatisfactory
15 condition. This is not to minimize the role that
16 nuclear safety must play in operating a nuclear power
17 plant. Nuclear safety must be paramount. Eliminating
18 safety problems is of the utmost importance. It must
19 be the first consideration given to any situation. It
20 is extremely important that great initiative is given
21 to anticipating and preventing safety problems. In my
22 opinion, a healthy organization is one that is self-
23 examining by nature, does not obscure the facts of a
24 situation, is ready to take responsibility for
25 problems, and initiates quick, effective corrective
26 action. During my observations at Diablo Canyon, I
27 found many instances to show that Diablo Canyon is such

1 a healthy organization and found no condition, word, or
2 deed to suggest otherwise.

3 Being alert to potential problems, ensuring that
4 problems are identified, making sure that problems are
5 entered on the proper tracking list, and taking timely,
6 effective corrective action on those problems are all
7 signs of a healthy environment. Indeed, to suggest
8 that the identification of a problem was a weakness
9 would reduce the probability of correcting it.

10 Q27 MFP also speculates in their contention that PG&E
11 is guilty of putting off necessary maintenance to keep
12 the plant running and to maximize profits. Did you see
13 any evidence of this occurring at Diablo Canyon?

14 A27 No. Furthermore, the speculation seems to me to
15 be completely unrealistic. It assumes that you can run
16 a nuclear power plant just because you want to. If all
17 it took was a high level manager saying "you are going
18 to run," all nuclear power plants would have 100
19 percent capacity factors. It is not that easy! It is
20 very difficult to keep the equipment running reliably.
21 It takes a strong commitment at a high level, as well
22 as a great deal of effort and experience. It has been
23 my observation that only a very strong organization
24 with a resolute commitment to success can keep a

1 nuclear power plant running at a high capacity factor
2 over a long time.

3 Being able to maintain a high capacity factor
4 demonstrates in my mind the existence of strong
5 programs. Once you have an organization that does
6 things well in one area, they tend to try to do things
7 well in all areas. I believe that the existence of a
8 consistently high capacity factor is the mark of a
9 well-run and well-maintained plant and, therefore, the
10 mark of a safely-run plant.

11 Q28 Do you have any additional observations?

12 A28 Let me make some final general observations. One
13 of the examples that I have referred to in my testimony
14 is the scaffold tagging program. It is my direct
15 observation that this is an effective program at Diablo
16 Canyon. I believe that this observation has more
17 significance than just a good scaffold program.

18 Some factors relating to scaffold tagging follow:

- 19 • It is relatively low on the priority list of
20 important things done at a nuclear power plant.
- 21 • If you were going to cut corners, it would be a
22 place to do it.
- 23 • It takes a while, in my experience, for an
24 organization to recognize that controlling
25 scaffold tagging is necessary.

1 • It is a fairly cumbersome process, as there are at
2 least five areas that are important and need to be
3 addressed in the process:

- 4 - Fire (as a transient fire load)
- 5 - Chemical (as a hydrogen release agent in
6 containment)
- 7 - Seismic (as a missile or attachment to
8 adjacent equipment)
- 9 - Ventilation (flow blockage to equipment)
- 10 - Industrial safety (slips, falls, dropped
11 objects, and blocked exits)

12 • It is difficult to control as many different
13 people build and use scaffolds in many areas of
14 the plant. In most cases, there is nothing to
15 physically prevent them from building and using a
16 scaffold.

17 • It takes a while for an organization to figure out
18 how to effectively control scaffold use.

19 • It takes a while longer, and some considerable
20 effort, to make it work.

21 There are several conclusions that I believe can
22 rightfully be drawn from having an effective scaffold
23 control program:

24 • You are not cutting corners. If you are doing
25 something like this well, you are probably also
26 doing more important work well too.

27 • You have been paying attention to problems in your
28 organization.

- 1 • You can develop and administer a relatively
- 2 cumbersome process.
- 3 • Your people can tell that you think it is
- 4 important and therefore other things are important
- 5 too.

6 In this light, my observations of the scaffolding
7 program at Diablo Canyon increase my confidence
8 regarding the overall effectiveness of the maintenance
9 program and the organization.

10 I believe that the same general conclusion can be
11 drawn from other programs by my direct observation:

- 12 • Equipment clearances
- 13 • Equipment tagging
- 14 • Hot work permits
- 15 • Attention to personnel safety
- 16 • Attention to fire and security doors

17 From my observations, PG&E appears to be effective
18 in these areas as well.

19 Finally, I want to reiterate that the plant is in
20 excellent overall condition. The operating performance
21 at Diablo Canyon has also been among the best in the
22 nation. The SALP ratings are just about as good as
23 they can be. Maintenance/Surveillance was a SALP 1 for
24 the most recent period, and I know that this is not an
25 easy thing to do. This plant is also on the NRC's
26 "Best Plants" list, which also is a very difficult
27 achievement. I believe these general assessments alone

1 demonstrate that the maintenance programs are in place
2 and that they are being implemented very well.

