ALDERSON REPORTING

(202) 678-9300

1 indicated.

2 Q 4875?

3 WITNESS WOYTCWICH: Yes.

4 I don't have a calculator to convert  
5 that to kilowatts for you.

6 Q That is all right.

7 I refer you to 34.3.2 of the rules, 1984  
8 rules. What is meant by the first phrase of that first  
9 sentence in the paragraph, that the design equations  
10 don't take into consideration the possibility of  
11 dangerous torsional vibration stresses?

12 Which design equations does the phrase  
13 refer to?

14 WITNESS GIUFFRÀ: For example, the basic  
15 crankshaft diameter formula, 34.17.1. That would  
16 assume that the stress values are lower than those  
17 appearing in the later table or the formulas in the  
18 1984 rules.

19 So that you would--you would approve the  
20 design with that consideration. If the stress values  
21 are higher, we have to go into a further detail in our  
22 review of the design.

1           Q       In this case, were the torsional  
2 vibration stresses higher than those indicated in the  
3 table?

4                   WITNESS GIUFFRÀ: Yes.

5           Q       They were higher?

6                   WITNESS WCYICWICH: Yes.

7           Q       Did the existence of those values as  
8 being higher than this allowable limit or limits have  
9 any effect on your prior calculations as to whether the  
10 design equations had been met for this crankshaft?

11                   WITNESS GIUFFRÀ: When we considered the  
12 vibration analysis itself, as part of that  
13 consideration, on the acceptability for marine service,  
14 we went back and re-examined the crankshaft for that  
15 particular application or installation.

16           Q       Were those higher vibratory stresses?

17                   WITNESS GIUFFRÀ: Yes.

18           Q       What were your conclusions?

19                   WITNESS GIUFFRÀ: We found them to be  
20 acceptable, in conjunction with the total submittal.  
21 Total submittal of Delaval.

22           Q       What do you mean?

1                   WITNESS GIUFFRÀ: Well, it means that we  
2   went back and did some additional calculations. We  
3   reviewed their strain-gauge measurements as well as  
4   torsionograph measurements and looked at the service  
5   documentation they had given to us, which is available  
6   here.

7                   We used those in conjunction with our  
8   own check calculations to determine that it was  
9   acceptable for a war--for a non-marine calculation.

10                  Q       Are those contained in Exhibit No. 3?

11                   WITNESS WCYTCWICH: Yes.

12                  Q       Can you point those out to me?

13                   WITNESS WCYTCWICH: First page of  
14   Exhibit 3 is a--I have it as the first page. Do you  
15   have that?

16                  Q       No.

17                   WITNESS WCYTCWICH: All right. You  
18   start at the front. I will state that the first thing  
19   we have here is a check of the national frequency  
20   calculations discussed this morning.

21                  Q       All right.

22                   WITNESS WCYTCWICH: Following that,

1     there is the discussion or the check calculations  
2     pertaining to the torsional vibration stress levels.

3             Q         Are those the handwritten or typed ones?

4                     WITNESS WOYTCWICH: Handwritten. We  
5     covered this morning as far as sheet No. 3 of six. I  
6     assume you will want to come back later to the  
7     remainder of that.

8                     Then, after the handwritten calculation  
9     that is marked "Sheet 6 of 6," there are two pages  
10    which consist of three pages which consist of copies of  
11    calculator printouts. These were the safety factor  
12    calculations which we made according to our modified  
13    version of the CIMAC draft method.

14                    Then, following that--

15             Q         If I can stop you there, what is "SI"?

16             A         System International, international  
17    system of units.

18                    Following that, there should be some--a  
19    sheet indicating safety factors. We calculated the  
20    safety factors in several ways. We began with the  
21    fatigue stress, which we obtained from the calculator  
22    printout marked "Sheet 3 of 3" by AJD/ETW.

1                   There is a--the fourth printout line up  
2 from the bottom gives the stress in Newton's per square  
3 millimeter, converted to psi.

