INTERVIEW OF TED LEHMAN

- - - - -

Interview of TED LEHMAN by the Nuclear
Regulatory Commission Fact Finding Task Force, taken
before me, Anne I. McBrayer, a Notary Public in and
for the State of Ohio, at the Site Emergency
Operations Center, Davis-Besse Nuclear Plant, Oak
Harbor, Ohio, on Wednesday, June 12, 1985, at 9:08
o'clock a.m.

1 TED LEHMAN

2 being called as a witness, was interviewed as
3 follows:

4 EXAMINATION

5 BY MR. ROSSI:

6 Q. Okay. This is Ted Lehman. And, Ted, why
7 don't you tell us what your position in the company
8 is?

9 A. Okay. I hold the position of shift
10 supervisor. I've held that since July 1st of 1981.
11 Before that, I was an assistant shift supervisor
12 since the beginning of the plant operation. I was
13 one of the original coal license members. Been in
14 the program since April of 1972.

15 Q. Okay. And you were on duty, I guess, the
16 night of the 9th?

17 A. 9th, yes, I was.

18 Q. At the time that you had the problem with
19 the main feedwater pump?

20 A. Yes.

21 Q. Maybe the best thing to do is to have him
22 describe what occurred and refer to any graphs or
23 records that you have?

24 BY MR. BEARD:

1 Q. Can I ask you one sort of administrative
2 thing?

3 A. Go ahead.

4 Q. You were on that shift. What time at this
5 plant does that shift start?

6 A. Twelve midnight.

7 Q. It starts at twelve midnight. In any
8 event, we're talking about it took place at roughly
9 1:30 in the morning, so you had been on duty an hour
10 and a half?

11 A. Hour and a half.

12 Q. And I presume when you came on duty in
13 your turnover, the shift from the previous shift to
14 you folks, there were no significant or unusual
15 plant conditions or maybe you could cover that so it
16 would give us a background of where we're coming
17 into this from.

18 BY MR. ROSSI:

19 Q. It might be good if you started at the
20 time you came onto the shift and tell us, you know,
21 what, if anything, occurred?

22 A. When we came on shift, the plant was at 90
23 percent power, 800, roughly 820 megawatts electrical.
24 We -- the only significant difference from normal

1 operations, we had had problems with the main feed
2 pump oil systems. As a result of that, we were
3 running with the No. 1 main feed pump in automatic,
4 and No. 2 main feed pump was in manual.

5 BY MR. BEARD:

6 Q. When you say oil system, Ted, you're not
7 talking about lube oil, are you?

8 A. No, control oil.

9 Q. Control oil. Okay. Just want to make
10 sure that's clear.

11 A. Yes. We had problems of -- when we were
12 coming up from the last trip that we'd had, during
13 that trip both main feed pumps had tripped shortly
14 after the reactor tripped. During the investigation
15 of that, they discovered an anomaly in the oil
16 system for the No. 1 main feed pump. They didn't
17 really have a resolution to that.

18 While they were down, they instrumented
19 both pumps. And then we brought the plant up, and
20 they were just going to watch the instrumentation.
21 See if they could find anything out about that.
22 They wanted one pump to be run in automatic, one
23 pump manually. They didn't have any preference
24 which one was which. We just, you know, we had the

1 line up we did in the way we started up.

2 Q. Was there some rationale as to why one
3 automatic and why one manual?

4 A. Just in case something -- if something
5 would happen, we'd have one pump that wasn't relying
6 on the control oil system as such.

7 Q. So the oil system that you were having
8 difficulties with was relating to the automatic
9 control and not related to the manual?

10 A. That was the theory.

11 Q. Okay.

12 A. It had problems before where both pumps
13 would tend to -- oh, what can I say. They were
14 thinking that -- we have a, what they called, rapid
15 feedwater reduction system on our feedwater pump
16 that is supposed to aid in our feedwater control
17 following a trip, post trip. One of the functions
18 of that system is to increase the main feed pump
19 speed to keep our feedwater delta P high due to the
20 increased steam pressure.

21 One of the theories was that the rapid
22 increase that the system would give to the feed
23 pumps might be causing the lube oil system to -- or
24 not the lube oil, but the control oil to fail in

1 some method. Not necessarily fail, but have a
2 malfunction, some method that would cause the pumps
3 to trip.

4 Because of that, they wanted us to run
5 with one feed pump in manual such that it would not
6 respond to that rapid feedwater reduction system in
7 the event it would trip.

8 Q. So the control system that was apparently
9 involved was the rapid reduction part, which as I
10 think is -- is that now part of the integrated
11 control system?

12 A. It's tied into the integrated control
13 system. It's not really a fault in a rapid
14 feedwater reduction, but more in response of the
15 feed pump to that. It would only appear usually
16 during a trip.

17 Q. Okay. So it wouldn't --

18 A. A post trip.

19 Q. It wouldn't be involved with the automatic
20 controls used to maintain the plant at stated power?

21 A. No.

22 Q. But only in a post trip situation?

23 A. Just in post trip is when it showed up
24 before this.

1 BY MR. ROSSI:

2 Q. What sort of problems -- well, let me go
3 back one step before that. Had this control system
4 for the main feedwater pumps, this was something
5 that was newly installed?

6 A. The control systems on the main feed pumps
7 were put in during the last fueling outage.

8 Q. Which would have been what date about?

9 A. It was last fall.

10 Q. That's close enough.

11 A. Sometime. I can't remember exact dates on
12 that. But it was installed during that outage.

13 This was a new system from GE that was supposed to
14 be of a considerable improvement over the original
15 systems that came with the pumps.

16 BY MR. BEARD:

17 Q. In case I'm confused a bit, maybe you can
18 help me understand this. Are you saying the rapid
19 feedwater reduction system was installed during this
20 outage or a new improved version of it was installed?

21 A. No. It was the actual control system for
22 the feed pump. The actual control cabinet and
23 control system for the feed pump itself was changed.

24 Q. Okay.

1 A. The rapid feedwater reduction, I couldn't
2 give you the exact dates when that had been put in.
3 It was sometime before even this. And that was just
4 a modification to the ICS to aid in plant response
5 to a reactor trip.

6 BY MR. ROSSI:

7 Q. Had they been having -- had you been
8 having problems with the feedwater control system
9 since last fall or --

10 A. No.

11 Q. -- had these --

12 A. Up until this time, it had been a pretty
13 nice system.

14 Q. The new one?

15 A. Yes. It ran very smoothly. Gave us much
16 better control of the pumps. The old one used to
17 be -- well, just cantankerous. Sometimes we'd have
18 trouble getting the pumps off gear when we were
19 bringing the pumps up. We'd have to go down and
20 crank on the controllers down there to get the thing
21 to come up and just various problems like that.
22 These were much better from that standpoint.

23 Q. And so the problems started like just
24 during a recent reactor trip or --

1 A. Oh, it had been like -- we had a trip
2 about a week before mine, and it started sometime
3 shortly before that that they started experiencing
4 some of these problems.

5 Q. So a couple of weeks is what you're saying?

6 A. At least.

7 BY MR. BELL:

8 Q. That was my -- you're talking like the
9 feed pump problem started in May of '85 then?

10 A. I can't give you an exact date, but yeah,
11 it was sometime previous to this they experienced
12 some of these problems.

13 BY MR. ROSSI:

14 Q. But it was on the order of maybe a month
15 previous?

16 A. Yeah.

17 Q. Not several months previous?

18 A. Usually on a post trip condition. They'd
19 never given us any problems while we were operating.

20 BY MR. BELL:

21 Q. And did, as a part of the recovery, did
22 anybody other than instrument No. 1 feed pump, did
23 anybody make any changes to the adjustments of the
24 control oil system or did they just decide to

1 instrument the system and not troubleshoot the
2 system?

3 A. They troubleshooted the system as well as
4 they could with the pump not running.

5 Q. Okay.

6 A. And there wasn't a lot they could see. So
7 they -- the decision was made to not delay the
8 start-up any longer, to just go ahead and put the
9 instrumentation on the pump and start the plant back
10 up and observe what would happen.

11 Q. Was there any discussion about limiting
12 plant power to the maximum power you can make on
13 only one feed pump while the other feed pump was
14 being troubleshooted?

15 A. No.

16 Q. So that you could get some actual -- there
17 was no discussion like that?

18 A. That wasn't really considered.

19 Q. And one final condition. One final
20 question, and I'll let you continue. You said the
21 anomaly appeared in No. 1 main feed pump.

22 A. That was the one we observed it in first.

23 Q. Okay. And what sort of anomaly was that?

24 A. It was something that occurred that they

1 never could really say that it was related to the
2 problems they had experienced with the pumps. With
3 the pump on turning gear, when you would initially
4 roll the pump up in speed, the standby pump would
5 start just because of the, you know, as the control
6 system picked up and the in-surge on the oil system,
7 the second pump would kick in momentarily.

8 Q. So just let me interrupt you a minute.
9 When this pump rolls up, then there's a reduction in
10 oil pressure that picks up the standby pump?
11 Apparent reduction in oil pressure?

12 A. Yeah, it's just. There's oil regulators
13 in the system. The pumps put out something like 250
14 pounds of oil. And that's stepped down once for
15 control oil and again for lube oil.

16 Q. Okay.

17 A. And it's just when you initially start
18 rolling the pumps up until the pressure regulators
19 can catch it, sometimes the pressure will just dip
20 low enough it will catch the standby pump and bring
21 it on. Then the, you know, the -- it will all level
22 back out, and you'll turn the standby pump off.

23 As it occurred, we were starting to roll
24 the pump up as such, and the standby pump came on.

1 And the operator looked down and saw that and he
2 tripped it. As soon as he tripped the oil pump, the
3 main feed pump tripped.

4 Q. So he caught it while pressure was still
5 low?

6 A. Well, the pressure had apparently
7 stabilized, but it shouldn't have done it under any
8 case.

9 Q. What tripped the feed pump then?

10 A. As they subsequently found out, it was,
11 for some reason, it was the thrust bearing wear
12 detector trips, for whatever reason.

13 Q. Okay. Now --

14 A. They never -- they couldn't find anything
15 that would say why this happened. It was just
16 something that, you know, if you caught it at just
17 the right time, just when the regulators were just,
18 you know, starting to catch it, if you dump that
19 standby pump, the main feed pump was tripped, and it
20 was the thrust bearing wear detectors that would
21 trip.

22 Q. Okay. Have you had any problems with dirt
23 or foreign material in this control oil system that
24 would make the system act erratically?

1 A. No.

2 Q. Plugs, small orifices or that kind of
3 thing?

4 A. No.

5 Q. Okay. Thank you, sir.

6 BY MR. ROSSI:

7 Q. Have you had these same kind of problems
8 with the main feedwater pump also; is that correct?
9 I mean, you --

10 A. It wasn't found on the No. 2 pump.

11 Q. This problem wasn't?

12 A. No.

13 Q. The one that was found during
14 troubleshooting. But the tripping of a after-
15 reactor trip had occurred on it too?

16 A. Yeah, on the last trip before this one,
17 both pumps tripped within a matter of seconds of
18 each other, immediately after the trip.

19 BY MR. BEARD:

20 Q. Let me make sure I understood what you
21 said earlier, Ted. The problem had been observed
22 with the No. 1 main feed pump. And then for the
23 start-up it was decided one in automatic and one in
24 manual.

1 A. Yes.

2 Q. I think you indicated that the guidance
3 that operators had received, it really didn't make
4 any difference which one but whatever. But now when
5 you did the start-up or when the start-up was done,
6 which ones did you have in automatic and which one
7 was in manual, do you remember?

8 A. When the plant finally got up on the line,
9 they had 2 in manual and 1 in automatic.

10 Q. So No. 1 was in automatic and No. 2 was in
11 manual?

12 A. Yes.

13 Q. And --

14 A. We discovered this problem one afternoon
15 when we were on afternoon shift, and we played
16 around with this. And, you know, everybody
17 scratched their heads and looked at this. Then
18 they decided they would go ahead and instrument
19 the pump. Before they started up they tried to
20 duplicate this problem again on the day shift, and
21 they couldn't do it.