3 Q29 Does this conclude your testimony?

4 A29 Yes.

TESTIMONY OF PACIFIC GAS AND ELECTRIC COMPANY
ADDRESSING CONTENTION I: MAINTENANCE AND SURVEILLANCE

I. INTRODUCTION

Q1 Please state your name, affiliation, qualifications
and current job responsibilities.

A1 (Giffin) My name is Bryant W. Giffin. I am the
Manager of Maintenance Services for Pacific Gas and
Electric Company ("PG&E") at the Diablo Canyon Power Plant
("DCPP"). I am responsible for all maintenance and outage
activities at DCPP. I have more than 25 years experience
working in the nuclear industry; 12 years with PG&E and
over 13 years as an officer in the United States Navy's
nuclear power program. A summary of my professional
qualifications and experience is provided in Exhibit 1.

(Miklush) My name is David B. Miklush. I am the
Manager of Operational Services for PG&E at DCPP. I am

1 responsible for Operations, Chemistry, and Environmental
2 Engineering. I have more than 20 years experience in the
3 nuclear industry, and have been working at DCPD for more
4 than 15 years. I maintained an SRO license at DCPD from
5 1982 to 1988. A summary of my qualifications and
6 experience is provided in Exhibit 13.

7 II. PERFORMANCE EVALUATION OF DCPD'S MAINTENANCE AND
8 SURVEILLANCE PROGRAMS

9 Introduction

10 Q2 What performance measures does PG&E use to determine
11 the effectiveness of the DCPD maintenance and surveillance
12 programs? How have the DCPD maintenance and surveillance
13 programs performed under each of these performance
14 measures over the last two SALP periods?

15 A2 (All) One of PG&E's most important corporate goals is
16 to "Operate the Diablo Canyon Nuclear Power Plant at the
17 highest level of safety, reliability, and performance."
18 In order to meet this goal, the Nuclear Power Generation
19 Business Unit ("NPG"), which includes DCPD, has defined
20 its goals and objectives in Program Directive OM2,
21 "Management Goals and Objectives." NPG's goals are
22 prepared annually and are formulated in the following
23 categories:
24 • Safety and Quality of Operations
25 • Energy Production

- 1 • Cost Management
- 2 • Continuous Improvement

3 Maintenance activities have a large impact on how NPG
4 performs in meeting its goals. Maintenance effectiveness
5 is not merely a function of day-to-day, individual
6 preventive and corrective maintenance tasks. A well
7 maintained plant exhibits long, uneventful runs between
8 refueling outages with plant generation at a high
9 percentage of generating capacity. Uneventful runs mean
10 minimal plant transients. High operating capacity factors
11 (percentage of maximum generation capability actually
12 delivered between outages) result in efficient delivery of
13 energy to customers. Thus, in a programmatic sense, the
14 effectiveness of maintenance is demonstrated by the
15 overall safe and reliable operation of the plant over
16 time.

17 With this in mind, NPG uses three broad performance
18 measures to evaluate the comprehensiveness and
19 effectiveness of the DCPD maintenance program in meeting
20 PG&E's corporate goal for DCPD. These performance
21 measures include:

- 22 • Plant Operating Performance,
- 23 • Maintenance Services Department Goals and Objectives,
- 24 and
- 25 • Regulatory Performance

26 Each of these performance measures will be discussed
27 below.

1 Plant Operating Performance

2 Q3 How does plant operating performance demonstrate the
3 effectiveness of DCPD's maintenance and surveillance
4 programs?

5 A3 (All) Experience has demonstrated that nuclear plants
6 with consistently high capacity factors, long continuous
7 operation, and short refueling outages are also the best
8 maintained plants. This is because reliable and
9 continuous operation at high capacity factors between
10 scheduled refueling outages and across many operating
11 cycles simply cannot be sustained unless plant equipment
12 and facilities are maintained in a superb condition. In
13 turn, reliable, event-free operation results in fewer
14 challenges to plant safety systems and less wear and tear
15 on safety equipment. Thus, good maintenance practices are
16 not only evidenced by reliable plant operation, but
17 reliable plant operation itself reduces the wear and tear
18 that can lead to increased maintenance.

19 Diablo Canyon's operating history provides ample
20 evidence of the effectiveness of the DCPD maintenance
21 program. The combined lifetime capacity factor for both
22 Diablo Canyon units since Unit 1 began commercial
23 generation in 1985 through July 1993 is 78 percent
24 including refuelings. In this respect, the Diablo Canyon
25 units are among the best operating nuclear units in the
26 nation. DCPD's capacity factor has steadily improved from
27 year to year over its operating history. Over the last

1 three years (1990-1992), the combined capacity factor for
2 both Diablo units has been 85 percent. See Exhibit 14.
3 Among all nuclear plants worldwide, Diablo's performance
4 consistently ranks among the best.

