2 ADVISORY COMMITTEE ON REACTOR SAFEGUARDS
3

4 In the Matter of:)
5 MEETING OF THE SUBCOMMITTEE)
6 ON DECAY HEAT REMOVAL SYSTEMS)

7 Thursday,
8 January 28, 1988
9 Room 1046
10 1717 H Street, N.W.
11 Washington, D.C. 20555

12 The above-entitled matter came on for hearing,
13 pursuant to notice, at 8:30 a.m.

14 BEFORE: MR. DAVID A. WARD
15 Research Manager on Special Assignment
16 E.I. du Point de Nemours & Company
17 Savannah River Laboratory
18 Aiken, South Carolina

19 ACRS MEMBERS PRESENT:

20 MR. CHARLES J. WYLIE
21 Retired Chief Engineer
22 Electrical Division
23 Duke Power Company
24 Charlotte, North Carolina

25 DR. CHESTER P. SIESS
Professor Emeritus of Civil Engineering
University of Illinois
Urbana, Illinois

1 MR. CARLYLE MICHELSON
2 Retired Principal Nuclear Engineer
3 Tennessee Valley Authority
4 Knoxville, Tennessee
5 and Retired Director, Office for Analysis
6 and Evaluation of Operational Data
7 U.S. Nuclear Regulatory Commission
8 Washington, D.C.

9 DR. CARSON MARK
10 Retired Division Leader
11 Los Alamos Scientific Laboratory
12 Los Alamos, New Mexico

13 MR. JESSE C. EBERSOLE
14 Retired Head Nuclear Engineer
15 Division of Engineering Design
16 Tennessee Valley Authority
17 Knoxville, Tennessee

18 CONSULTANTS:

19 P. Davis
20 I. Catton

21 ACRS COGNIZANT STAFF MEMBER:

22 Paul Boehnert

23 NRC STAFF PRESENTERS:

24 Jerry Mazetis
25 E. Chelliah

P R O C E E D I N G S

CHAIRMAN WARD: The meeting will now come to order.
This is a meeting of the Advisory Committee on Reactor
Safeguards Subcommittee on the Decay Heat Removal Systems.

I am David Ward, the Subcommittee Chairman. The
other ACRS members in attendance are Mr. Ebersole, and Mr.
Mark, Mr. Michelson, and Mr. Siess will be here I believe.
Mr. Wylie is here, Charlie.

Also in attendance are two ACRS consultants, Mr.
Catton and Mr. Davis.

The purpose of the meeting is to continue our review
of the NRC staff resolution for USI A-45. Paul Boehnert is
the cognizant ACRS staff member for the meeting.

Rules for participation in today's meeting have been
announced as part of the notice of the meeting, previously
published in the Federal Register on January 13th, 1988. A
transcript of the meeting is being kept and will be made
available as stated in the Federal Register notice. It is
requested that each speaker first identify herself or himself
and speak with sufficient clarity and volume so that she or he
can be readily heard.

Before we go to the advertised speakers, I want to
make a couple of comments to the members. A-45, of course,
has been proceeding along at its measured pace for many years.
We seem to be approaching a resolution. I had hoped that in

1 advance of this meeting, we would get some documentation,
2 draft documentation, from the NRC staff with some more
3 specific information on the resolution position they are
4 proposing.

5 We haven't gotten that. We have had indications of
6 approximately what the position is going to be, and I think we
7 will hear more about that today.

8 We don't intend to go to the Full Committee with
9 this in February since we didn't have written material and
10 time is kind of short, but I am kind of reluctant to see the
11 thing drag out too far and so depending on what we hear today,
12 I may propose to you that we go to the Full Committee in March
13 even though we may or may not have any further formal
14 documentation from the staff in the interim.

15 If we hear enough today so that we think it would be
16 useful for the Full Committee to have to form some sort of
17 consensus our own position on resolution of the A-45, then I
18 will propose that we go ahead and try to do that in or at
19 least begin to do it in the March Full Committee meeting.

20 One other thing, and we are going to hear about this
21 today, but I wanted to call your attention to something.
22 There was a, and I think we saw this sometime ago, an industry
23 group I guess under the auspices of EPRI and the Westinghouse
24 owners group and through NSAC, the NUCLEAR SAFETY ANALYSIS
25 CENTER, published a report, NSAC1-113, which was their review

1 of the risk analysis of decay heat removal that had been done
2 for the Point Beach plan by the NRC staff contractors. Using
3 essentially the same inputs that the staff contractors had
4 used, they came to some rather different conclusions.