22 BY MR. ROSSI:

23 Q. This problem being the one where you
24 tripped off the standby pump?

1 A. They couldn't duplicate the problem. So
2 they figured maybe it was just -- maybe they just
3 had to exercise the system or whatever. That was
4 their explanation of it.

5 A decision was made to go ahead and take
6 the plant up with the pumps in that configuration,
7 and they didn't care which one we had in manual and
8 which one we had in auto. It was up to our
9 discretion.

10 BY MR. BELL:

11 Q. When the rapid feedwater reduction system
12 sends a signal to increase main feed pump speed,
13 does that involve an increase in control pressure in
14 that feed pump to position the governor valve?

15 A. Not an increase.

16 Q. How do we ramp those valves up to a higher
17 position then?

18 A. Well, they're hydraulic. There's -- the
19 system will put just -- put more oil to the cylinder,
20 the operating cylinder, and it hits the valves.

21 Q. So when it does put more oil to this
22 operating cylinder in the position, the low pressure
23 poppets, then there -- then this regulator has to
24 reposition to hold a constant control oil pressure?

1 A. I would assume that much.

2 Q. Okay.

3 A. I can't -- you know, you're getting a
4 little bit past my knowledge of the -- just how the
5 system operates. But it's my understanding of it.

6 Q. All right, sir. Thank you.

7 BY MR. BEARD:

8 Q. In summary then, when you came on shift at
9 midnight, the only, quote, unusual thing you had to
10 contend with was this problem on the main feed pumps.
11 And everything else ran pretty much as typical?

12 A. Yes.

13 BY MR. ROSSI:

14 Q. And then things stayed that way until 1:30,
15 just steady state of operation?

16 A. Steady state.

17 Q. Uneventful.

18 A. It was quiet, you know. Night shift.
19 Nothing abnormal was happening. The weekend, there
20 were no extra maintenance personnel then. So there
21 was no testing, no maintenance of any kind going on.
22 Just a very quiet Sunday morning.

23 BY MR. LANNING:

24 Q. Do you recall any problem with the source

1 range detectors or anything to do with the source
2 range?

3 A. The No. 1 source range was declared
4 unoperable.

5 BY MR. BEARD:

6 Q. Was it really inoperable, Ted, or was it
7 legally inoperable on some technicality?

8 A. We've had the problem with the No. 1
9 source range in that as it's -- when it's -- the
10 source range during power operation is normally
11 deenergized.

12 Q. Right.

13 A. For whatever reason a static charge tends
14 to build up on the center probe or the center lead
15 of the cable, and that feeds through the circuit.
16 And with the thing deenergized, it will sit there,
17 and it will read counts, 30, 40, 50, maybe higher
18 counts on source range. And, you know, by rights,
19 it's not right and we declared it inoperable per
20 textbooks.

21 BY MR. LANNING:

22 Q. How long has it been in this condition?

23 A. Really it's been quite a while. It will
24 be in a condition like that. If the instrument and

1 control technicians come over and they'll do the ST
2 on it, it will straighten back out and come down and
3 it will read right.

4 Q. I see.

5 BY MR. BEARD:

6 Q. And then I guess after a period of time,
7 the misbehavior reoccurs?

8 A. Sometimes it will reoccur and wind up in
9 the same condition again.

10 Q. Following up on that same line, was it
11 inoperable such that in your opinion that on a plant
12 trip you wouldn't be able to depend upon its release
13 or did it have this misbehavior that only seemed to
14 occur related to when you were at power and the
15 detector was turned off so that it's been --

16 A. It only happened when we were at power and
17 the detector was off.

18 Q. So you, as a supervisor or as an operator,
19 you -- did you feel that you could have depended
20 upon its reading on a post trip situation or --

21 A. I wasn't concerned about it.

22 Q. Okay.

23 A. As such. That was no concern.

24 Q. Okay.

1 BY MR. ROSSI:

2 Q. Okay. Why don't you go on then and
3 describe how you first noted that something was
4 happening and tell us what you observed about the
5 event.

6 A. I was in my office, and I had just gotten
7 up. I don't even know where I was going to go now.
8 But I heard something start to wind down. The shift
9 supervisor's office sits in somewhat of a unique
10 position in that in that one spot, you can hear a
11 majority of the larger equipment that runs in the
12 plant. And I heard something just start to wind
13 down.

14 I immediately went over to the control
15 room and discovered that the No. 1 feed pump had
16 tripped. The plant was in a runback. The RO had
17 gone to the No. 2 feed pump controller and was
18 attempting to raise it in manual and attempt to
19 bring the fee water pressure and the flow up. He
20 wasn't successful in this. The plant tripped on
21 RCS pressure. We went into our emergency procedure
22 for reactor trip. Started --

23 BY MR. BELL:

24 Q. This --

1 A. That one right there.

2 Q. This is their emergency trip procedure EP
3 1202.01.

4 BY MR. BEARD:

5 Q. This is your -- you use the term emergency
6 procedure, and that's a proper name. But it's
7 really the procedure that you use on any plant trip;
8 is that correct?

9 A. Yes.

10 Q. Okay.

11 A. The assistant shift supervisor had opened
12 the procedure up, gone to the immediate actions and
13 read through those. And then started through the
14 supplementary actions in the procedure which
15 verifies the reactors trip, turbine trip, rods in
16 the bottom, turbine valves are closed, electrical
17 power, station air, instrument air, it goes through
18 a whole list of parameters to check.

19 Q. Now, in that area comes up the question
20 about what indication did you have on your nuclear
21 instrumentation system of the flux level at that
22 time?

23 A. Normal post trip. It would be in the
24 intermediate range.

1 Q. You were still in the intermediate range
2 at that time?

3 A. Yes, decaying down immediately after trip.
4 It takes quite a few minutes to get down into the
5 source range post trip. We were going through that.
6 At the same time I was observing the feedwater
7 system along with the RO that had been trying to
8 bring the feed pump up. One of our concerns was too
9 that the feedwater system would cut back and come
10 down onto low level limits on the steam generators
11 and hold there.

12 We've had occasions where it would
13 undershoot, and we would have a SFRCS actuation on
14 low steam generator level. So I was watching this
15 pretty close as the levels came down. And levels
16 came down nicely, came right in. We watched the
17 valves, the start-up feedwater valves pick up. The
18 levels came in right at low level limits and
19 appeared to be stable. Was looking real good.
20 During this period of time the safeties had been
21 lifting, and then they reseated.

22 Q. You're talking about steam line safeties?

23 A. Yes, main steam line safeties, which, you
24 know, as they should have. And then as we were

1 observing this, all of a sudden the safeties picked
2 up again, which was unusual. I looked up to see
3 what was causing this and discovered that the MSIVs
4 had gone closed for no apparent reason that we could
5 discern.

6 We immediately checked the enunciators.
7 We had no SFRCS trip as would be indicated by those.
8 We had no other equipment actuation which would
9 indicate an SFRCS trip. No --

10 Q. No ESF either?

11 A. Nothing. Just had gone closed.

12 Q. With regard to enunciators, just to give
13 me a feel for it, how many enunciators were on
14 roughly prior to the start of the event? I mean,
15 are we talking half a dozen, a dozen?

16 A. We would normally have maybe -- maybe a
17 dozen.

18 Q. Okay. So that prior to the event, there
19 was maybe a dozen lit. Now, at the time that you
20 found out that the MSIVs were closing, you were
21 looking around for causes. And one of the places
22 you had looked was the enunciator panels. About
23 roughly, if you can remember, how many panels were
24 lit at that time? 200, 20?

- 1 A. No. Let me think about this for a minute.
- 2 A. I'd have to say maybe 30, 40.
- 3 Q. 30 or 40, okay.
- 4 A. That is a rough guess.
- 5 Q. I was just trying to get a feel for about
- 6 how many.
- 7 A. The enunciator panel that I was looking at
- 8 had none lit on it.
- 9 Q. Now, is this a special enunciator panel?
- 10 A. The enunciators are divided up into
- 11 sections around there, and there's one section that
- 12 has all the SFRCS alarms on it.
- 13 Q. That's it was the SFRCS enunciator panel?
- 14 A. And it had nothing lit on it. It's got
- 15 the SFRCS alarms and steam generator level on it.
- 16 And it's the first place I looked, and it was blank.
- 17 Nothing lit.
- 18 Q. Do you have a separate enunciator panel
- 19 for the ESF actuation system?
- 20 A. Yes, clear over on the other side.
- 21 Q. Were any of those lit as you remember?
- 22 A. For emergency safety features?
- 23 Q. Yes.
- 24 A. Nothing for that.

1 Q. Okay.

2 A. We had enunciators for the RPS system that
3 would be associated with the reactor trip. Most of
4 the enunciators were normal for the reactor trip and
5 for the trip of the main feed pump.

6 Q. Okay.

7 A. There was really nothing abnormal in the
8 enunciators that we had for the conditions we had.

9 Q. So I guess I interrupt you quite a bit,
10 but I think the point you were at was that you found
11 that the one steam safeties had basically lifted and,
12 I guess you were saying, stayed open. And in
13 looking to that, you found the two MSIVs closed, and
14 you looked around and found no obvious reason why
15 they closed, is that about where you were?

16 A. It wasn't just one safety. A number of
17 them lifted again. It's hard to tell. A loud roar.
18 And when I looked up to see what the cause of that
19 was, the first thing that caught my eye, we got two
20 big lights over there that are indicators for the
21 MSIVs, and they are closed.

22 BY MR. BELL:

23 Q. Ted, it's normal on any reactor lift to
24 lift the safety valves?

1 A. Yes.

2 Q. And when they closed, you thought
3 everything was normal. And when the steam shot up,
4 that increased steam pressure for the second time,
5 and safeties lifted for the second time, and that's
6 the abnormal lift?

7 A. It was the second lift of the safeties
8 that caught my attention, yes. The initial lift of
9 the safeties is normal. We'll lift all 18 safeties,
10 and they'll blow for a given period of time and then
11 reseal. Sometimes you'll get one that -- well, you
12 know, any main steam safety, code safety, is -- can
13 be erratic. Sometimes when they get hot, they'll
14 simmer and sometimes relift a little bit. But this
15 was a major blow the second time, and that was what
16 brought my attention up. And I looked around and
17 saw the MSIVs were closed.

18 BY MR. BEARD:

19 Q. So the first abnormality in this post trip
20 situation was the closure of the MSIVs?

21 A. Yes, because up until that time, the --
22 for a post trip, the conditions were looking good.
23 I felt our chances of stabilizing out were very good
24 at the time. And I was surprised to see those

1 things going shut especially with no other
2 indications as to what closed them.

3 BY MR. LANNING:

4 Q. What type of signals would normally close
5 the MSIVs?

6 A. The only thing that we've got would really
7 close them would be an SFRCS actuation.

8 BY MR. BEARD:

9 Q. You mentioned in answer to the question
10 about what signals would operate the MSIVs?

11 A. Yes.

12 Q. That the steam feed rupture control system
13 would cause that?

14 A. Yes.

15 Q. My question was, would the ESF actuation
16 system also cause it?

17 A. Yes.

18 Q. Okay. Are those basically the only two
19 sources of automatic closure signals to the MSIVs?

20 A. Yes.

21 Q. Okay.

22 A. Okay. Having seen the safeties were --
23 having seen that the MSIVs were closed, we knew
24 there wasn't going to be any easy way out of it.

1 You know, it's not something that you can
2 immediately reopen. They were closed, and they were
3 going to stay that way.

4 So in anticipation of an SFRCS actuation,
5 which we knew we would get if we waited long enough,
6 the steam generator levels would boil down, and we
7 would pick up a low level trip, the reactor operator
8 asked permission to trip SFRCS manually.

9 Q. It's anticipatory?

10 A. Anticipatory. It's just an anticipatory
11 action, you know. The quicker we can get ourselves --
12 the sooner we catch the steam generator levels, the
13 better off we'd be. He went over to the back panel
14 and tripped the SFRCS.