5 Q4 What measures are there of operating performance?

6 A4 (All) A plant's overall operating performance is
7 defined by two components: (1) capacity factor between
8 refuelings, and (2) duration of its refueling outages. A
9 commonly used measure of performance for the first is
10 "operating capacity factor," the percent of maximum
11 generation that is achieved from the time the breakers are
12 closed at the end of a refueling outage, to the time power
13 production ends when the breakers are opened again at the
14 next refueling outage.

15 Q5 Please address DCP's performance in terms of capacity
16 factor.

17 A5 (All) For a plant like Diablo Canyon with constant
18 temperature ocean cooling, a 100 percent operating
19 capacity factor is not attainable since the plant goes
20 through a period of power ascension testing coming out of
21 an outage. Moreover, ocean-cooled plants like DCP need
22 to conduct periodic scraping of the intake tunnels at
23 reduced power to remove barnacles and other sea life.

1 Diablo Canyon's operating capacity factor has averaged
2 95 percent over the last three years, has been over 92
3 percent each year over the last five years including 1993
4 year-to-date, and reached over 96 percent in 1992. See
5 Exhibit 15. This is the best among similar plants in the
6 United States, and consistently among the very best of all
7 nuclear plants worldwide. In 1991, Unit 2 set a world
8 record for length of continuous run, 481 days at power,
9 breaker-to-breaker between refueling outages. World class
10 performance like this is not achieved without a superb
11 maintenance program. This is a further indication that
12 PG&E's preventive maintenance program has been effective
13 in precluding equipment failure and forced outages across
14 multiple operating cycles.

15 Another, and perhaps more subtle, reason that our
16 excellent plant operating capacity factor is indicative of
17 an effective maintenance program has to do with the
18 numerous Technical Specification surveillance tests which
19 are required to be performed during operation on the
20 thousands of SSCs important to safety. All of these
21 surveillances have Technical Specification mandated
22 "ACTION STATEMENTS" which are required to be initiated if
23 an SSC is not operable because the surveillance result is
24 not satisfactory in every respect. This includes all
25 supporting equipment, administrative requirements and test
26 results. The great majority of these "ACTION STATEMENTS"
27 require the plant to begin reducing power toward shutdown
28 if the problem is not fully resolved within a limited

1 period of time. To achieve a consistently high plant
2 operating capacity factor, the plant's maintenance program
3 must maintain and test SSCs in a well coordinated manner
4 at a very high level of performance to avoid "ACTION
5 STATEMENT" power reduction or unit shut-down.

6 Q6 How is DCP's performance of maintenance reflected in
7 the duration of planned refueling outages?

8 A6 (Giffin) Certain periodic maintenance activities are
9 performed every refueling outage, and the duration of the
10 outage (along with event-free post-outage operation) is an
11 indicator of how efficiently outage maintenance activities
12 are planned, scheduled and performed by a skilled,
13 highly-trained workforce. Since DCP began operation in
14 1985, refueling outage times have been cut in half. See
15 Exhibit 16. DCP refueling outages are now consistently
16 among the shortest in the industry. In 1992, even with
17 the additional scope of DCP's ten-year ISI and reactor
18 vessel steam generator shotpeening work, the Unit 1 fifth
19 refueling outage took only 59 days, a record for the unit.
20 In 1993, Unit 2 completed a similar scope refueling outage
21 in 57 days. This performance set a United States record
22 for Westinghouse and Combustion Engineering plants
23 undergoing a 10-year ISI refueling outage. These short
24 outage durations reflect the comprehensive training of
25 DCP maintenance personnel and thorough planning of
26 maintenance activities necessary to perform outage

1 maintenance tasks. The quality of the work performed has
2 a been demonstrated by the reliable, event-free operation
3 of both units since the outages were completed. Once
4 again, DCPD's consistency and quality are the hallmarks of
5 a top-flight maintenance program.

6 Maintenance Goals and Objectives

7 Q7 How do DCPD's internal goals and objectives measure
8 the effectiveness of the DCPD maintenance program?

9 A7 (Giffin) As discussed previously, PG&E uses a
10 formalized set of goals and objectives for managing DCPD.
11 The objectives established for the Maintenance Services
12 Department are a subset of DCPD's overall goals, and
13 provide constant feedback to the workforce and to senior
14 management concerning overall effectiveness in the key
15 areas of maintenance activities. Each of these internal
16 indicators provides a different view of the process to a
17 specific organizational level or group. Some are
18 quantitative reports generated from PIMS records and some
19 are based on qualitative assessments. A comprehensive
20 analysis of maintenance performance is dependent on a
21 review of all available data at any given point in time.
22 The primary Maintenance Services Department objectives
23 include:

- 24 • Industrial Safety
- 25 • Radiation Exposure
- 26 • Personnel Contamination

- 1 • Personnel Error Reduction
- 2 • Refueling Outages
- 3 • Corrective Maintenance Backlog
- 4 • Overdue Preventive Maintenance Items
- 5 • Ratio of Preventive Maintenance to Total Maintenance
- 6 DCP's performance in each area is discussed below.