5 I asked our consultant, Mr. Davis, to review the
6 report and make some sort of accounting and assessment of the
7 differences, and he has done that in a report which I think
8 has been available to you. His report was issued January
9 11th. You probably got that at home. If not, it was attached
10 to the meeting notice that Mr. Boehnert put out I believe, so
11 we may be discussing that and may have a few questions for Mr.
12 Davis also in that part of the meeting.

13 Any other members have something they would like to
14 say before we start out?

15 MR. MICHELSON: Yes, I had one small comment. I
16 think we use the term dedicated decay heat removal, and I
17 think that when we use the term each of us has in mind
18 something maybe a little different than the next person as to
19 what do you mean by dedicated heat removal?

20 It is not clear to me that the Committee has a
21 position on what they mean. It is not clear to me that the
22 staff does, and maybe some time during the day today we could
23 get a clarification of exactly what kind of a system does the
24 staff have in mind? It is covered a little bit in the NSAC
25 document. It is covered a little bit in the Point Beach

1 document. I would like to know what does the staff really
2 have in mind when they are thinking about evaluating dedicated
3 decay heat removal?

4 CHAIRMAN WARD: Well, I think, you know, since
5 dedicated system is part of one or two of the options, I think
6 that it would be appropriate when they describe those for
7 you--

8 MR. MICHELSON: Just to clarify for sure exactly
9 what they have in mind because it is a little different than I
10 think the Committee has, along the lines the Committee has
11 been thinking, although I am not sure of that, either. We
12 never really got into it. we just kept using the term without
13 necessarily defining it.

14 MR. EBERSOLE: Since that came up, I would like to
15 add to it one of the most difficult problems is to identify
16 the conditional state at the time of entry, decay heat removal
17 system into service, because I know quite well, for instance,
18 accommodate a large LOCA, I don't think it will, yet it might
19 accommodate a small one or certain other transients or upsets,
20 but it is not going to be all-encompassing in its
21 capabilities.

22 CHAIRMAN WARD: Dedicated system concept.

23 MR. EBERSOLE: Will have boundaries of performance
24 that we need to identify.

25 MR. WYLIE: In that regard, maybe we need to

1 redefine what the objective to dedicated heat removal system
2 is. I mean what are you trying to accomplish?

3 MR. EBERSOLE: Right.

4 MR. WYLIE: Maybe they could comment on that. I
5 think I've got my idea. Certainly mine doesn't include LOCAs.

6 MR. EBERSOLE: Not any at all?

7 MR. WYLIE: Not at all.

8 MR. MICHELSON: This is something we certainly do
9 have a mixed mind on in the Committee and I'm not sure the
10 staff has one mind on it, and that's what I am kind of curious
11 to find out.

12 CHAIRMAN WARD: I assume they know what they mean by
13 it

14 MR. MICHELSON: I assume so.

15 CHAIRMAN WARD: The system.

16 MR. MICHELSON: I just want to make sure that I
17 understand where they are coming from.

18 CHAIRMAN WARD: Okay. Thank you. Let's--the first
19 speaker for the staff will be Warren Minners.

20 MR. MINNERS: Well, I just want to make a few
21 introductory remarks. Jerry Mazetis will be giving you a
22 presentation which will be a summary I guess of the regulatory
23 analysis which we are now working on and have in draft form
24 and will try to provide you, but in this measured case of
25 A-45, I guess we have gone along more than is usual in sharing

1 with the ACRS the resolution of the issue before the staff has
2 all of its positions lined up, and I have no problem with
3 that. In fact, I think it is a good procedure. I just want
4 to remind the ACRS that what you are hearing is, you know,
5 preliminary stuff, and don't expect us to stand up and defend
6 it to our last breath.

7 We also will later on have a discussion of the
8 EPRI-Westinghouse owners group analysis of Point Beach which I
9 think is an important question of is decay heat removal a
10 problem? And industry has asked that question and I think we
11 are obligated to answer it, and the purpose or one purpose of
12 the case studies was to answer that question--what is the risk
13 to failure of the decay heat removal function? And once
14 again, what you are going to hear is going to be very
15 preliminary. We haven't discussed this stuff in detail with
16 our contractor. We haven't had a meeting with the people who
17 did the report, so this is all again very preliminary stuff.