15 Q. By back panel --

16 A. The vertical panels.

17 Q. The vertical panel in the main control
18 room, not a back panel in the sense of --

19 A. No, just the vertical panels as opposed to
20 the bench panels in the front. He went back and
21 tripped the SFRCS. Came back around. And we
22 watched for proper actuation of the auxiliary
23 feedwater system. The first thing I saw were the
24 aux. feedwater segregation valves. It's AF 69

1 through 72. These are the runs that line up the
2 feedwater flow for whichever steam generator.

3 I looked at those, and the valves were
4 lined up such that 1 would feed 2 and 2 would feed 1.
5 This was abnormal for a low level trip. They should
6 have lined up so that No. 1 system would fit in No.
7 1 generator and No. 2 would feed No. 2.

8 The RO looked at that and immediately
9 looked over to the back panel and observed that he
10 had tripped the SFRCS system on low steam generator
11 pressure rather than low levels.

12 Q. So it was at the point that you realized
13 the aux. feedwater trains had lined up in a
14 crisscross pattern rather than a straight-in
15 pattern --

16 A. Yes.

17 Q. -- that you deduced that the actuation had
18 not been a desirable one?

19 A. Yes. I immediately walked to the back
20 panel myself. We reset the low pressure trips and
21 retriipped it on low level.

22 Q. Okay.

23 A. It was during this same time that the aux.
24 feed pumps had started, come up in speed. And the

1 RO observed them coasting back down again and looked
2 up, and we had the overspeed trip alarms in for both.

3 Q. On both?

4 A. For both aux. feed pumps.

5 Q. What's a normal start-up time on one of
6 your aux. feed pumps from the time, for example, if
7 the -- if the operator had gone over and hit this
8 manual actuation, what's a typical response time
9 that the pump would be up to proper feed and be able
10 to put out water?

11 A. It could be 25, 30 seconds.

12 Q. Okay.

13 BY MR. LANNING:

14 Q. Did the RO realize he had pushed the wrong
15 buttons?

16 A. He was the first one to see it. He
17 discovered his own mistake. And we immediately
18 reset it.

19 BY MR. ROSSI:

20 Q. And you noticed both aux. feed pumps now
21 had tripped?

22 A. Yes. At the same time, while this was
23 occurring, the assistant shift supervisor had walked
24 around to the back panel to verify proper actuation

1 of the steam valves that supply the aux. feed pumps.
2 It was while he was back there that he observed that
3 AF 599 and AF 608, which are the aux. feedwater stop
4 valves, had closed. He attempted to reset and open
5 these valves.

6 BY MR. BEARD:

7 Q. Excuse me, was the closure of those valves
8 a proper response or something abnormal?

9 A. It was a proper response for the low
10 pressure trips that was initially inserted.

11 Q. Yes.

12 A. They should have come back open.

13 Q. Based on the resetting of the low pressure
14 actuation, manual input of the low pressure
15 actuation followed by the manual input of low level
16 actuation?

17 A. Yes, sir.

18 Q. Okay.

19 BY MR. ROSSI:

20 Q. Those valve numbers, again, those were
21 aux. feed numbers, and their numbers were?

22 A. AF 599 and AF 608. Okay. These valves
23 were observed to be closed. He immediately hit the
24 resets and tried to reopen them.

1 BY MR. BEARD:

2 Q. Now, resets here, you're talking about a
3 local component reset versus a system?

4 A. Yes. It's a local -- it's a local
5 component reset on each valve. They've each got a
6 reset button. And then each valve has two
7 controllers. Both of those have to be hit to open
8 them.

9 Q. Okay.

10 A. He tried those. And the valves did not
11 respond. He then immediately went to the cabinet
12 room in the back to the SFRCS cabinets.

13 BY MR. ROSSI:

14 Q. This is the assistant shift supervisor?

15 A. This is the assistant, yeah, shift
16 supervisor. And went to what we call initial bypass
17 and block. This is a procedure that will clear any
18 trips that are in the system and block them. Once
19 he released on that, the system would have lined
20 back up by the low level trips that were locked into
21 them.

22 BY MR. BEARD:

23 Q. But it would -- would it block the manual
24 input or --

1 A. No, it would not block the manual input if
2 manual input was locked into them. Once you push
3 those buttons, they're locked in.

4 Q. I guess I'm getting a little confused on
5 the word lock and block.

6 A. The manual trip buttons that we have in
7 the control room for the SFRCS system are the type
8 that once you depress them, they lock in place.

9 Q. Physically stay depressed?

10 A. They physically stay depressed. You have
11 to hit a -- I don't know what it's labeled, but it's
12 a little button on the side to release that.

13 Q. Okay.

14 A. Those low level trips were locked into
15 place. He went to initial bypass and block which
16 clears all the trips that would be in it and let go
17 of it.

18 Q. The manual low levels still being locked
19 in. Okay.

20 A. You know, would have cleared the logic.
21 And the system, if there was any problems in the
22 logic, should have lined back up. As it turns out,
23 the system was lining back up as it should have
24 anyway. AF 599 and 608 apparently, when they went

1 closed and tried to reopen, torqued out.

2 BY MR. BELL:

3 Q. Let me interrupt your train of thought one
4 second. This initial bypass and block then would
5 clear out any trip signals that had been sensed
6 because of transmitter inputs?

7 A. Yes.

8 Q. Okay. But since you had manually
9 initiated it, you said you manually initiated low
10 level.

11 A. Yes.

12 Q. That signal would have remained sealed in
13 because it would be --

14 A. Yes.

15 Q. -- still present because the buttons are
16 still depressed?

17 A. Yes.

18 Q. Okay.

19 A. Now --

20 BY MR. ROSSI:

21 Q. Okay. The two valves are still -- he's
22 still not able to get the two valves open?

23 A. They're still closed.

24 Q. Still closed.

1 A. Now, when --

2 BY MR. LANNING:

3 Q. Excuse me a second. Let me ask a question.
4 Are we on procedures now, training to go and perform
5 this or --

6 A. Well, that was not. That was not. That
7 is not a procedural step, but it was not a bad step
8 to do at the time.

9 Q. Okay.

10 A. Now, let me back up a little bit here.
11 When the RO observed that the aux. feed pumps had
12 tripped, two EOs were immediately dispatched to the
13 aux. feed room.

14 BY MR. BEARD:

15 Q. EO being equipment operators?

16 A. Equipment operators.

17 Q. Nonlicensed equipment operators?

18 A. Nonlicensed equipment operators. Were
19 immediately dispatched to the aux. feed room. Let
20 me catch my train of thought here. After the
21 assistant shift supervisor came back into the
22 control room and observed that the valves were still
23 closed and the pumps had tripped, he immediately
24 left the control room to enable the start-up feed

1 pump. This is something that has to be done out in
2 the plant. It is kept valved out of service and the
3 breakers racked out.

4 Q. This is the start-up feed pump?

5 A. This is the start-up feed pump. This is a
6 motor driven feed pump that takes the suction off
7 the main feedwater and is used just for start-up
8 conditions. He immediately left the control room to
9 go put that pump in service. At the same time, I
10 went to my office to the locked valve key locker,
11 took out a locked valve key, gave it to another
12 equipment operator, and directed him to go into the
13 aux. building and manually open AF 599 and 608.

14 Q. So at this point, if I -- trying to get
15 the big picture here, you'd lost main feed. The
16 aux. feeds didn't seem to work right. And the
17 region was a problem with the pumps on trip and the
18 valves?

19 A. And the valves.

20 Q. And so at this point you seemed to be
21 saying the assistant shift supervisor was working on
22 a new pump which would be activating the start-up
23 feed pump?

24 A. Yes.

1 Q. You were working with an equipment
2 operator on the valve side of the auxiliary feed
3 pumps?

4 A. Yes.

5 Q. And so you had a parallel pass there in
6 order to get feedwater someplace?

7 A. Yes.

8 BY MR. ROSSI:

9 Q. Now, the RO had observed the aux. feed
10 pumps that tripped and sent two EOs to reset the
11 aux. feed pumps. Where did they have to go, the EOs,
12 to do that?

13 A. They had to go down into the aux. feed
14 pump room.

15 Q. Okay. And these other valves, or the
16 valves AF 599 and AF 608, where are they?

17 A. They are over in the auxiliary building.

18 Q. And he needed keys to manually open the
19 valves?

20 A. Yes, those are locked valves, and they are --
21 the hand wheels are chained. They had to be
22 unlocked so that they could manually operate the
23 valves.

24 BY MR. BEARD:

1 Q. What about security of getting through
2 locked doors for vital areas and things of this
3 nature? To what extent were they involved in either
4 of these two in-plant manipulations?

5 A. In the aux. building, all the doors were
6 on card readers.

7 Q. Card readers?

8 A. Card readers, which their ID badge would
9 open. There was no problem with that. The men that
10 went to the aux. feed pump room had to unlock a
11 padlock and slide back a hatch to get down into the
12 room.

13 Q. Now, the unlocking of the padlock, where
14 do they have to go or how do they get a key to this
15 padlock?

16 A. They have a key on the key rings that they
17 normally carry.

18 Q. Okay.

19 A. That would give them access to that room.

20 Q. So they didn't have to go any special
21 place or call the guard or anything to go in there?

22 A. No.

23 Q. They just whip it out from the side of
24 their hip?

1 A. That's right. They had the keys on them.
2 The only key that had to be obtained was the locked
3 valve key that I gave to the primary equipment
4 operator to unlock the valves.

5 Q. Okay.

6 BY MR. ROSSI:

7 Q. Let me ask you another question about the
8 card readers that allow the people to go through the
9 doors to get to the auxiliary building. They're
10 controlled by a computer?

11 A. Yes, sir.

12 Q. If that computer is out of service, what
13 happens to the doors?

14 A. The doors will not respond to a card.
15 Then they have to go -- resort to keys.

16 Q. And did they have the keys with them to do
17 that had the doors not responded to the card readers?

18 A. I don't know. The equipment operators on
19 the primary site don't normally carry a key ring.
20 They have no need for it. I would say that he
21 probably did not have any keys on him as such.

22 BY MR. BEARD:

23 Q. Well, in the event that should occur, what
24 would be the normal thing that you would expect your

1 people to do when they get down there and find the
2 card readers misbehaving? Would it be to call
3 security to get a guard over so they could open it
4 for them or what would you typically expect?

5 A. It would probably be quicker for the man
6 to come back to my office and take a set of master
7 keys.

8 Q. I see. Okay.

9 BY MR. BELL:

10 Q. He wouldn't have to suit out or suit in to
11 go into this part of the auxiliary room?

12 A. No. That was not required for any of the
13 operations that had to be done in this instant.

14 Q. Okay. So now you've got gentlemen going
15 down to -- the assistant shift supervisor's going
16 down to line the start-up feed pump. And one of
17 your equipment operators is going to line up the
18 auxiliary feed pump turbines, reset those?

19 A. Two men.

20 Q. Two men. And the fourth man is going to
21 open AF 599 and 608.

22 A. And 608.

23 Q. Would you tell me how close valves FW 106
24 and FW 89 are physically? I've got a print here.

- 1 Q. Okay.
- 2 A. 106 and 85.
- 3 Q. Those are the two possible suction sources
- 4 to the start?
- 5 A. Yeah, he jumped on 106. How close.
- 6 Q. He opens 106, right?
- 7 A. Um-hmm.
- 8 Q. And if he opens 85, we put the DFT right
- 9 to the suction of the off-speed pumps; is that right?
- 10 A. Yes. Let me see your print.
- 11 Q. This was given to us yesterday.
- 12 MR. BURNS: Why don't you identify what
- 13 you're showing him?
- 14 Q. This is training print figure 1 that came
- 15 from P&IDM 006 B. Here is 106. This is the normal
- 16 suction valve, right?
- 17 A. Wait a minute. That's the discharge.
- 18 Q. Yes, excuse me, discharge. He has to
- 19 open --
- 20 A. He got 85.
- 21 Q. He opens 85? Or does he open 32?
- 22 A. No, wait a minute. This is 32. It would
- 23 be 32. And then 106 would be the discharge.
- 24 Q. And 32 then lines up the start-up feed

1 pump from the DFT?