7 1. Industrial Safety

8 Q8 How has DCP's performed relative to its industrial
9 safety goal in the maintenance area?

10 A8 (All) DCP's industrial safety accident rate overall
11 has been 0.22 per 200,000 man-hours, substantially better
12 than the U.S. nuclear industry median of 0.77 and the U.S.
13 best quartile of 0.27 per 200,000 man-hours. A culture
14 which stresses attention to detail to produce safe working
15 conditions also promotes professionalism and quality
16 overall.

17 The Maintenance Services Department experienced four
18 industrial injuries in 1990, zero in 1991, and one in
19 1992. So far in 1993, there has been only one injury.
20 Even though Maintenance Services has not met its stated
21 objective of reducing industrial accidents to zero, the
22 Department is performing at a rate better than NPG's goal
23 of 0.5 per 200,000 manhours. DCP's performance in this
24 area has usually been the best safety record in PG&E.

1 2. Radiation Exposure

2 Q9 How has DCPD performed relative to its goal for
3 minimizing radiation exposure in the maintenance area?

4 A9 (All) PG&E establishes a goal each year designed to
5 minimize the radiation exposure that employees receive.
6 It has always been PG&E's philosophy to keep the dose
7 as-low-as-reasonably-achievable ("ALARA").

8 DCPD maintenance personnel achieved a collective dose
9 of 95 manrem in 1992 compared to our internal objective of
10 96 manrem. This year our objective for similar scope of
11 work is 91 manrem and we are projecting a dose of about 60
12 manrem. During 1992, the majority of the dose, as in any
13 year, was received during the refueling outage. The dose
14 received in the 1992 Unit 1 outage was higher than we had
15 targeted. Consequently, in order to reduce the dose for
16 1993, we formed a High Impact Team ("HIT") with the
17 responsibility to understand the reasons for the increased
18 dose and to implement improvements.

19 Due in a large part to these HIT team efforts, we were
20 able to reduce the dose received in the 1993 Unit 2 fifth
21 refueling outage by about 30 percent. This reduction is
22 also being seen in Maintenance Services personnel dose.
23 The improvement was an outstanding effort. We did as much
24 work in the 1993 refueling outage with fewer people and
25 received less exposure.

1 3. Personnel Contamination

2 Q10 How has DCPD performed relative to its goal for
3 minimizing personnel contamination in the maintenance
4 area?

5 A10 (All) In 1991 and 1992, Maintenance Services
6 Department personnel incurred 107 and 87 personnel
7 radioactive material contaminations, respectively. This
8 year, we estimate that the number will be about 55.
9 Again, the improvements that we have experienced in this
10 area have been due to the efforts of the plant staff. By
11 carefully planning work, taking time and being observant,
12 it is possible to reduce the number of instances of
13 contaminations to almost zero. PG&E has expended
14 substantial effort in developing and providing a training
15 program to provide workers with the knowledge necessary to
16 reduce the potential for contamination.

17 4. Personnel Error Reduction

18 Q11 How has DCPD performed on its personnel error
19 reduction goal in the maintenance area?

20 A11 (All) We have established goals to reduce the number
21 of personnel errors which cause a plant transient or a
22 formal report to a regulatory agency. The goal for 1993
23 is 3 for each 1,000,000 hours worked at the plant. So far
24 this year there have been two instances of personnel

1 errors which fall into this category (one in maintenance)
2 which equals approximately 1.7 per 1,000,000 hours worked.

3 We have seen a continuous decrease in the number of
4 personnel errors since 1989. This is based on a reduction
5 in such events identified in LERs, Quality Evaluations,
6 and Nonconformance Reports. We will continue to devote
7 attention to this area with the ultimate goal of reducing
8 personnel errors to zero.

9 5. Refueling Outages

10 Q12 How has DCPD performed on its goals for refueling
11 outages in the maintenance area?

12 A12 (Giffin) During a refueling outage, over a million man
13 hours of work and several thousand work activities are
14 scheduled. Our performance in outage duration, radiation
15 exposure, and accident rate during refueling outages has
16 continued to improve. As discussed above, a key indicator
17 related to outage performance is the low level of
18 equipment problems experienced during subsequent
19 operation. The duration of outages at DCPD has been
20 reduced by almost 50 percent in the past five years. In
21 addition, the fact that we were able to reduce the
22 radiation dose by 30 percent in the recent Unit 2 fifth
23 refueling outage is outstanding.

1 6. Corrective Maintenance Backlog

2 Q13 How has DCPD performed on its goal for corrective
3 maintenance backlog?

4 A13 (Giffin) PG&E tracks the number of outstanding
5 corrective maintenance work requests at DCPD. The
6 objective of this goal is to provide an overall indication
7 of the condition of the maintenance program.

8 DCPD has consistently improved its performance on
9 corrective maintenance backlog over the last five years,
10 even while DCPD management has continuously raised the
11 "stretch" goal set for this indicator. As Exhibit 17
12 indicates, the corrective maintenance backlog has been
13 reduced from about 1,200 items prior to 1989 to about 600
14 items as of the end of July, 1993. Since DCPD performs
15 over 7,000 corrective maintenance work orders on an annual
16 basis, this backlog indicator demonstrates an excellent
17 and continuously improving trend in overall backlog
18 management.