18 I would, since Carl brought it up, I would like to
19 address this point. I'm not sure that you have to define very
20 well what the decay heat removal system would be to address
21 the issues, but at this point we are trying to address the
22 issue, not trying to address fine technical detail. The
23 question comes that any reasonable dedicated system is going
24 to cost a lot of money, and is it worth it? And that's the
25 question I think we have to be focusing at this point rather

1 than any technical design details of decay heat removal.
2 Dedicated systems are described in the case studies and those
3 are the systems that were used for making a cost estimate. So
4 I think we do have a very specific idea of at least one
5 system. That doesn't mean that has to be the system, but
6 that's the one we used as an example for doing the
7 cross-studies, and I think they are described in fairly good
8 detail in the case study.

9 Unfortunately, we didn't bring any of that material
10 with us so I can't flash it on the screen, but maybe later on,
11 Jerry could give a description of the system, so with that
12 cautionary note that this is all preliminary information, I
13 would like to discuss it with you free and technical
14 discussion, and why doesn't Jerry go ahead? <PHAZ> <PHAZ>.

15 CHAIRMAN WARD: Thank you. Jerry Mazetus.

16 DR. MAZETIS: My name is Jerry Mazetis, with the
17 Reactor and Safety Issues Branch in Research, and I'm sorry to
18 say that the new task manager, Dr. Woods, has reported sick
19 call this morning, so I will fill in for him, and forgive the
20 rough edges on the slides.

21 (Slide)

22 DR. MAZETIS: This slide is intended to refresh our
23 memory on some of the background on how we got where we are,
24 and it goes way back. It actually seems like yesterday to me,
25 but even before TMI, there were concerns of decay heat

1 removal, concerns being discussed and debated in-house, and
2 TMI essentially served as a springboard to formalizing a
3 variety of decay heat removal issues, some of which were
4 implemented post-TMI with some corrective actions related to
5 decay heat removal components.

6 However, there was still as a result of discussions
7 post-TMI in-house through ACRS various task forces and
8 commissions, still recommendations that high priority be given
9 to further study of improving the shutdown decay heat removal
10 function.

11 The studies the past seven years conducted by Sandia
12 focusing on six power plants were included to cover a special
13 emergency such as fire, flood, seismic and sabotage.

14 Not too long after TMI, when a lot of these concerns
15 had been documented, USI A-45 was formally identified and
16 approved in 1980, and the key questions focused on A-45 was do
17 current designs provide the reliability needed to meet the
18 safety goals, core damage frequency guidelines of safety
19 goals, and are there improvements to the decay heat removal
20 function in operating plants which aren't cost effective?

21 (Slide)

22 MR. MICHELSON: Question--if you don't really define
23 what you mean by dedicated decay heat removal very explicitly,
24 how do you do the evaluation of the improvements that, and
25 risks that come from adding a decay heat removal of undefined

1 state? How do you go about doing that?

2 DR. MAZETIS: Sandia years ago when the plants were
3 selected and some ground rules were made, Sandia and the staff
4 agreed on a certain level of detail to one of their
5 alternatives. As I will show later, there are six
6 alternatives that were costed out in the past seven years in
7 the case studies, one of which is a so-called dedicated heat
8 removal system where certain system assumptions were made in
9 order to cost the components out, and essentially the
10 system--and perhaps later on this morning Sandia can get into
11 more details--but the system is a, an aux feedwater type
12 system, separate from the normal auxiliary system in a
13 separate structure along with a certain amount of makeup
14 capability, and the makeup capability is limited to the small
15 breaks that were analyzed in the studies.

16 MR. MICHELSON: What I didn't find but what I was
17 somewhat interested in is well, how does high pressure decay
18 heat removal show up? If I were to build high pressure decay
19 heat removal dedicated system, if I were to put in inside
20 containment versus outside containment, how does that show up
21 and so forth?

22 Was that kind of work done, or did you just pick one
23 system which was really nothing more than an additional
24 auxiliary feedwater and additional high pressure makeup?

25 DR. MAZETIS: The makeup, the assumptions, as you

1 know, for small breaks, my recollection is the system was
2 capable of handling small breaks.