2 A. Yes.

3 Q. And 106 lines up the discharge of the
4 start-up pump up through to the normal feed header?

5 A. Yes.

6 Q. Okay. Are 85 and 32 very close together
7 physically? This valve and this valve?

8 A. They're not that far apart. They're in
9 close proximity.

10 Q. Okay. Thank you, sir.

11 BY MR. BEARD:

12 Q. I hope you understand, Ted, that the
13 barrage of questions that we're giving you are
14 intended only to get a detailed knowledge of what
15 happened and what did not happen. We are not
16 criticizing your actions whatsoever?

17 A. No, I'm not -- that's the impression I get.

18 Q. We're just trying to understand. I mean,
19 after all, you know this plant a lot better than we
20 do.

21 BY MR. ROSSI:

22 Q. Okay. So the two EOs have gone off to
23 reset the aux. feed pump controls. The assistant
24 shift supervisor has left the control room to put

1 the start-up feedwater pump in service. And the
2 third EO has gone to open AF 599 and AF 608.

3 A. Yes, sir.

4 Q. I think that's where we were with that
5 story?

6 A. Yeah.

7 Q. Okay. Why don't you continue?

8 BY MR. BEARD:

9 Q. Can I -- just to get it in perspective,
10 when all these things were going on, what was your
11 feel for the overall plant condition in terms of did
12 you have on your hand -- obviously, some of these
13 are absurd answers, but let me give you a couple --
14 a routine reactor trip, an accident that could
15 possibly lead to core melt, a slightly complicated
16 reactor trip or a near miss to an accident or, you
17 know, what overall feel did you have for the plant
18 condition you were trying to cope with?

19 A. We realized that we were in a total loss
20 of feedwater. We also realized that this was the
21 condition that started off TMI-2. By this time,
22 things were getting a little shaky. I had been on
23 the telephone probably since the time we discovered
24 that the MSIVs had gone closed. I'd gotten Bill

1 O'Connor, the operations engineer, on the telephone
2 and I talked with him. It's probably somewhere in
3 the period we're in right now. He hung up so he
4 could make other phone calls to other people.

5 Q. Were these phone calls for notification or
6 technical advice?

7 A. No for notification. He wanted to get
8 ahold of the plant manager and the operations
9 supervisor. During this period of time I attempted
10 one more time to open AF 599 and 608. It was while
11 I was attempting to do this I noticed that one of
12 them came open. A couple of minutes later the
13 second one came open.

14 We had the steam valves were already open,
15 and the valves on the feedwater side of the system
16 were now open. So we had a flow path, steam too and
17 feedwater from the aux. water feed pumps. We were
18 now relying on, for that system, on the EOs that
19 were in the room to get the pumps started.

20 BY MR. ROSSI:

21 Q. The opening of AF 599 and AF 608, was
22 that -- or maybe you don't know the answer to this.
23 Was that because of the EO that had gone to open
24 them?

1 A. Yes.

2 Q. Or -- not your attempt?

3 A. That was his efforts.

4 Q. His efforts. Okay.

5 A. Because they opened while I -- I wasn't
6 pushing anything.

7 Q. Okay.

8 A. By this time, I just notice that the one
9 came open, and then a couple minutes later the
10 second one came open. That was his efforts that
11 opened those valves.

12 BY MR. BEARD:

13 Q. I'm really trying to get a feel, Ted, for
14 the gravity of the overall situation as it was
15 perceived, not the way the equipment is responding
16 at the minute. Just to take a snapshot, you know,
17 how big or how bad did you see it?

18 A. Okay. By this time, each time I looked
19 up -- we've got a big T ave meter on the back panel.
20 Each time I looked up, the temperature was higher
21 and higher. We realized this. It had been
22 mentioned once from Bill O'Connor, as I was talking
23 to him, you know. He says we have to consider the
24 possibility of HPI PORV cooling.

1 As the RO and I were waiting for the
2 equipment operator to get the aux. feed pumps
3 running, it was mentioned again. And we realized
4 the gravity of the situation. As the temperature
5 got higher, we were approaching a point where we
6 were going to have to do it if something didn't
7 occur quickly.

8 By this time, Bill O'Connor had called me
9 back, and we were talking. And he mentioned it
10 again, that if we didn't get it back shortly, we
11 would have to go to make up HPI PORV cooling. It
12 was just at this time, 'cause I mean, by now it was
13 getting right to the fine edge. It was right at
14 this time that the start-up feed pump came available.

15 Q. The start-up was the first one available?

16 A. The start-up was the first one to come
17 back. The RO immediately started the pump. Opened
18 the start-up feedwater valve for the No. 1 steam
19 generator. Those have SFRCS closures to them.
20 During this period of time, the second RO had gone
21 to the back of the cabinet room and reset those. So
22 we were set that way.

23 He immediately started the pump and opened
24 the valve and got feedwater flow into the No. 1

1 steam generator. That immediately turned our
2 temperature rise and started decreasing RCS pressure.
3 This gave us a little bit of relief, mental relief.

4 Q. Yes. What was the emotional state of your
5 people in the control room, the operators that
6 worked for you, in the sense of how were they
7 handling themselves? This obviously was a tense
8 situation I would presume?

9 A. They handled themselves quite well.

10 Q. Well, I didn't mean it that way, Ted, I'm
11 sorry. I meant -- well, let me just let you answer.
12 I'm sorry.

13 A. The operator that was handling the primary
14 side was -- was doing it quite well. I did not get
15 the impression from him that he was having any
16 problems. He didn't convey to me that he had any
17 problems on his side. I left him do his job.

18 The reactor operator who was on the
19 feedwater side realized just how close we were
20 getting, and he wanted a feed pump of some kind back
21 in the worst way. I don't know what more I could
22 say.

23 Q. Okay. The last --

24 A. You know, it was a tough situation. You

1 know, the adrenaline was flowing.

2 Q. The last question I had in mind in this
3 line is with regard to the HPI and PORV cooling mode,
4 which is sometimes referred to as feed and bleed,
5 did your training or your procedures have some
6 predecided threshold at which you would enter that
7 mode of operation or was it a judgment call?

8 A. Okay. It's right in the procedure that if
9 both generators go dry, as defined by levels less
10 than eight inches or pressures less than 960 and
11 decreasing, you're there.

12 Q. Okay.

13 A. We never observed levels in the generators
14 less than 10. And I personally never saw pressures
15 any less than in the range of 950 to 975, and they
16 held fairly stable. Generators were bottled up
17 fairly tight. They were holding steam pressure. So
18 we were, you know, still clear on that standpoint of
19 it. It was an option, but it was one that was
20 coming very close.

21 Q. I guess I was thinking of earlier you
22 mentioned that the T ave indications were continuing
23 to rise.

24 A. Yes.

1 Q. And I got the impression that maybe that
2 was a key indicator to you that it was getting close
3 to time to do something?

4 A. Well, it was one that I could see the
5 clearest.

6 Q. Okay.

7 A. We realized that, that you know, that
8 temperature rise was coming because, you know, we
9 were getting insufficient cooling. The highest I
10 saw it go was 590 degrees.

11 BY MR. ROSSI:

12 Q. Steam generators being empty by having
13 levels less than 8 inches or pressures less than
14 960, is that in itself the trigger point for going
15 to HPI PORV cooling?

16 A. That's as it's stated in the emergency
17 procedure.

18 BY MR. BEARD:

19 Q. Okay. Was there anything done or did you
20 direct anything to do to line up the systems in
21 anticipation or in preparation for going into that
22 feed and bleed mode of cooling?

23 A. Not at that time.

24 Q. Not at that time?

1 A. It's a procedure that is quick. It
2 wouldn't take very much at all for us to do it.

3 Q. I'm not criticizing you for that.

4 A. No, I know. But it would just be a matter
5 of starting the pump and opening the valves. And
6 then the primary operator would open up the PORV and
7 lock it open.

8 Q. What about the area of piggybacking the
9 HPI on top of the LPI?

10 A. That could be done if needed.

11 Q. All right. Do you know whether or not
12 such a configuration was, in fact, established?

13 A. Not at that time.

14 Q. Okay.

15 A. We had the start-up feed pump back, and we
16 were putting water in the No. 1 generator. Shortly
17 after this, the number two aux. feedwater pump
18 started up. The EOS in the room had considerable
19 trouble getting the pumps --

20 BY MR. ROSSI:

21 Q. I'm sorry, which one started?

22 A. The No. 2.

23 Q. The No. 2 aux. feed. Okay.

24 A. The EOS in the room had considerable

1 trouble getting the pumps latched. It's got a, what
2 they call, a trip throttle valve that has to be
3 latched up and then opened. And they had
4 considerable trouble getting these valves latched.

5 They finally got the No. 2 pump started.
6 It came up to speed and gave us a lot of feedwater
7 quickly. He had trouble -- the RO had trouble
8 getting control of this pump to start with. And we
9 really filled the generator higher than he would
10 have wanted to at the time.

11 The SFRCS system only brought the level up
12 to 46 inches. We took it in excess of that, close
13 to a hundred. I know it was in excess of 75 inches.
14 This caused a rather rapid shrink on the RCS and
15 pressure. Pressure fell rapidly. It got down to
16 1700 pounds. Primary side RO requested permission
17 to put on HPI to help recover his pressure in the
18 system.

19 BY MR. BEARD:

20 Q. May I interrupt at this point. Do you
21 believe that the depressurization on the primary
22 side was largely caused by the higher than desirable
23 level on the steam generator?

24 A. Yes. I have no doubt.

1 Q. Okay.

2 A. That was -- we put a lot of cold water in
3 the generator quickly. And there was no doubt that
4 that's what caused it to shrink. He asked
5 permission to put on HPI. We told him to piggyback
6 LPI to HPI. And he did such. That was on for a
7 period of maybe five minutes.

8 We never observed any flow from the HPI
9 system during this time. We were told later by the
10 tech section that their printouts indicated that we
11 had put some water in. It was just of such a
12 magnitude that we couldn't see it. By this time,
13 the secondary side RO had gotten his other aux. feed
14 pump started. And it was blind water also.

15 He had level control problems with this
16 pump to the extent that he never did get control of
17 it in the control room. That pump was controlled
18 using that trip throttle valve as a throttle valve
19 by one of the equipment operators in the aux. feed
20 pump room being directed over the Gai-Tronics system.

21 Q. You're saying I think on the No. 2 feed --
22 No. 1?

23 A. No. 1.

24 Q. No. 1, the automatic controls in the

1 control room apparently weren't functioning properly?

2 A. They did not function properly.

3 Q. And the manual controls in the control
4 room, the operator could have used, apparently
5 weren't functioning properly also. So what you
6 ended up with was local manual, if you will?

7 A. Yes.

8 Q. Via communications on it?

9 A. Yes. And he did subsequently get manual
10 control of the No. 2 aux. feed.pump on his panel.
11 So we at this time had three pumps giving us
12 feedwater. The configuration we wound up in was the
13 No. 1 steam generator was being fed by the start-up
14 feed pump. The No. 2 steam generator was being fed
15 by the No. 2 steam aux. feed jump. The No. 1 aux.
16 feed pump was left rolling just with the pressure
17 backed off just enough that it wasn't feeding just
18 because of the control problems he was having with
19 that.

20 Q. Okay. Does that pump have a miniflow
21 recirc line it was using there?

22 A. Yes.

23 Q. > that gets you in pretty good shape, I
24 would imagine, now that you've got three feed pumps?

1 A. By this time everybody was a little more
2 relaxed. We had a chance to step back and look at
3 our plant conditions.

4 Q. Yes.

5 A. The RO was establishing levels of 50 --
6 roughly 50 inches in each steam generator. The
7 primary side RO was getting good control of the RCS
8 back. His pressure was coming back up. He was
9 getting control of his pressurizer level. He was
10 getting stable on that side.