19 7. Overdue Preventive Maintenance Items

20 Q14 How has DCPD performed relative to its goal for
21 minimizing overdue preventive maintenance items?

22 A14 (Giffin) This indicator provides an overall measure
23 of the timeliness of DCPD's Preventive Maintenance ("PM")
24 program. We monitor the number of PM tasks overdue. This
25 number has continued to be reduced because of an

1 aggressive effort by the maintenance engineers and
2 craftsmen. See Exhibit 18. What is important is the
3 overall trend, which at DCPD has been positive, i.e.,
4 decreasing. Again, the curve has a consistently
5 decreasing number of overdue PM tasks for the past five
6 years. At the beginning of 1992 there were 137 overdue PM
7 tasks; this was reduced to 56 by the end of the year, and
8 PG&E's goal is to reduce that number to 35 by the end of
9 this year.

10 8. Ratio of Preventive Maintenance to Total
11 Maintenance

12 Q15 How has DCPD performed relative to its goal for the
13 ratio of preventive maintenance to total maintenance?

14 A15 (Giffin) The purpose of the ratio of preventive to
15 total maintenance indicator is to monitor progress in
16 achieving and maintaining a proactive maintenance program.
17 DCPD's trend has been steady and positive, and we have
18 achieved the long-term objective of a 60 percent ratio of
19 preventive to corrective maintenance over the past three
20 years. This year we have averaged about 68 percent.

21 Qualitative Evaluations and Self-Assessments

22 Q16 Please describe the self-evaluations performed by DCPD
23 prior to INPO evaluations.

1 A16 (Giffin) DCPD conducts a performance-based review of
2 the maintenance program once every INPO evaluation period.
3 This self-evaluation provides for a qualitative assessment
4 of maintenance effectiveness, rather than a quantitative
5 score as is generated from the INPO evaluation itself. A
6 final report (Summary of Findings) is produced at the
7 conclusion of each assessment period. This report lists
8 the assessment group's findings (both strengths and
9 weaknesses) and recommendations for improvement. This
10 program is viewed as one means of assessing the
11 administrative structure, programmatic controls and
12 working environment in the maintenance organization. PG&E
13 uses the report as a tool for continuously identifying
14 areas for further improvement in our maintenance and other
15 programs.

16 The most recent two self-evaluations were conducted in
17 1990 and 1993. In the maintenance and surveillance areas,
18 as would be expected in these types of self-critical
19 assessments, the evaluations concluded that there were
20 areas which could be improved. Action plans were prepared
21 and implemented for the 1990 evaluation, and they are
22 being prepared and implemented for the draft evaluation
23 which was distributed in preliminary form in July 1993.
24 (The 1993 evaluation will be finalized prior to the next
25 INPO evaluation in October 1993.) PG&E management
26 requires that each finding in these self-evaluations be
27 formally tracked, responded to, and corrected. In the
28 case of the specific findings of the 1990 and 1993 self-

1 evaluations, the overall corrective actions that need to
2 be addressed are to improve maintenance personnel's
3 attention to detail on routine plant evolutions. The
4 Maintenance Services Department is responding to these
5 issues by using continuous improvement techniques with
6 employee involvement. Even though areas for improvement
7 were identified in these self-assessments, there was no
8 indication of any programmatic breakdown in maintenance.

9 Maintenance Quality Assessment

10 Q17 How has PG&E's Quality Assurance program assessed the
11 DCPD maintenance program?

12 A17 (Giffin) Maintenance Quality Assessments ("MQA"),
13 conducted under the DCPD Quality Assurance Program, audit
14 multiple areas of outage related maintenance and evaluate
15 the operational readiness of selected plant systems.

16 The most recent MQA issued May, 1993, included
17 maintenance activities during the Unit 2 fifth refueling
18 outage. The assessment concluded that each of the audited
19 activities had been effectively implemented. The report
20 also stated that the overall quality of maintenance and
21 technical support demonstrated by each organization
22 provides confidence in the operational readiness of DCPD's
23 systems. Specifically, the audit noted that the steam
24 generator shotpeening had exceeded all expectations. The
25 planning and coordination led to a well-executed evolution
26 and the work was performed on time and with significantly

1 less radiation exposure than anticipated. Also especially
2 effective, according to the audit, was the Generic Letter
3 89-10 MOV Testing. Field support by the foremen and
4 Electrical Maintenance engineers facilitated problem
5 solving and helped keep the work moving smoothly. The
6 audit found some areas for improvement, and these areas
7 have been documented on quality problem reports.

8 There were four Audit Finding Reports issued, three of
9 which were not maintenance-related but addressed design
10 documentation problems (associated with four air operated
11 valves) which were discovered in the course of the
12 assessment. The fourth finding was for incorrect torquing
13 of feedwater regulating valve capscrews to 16 ft-lbs
14 rather than the required 19 ft-lbs. These deficiencies did
15 not indicate a lack of programmatic control or overall
16 effectiveness. They are currently being resolved and
17 responded to in accordance with DCP's required
18 procedures.