3 MR. MICHELSON: Two hundred gallons; it is capable
4 of 200 gallons a minute.

5 CHAIRMAN WARD: You are talking about small, about
6 a--

7 MR. MICHELSON: High pressure makeup for whatever
8 reason.

9 CHAIRMAN WARD: High pressure makeup.

10 MR. MICHELSON: That's what they show. And another
11 auxiliary feedwater pump, 200 GPM on high pressure and 1200 on
12 auxiliary. I think that was it. And you know, is that what
13 we have in mind, or is there other systems? And I wanted to
14 see a discussion of other kinds of systems and how they would
15 appear. This may not be the best option.

16 DR. MAZETIS: Sandia may have a comment. Dave? Dr.
17 Ericson from Sandia.

18 DR. ERICSON: There was a comparison of high percent
19 RHR, these kinds of shutdown systems done, and that was
20 published in the '83 studies on decay heat removal.

21 MR. MICHELSON: That was '83, though, and I was--

22 DR. ERICSON: This was selection as a result, this
23 approach was selected as the way to, as the result of those
24 studies.

25 MR. MICHELSON: Showed this to be the cheapest.

1 DR. ERICSON: This was a, based on those studies,
2 this was a reasonable way to go.

3 MR. EBERSOLE: I would like to ask a question. You
4 are obligated by law in fact to accept a hodgepodge of
5 designs. And you consider them here, six of them. I would
6 expect in the course of your investigation you would find
7 substantial differences in dealing with decay heat removal
8 from plant to plant, from type of plant to type of plant.

9 I was somewhat enthusiastic about the GSAR 2 new PPS
10 which approached in my view pretty close to what might be
11 called the decay heat removal system of extreme simplistic
12 character.

13 In your course of assessment, did you characterize
14 these differences or degrees of difficulty as you wing through
15 the plants, and ascribe to them whether, you know, this one or
16 that one needed it more or less?

17 DR. MAZETIS: As you will see in subsequent slides,
18 one of the reasons, maybe the main reason being considered for
19 not backfitting the dedicated heat removal system or for that
20 matter any hardware right now is the fact that there was this
21 variety of plant-specific differences that was significant in
22 the results of the study.

23 As you will see in two or three slides, that it was,
24 a major part of the risk vulnerabilities for decay heat
25 removal was seen to be in the balance of plant area.

1 MR. EBERSOLE: What bothers me there is that because
2 you have this composite assignment, you find, you may find
3 that if you can't find it is applicable to all of them, you
4 won't apply it to any of them. And I think that's a mistake.

5 DR. MAZETIS: Yes, I agree, and we think we proposed
6 a path that will try to avoid the situation of ending up with
7 nothing.

8 In this slide, we go over the objectives of A-45
9 which was to--this bullet--determine the adequacy of decay
10 heat removal in existing plants for achieving both hot
11 shutdown and cold shutdown conditions; developing and
12 evaluating again alternative method for improving the
13 reliability of the decay heat removal function; assessing the
14 value and impact of alternative methods following the backfit
15 rule; and establishing new requirements, if needed, to reach
16 the decay heat reliable compatible with our interpretation of
17 the core damage frequency guidance goals.

18 (Slide)

19 DR. SIESS: What is your interpretation?

20 DR. MAZETIS: I think what I was referring to there
21 was the discussion of avoidance of significant release of
22 radioactivity of ten to the minus 6 and backing off to produce
23 a, an interpretation of core damage frequency in the area of
24 ten to the minus 5th.

25 DR. SIESS: I'm sorry. Ten to the minus 6 for large

1 release and then you back that down to ten to the minus 5 for
2 core damage frequency?

3 DR. MAZETIS: Right, because you have to.

4 DR. SIESS: Core damage means core on the floor?

5 DR. MAZETIS: Core damage, core melt frequency, core
6 damage frequency because on top of that, you have to add the
7 containment failure probability.

8 DR. SIESS: Core damage means what? Core on the
9 floor? Or TMI?

10 DR. MAZETIS: I don't think we have identified
11 either way. I'm not sure.

12 MR. MINNERS: I think it means core on the floor,
13 Dr. Siess, but as you know, we can't differentiate in a PRA
14 between those, but I think, I mean when you get to the minus 6
15 we take it a factor of ten for the containment and that means
16 core on the floor.

17 DR. SIESS: Core on the floor and you say we don't
18 know enough from our research to establish any relationship
19 between severe core damage like TMI and core on the floor?

20 MR. MINNERS: Well, I didn't mean to be that
21 extreme. I think in the PRAs that are done, we don't make the
22 distinction, but no, I think there is in the research, in fact
23 part of the accident management program is to try to have some
24 procedures for controlling the phenomena between core damage
25 and core on the floor.