4                   Q           What is that figure?

5                   WITNESS WOYTOWICH: 29,940 psi.

6                   Q           Relating to what?

7                   WITNESS WOYTOWICH: That relates to the  
8 equivalent combined alternating stress by Von Ness'  
9 theory.

10                   Going back to the handwritten sheet, we  
11 compared that stress against each of the three fatigue  
12 strength values, which we had to consider. One was the  
13 result of the theoretical formula proposed by CIMAC.

14                   That indicated a safety factor of  
15 1.105. Then we compared it to the fatigue strength  
16 value which TDI Indicated was derived from tests of the  
17 failed crankshaft, without shot peening.

18                   And the safety factor was found to be  
19 1.309.

20                   Then we concluded the 20 percent extra  
21 strength which they claimed for shot peening, and that  
22 increased safety factor to 1.57.

1                   We then went to do a combined steady and  
2 alternating fatigue analysis, similar to what is shown  
3 on page 27 of Exhibit 2. You don't have to look  
4 through Exhibit 2. That is attached as the next page  
5 of Exhibit 3.

6                   We found the equivalent alternating  
7 stress and the equivalent mean stress, again, by our  
8 in-house adaptation of the CIMAC method.

9                   We found a combined safety factor, and  
10 those numbers are indicated on the page, when comparing  
11 against each of the three fatigue limits.

12                  Q        Located where?

13                        WITNESS WOYTCWICH: On the sheet marked  
14 "Sheet 1 of 3, Safety Factors Calculations."

15                        That was a bit of a--ch, that sheet that  
16 you have is the tail end of a sheet before it, that got  
17 mixed up in Xeroxing. What runs off the right of the  
18 page matches up there.

19                  Q        And the safety factor on that page 1 of  
20 3, 1.16643, is that correct? Page 1 of 3?

21                  A        No. This page 1 of 3, handwritten, that  
22 I have.

1 Q One moment.

2 WITNESS WOYTCWICH: Maybe I could  
3 arrange this for you, right here. (Indicating)

4 Q Thanks.

5 WITNESS WOYTCWICH: Okay.

6 Q The second line of that, "Safety  
7 Factors," underlined, with a dash, "desired minimum  
8 equal 1.34"?

9 WITNESS WOYTCWICH: Right.

10 Q Okay.

11 WITNESS WOYTCWICH: I have discussed the  
12 first few lines of that. Now we are looking at the  
13 next heading down, "Combined S.F. Goodman Method."

14 Based on the ultimate tensile strength  
15 of the forgings and on the steady and alternating  
16 loads, we calculated combined safety factors, once by  
17 the Goodman method, which uses reciprocal addition of  
18 the steady and alternating safety factors, once by the  
19 elliptical theory for combined loadings, which uses the  
20 squares of each of those safety factors.

21 Different authorities prefer different  
22 ones, so we ran it both ways.

1           The numbers are all there. As you can  
2 see, with the submitted fatigue limit established by  
3 strain-gauge testing and no shot peening, the safety  
4 factors are marginal, but when we included the 20  
5 percent credit for shot peening, they went well over  
6 the desired minimum.

7           I might also add here that in this case,  
8 those numbers were determined at the 110 percent load  
9 rating. We didn't go back and recalculate when we  
10 decided not to address that question in our letter,  
11 because we felt since it was acceptable, for the most  
12 part, under these circumstances, that we would not go  
13 back and recalculate it, for the maximum continuous  
14 rating.

15           We also compared the values we found  
16 against the values submitted by TDI. That is the next  
17 sheet back.

18           We marked it on there, a copy of their  
19 Goodman diagram. We agreed quite closely, as you can  
20 see, especially considering the fact that we were  
21 including somewhat higher loads than TDI had included.

22           Q       Were all of these calculations based on

1 1700 psi as being the maximum firing pressure?

2 WITNESS WCYTCWICH: Let me go back and  
3 make sure.

4 Q Take your time.

5 WITNESS WCYTCWICH: We need a calculator  
6 to be sure, because the maximum firing pressure is  
7 expressed in different units.

8 Q Maybe we will get back to the desired  
9 minimum that you referred to, on that page, safety  
10 factors-desired minimum equal 1.34.