19 In December 1992, an MQA was issued for the Unit One
20 fifth refueling outage. This audit also concluded that
21 the maintenance program, technical support of maintenance
22 and technical specification surveillance had been
23 effectively implemented. Specifically cited as effective
24 were diesel generator maintenance and installation, and
25 calibration and placement into service of the Reactor
26 Vessel Refueling Level Indication System ("RVRLIS").

27 Some deficiencies were noted and resulted in six Audit
28 Finding Reports relating to specific issues, such as an

1 incorrect radiographic test; procedural noncompliance
2 regarding reactor vessel water level during reactor head
3 removal maintenance; incorporation of design criteria
4 memoranda requirements into certain surveillance test
5 procedures; procedural noncompliance in control of some
6 M&TE; airborne radioactive contamination during steam
7 generator shotpeening; and a replacement parts evaluation
8 deficiency for a diesel engine fuel oil switch. DCPD has
9 responded with root cause analysis and corrective actions
10 identified for five of the six findings, and corrective
11 actions for three of these already have been completed.
12 The sixth, an incorrect radiographic test, is still under
13 investigation to determine if deficiencies exist.

14 Again, these findings did not indicate any
15 programmatic problems, but did provide important feedback
16 to the DCPD maintenance program.

17 Continuous Program Improvement

18 Q19 What are some examples of "continuous improvement"
19 initiatives involving the DCPD maintenance and
20 surveillance programs?

21 A19 (Giffin) PG&E's operating and maintenance strategy
22 for DCPD is focused on continuous improvement. Over the
23 past few years, PG&E has conducted a number of internal
24 reviews of the maintenance program as part of its
25 continuous improvement strategy. Although these reviews
26 are specifically targeted at improving the efficiency of

1 the maintenance process, they provide a mechanism for
2 evaluating the quality of the maintenance organization in
3 terms of its internal processes. Examples of these
4 continuous improvement initiatives include:

5 **1. Maintenance Process Improvement Project**

6 In February 1992, DCPD initiated the Maintenance
7 Process Improvement Project. The Project consisted of a
8 task force made up of employees from all levels of the
9 organization representing the DCPD maintenance process and
10 other related departments and sections. This task force
11 used continuous improvement techniques to identify
12 opportunities for improved efficiency in the maintenance
13 process. The Project was completed in December 1992, and
14 identified four specific recommendations with action plans
15 and eleven other recommendations worthy of further
16 evaluation. The four specific recommendations are:

- 17 • Establish integrated maintenance teams aligned by
18 plant "systems";
- 19 • Establish a combined consumables, tools and
20 equipment group;
- 21 • Modify the work priority system to provide an
22 integrated priority system for DCPD maintenance,
23 engineering and procurement personnel;
- 24 • Modify the minor maintenance program to improve
25 its utilization.

26 Each of these recommended improvements, along with
27 necessary computer enhancements, is being implemented and

1 will add substantial efficiencies to DCP's overall
2 maintenance process.

3 2. Reliability Centered Maintenance

4 PG&E has an active process in place at DCP to
5 incorporate reliability centered maintenance ("RCM")
6 improvements into DCP's preventive maintenance programs.
7 RCM is a reliability-based methodology for optimizing
8 preventive maintenance by analyzing the failure modes and
9 safety significance of equipment on a system-by-system
10 basis, and then improving condition-monitoring programs
11 for those systems to reflect the insights gained from the
12 analysis. PG&E has completed the first phase of its RCM
13 Program by completing a rigorous system analysis of the
14 DCP feedwater system and developing preventive
15 maintenance program administrative procedures to reflect
16 the RCM process. The second phase of the program is well
17 underway at the plant, and involves analysis of 12
18 additional safety-related systems. Currently, the project
19 is nearing completion of the fifth and sixth systems (CCW
20 and 4kV). If the second phase produces positive results,
21 a third phase will perform generic analyses of additional
22 systems and components, and incorporate the insights into
23 DCP's "Living Preventive Maintenance Program."

24 3. Procurement Task Force

25 In 1991, PG&E completed a multi-disciplinary review of
26 the procurement process at DCP. The purpose of this
27 review was to reduce overlap and duplication among various
28 departments, and to improve the reliability and timeliness

1 of procurement of parts and equipment to support DCPD
2 maintenance and operations. The recommendations of the
3 Task Force have been implemented, and the DCPD procurement
4 organization has achieved a higher level of efficiency and
5 timeliness in meeting maintenance needs.

6 Regulatory Performance

7 1. NRC Programmatic Assessments

8 Q20 Please discuss examples of NRC assessments of the DCPD
9 maintenance and surveillance programs.

10 A20 (All) As discussed above, the overall operating
11 performance of DCPD, as well as the numerous self-critical
12 evaluations conducted by PG&E, are indicators which PG&E
13 uses to monitor, assess and continuously improve the
14 performance of the DCPD maintenance and surveillance
15 programs. These measures demonstrate that the DCPD
16 maintenance and surveillance programs are comprehensive,
17 effective and superior. In addition, inspection,
18 enforcement and assessment activities by regulators such
19 as the NRC also provide PG&E with important information
20 concerning the overall performance of all its programs,
21 including maintenance and surveillance. These NRC
22 activities are discussed below.