1 DR. SIESS: Yet you think we know enough to state
2 that the additional probability of containment failure given
3 core on the floor is approximately one 10th, which is what you
4 are using to get from the ten to the minus 6 back to the ten
5 to the minus 5, but that you are not able to put a conditional
6 probability of core on the floor given some severe core
7 damage.

8 MR. MINNERS: Well, these are very rough numbers. I
9 mean there is not a lot of precision --

10 DR. SIESS: Factor of ten is a guess, but it is
11 just, it is, just seems interesting that we know enough to
12 apply that factor on containment failure; with all the
13 research that we have done, we can't put any kind of a factor
14 at all on the conditional probability between core damage and
15 core on the floor.

16 MR. MINNERS: Well, I think you probably could. If
17 people were pushed into it, people would be willing to make
18 some guesses, but it doesn't seem worthwhile because the PRA
19 methodology document doesn't do that. You do a PRA, you just
20 say you lose cooling and don't really say that this results in
21 core damage or core melt or whatever.

22 DR. SIESS: Why are we doing all that research?

23 MR. MINNERS: To try to get some accident management
24 procedures that we can go and, and give guidance to operators
25 that when they do start to get core damage they will be able

1 to do something about it. I mean the purpose of the research
2 is not to do PRAs, although that's a useful function, but what
3 you want to try to do is have something at the plant and
4 that's my view of why we are doing research is accident
5 management.

6 DR. SIESS. You think that view is shared by the
7 people doing the research? That's a very interesting
8 statement. I am inclined to agree with it. But--

9 MR. MINNERS: Since we have one of the research
10 laboratories here, I won't embarrass him by asking him why he
11 is doing the research. I don't know. I can't speculate why.
12 I presume that they understand that part of the purpose of the
13 research is for accident management. I mean certainly there
14 is a lot of effort now to try to have accident management. We
15 had one lab write up a report on I insight for severe core
16 damage accidents with a very purpose of trying to make people
17 and operators aware of what the phenomena are; maybe something
18 happens, that they will be able to respond more intelligently
19 to it having the background information.

20 DR. SIESS: I am not disagreeing. I think that's
21 great, but you did state that the purpose wasn't to do PRAs.

22 MR. MINNERS: Not completely to do PRAs. That's one
23 purpose, but I think from our view if you really want to
24 increase safety, that research has to be applied in accident
25 management procedures.

1 DR. SIESS: Okay.

2 CHAIRMAN WARD: Jerry, before you go on, you know,
3 on the last chart, you talked about the, being compatible with
4 the core damage frequency goals specifically.

5 DR. MAZETIS: Right.

6 CHAIRMAN WARD: You seem to come up with a number of
7 ten to the minus 5th for that.

8 DR. MAZETIS: That's the number being discussed now
9 that may appear in the reg analysis.

10 CHAIRMAN WARD: That's the number that you are using
11 in the reg analysis. Do you intend that to be--but that's not
12 necessarily the number that is being discussed in the safety
13 goal policy implementation?

14 DR. MAZETIS: No. I am saying that was an
15 interpretation of the guidance in the safety goal. That's
16 being discussed in the staff to use as a screening tool.

17 CHAIRMAN WARD: Another interpretation of the
18 guidance in the safety goal which is yet not completely formed
19 is ten to the minus 4th core damage frequency. So why, I
20 don't know how important this distinction is in what you do,
21 but why have you chosen to, seemingly to hang your hat on ten
22 to the minus 5th instead of ten to the minus 4th?

23 DR. MAZETIS: All I can say is that in our
24 discussions with the--as you will see later, we are working
25 closely with the IPE severe accident group, with the

1 individual plant examination evaluation program, and that's
2 compatible with their thinking right now. I don't know. I
3 don't know why the, I can't explain the difference between
4 what the current thinking is compared to previous thinking at
5 ten to the minus 4th. All I am saying is right now, with A-45
6 and the thinking on screening tool, it's going to be, it is
7 compatible with the thinking in the IPE severe accident group,
8 and it looks like the numbers being discussed are ten to the
9 minus 5th.

10 DR. SIESS: It bothers me that the decisions that
11 can cost hundreds of millions of dollars are going to be made
12 on an interpretation, rather fuzzy one, of the safety goal
13 that presumably was promulgated by the Commission to give us
14 some guidance what is safe and what isn't.