11 How is the desired minimum derived?

12 WITNESS WCYTCWICH: That was the lowest  
13 value for which we had previously approved an engine of  
14 a different manufacturer, according to the same method.

15 Q How as that value derived?

16 WITNESS WCYTCWICH: From consideration  
17 of that other manufacturer's supporting data.

18 Q What kind of calculations were involved  
19 in reaching that figure?

20 WITNESS WCYTCWICH: Essentially the same  
21 ones that you see here, just repeated for the other  
22 engine and compared against submitted results and again

1 compared against the manufacturer's stated service  
2 experiences with those engines.

3 Q For the Goodman method calculations--

4 WITNESS WOYTCWICH: Yes.

5 Q --does this document indicate that, for  
6 the CIMAC theoretical fatigue limit and for the fatigue  
7 limit without shot peening, that the values calculated  
8 do not meet the desired minimum?

9 WITNESS WOYTCWICH: They do.

10 Q For purposes of clarification, sir, is  
11 it your testimony that those values do not meet the  
12 desired minimum value? That is, 1.34?

13 WITNESS WOYTCWICH: That is correct.

14 Q You answered the question properly, but  
15 it is just that it raised some doubts.

16 WITNESS WOYTCWICH: Okay.

17 Q Back to my original question, sir, which  
18 was, does the fact that the vibratory stresses exceeded  
19 ABS allowable limits have any effect on the design  
20 equations, other than--the design equations that you  
21 referred to concerning crankshaft--

22 WITNESS WOYTCWICH: Rather than going

1 back to the formula in the book, we went to the fatigue  
2 method I described. This is in--this is used in lieu  
3 of the equations in the rule book, though.

4 WITNESS BLANDING: No, it doesn't have  
5 any effect on the equations. That is an additional  
6 consideration for a complete system. The equations in  
7 the book for the crankshaft are based on the engine  
8 itself.

9 When you add something to the engine,  
10 like a generator, or these rules are directed more  
11 towards the main propulsion system, possibly with  
12 reduction gears and so on, so it doesn't change the  
13 basic equation referred, but it gives you another  
14 dimension.

15 That is what this refers to.

16 With a slow-speed diesel engine, you  
17 will probably exceed allowable vibratory stresses,  
18 where it--in that case, it mentions a range.

19 Most of the engines we are dealing with  
20 in this section on main propulsion engines, which don't  
21 have a constant speed, necessarily.

22 Q So you didn't perform any calculations

1 under the formulas for size of the crankshaft webs,  
2 with regard to this particular submission by TDI?

3 WITNESS WOYTCWICH: That is what these  
4 fatigue analyses are.

5 Q You didn't use the formulas in the rule  
6 book?

7 WITNESS WOYTCWICH: No.

8 WITNESS GIUFFR : They had been used  
9 when we did the original approval on the engine.

10 Q Referring to Exhibit No. 3, sir, or  
11 rather Exhibit No. 5, the second page thereof, which,  
12 the top of which is form No. M-341NBO--

13 WITNESS WOYTCWICH: Yes.

14 Q --dated April 3, 1984.

15 WITNESS WOYTCWICH: All right.

16 Q What does this page involve?

17 WITNESS WOYTCWICH: That is the  
18 calculator program which we have in-house, to perform  
19 the calculation of 14.17.1 of the rules.

20 Q WT squared must be greater than or equal  
21 to--

22 WITNESS WOYTCWICH: No, this is the

1     crankshaft diameter formula.

2             Q       What is that?

3                     WITNESS WOYTCWICH: The formula. I  
4     can't repeat it.

5                     Ch, here,  $d = c$  cube root of--that  
6     formula.

7                     The web calculation is not shown here,  
8     but the surveyor did make a note, "web okay," from  
9     DiDonato, so that I have to assume that he did perform  
10    that calculation very quickly on his hand calculator  
11    and didn't write down all of the numbers.

12                    He did make a check.

13             Q       What is the maximum firing pressure  
14     indicated?

15                     WITNESS WOYTCWICH: Clearly shown to be  
16     1700 psi.

17             Q       That factor does have an effect on the  
18     adequacy or non-adequacy of the pins and journals?