1 a. NRC "Best Plants" List

2 Q21 DCPP is on the NRC "best plants" list. How does this
3 relate to effectiveness of maintenance and surveillance at
4 DCPP?

5 A21 PG&E's excellent overall safety performance in
6 operating and maintaining DCPP has been recognized by the
7 NRC numerous times since issuance of the initial operating
8 licenses for the plant. Most importantly, four
9 consecutive times over the last two years, the NRC has
10 commended PG&E's outstanding safety record as part of the
11 Commission's semi-annual review of licensee performance -
12 in February and June 1992, and again in February and June
13 1993. These commendations, typically referred to as the
14 NRC's "best plants" list, are among the select few awarded
15 to NRC licensees nationwide. DCPP's commendations
16 specifically reference the excellent performance of PG&E
17 personnel and programs, and recognize DCPP as being one of
18 the best operated nuclear plants in the nation. These NRC
19 commendations of DCPP's overall safety performance are
20 strong indicators that DCPP's regulatory performance in
21 all areas - including maintenance and surveillance - has
22 attained a level of excellence among the highest in the
23 United States. Copies of each of the four NRC letters
24 commending DCPP are attached as Exhibit 19.

1 b. SALP Ratings

2 Q23 What have been the NRC SALP ratings of the DCP
3 maintenance and surveillance programs?

4 A23 (Giffin) The NRC periodically assesses the
5 programmatic performance of DCP in key functional areas
6 such as maintenance and surveillance through the
7 Systematic Assessment of Licensee Performance ("SALP")
8 program. According to NRC SECY 90-189 (May 25, 1990), the
9 SALP program is an integrated NRC staff effort to
10 consolidate available information to support a periodic
11 evaluation of a licensee's overall performance. The SALP
12 process is a means of expressing NRC senior management's
13 observations and judgments on licensee performance. SALP
14 reviews are conducted by a SALP Board which is
15 multidisciplinary in nature. SALP reviews are intended to
16 result in an integrated assessment of licensee
17 performance. SALP Board members consist of a mixture of
18 NRC regional and headquarters personnel.

19 NRC Manual Chapter 0516 dated September 28, 1990
20 establishes the specific performance criteria applicable
21 to each functional area, and defines the
22 maintenance/surveillance functional area as including:

23 "...[A]ll activities associated with either
24 diagnostic, predictive, preventive or corrective
25 maintenance of plant structures, systems, and
26 components; procurement, control, and storage of
27 components, including qualification controls;
28 installation of plant modifications; and maintenance
29 of the plant physical condition. It includes conduct
30 of all surveillance (diagnostic) testing activities as
31 well as all inservice inspection and testing

1 activities. Examples of activities included are
2 instrument calibrations; equipment operability tests;
3 post-maintenance, post-modification, and post-outage
4 testing; containment leak rate tests; special tests;
5 inservice inspection and performance tests of pumps
6 and valves; and all other inservice inspection
7 activities."

8 Thus, the SALP report provides PG&E - as well as the NRC -
9 with an integrated, multidisciplinary, programmatic
10 evaluation of the effectiveness of a licensee's
11 performance in key functional areas, including maintenance
12 and surveillance.

13 NRC's SALP ratings have recognized the high quality
14 and effective performance of DCP's maintenance and
15 surveillance programs. For the most recent SALP review
16 period, July 1, 1991 through December 31, 1992, the NRC
17 rated PG&E's performance with six "1" ratings and one "2
18 and improving" rating. The NRC rated
19 Maintenance/Surveillance at DCP as Category 1, the
20 highest possible rating. Category 1 is defined as a
21 "superior level of performance" based on licensee
22 management attention and involvement in licensed
23 activities (NRC Manual Chapter 0516, Section 08.a). More
24 specifically, the SALP report cited the following bases
25 for its "Category 1" rating of DCP maintenance and
26 surveillance:

- 27 • Virtually trouble-free plant operation evidenced a
28 high quality of maintenance work;
- 29 • The high-level of management involvement in scheduling
30 and planning maintenance and surveillance work
31 maximized safety system availability;

- 1 • Maintenance and surveillance work was generally of
- 2 high quality;
- 3 • The training and qualification program for maintenance
- 4 personnel was strong;
- 5 • Management of outages was marked by an overriding
- 6 understanding and emphasis of the risk of each job.
- 7 Work crews and planners were trained and aware of the
- 8 safety significance of the jobs and systems on which
- 9 they worked;
- 10 • Work items were well prioritized, with safety-
- 11 significant issues given high priority. Backlog of
- 12 non-outage safety related work was low;
- 13 • The involvement and leadership shown by maintenance
- 14 staff in root cause investigations was a significant
- 15 strength, as was the integration of maintenance,
- 16 operations and engineering staff in maintenance and
- 17 surveillance activities;
- 18 • The number of personnel errors was reduced due to the
- 19 high level of management involvement throughout the
- 20 organization; and
- 21 • The maintenance staff overall improved their response
- 22 to problems by identifying, analyzing and correcting
- 23 maintenance and surveillance problems promptly.