15 Are we ever going to get better guidance on what the
16 safety goal really is in terms of things that are meaningful
17 in a plant, hardware, or procedural or whatever? Whether it
18 is ten to the minus 5 or ten to the minus 4, we make a
19 tremendous difference in the amount of money that is spent to
20 meet it.

21 DR. MAZETIS: I agree. I hope the Commission reads
22 your statement in the transcript.

23 DR. SIESS: You know, we are still trying to
24 interpret a large release. We have got a fair amount of
25 fuzziness around it. Ten to the minus 6th was pretty explicit

1 but the large release, we have had at least four different
2 definitions of it that I know plus a couple more maybe. And
3 then the factor of ten, this Committee suggested as a goal for
4 containment reliability, but I don't know of any data that
5 tells us overall it is a factor of ten or that it is a factor
6 of ten for all reactors or that is just an average.

7 CHAIRMAN WARD: This--well. Chet, there is a meeting
8 with, another subcommittee is meeting with another branch of
9 the staff on February 9th to talk about this, but you know, in
10 the meantime, these user programs of the safety goal are
11 having to go ahead without safety goal implementation being
12 finished so it presents a problem and I think it could be a
13 serious one.

14 DR. SIESS: We are setting ad hoc safety goals as we
15 go along.

16 CHAIRMAN WARD: Neither this program nor the JFE
17 program should be setting its own safety goals because there
18 is a program which is intended to do that for the full agency.

19 MR. MINNERS: The staff operates in the vacuum.

20 CHAIRMAN WARD: Right. Pete, you wanted to say
21 something?

22 MR. DAVIS: I guess I have problems with trying to
23 translate the probability of a serious release into a core
24 damage frequency. I don't know of any PRA that has come out
25 with a core damage frequency less than ten to the minus 5th,

1 and furthermore, if one examines the PRAs that are available,
2 you find a very wide range of conditional containment failures
3 given a core damage frequency. For example, Seabrook,
4 Seabrook PRA has a core damage frequency in excess of ten to
5 the minus 4th, but the conditional probability of containment
6 failure is less than ten to the minus forth, so that plant
7 meets the safety goals with considerable margin but certainly
8 would not even come close to your ten to the minus 5th core
9 damage frequency.

10 Other plants, some PWR, do I believe approach a
11 factor of ten conditional probability of containment failure.
12 The point is I guess you can't, I don't think you can
13 establish a ten to the minus 5th core damage frequency and
14 apply it to all plants as appears to be what you are trying to
15 do here. I realize there is more work that needs to be done
16 in this area, but I think that it is going to be a problem to
17 establish ten to the minus 5th as the, as at least an informal
18 criteria for core damage frequency.

19 MR. MINNERS: What you are suggesting, Pete, is that
20 we have different goals for different plant designs?

21 MR. DAVIS: Well, I think you about have to if you
22 are going to use core damage frequency. You need also to look
23 at the capability of the containment. I don't have an answer,
24 really, but I think that--

25 MR. MINNERS: I think the discussion is not focused,

1 and the other question is that core damage frequency by itself
2 you have, can have a number. The Commission has stated in the
3 safety goal policy statement that they don't want to have any
4 more core melts, so that also gives some kind of guidance to
5 the staff.

6 CHAIRMAN WARD: Ten to the minus 5th satisfy that?

7 MR. MINNERS: I think so.

8 MR. DAVIS: I don't know of a plant out there --

9 CHAIRMAN WARD: That is interesting.

10 MR. DAVIS: If that in fact is the requirement, I
11 think most plants are going to need some kind of modifications
12 because if one looks at the PRAs, as I said, I don't think
13 that there is a plant out there that meets ten to the minus
14 5th or less.

15 MR. MINNERS: I agree with you. If--we had the same
16 problem in, ATWS okay. The unavailability of the SCRAM system
17 hasn't changed over ten years. The only thing that changed
18 this ATWS was the goal. Start at ten to the minus 7th, and
19 when it finally got to ten to the minus 5 we declared victory.

20 MR. DAVIS: The initial safety goals had a core melt
21 frequency requirement of ten to the minus 4, and I thought
22 that was based in part on consideration of the existing
23 population and how long they were going to operate, and then
24 looking at what the probability should be to gain some
25 assurance that you wouldn't have one over the remaining

1 lifetime.