19                     WITNESS WOYTCWICH: According to this  
20     formula, yes, it does.

21                     I might also point out that in this  
22     particular calculation, the ultimate strength was the

1 design minimum specified on the drawing reviewed,  
2 83,000 psi.

3                   Whereas the engines discussed in the TDI  
4 submittal of torsional stresses were stated to have an  
5 ultimate strength considerably higher than that.

6           Q           In that formula, there is a reference to  
7 an I value, span between the bearings?

8                   WITNESS WOYTOWICH: Yes.

9           Q           How is that figure derived, if you know?

10                   WITNESS WOYTOWICH: Normally, it would  
11 be taken between the ends of the web--sorry, between  
12 the ends of the main bearings, not from center line to  
13 center line of the main bearing, but from inner edge to  
14 inner edge.

15                   In this case, I would not be able to  
16 guarantee without going back and looking at the  
17 drawings, which of those two values was used.

18                   Either is acceptable. We sometimes try  
19 to be a little conservative in our approach and use  
20 center line to center line, even though in the rule  
21 section it is quoted as being from bearing edge to  
22 bearing edge.

1 Q Referring you to 34.17.4, relating to  
2 solid crankshaft webs.

3 WITNESS WOYTCWICH: All right.

4 Q Does ABS Only take the diagonal distance  
5 referred to in the last sentence of the rule, when  
6 there is an overlap of the pin and journal?

7 WITNESS WOYTCWICH: That would be our  
8 usual procedure.

9 Q do you ever make any allowance for the  
10 section formed by the diagonal drawing of the fillet  
11 radii?

12 WITNESS WOYTCWICH: I'm not sure how  
13 that differs.

14 Q In your mathematical analysis of  
15 crankshaft webs, would you treat the webs of the  
16 crankshaft with a deep re-entering fillet the same as a  
17 crankshaft with a normal fillet?

18 WITNESS WOYTCWICH: Under the formula  
19 given here, I honestly am not sure, because I haven't  
20 done detailed plan review of diesels, and--would you  
21 know, whether we usually take the actual metal  
22 dimensions or the nominal dimensions from web to web?

1 I think we take the actual metal  
2 dimensions.

3 WITNESS BLANDING: I'm not sure what the  
4 question is regarding re-entrant fillet.

5 WITNESS WOYTCWICH: An undercut into the  
6 web?

7 I think we would measure from metal to  
8 metal rather than from arbitrary line to arbitrary line.

9 Q In that same rule, what is meant by the  
10 term, the effect of resisting moment of the web in  
11 bending? Can you define that term for us or that  
12 phrase?

13 WITNESS WOYTCWICH: The section  
14 modulus. Quotient of moment of inertia of the section  
15 divided by the distance from the neutral axis to the  
16 outer fiber.

17 MR. STROUFF: Makes perfectly good sense.

18 Q If you take into account the actual  
19 measurement of the re-entering fillet in determining  
20 the effect of moment of resistance--

21 WITNESS WOYTCWICH: I believe that our  
22 normal practice would be to measure that dimension from

1 the boundary of the actual crankshaft material, at one  
2 fillet to that at its opposite fillet, rather than  
3 constructing the arbitrary lines of a face of the web  
4 and going between them.

5 Essentially it makes sense to count only  
6 the metal that is actually there.

7 Q Is the maximum firing pressure value a  
8 factor which affects the adequacy of the crank webs  
9 under the ABS rules?

10 WITNESS WOYTCWICH: Yes. Because it  
11 affects the rule required diameter, and the rule for  
12 the crank webs proportions the webs according to the  
13 crank pin value.

14 Q In paragraph 34.17.2, which related to  
15 maximum firing pressure and EHF, it states the surveyor  
16 is to verify the maximum firing pressure, P, and full  
17 brake horsepower during a trial of the engine.

18 Was this done in this case for the TII  
19 submission?

20 WITNESS GIUFFFA: No, it wasn't, as far  
21 as we are aware.

22 Q Is it required to be done?