24 The SALP report cited four Level IV violations that had
25 occurred in the maintenance/surveillance area, but
26 concluded that the concerns associated with each appeared
27 to have been isolated. Some additional minor weaknesses
28 were noted as having occurred early in the SALP assessment

1 period. However, the SALP report stated that most had
2 been identified by PG&E immediately upon occurrence, and
3 PG&E management involvement was effective in promptly and
4 appropriately correcting the problems. A copy of the SALP
5 report is attached as Exhibit 20.

6 Previous SALP evaluations also have recognized the
7 effectiveness of DCP's maintenance and surveillance
8 programs from an overall perspective. The NRC judged
9 DCP's performance in maintenance/surveillance to be
10 Category 2 (a "good level of performance") in each of the
11 three SALP assessment periods spanning August 1987 through
12 June 1991. It is important to note that every SALP
13 evaluation, including those in which PG&E's
14 maintenance/surveillance programs have been rated "good"
15 or "superior," contains qualitative assessments of various
16 individual weaknesses and strengths exhibited within the
17 particular functional area during the assessment period.
18 This "feedback" from the regulators is subject to the same
19 formal followup evaluation and corrective action by PG&E
20 management as internal problem reports. PG&E maintenance
21 and surveillance management track each item to closure to
22 assure that corrective actions have been implemented in
23 response to the SALP findings.

24 The SALP ratings and NRC "best plants" list also must
25 be considered in the context of the entire nuclear
26 industry. DCP's current SALP "1" rating in
27 maintenance/surveillance places it high among current
28 licensees in that functional area. DCP is one of only

1 five plants nationwide which was commended by the NRC in
2 June 1993 for its overall superior safety performance.
3 This indicates that, in terms of overall regulatory
4 performance, DCP's maintenance and surveillance program
5 is at a very high level when "benchmarked" against its
6 peers in the industry.

7 2. NRC Inspection and Enforcement Activities

8 Q24 Please discuss how NRC inspection and enforcement
9 activities evaluate DCP's maintenance and surveillance
10 programs?

11 A24 (Giffin) Routine and special NRC inspections provide
12 continuous information to PG&E on specific aspects of the
13 DCP maintenance and surveillance programs. For example,
14 NRC inspectors routinely review DCP LERs and other plant
15 events. Open items on such events are identified in
16 monthly NRC inspection reports, and PG&E's response to
17 each open item is evaluated in a subsequent NRC inspection
18 report. Each LER event is fully evaluated by PG&E through
19 root cause analysis, corrective actions and/or program
20 improvements.

21 Other NRC inspections and reviews provide PG&E with
22 in-depth NRC evaluations of important maintenance and
23 surveillance activities and programs. Examples include:

- 24 • NRC Inspection Report ("IR") 93-08, in which the NRC
25 reviewed the DCP 10-year In-service Inspection
26 ("ISI") performed during the Unit 2 fifth refueling

1 outage, and concluded that PG&E was implementing a
2 comprehensive ISI program in accordance with Technical
3 Specification, ASME Code and other NRC and industry
4 requirements;

- 5 • IR 91-39, concluding that PG&E was developing an
6 aggressive, well-integrated program for assuring
7 safety-related MOV reliability under Generic Letter
8 89-10, and at the same time noting certain areas
9 requiring further development;
- 10 • IR 92-201, concluding that PG&E was implementing a
11 strong program for evaluating and minimizing safety
12 risks associated with maintenance activities performed
13 while certain safety systems are unavailable during
14 refueling outages;
- 15 • NRC Safety Evaluation (TAC No. M83285), dated
16 September 4, 1992, concluding that PG&E's supplemental
17 reactor vessel surveillance program meets NRC
18 requirements.

19 Other NRC inspections may identify isolated areas in
20 PG&E's maintenance and surveillance programs which need to
21 be addressed. PG&E evaluates the safety significance of
22 major items, performs a formal root cause analysis, and
23 implements corrective actions to avoid recurrence.

24 Based on a review of thousands of hours of NRC
25 inspection and enforcement activities, and hundreds of
26 pages of NRC inspection reports issued over the last two
27 SALP assessment periods, PG&E believes that the regulatory

1 performance of DCPD's maintenance and surveillance
2 programs has been excellent.

3 III. CONCLUSION

4 Q25 Based on the content, performance and history of
5 PG&E's maintenance and surveillance programs for DCPD, are
6 the programs sufficiently effective and comprehensive to
7 assure that the public health and safety is protected if
8 PG&E is granted a full 40-year operating license for DCPD
9 as requested by the license amendment at issue in this
10 proceeding?

11 A25 (All) Yes.

12 Q26 Does this conclude your testimony?

13 A26 (All) Yes.