11 Q. One area that you haven't talked about,
12 let's go back to the primary side of the plant. Let
13 me see. I think you indicated that because of the
14 high level, the overfeed, if you will, on one of the
15 steam generators, the primary side experienced some
16 shrink, the pressure started coming down with that
17 as a primary driving force, and I think you
18 indicated you may have gotten as low as say 1700
19 pounds?

20 A. Yes.

21 Q. Okay. What about earlier in the event,
22 before the aux. feed pumps were brought on on the
23 primary side, did you have any experience with
24 regard to relief valves?

1 A. The PORV lifted.

2 Q. PORV is P.O.R.V.?

3 A. Power operated relief valve lifted at
4 least once that I knew of, 'cause I heard him say it.
5 But it popped and reseated, which was -- it was
6 doing the function it was designed for.

7 Q. Right.

8 A. He never indicated he was having any
9 problems with it. As it turned out later, it lifted
10 three times. And on the -- on the decrease in
11 pressure, he isolated the valve as the pressure fell.

12 BY MR. BELL:

13 Q. Was that just a gut reaction?

14 A. That was a gut reaction on his part. He
15 just -- he didn't like the way the pressure was
16 falling. He wanted to get control of it quickly.
17 And as the history of power operated release, his
18 pressure was low enough he felt confident. He
19 isolated it for a period of time.

20 BY MR. ROSSI:

21 Q. That was an RO that did that?

22 A. Yes.

23 BY MR. BELL:

24 Q. Was there any time during -- I'm asking

1 you to read the other gentleman's mind, but was
2 there any time that PORV -- that it was thought that
3 the PORV had failed open?

4 A. At the time there was no conditions we
5 could really point at. As it turned out later, his
6 gut reaction was probably right because the printout
7 showed that on that last decrease, the PORV had not
8 gone closed yet.

9 Q. Okay. And --

10 A. And did not close until after he shut the
11 block.

12 Q. Okay. And this decrease in pressure that
13 caused the operator to shut the PORV block valve was
14 caused by the introduction of feedwater into the
15 steam generator?

16 A. Yes.

17 Q. And it was the PORV blowing you down?

18 A. It could have been both. We never did
19 blow the rupture disk on the quench tank, so it
20 couldn't have been excessive.

21 Q. If it was leaking, it was small?

22 A. That valve can't stay open long and
23 maintain the integrity of the tank. It will blow
24 the rupture disk out.

1 BY MR. BEARD:

2 Q. If I remember right from some of the
3 design constructions, on the design basis, the
4 quench tank is sized for about 15 to 30 seconds,
5 somewhere on that? In other words, you could have a
6 PORV open starting from full power and full pressure
7 for something like 15 to 30 seconds before the
8 rupture disk would go. Do you have any rough feel
9 for how much of a pressure falloff that would amount
10 to or -- I'm trying to understand, Ted, what's the
11 significance of the point you didn't get to where
12 the rupture disk would blow?

13 A. Well, you're asking me a question I don't
14 know if I can answer.

15 Q. That's all right. That's all right. No
16 problem.

17 A. The initial openings of the valve were
18 very quick. They were just pops. It popped and
19 blew the pressure down, and it pops back up a second
20 time and then a third time. I can't give you a good
21 feel for what our pressure would be when the
22 ruptured disk would blow.

23 If conditions were stable and you opened
24 the PORV, that's one thing. But we had -- we had a

1 high level on the pressurizer because of the
2 overheating of the RCS. Plus we had been chucking
3 excess water into it in response to the trip in an
4 effort to, you know, maintain pressurizer level
5 which was then subsequently heated, and that
6 contributed. So the high pressurizer level would
7 contribute to the overpressure. And I just can't
8 give you a good feel for what kind of pressure we
9 might be talking about on that.

10 Q. I guess the bottom line of what I think
11 you're trying to convey to us, and correct me if I'm
12 wrong, is that the -- a primary contributor to the
13 decrease in pressure on the primary side was the
14 high level and steam generator. And it's possible
15 that the PORV was blowing down and contributing to a,
16 let's say, a faster reduction in pressure?

17 A. Yes.

18 Q. And maybe it was the rate of pressure
19 reduction that the operator reacted to and was, I'll
20 say, suspicious of the PORV and chose to block it.
21 And then subsequently you found out, in fact, that,
22 yes, the PORV was open and did not reclose until
23 after the block valve had been closed?

24 A. Yes.

1 Q. Is that the flavor you're trying --

2 A. That's, yeah, the majority of it. The
3 major contributor to the pressure decrease was the
4 overfeed of the steam generator.

5 Q. Okay.

6 A. It would have -- the amount of water we
7 put in there at the rate we put it in probably would
8 have masked the pressure decrease that he might have
9 seen from the PORV being open. But just as a
10 precaution on the pressure decrease, when the
11 pressure was down to a point that he felt
12 comfortable with, he isolated the thing.

13 Q. I see. But I gathered that you felt --

14 A. And a couple three minutes later he opened
15 it back up.

16 Q. I gather you felt he was uneasy about it
17 or decided that would be a prudent thing to do?

18 A. Yes, that was just a decision on his part.

19 Q. Were there any other systems, either
20 primary or secondary side, that could have come into
21 play that you happen to remember that would
22 contribute to the pressure reduction? For example,
23 the pressurizer sprays or anything of this nature?
24 Maybe the heaters cut off or any other contributors

1 that you happen to remember?

2 A. Nothing that I heard of at the time.

3 Anything that I know of now came after the incident
4 was over that I learned of it. There was nothing at
5 the time to indicate to me. It was just the initial
6 pressure fall from the -- from the overflow of the
7 generator was the biggest thing, which we all
8 anticipated. He, to keep from a possible safety
9 features actuation, requested and received
10 permission to put in HPI for a short period of time,
11 which might have helped. Other than that --

12 Q. So getting back to where we are then, I
13 guess you've got a lot of feed available to you so
14 the plant's pretty much back in good shape. Things
15 are beginning to stabilize out.

16 A. Yes.

17 Q. And so now you're basically in a recovery
18 mode of some sort, I guess?

19 A. Yes. Now our primary concern was just
20 stabilizing the plant at a point. We wound up with
21 RCS temperature at 546, about 50 inches in each
22 steam generator. RCS pressure came back up to about
23 2100 pounds. The pressurizer level was high because
24 of the amount of water that we put into the system

1 during this time. That was of no problem or concern
2 as such. And we just tried to hold it at that point.

3 Q. Where were you at this time in regard to
4 your nuclear instrumentation?

5 A. It was somewhere -- I can't give you an
6 exact time. Somewhere in here we came onto the
7 source ranges. The high voltage comes on
8 automatically, and we discovered that neither one of
9 them really worked. One was giving us what we felt
10 to be an erroneous reading. The other one was off
11 scale.

12 Q. Was it off scale high or low?

13 A. I want to say it was high. I can't really
14 verify that. I looked at it quick, and it wasn't on
15 scale one way or the other.

16 Q. Okay.

17 A. We went to our abnormal procedure for loss
18 of neutron indication. Per that procedure, we went
19 to an emergency boration condition.

20 Q. Before you get into that part, Ted, you
21 said that both of them basically were misbehaving.
22 You said one was off scale, and the other one was
23 acting in a way to give you a reading that you
24 didn't believe?

1 A. Yes.

2 Q. Could you give me some feel as to what
3 kind of reading you saw, what kind of reading you
4 would have expected? Like was it reading grossly
5 abnormally low or grossly abnormally high or what?

6 A. No, really it was like mid scale.

7 Q. Mid scale.

8 A. But it -- it was mid scale when the high
9 voltage came onto it.

10 Q. I see. And it should have been high?

11 A. It should have been high at that time and
12 then decayed off, and it didn't. It just stayed
13 where it was and just sat there.

14 Q. So it was a -- the abnormality was it was
15 lower than it should have been, and it was
16 relatively constant rather than falling as you would
17 expect neutronics before to behave?

18 A. Yes. So we initiated emergency boration
19 for that. We weren't overly concerned. We knew
20 that we had been feeding water from the borate water
21 storage tank into the system for a while. That's
22 1800 PPM boron. We knew we would have increasing
23 Xenon from the post trip conditions which aids in
24 our shutdown margin. And then we did start pumping

1 in concentrated boric acid. So the -- from the
2 conditions that had gone before, this was something
3 that had to be watched but was not a major concern
4 at the time.

5 Q. What about the condition of the -- or the
6 position of the control rods?

7 A. They were all on the bottom. That had
8 been verified early in the trip. Just part of the
9 post trip operator response, that the conditions
10 we'd have to check. Those had been, immediately
11 after the trip, had been verified all on the bottom.

12 Q. So would it be a proper summary to say
13 that your feeling was that were the rods on the
14 bottom and this that and the other, the core was
15 not criticality in danger, but you only had an
16 instrumentation problem?

17 A. Yes. I had no concerns about, you know,
18 any inadvertent criticality at the time.

19 BY MR. BELL:

20 Q. I have about three quick questions.

21 A. Yes, sir.

22 Q. When, on a normal trip, when that high
23 voltage is reenergized to a source range, and we're
24 talking source range channel 2 that's not on scale

1 now?

2 A. Yes.

3 Q. You already told us source range channel 1
4 was not in service?

5 A. NI 2, yes. Well, you're going to have
6 to -- NI 2 is channel 1 if you want to talk channels.
7 You want to talk NI numbers?

8 Q. Okay. You tell me which one was out of
9 service. What do you call it?

10 A. NI 2.

11 Q. NI 2 was out of service?

12 A. Yes, it was off scale.

13 Q. Now. NI 1 -- now, I'm talking about
14 before the trip, NI 2 was the one you declared
15 inoperable?

16 A. No, NI 1 was the one declared inoperable
17 before the trip.

18 Q. NI 2, when the interchange turns it on,
19 you should get a high start-up rate alarm comes on,
20 right, because it spikes -- sees a rapid change in
21 neutron level, did that enunciator come on?

22 A. I can't tell you.

23 Q. Did you have high voltage on the
24 enunciator?

1 A. Yes, that was verified. The primary side
2 RO went to the back cabinet.

3 Q. To the RPS?

4 A. To the RPS. Opened the cabinet to see the
5 indication that was in there. It was also failed,
6 but he did observe approximately 2,000 volts, high
7 voltage, through the detectors.

8 Q. All right.

9 MR. ROSSI: Well, see, I had a question
10 there. Was -- go ahead, finish.

11 MR. BELL: I've got two more, and I'll
12 shut up.

13 BY MR. BELL:

14 Q. Also you haven't -- we were told in the
15 earlier interview that SP6A failed.

16 MR. BEARD: 7A.

17 A. 7A.

18 Q. Excuse me, 7A failed during this transient
19 also.

20 A. Yes.

21 Q. Did that give you any concern?

22 A. When we put the start-up feed pump on, the
23 reactor operator grabbed for the control that was
24 closest to him. That was 7B for the No. 1 generator.

1 And he got feedwater established to that.

2 Q. Okay.

3 A. He subsequent to that tried to get flow to
4 the other steam generator through SP7A and got no
5 satisfactory response from the valve that he could
6 observe. Then, like the same time, he got the No. 2
7 aux. feed pump available. So he fed the No. 2
8 generator with the No. 2 aux. feed pump.

9 Q. Okay. Finally, during this trip that
10 occurred in, I think you said, June the 2nd or so,
11 the trip before this trip.

12 A. Yes.

13 Q. What caused those feed pumps to trip on
14 that occasion? What -- you have no idea?

15 A. Can't tell you.

16 Q. Okay. I'm through.

17 MR. ROSSI: You asked the question that I
18 wanted to ask, was about the SP7A, so you covered
19 that. That's it.

20 BY MR. BEARD:

21 Q. I had a couple that were along the same
22 line. This is, I think, a little further into the
23 recovery stage or stabilization phase, Ted.

24 Do you remember any problems with regard

1 to the source of water for the No. 1 aux. feedwater
2 pump?

3 A. Yes. That happened. When they were
4 trying to bring the No. 1 aux. feedwater pump up, it
5 tripped a second time. And at the same time it
6 tripped, I don't know which came first, the suction
7 to the pump swapped over to service water.

8 Q. That was unexpected or --

9 A. That was unexpected. I -- I don't know.
10 I still don't know what caused it. There's a -- I
11 saw the enunciator for high DP come in -- or --
12 there's a suction strainer for those pumps and it
13 has a DP alarm across it. The enunciator came in.
14 Same time the pump tripped, and the RO observed that
15 the suctions had swapped.

16 Q. Okay.

17 A. We -- the EOS that were down in the aux.
18 feed pump immediately started to relatch the pump.
19 At the same time the RO opened the suction from the
20 condensate storage tanks to the pump, and then I
21 closed the service water valve, which lined up
22 normal suction to the pump. Was after -- then after
23 this was accomplished, they brought that pump up and
24 in speed, and we kept it on.

1 Q. Okay. So there were -- if that spurious
2 action -- it was a spurious action. It basically
3 occurred once and didn't reoccur. In other words
4 when you refigure back to the original configuration,
5 it held in there?

6 A. Yes, that only happened that one time. I
7 have no explanation for why that happened.

8 Q. Did you have any problems with turbine
9 bypass valves?

10 A. Much later into the recovery. The SFRCS
11 actuation, when it -- well, with the MSIVs closed,
12 the turbine bypass valves served no purpose.
13 There's no steam. Control goes to the atmospheric
14 vent valves. We were using those for pressure
15 control on the steam generators.

16 When they finally got the atmos -- or the
17 MSIVs open, we swapped control to the turbine bypass
18 valves. When they did this, on the -- let's see.
19 It's SP13A. Would be on the No. 2 steam line. When
20 they opened the MSIV for the No. 2 steam line, I was
21 sitting in my office at the time.

22 I heard a rather loud -- it almost sounded
23 like a rattle, but it was a water hammer. And
24 sometime shortly after this, one of the equipment

1 operators called up and said that the -- one of the
2 turbine bypass valves on that line was rather
3 severely damaged. Broke it.

4 BY MR. BELL:

5 Q. Do you think that's a result of the
6 opening the MSIV on that side?

7 A. They figured it got a slug of water in the
8 line.

9 BY MR. BEARD:

10 Q. Is that typical, that you can get a water
11 slug when you reopen the MSIVs or --

12 A. Here's what, in conjecture, happened is
13 the main steam to aux. steam reducer, this is a
14 valve that takes main steam, reduces it down 235
15 pounds for the auxiliary steam system of the plant.
16 There is a desuperheating valve associated with
17 that. So when the pressure on the steam is dropped,
18 it doesn't super heat.

19 That valve malfunctions. We have a hard
20 time with it because that comes off of main
21 feedwater, and it will wind up with like 1100 pounds
22 of pressure on one side of it, and it has a hard
23 time controlling. The valve, as it turns out, the
24 controller to this valve was out of service for

1 whatever reason.

2 INC was working on it. And the manual
3 bypass was cracked open to provide desuperheating
4 water for this thing. They figure while the MSIVs
5 were closed, this desuperheating water just filled
6 up the steam line, backed up the aux. steam system
7 and put a slug of water in the main steam line.
8 When the MSIV was subsequently opened and turbine
9 bypass valves opened, that slug of water went right
10 down the line and hit the turbine bypass valves.

11 BY MR. ROSSI:

12 Q. What did it do to the valve when you say
13 it was severely damaged? Was it then leaking or --

14 A. It broke it. It broke the yoke right in
15 half, and -- that's a rather substantial yoke on
16 those things. It's quite heavy. Snapped it right
17 in half. And broke the actuator. These things work
18 on an air piston, and it just cracked it all the way
19 around.

20 BY MR. BELL:

21 Q. You're talking both sides of the yoke?

22 A. Both sides of the yoke. The actuator was
23 sitting there going up and down as the valve wanted
24 to move. So with the valve moving, the actuator

1 went up and down, it broke off the valves and
2 snapped the position feedback.

3 BY MR. BEARD:

4 Q. So a rather severe water hammer, wouldn't
5 you say?

6 A. It was probably rather nasty at the time.

7 Q. Well, in the process of reopening the
8 MSIVs, help me understand this one, does one
9 normally open, say, a smaller valve around the MSIVs
10 first?

11 A. Yes, we open up the bypass valve and
12 pressurize the steam line. We have to get the delta
13 P reduced down to --

14 Q. So you opened the main one?

15 A. As low as we can get it.

16 Q. Does that serve the purpose of warming the
17 line downstream also?

18 A. It will warm the line as such.

19 Q. Okay.

20 A. And it's pressure -- you know, pressurizes
21 the downstream side.

22 Q. And was that done during this?

23 A. Yes.

24 Q. So that the opening of the MSIV was done

1 in the normal sort of way. And the reason you had
2 damage apparently was because an unusual source of
3 water would fill up the lines is what did you?

4 A. Yes. Yes, that's not -- we normally don't
5 have that kind of a problem.

6 BY MR. LANNING:

7 Q. I'd like to go back and discuss what
8 alternative methods that you might have used if you
9 had not been successful in getting this start-up
10 feedwater pump operating. Did you give any thought
11 to restoring the main feedwater pumps to operation?

12 A. That was completely out of the question.

13 Q. And why is that?

14 A. There was no steam available.

15 Q. Because the --

16 A. MSIVs were closed.

17 Q. And it must take a long period of time --

18 A. It takes a period of time, maybe 20, 30
19 minutes just to repressurize the line. Once you get
20 the condition, you can do that.

21 Q. Now, if the MSIVs had not closed, could
22 you have possibly used those pumps?

23 A. If the MSIVs had not closed, we would not
24 have been in this condition at all.

1 Q. I don't understand.

2 A. We would not have -- the No. 2 feed pump
3 would have supplied us all the feedwater we needed.
4 The steam generators had come onto low level limits
5 nicely. We would have gone out into a normal post
6 trip configuration. We would have wound up right in
7 a post trip window and we would have been in pretty
8 decent shape.

9 Q. When would you have decided to use the
10 feed and bleed method of removing heat from the
11 reactor vessel?

12 A. When the start-up feed pump became
13 available to us, at that period of time I was to
14 the point where if it didn't happen within the
15 next few seconds, I would have gone to the HPI PORV
16 of cooling. And it was just -- you know, we had
17 gone -- time was starting to stretch out, and we
18 were to appear there in the control room where
19 nothing was happening.

20 You know, we were just standing there.
21 The guys were out working, and nothing was happening,
22 and the plant was heating up. And it was just at
23 the point where if it didn't happen now, we were
24 going to have to go the other way. And right at

1 that time the start-up feed pump became available to
2 us. And it was just a close decision right there.

3 Q. Do you have a lot of confidence in that
4 method?

5 A. I have, you know, we've had training on
6 that from B&W. We've observed it on the
7 similarities. We have gone through the casualties
8 that they've given us similar to this where you have
9 a total loss of feedwater and you go to that
10 situation, and we have followed it all the way down
11 to cold shutdown.

12 And it appears to work well, if you want
13 to say that. I mean, it's a method that works. It,
14 you know, it makes a mess out of your plant, but it
15 works. But, you know, you got to realize what your
16 primary concern is, core integrity. You can't --
17 you know, if it comes to that, it comes to that.

18 Q. Were the subcooling meters of use during
19 this transient?

20 A. Yes.

21 Q. How did you use them?

22 A. I mean, you know, they're right there.
23 And we observed those things closely at various
24 times, keeping track of our subcooling margin. And

1 we never observed a subcooling margin of any less
2 than 47 degrees is the lowest we ever got. So we
3 always --

4 BY MR. BEARD:

5 Q. What time during the event, do you
6 remember the minimum subcooling occurring roughly?
7 I don't mean clock time. I mean, what was going on?

8 A. Let me think.

9 Q. Was this before the aux. feed and start
10 feeds got running, for example?

11 A. Yes, it would have been.

12 Q. Okay.

13 A. That was the lowest we saw. Once we got
14 the feedwater in there and it cooled off, the margin
15 became greater.

16 Q. Okay.

17 A. 47 -- 47 degrees was the lowest we saw at
18 any one time.

19 BY MR. LANNING:

20 Q. From an operating standpoint, would you
21 have preferred to have the start-up feedwater pump
22 not locked out, not valved out?

23 A. Sure.

24 Q. Now, has it always been valved out?

1 A. No. I can't give you the dates that this
2 came about, but it was discovered that the lines for
3 the start-up feed pump had not been properly
4 analyzed by Bechtel Engineering when the place was
5 constructed, and there was the danger of a high
6 energy line break from either the feedwater lines to
7 the start-up feed pump or the cooling water lines
8 which could endanger the aux. feed pump that sits in
9 the same room. As a result of this, they made us --
10 when the pump was not in service, it has to be
11 valved out.

12 Q. They is -- who is they?

13 A. The NRC.

14 Q. Okay.

15 BY MR. BEARD:

16 Q. Along the same line, when you say there is
17 a danger of a high energy line break, are you
18 referring to the case where a -- just a failure
19 occurs or are you referring to the situation where
20 there's some external phenomena such as seismic
21 event which might cause such a failure?

22 A. Whatever condition would cause it. It
23 could be anything. That if you, you know, if the
24 feedwater line would rupture, the concern was the

1 damage it would cause to the aux. feed pump in the
2 same room. When we have the pump in service, we
3 are required to keep a man in the room that is
4 knowledgeable in the actions that have to be taken
5 to isolate the pump in case of a break.

6 Q. So the concern then is that the
7 pipe related to the start-up feed pump may not
8 be adequately designed or analyzed such that
9 its failure potentially could affect the
10 safety-related aux. feed pump that is in the room?

11 A. Yes, sir.

12 Q. Okay.

13 MR. LANNING: Is there --

14 BY MR. ROSSI:

15 Q. You started to say something about how
16 long ago you were required to do that. Do you
17 roughly remember about when? I mean --

18 A. At least last year sometime.

19 Q. So it's about a year ago?

20 A. At least. I don't -- I just don't have a
21 good feel for that number.

22 BY MR. LANNING:

23 Q. If you were going to factor this event and
24 experience you gained from this event into a

1 training program for the operators, is there --
2 which parts would you emphasize most and is there
3 areas which you felt that you could have benefited
4 by either additional experience, additional training
5 or whatever?

6 A. I feel that the training that we have
7 received since the Three Mile Island 2 event dealing
8 with overheating conditions in the RCS have been
9 adequate for the conditions I observed during this
10 incident. We knew what had to be done. We knew
11 what the results would be. I don't think there's
12 anything that we could emphasize that hasn't already
13 been done in a case like this.

14 Q. Or anything you would have done
15 differently during this event?

16 A. I might have ordered the start-up feed
17 pump put in service sooner. It could have been by a
18 matter of two, three, four minutes. But, you know,
19 it would have helped. That's about the only thing I
20 can see.

21 BY MR. BELL:

22 Q. Was the ATOG, A.T.O.G., display in service
23 during this transient?

24 A. No.

1 Q. Why not?

2 A. It just wasn't functioning.

3 Q. You don't -- would it be normal for that
4 system to function? Would it not normally be done
5 if the system were operational?

6 A. Its reliability has been marginal for
7 having it available to the operators.

8 Q. Would you have liked that display to be in
9 operation during that transient?

10 A. Yes, I would have. We all would have.
11 We've gotten used to seeing those displays in our
12 planning at B&W and they are quite helpful,
13 especially in the event of this kind.

14 BY MR. BEARD:

15 Q. Point of clarification, ATOG display, is
16 that the same as a safety parameter display system
17 display or is that different?

18 A. Yes. That's your SPDS?

19 Q. Yes.

20 A. Yes.

21 Q. That's the same interval?

22 A. Same critter.

23 Q. I have a question with regard to -- it's
24 along the line of T sat meters. To what extent were

1 the acoustic monitors on the PORV used or of benefit
2 or not of benefit during the event as you remember
3 it?

4 A. I didn't personally observe them at all.
5 The primary operator, I believe, looked at those in
6 relation to his operations on the PORV. Those
7 displays are available right to his right as he --
8 or to his left as he was standing in front of his
9 panel.

10 Q. Do you think this had -- or do you
11 remember whether or not what he observed on the
12 acoustic monitors for the PORV is to have, that may
13 have inputted to his decision to use the PORV block
14 valve?

15 A. I couldn't tell you.

16 BY MR. LANNING:

17 Q. When management arrived in the control
18 room after the event, can you sort of give us some
19 insight as to what their reactions were or comments
20 or interactions with the operators?

21 BY MR. ROSSI:

22 Q. You might start by telling us at what
23 point did others arrive?

24 A. Okay. Let me catch up to where I had left

1 off and will continue.

2 We were to the point where the plant was
3 fairly stable. We had good control of most
4 everything. I stood back and took a look at the
5 emergency plan. I realized that during this
6 transient, we were deep into the emergency plan, but
7 there was no way that I could take time at the time
8 to declare any kind of an event.

9 By the time I could stand back and look at
10 it, we were not in any emergency action level. The
11 one that would have been called would have been a
12 site area emergency, which is a rather severe
13 emergency action level.

14 Q. What would have triggered the site area
15 emergency?

16 A. A loss of all feedwater.

17 BY MR. BEARD:

18 Q. In terms of the events, you have, I guess,
19 an unusual event is the lowest and then you have an
20 alert.

21 A. Alert.

22 Q. And then site emergency and then a general
23 emergency?

24 A. General.

1 Q. So you would have been at the No. 3 out of
2 4?

3 A. Yes. Realizing that I was in that
4 condition for a while, I felt that some declaration
5 of some kind was warranted. Between myself and the
6 assistant shift supervisor and the shift technical
7 assistant, the STA, we debated back and forth for a
8 minute.

9 I decided that I would declare an unusual
10 event just as a notification process. My feeling
11 was more just to wake people up such that if
12 conditions would get worse for me, people would be
13 aware of what had already occurred.

14 Just as I was sitting down -- I was going
15 to sit down and write up the message that would be
16 put onto the tape for the automatic pager -- it was
17 right at this time when Louie Simon, the operations
18 supervisor, arrived. His major concern was, you
19 know, what is the plant condition and, you know, how
20 do we stand. And, you know, he started looking at
21 that, bringing himself up to date on the conditions.

22 I sat down and wrote out a message for the
23 emergency plan notification. I gave that to the
24 admin assistant, and she proceeded to put the

1 message on the tape. It was shortly after this that
2 Steve Quennoz, the plant manager, arrived, and then
3 Bill O'Connor, the operations engineer, arrived.
4 And we started looking at just plant stabilization,
5 what we would have to do to put the plant in a hot
6 standby condition.

7 We were a secondary site system. We had
8 no vacuum. That had been broken because we lost all
9 steam. For that period of time that the MSIVs were
10 closed, we lost seals to the turbine. We lost steam
11 to the air ejectors, and we broke vacuum just to
12 prevent any -- it's just not good to draw cold air
13 along the hot turbine shaft, so we broke vacuum
14 because of that, so we had no vacuum.

15 When the turbine coasted to a stop, the
16 turning gear would not engage. This had happened on
17 the last trip. That gave me an indication of where
18 to look. We had one electrician there, and I
19 instructed him on the circuits to investigate. They
20 had found blown fuses before in a sensing circuit
21 that enabled the turning gear. I directed him to
22 look at that.

23 BY MR. BELL:

24 Q. Zero speed circuit?

1 A. No, it was lift pressure. It's a circuit
2 that observes lift pressure to the turbine bearings.
3 And if that's available, then the turning gear will
4 start and engage. So we were in a condition where
5 we had no vacuum. The turbine was off gear. There
6 wasn't much I could do at that time until I could --
7 I had to get the turning gear -- or the turbine on
8 gear before I could put seals on.

9 I had to have seals before I could put
10 vacuum. I had to have vacuum back before I could
11 get the MSIVs back open. It was that kind of chain
12 reaction, so we were stuck right where we were at.
13 Between Bill O'Connor and Steve Quennoz, they
14 started looking at what support we would need for
15 the problems that we had.

16 They called in people from the tech
17 section to delog the computers that would have all
18 the transient data on it. We got extra instrument
19 and control people in here to look at the -- well,
20 like we had problems with the NIs, problems with
21 the -- starting the feedwater valve control circuit.

22 They called in maintenance people from the
23 maintenance shop to look at problems like controls
24 for the aux. feedwater pumps. Well, you know, the

1 governor control problems we had that way. They got
2 some engineers in there -- well, let's see. They
3 called in the maintenance engineer.

4 He got other maintenance engineers in
5 there to aid in writing work requests for the work
6 that had to be done. It pretty well geared up the
7 whole plant staff that way. Extra operations people
8 were called in. They called in the day shift of
9 operators to aid because the -- you know, I've only
10 got five equipment operators on the shift, and we
11 were pretty well strapped by what we had, so they
12 called in the day shift to aid in what would have to
13 be done just to bring the plant to a hot standby
14 condition.

15 BY MR. BEARD:

16 Q. Hot standby? Terminology question?

17 A. Mode 3.

18 Q. Mode 3. You were in mode 2 I guess?

19 A. Yes.

20 Q. So you were wanting to go --

21 A. Well, we were really in mode 3 at the time,
22 but we were sitting at 546. We had to cool down 532.
23 There was a lot that had to be done on the secondary
24 side of the plant in the way of the turbine seals

1 and the vacuum and just that kind of thing that
2 would take people.

3 Q. Going back to Wayne's question about the
4 management people, I get the flavor from what you're
5 saying that the kinds of things th t they did appear
6 to be very supportive --

7 A. Yes.

8 Q. -- of your running the show and getting
9 you help?

10 A. Yes.

11 Q. Did management people give you any -- or
12 did you perceive any reaction from the management
13 types of their perception of the gravity of the
14 situa*

15 A. They knew it was serious. The feeling I
16 got was that they were surprised we could get it
17 back as quick as we did. That was stated more than
18 once. We were only for a period of --

19 BY MR. ROSSI:

20 Q. That you could get it back as quick as you
21 could?

22 A. Yes, we were only in that condition for a
23 period of twelve minutes. For having everything
24 dead and in the water like that, the entire shift

1 did an excellent job. It was good efforts made by
2 everybody.

3 BY MR. LANNING:

4 Q. So the move was to do what? Get ready to
5 come back up to power or --

6 A. No, they knew that was a long way off. It
7 was just to get us down into a normal plant
8 configuration. We were at an in-between spot. Our
9 normal conditions for post trip would be to come
10 down to 532 low level limits on the steam generators.

11 Q. Which is hot standby?

12 A. Which is hot standby. We weren't there as
13 such.

14 BY MR. BEARD:

15 Q. I don't know whether I'd be interrupting
16 Wayne's train of thought or not, but along that same
17 line I'd be curious as to the shift technical
18 advisor.

19 A. Yes.

20 Q. Who was he, what did he do. Did he
21 provide you good assistance? Was he involved in
22 doing things for you? How did that seem to work out
23 there during this event?

24 A. The fellow's name is Ted Lang. That's

1 L-a-n-g. He's one of our newer STAs. As it turned
2 out, this was his first trip as an STA. He did
3 provide some assistance in going through the
4 emergency procedure, helping me sort out the
5 emergency plan. He made the initial red phone call
6 to the NRC. Provided more administrative assistance.
7 But he was of some help.

8 Q. Did you feel like that the overall
9 diagnosis of what the overall plant condition was
10 from a global perspective, in this particular event
11 did you do the majority of that or was it you and
12 the assistant supervisor or how did that -- how
13 would you describe that?

14 A. I think everybody that was in the control
15 room the way of licensed operators and the STA was
16 aware of what the conditions were. They really
17 didn't have to be pointed out by somebody -- by one
18 person to anybody else. We all were aware of the
19 situation and the gravity of it.

20 Q. Okay.

21 A. Wasn't something that really had to be
22 pointed out as such.

23 Q. So I guess I get the flavor that your
24 training, especially the post TMI part of various

1 scenarios, well enveloped the situation. It was
2 recognized.

3 A. Yes, indeed.

4 Q. There weren't any unusual developments
5 that maybe the shift technical advisor was
6 originally envisioned to help you diagnose?

7 A. That's true. I don't think anybody that
8 was in there had any trouble recognizing the
9 conditions that we were in or what it would
10 eventually lead to.

11 Q. Okay. And all the actions were within, I
12 guess, the envelope of your procedures and training?

13 A. Yes.

14 BY MR. BELL:

15 Q. So the --

16 A. The effort was all in one direction.

17 Q. If I may summarize both his question and
18 your answer then, the STA really wasn't required for
19 this event?

20 A. Not for the original purpose that the STA
21 was envisioned for.

22 MR. BEARD: Excuse me. Did I interrupt
23 your train of thought there, wayne?

24 BY MR. LANNING:

1 Q. I wanted to get back to the management
2 question. And are they generally supportive of the
3 operations personnel? I guess I'm talking about
4 management at the corporate level now. Like, is
5 there a relationship there that warrants some sort
6 of discussion or you feel has some strong feelings
7 about it one way or the other?

8 A. Nothing one way or the other. They've
9 always been supportive. Dick Crouse, the vice
10 president of nuclear, did come in also. I can't
11 tell you exactly what time he showed up, but he was
12 there. He realized that he was of no real help of a
13 technical nature, but he said he would -- he was
14 there to give any help in obtaining resources that
15 we might need as such. No, we had no -- no problems
16 with support. Everybody was very supportive.

17 Q. Suppose this had been a more routine
18 reactor trip?

19 A. It wouldn't have been nearly as involved.

20 Q. And management's attitude would have been
21 what?

22 A. If it had been a routine trip, when we had
23 finally stabilized out I would have called the
24 operations engineers required. And we would have

1 discussed, you know, any problems that we might have
2 had, you know. If it had been a normal trip, there
3 wouldn't have really been any. We would have
4 stabilized ourselves out at standby and probably
5 stayed there until morning. People probably would
6 have come in on day shift. I don't know if anyone
7 would have come in in the middle of night.

8 BY MR. BELL:

9 Q. Why would you have not restarted the plant?

10 A. They probably would not have just because
11 of the problems with the main feed pump. We had
12 problems with it before, and some people were uneasy
13 about going up with them in the condition they were
14 in. But we did anyway. And to have it trip again
15 just out of the blue, they would have had to, you
16 know, do some kind of troubleshooting.

17 BY MR. LANNING:

18 Q. Now, who is some people? Did you feel
19 personally that --

20 A. We would -- they would have had to get --
21 it would have been between like the plant manager
22 and upper management, you know. They're the ones
23 that will say, you know, push for getting plant on
24 the line, make money.

1 Q. This is corporates you're talking about
2 now?

3 A. Yes. It would have been from that
4 standpoint. And, you know, decision would have had
5 to have been made to bring in factory
6 representatives from GE to, you know, troubleshoot
7 this situation some more.

8 BY MR. ROSSI:

9 Q. Had that been done before? Had GE people
10 come in to look at the --

11 A. Yes.

12 Q. They had been here before?

13 A. They were the ones that had come in and
14 instrumented the pumps before this last start-up.

15 BY MR. BELL:

16 Q. Does it irk you that you put in trouble
17 reports on the nuclear instrumentation system and it
18 doesn't seem to get fixed, and you also put in -- I
19 assume you put in trouble reports on this ATOG
20 display, and it doesn't get fixed, does that get
21 under your skin?

22 A. A little bit. It does. I mean, it's an
23 ongoing situation. And there's -- I've been told
24 that there's some kind of a fix being drawn up that

1 will correct this problem, but, you know, it's not
2 there yet.

3 Q. You know, these are problems that
4 evidently have been going on for several months.
5 And do you feel like that people aren't responsive
6 to the trouble reports that the operators submit?

7 A. Sometimes. I can't say that all the time.
8 But, you know, this occurs again and again.
9 They'll -- we'll declare the thing inoperable, and
10 then if we trip and the seal comes off and they'll
11 do ST on it and it comes back and it's good and it
12 comes back up, then it's inoperable again. Same
13 conditions.

14 BY MR. BEARD:

15 Q. You're referring to the NI?

16 A. To the NI in this case.

17 Q. Do you feel like that the reason you're
18 not getting things fixed either in a timely or in a
19 good way relates to more of management providing
20 resources or that maybe when the technicians do get
21 around to looking at a piece of equipment like an NI,
22 they basically go through and do a surveillance test
23 on it. And if it passes, they write it off versus
24 doing really investigative troubling shooting? I'm

1 trying to understand where you would like to see the
2 more improvements?

3 A. Well, improvements would probably have to
4 come from the top down. You know, it's a problem
5 that it takes an engineering fix to correct. You
6 can't really throw it onto the technician. I mean,
7 he -- they'll get sometimes just as frustrated as
8 anybody else because they'll go in, they know what
9 the problem is, and they can look at it. And it
10 winds up the same way.

11 Q. So the problem is not one that they're not
12 doing enough investigative troubleshooting for you.
13 It's just that the --

14 A. A lot of times the conditions are known.
15 They're just not fixed.

16 Q. Okay. Because it's beyond a repair effort
17 that a technician would do?

18 A. Yes. It takes some kind of engineering
19 fix to do it, and sometimes they're a long time
20 coming.

21 BY MR. BELL:

22 Q. But if this were -- these problems were of
23 a technical specification nature, that required them
24 to be repaired before you could restart the unit or

1 if they weren't repaired, you'd have to shut the
2 unit down, do you get prompt response?

3 A. Yes, it's no choice. It costs money when
4 the unit is down. It costs them a lot of bucks a
5 day. And, you know, they don't like that either.
6 So if it comes down to it, if there's something in
7 the road that can't be bypassed that has to be fixed,
8 then, you know, a good effort will be made to fix it.

9 Q. So if we have to fix it to make it run.
10 If we can get along without it, it's something
11 that's nice to have in order to run, we just sort of
12 let that slip?

13 A. I won't say they let it slip, but it might
14 not have the prompt attention and response that
15 something else might get.

16 BY MR. BEARD:

17 Q. While we're on the quick fix issue for
18 your plant, with one start-up source range nuclear
19 instrumentation inoperable, I guess that leaves you
20 with a second one, are you allowed to start up in
21 that condition?

22 A. No, not start up. Once you're up, they
23 can go out of service and they're not required.

24 Q. One or both of them?

1 A. I'd have to read it to be sure, but at
2 least one. I think both of them. You don't need
3 source range when you're at power. Once you trip --

4 Q. Then you need it?

5 A. Then you need them.

6 BY MR. ROSSI:

7 Q. But you can't start up without both being
8 in service?

9 A. You can't start up with one of them being
10 broke.

11 BY MR. BEARD:

12 Q. I guess the last time you restarted the
13 plant prior to this event, I get the flavor this
14 source range channel that was on-again, off-again
15 operability status and it happened to be operable at
16 the time you wanted to start up, so you went up.
17 And then apparently it died, if I can use that term,
18 after you got out of the source range?

19 A. Um-hmm.

20 Q. Okay.

21 BY MR. LANNING:

22 Q. Had you had an opportunity to meet Mr.
23 Crouse before this event?

24 A. Oh, yes.

1 Q. Does he visit the plant frequently?

2 A. Yes, he does. Comes around quite often.

3 Q. Just as a matter of general information
4 gathering?

5 A. That and just to show the presence.

6 Q. Goodwill?

7 A. He's an old power plant man as it is, and
8 I think he sometimes enjoys just coming out to the
9 plant, walking around, talking to the operators.

10 Q. Now, that sort of implies there's a good
11 relationship between labor and management. Is that
12 true?

13 A. At least for my part. You know, I enjoy
14 talking to Dick. He's --

15 Q. How about on a broader scale?

16 A. I don't know. Right now conditions, you
17 know, if you're talking union people, it's kind of
18 rocky just from negotiations that are going on,
19 contractual-wise and such, but --

20 Q. Have you seen any impact of that on plant
21 operations or with plant maintenance has to be done
22 or --

23 A. Not really.

24 Q. Not really?

1 A. Not really. At least not with me.
2 Sometimes it's personal from, you know, from shift
3 foreman to shift foreman. Some guys get along
4 better with people than others. It's --

5 BY MR. BEARD:

6 Q. When you're talking union people versus
7 nonunion people, does the union include the licensed
8 reactor operators?

9 A. Yes.

10 Q. Does the union include the supervisors of
11 the -- the licensed supervisors of the reactor
12 operators?

13 A. No.

14 Q. So that's the interface?

15 A. Yes.

16 BY MR. BELL:

17 Q. So you and the assistant shift supervisor
18 are not union members?

19 A. No, we're management.

20 Q. You're management. Yes.

21 BY MR. BEARD:

22 Q. Have there been any particular management
23 efforts or activities in the last few months that
24 have been particularly troublesome to the operators

1 maybe with regard to maintenance or code of dress or
2 things of this nature?

3 A. Yes, you've obviously heard. They are
4 enforcing a dress code for the operators that has
5 rubbed some fur the wrong way. They have put
6 maintenance personnel on night shift coverage, which
7 most of them do not like.

8 Q. Is it because it's shift work as a
9 different class of work that they are objecting to?

10 A. They just don't like working nights.

11 Q. Well, I mean, are these maintenance people
12 that we're talking about normally in the past,
13 they'd been single shift people and they worked days?

14 A. Day shift.

15 Q. And now they're being asked to work either
16 nights or some rotating shift kind of situation?

17 A. Yeah, wasn't -- well, wasn't so much as
18 asked. They were said they will.

19 Q. No, I don't mean that part. I mean the
20 part they objected to was the fact they were being
21 asked to either work nights or rotating shifts?

22 A. Back shifts.

23 Q. Because when I was a technician many years
24 ago, a sort of a status symbol at that time was are

1 you a shift worker or are you a day person. I don't
2 know whether there's any of that kind of feel up
3 here or not.

4 A. The maintenance staff and the rest of the
5 Edison system, fossil plants, has always been
6 strictly day shift. And they just don't like
7 working back shifts.

8 BY MR. LANNING:

9 Q. What was the rationale for this back shift
10 work in need of the maintenance? Was it to catch up
11 on maintenance backlog?

12 A. Well, I'm told it was more for to make
13 people available for testing, and plant maintenance
14 type of activities on the back shift.

15 BY MR. BEARD:

16 Q. What was the idea behind the dress -- new
17 dress code? Could you tell us what the new dress
18 code requirements are or when they went into effect?

19 A. Well, like I'm wearing the uniform now
20 that's required for the management people.

21 Q. How would you describe that uniform for
22 the record? I mean --

23 A. It's just a dress shirt and slacks.

24 Q. Okay.

1 A. The --

2 BY MR. ROSSI:

3 Q. No color requirements or anything of that?

4 A. Well, yeah, I've got the dark blue pants
5 and light blue shirt. The union people are going to
6 have the same pants with a darker colored shirt,
7 blue.

8 BY MR. BELL:

9 Q. Is the company furnishing these?

10 A. Yes.

11 BY MR. BEARD:

12 Q. No ties involved?

13 A. No ties. They're a safety hazard. Can't
14 have ties around rotating equipment. But the whole
15 thing, the reason behind the whole thing kind of
16 rankles a lots of people because it got into just a
17 contest between our chief executive officer and Mr.
18 Keppler.

19 Q. Mr. Keppler?

20 BY MR. BURNS:

21 Q. Region 3.

22 A. Region 3.

23 BY MR. BEARD:

24 Q. What do you think the objective of -- I

1 guess you're saying --

2 A. The objective was that for Toledo Edison
3 to prove it had sufficient control over its people.

4 Q. But you're saying the dress code for union
5 people which would include reactor operator showroom
6 would be the same for union people?

7 A. Yes.

8 Q. Were there other distinctive classes
9 involved?

10 A. No.

11 Q. Did you feel like that this dress code had
12 a adverse impact on the attitude of your reactor
13 operators that was -- would you describe that
14 significant or how would you describe the magnitude
15 of the feeling?

16 A. Oh, it hasn't improved morale any, if you
17 want to put it that way. Some people don't care.
18 Some people, you know, some don't have other clothes.
19 Some people, being ex-Navy, don't like uniforms at
20 all. It's an individual thing. But it's just
21 rankled a lot of feelings.

22 BY MR. BELL:

23 Q. Does the operating staff feel that the NRC
24 has mandated these uniforms, if we may call them

1 uniforms?

2 A. I don't know if they go so far as that,
3 but I think everybody realizes the underlying cause.

4 Q. And they blame the regional administrator,
5 Keppler, for forcing this on Toledo Edison?

6 A. Not necessarily.

7 BY MR. BEARD:

8 Q. I got the feeling earlier that you were
9 saying it was as a result of some sort of a contest
10 between your chief executive officer and the
11 regional administrator.

12 A. Um-hmm.

13 Q. I could speculate on things, but I don't
14 think that's appropriate.

15 A. No.

16 BY MR. BELL:

17 Q. This is leaving the incident behind?

18 A. I don't have the details, and a lot of
19 it's by rumor. I'm not going to say anymore.

20 BY MR. BEARD:

21 Q. Let me say another area. I understand you
22 do have a union shop here, and contract renewal is
23 coming up. And could you tell us how the -- how you
24 stand on that with regard to possibility of strikes

1 and things of that nature?

2 A. It looks like a strike may be very
3 probable. They're changing the health benefits,
4 cutting the health benefits of the union personnel.
5 It's not going over very well at all.

6 Q. Is the cut in effect now on the benefits?

7 A. Not for the union people.

8 Q. Or is that something that is proposed for
9 the new contract?

10 A. That's what's trying to be -- that the
11 company wants in the new contract.

12 Q. If they were to go out on strike -- have
13 they had strikes here at this plant before?

14 A. Not at this plant. Not since the plant's
15 gone in. Well, they've had -- they haven't had a
16 strike of the operations personnel. They did for
17 the office workers.

18 Q. Okay.

19 MR. ROSSI: Do you have anything more
20 anybody?

21 BY MR. BEARD:

22 Q. I think the only thing I'd like to do is
23 say we've asked you a tremendous amount of questions,
24 and I think you've done a really superb job in

1 giving us good answers, honest answers I feel.

2 A. Tried to keep it straight.

3 Q. That's the only way to go.

4 MR. ROSSI: You have a good knowledge of
5 what went on during the event.

6 BY MR. BEARD:

7 Q. I'm trying to say can we turn the table
8 and say rather than asking us questions, is there
9 anything that maybe we haven't touched on you'd like
10 to convey to us of any general nature?

11 A. You've been pretty thorough. I can't
12 think of anything that's happened that I feel
13 anywhere near significant that you haven't touched.
14 You just about covered it all.

15 BY MR. LANNING:

16 Q. Well, if anything does occur to you, next
17 couple days, we'll be here.

18 A. Okay.

19 BY MR. BEARD:

20 Q. Certainly want to thank you for staying
21 over. I realize this is at the end after a shift of
22 working hard, and you're obviously tired, and maybe
23 now you can go home and get some sleep.

24 A. I'm surprised I was as alert, to tell you

1 the truth.

2 MR. ROSSI: Let's go off the record.

3 - - - - -

4 Thereupon, the interview was
5 concluded at 11:05 o'clock a.m.

1 CERTIFICATE

2 I, Anne I. McBrayer, a Notary Public in
3 and for the State of Ohio, do hereby certify that I
4 took the interview of Ted Lehman and that the
5 foregoing transcript of such proceedings is a full,
6 true and correct transcript of my stenotypy notes as
7 so taken.

8 I do further certify that I was called
9 there in the capacity of a Court Reporter, and am
10 not otherwise interested in this proceeding.

11 IN WITNESS WHEREOF, I have hereunto set my
12 hand and affixed my seal of office at Columbus, Ohio,
13 on this 14th day of June, 1985.

14 

15 ANNE I. MCBRAYER, a Notary
16 Public in and for the
17 State of Ohio.

18 My Commission expires February 3, 1988.