2 MR. MINNERS: That got deleted for some reason, so
3 somebody didn't like it.

4 MR. DAVIS: Now you are using --

5 CHAIRMAN WARD: No, it might be coming back in in
6 the implementation policy.

7 MR. MINNERS: It is a very useful discussion because
8 the staff is at sea as to what is, the goals to be attained,
9 so it is a question that really has to be answered and
10 discussed and some decisions made.

11 MR. DAVIS: I think there should be a core damage
12 frequency goal, and I think that ten to the minus 4th is a
13 reasonable value for it, but I don't think other people agree
14 with that.

15 CHAIRMAN WARD: I wouldn't say that. I think that
16 the ACRS letter of when was it, last April I guess, which the
17 commissioners have told the staff to use in large measure for
18 development of the implementation plan, has that sort of a
19 number in it.

20 MR. DAVIS: All right.

21 DR. MAZETIS: Yes, sir.

22 MR. EBERSOLE: After you get done with the core
23 damage frequency or the severe release probability, it is
24 unclear to me now how you get to the money question because
25 there is two kinds. There is the physical damage to the

1 public, the man rim, there is the loss of resource which is
2 substantial.

3 I, in my own view, it would take a view of both of
4 these, and a view as to how this loss will be borne. It is
5 going to be borne by the public, the rate payers, and we have
6 a public consideration and loss of resource.

7 If it is borne by the corporate entities, that's
8 another picture. They can bear it if they wish. I think you
9 should look at both of these, whether it is borne by the
10 public or borne by the corporate structure, and come to grips
11 with whether you are dealing with a public problem there or a
12 private one.

13 MR. MINNERS: We have done that, Jesse. We 'don't
14 feel that we can tell people how to make decisions, how they
15 do it, but we have tried to present all of the facts, so we
16 have all of the different costs cut every which way you want
17 to. In fact, maybe it is too complicated. If you want to ask
18 about a cost, we have got it.

19 MR. EBERSOLE: Great. That will come to the front
20 then.

21 MR. MICHELSON: Question -- you said in your second
22 bullet that you evaluated such systems for vulnerability to
23 fire, flood, seismic, and sabotage.

24 Are we going to discuss later today in a little more
25 detail what might be some serious shortcomings about the way

1 in which you do that evaluation?

2 DR. MAZETIS: I suggest --

3 MR. MICHELSON: The effect upon perhaps the
4 usefulness even of your proposed changes?

5 DR. MAZETIS: Let me respond to that in two parts.
6 The direct answer is we didn't plan on it, and no, because as
7 Warren indicated, you don't have the benefit of our regulatory
8 analysis yet, what discusses the details of these areas, and
9 that it probably is more appropriate to give you a chance to
10 take a look at the details and at that time, we can come down
11 again sometime within the next month or so and discuss the
12 details with the Committee.

13 MR. MICHELSON: Is that the intent, David, to have
14 another subcommittee meeting when we get the regulatory
15 analysis?

16 CHAIRMAN WARD: Sure.

17 MR. MICHELSON: Then I will just hold until then.

18 MR. MINNERS: I am not sure.

19 CHAIRMAN WARD: You have seen a lot of that stuff in
20 the past.

21 MR. MICHELSON: I have seen it also in this NSAC-13,
22 and I have a number of comments about the, the superficial way
23 in which we treat fire in a PRA and to a great extent, flood,
24 internal flooding and so forth.

25 MR. MINNERS: If the Committee would like to have a

1 meeting on document studies and discuss the methodology, I
2 guess that could be arranged. I mean that's all laid out for
3 you, Carl.

4 MR. MICHELSON: I have no problem with that. I just
5 want to go on record as do we believe our fire PRAs that we
6 have been doing? If you do, then there is something wrong.
7 There is something wrong with your head.

8 DR. SIESS: There is something wrong with you if you
9 believe them.

10 MR. MICHELSON: And if we don't believe it, then is
11 what you are proposing going to solve the problem of fire
12 vulnerability and how do you know it when your analyses are so
13 superficial? I just have a problem knowing that we really are
14 improving the situation at all with your proposed dedicated
15 decay heat. I am not saying you are proposing, but if you did
16 go to the dedicated aux feedwater, for instance, how do we
17 know that is any less vulnerable from fire than what we
18 presently have when we do such a superficial analysis on our
19 present situation? Just an inquiring question.

20 CHAIRMAN WARD: Carl, maybe--excuse me just a
21 minute, Jerry. Maybe at the end of the meeting today we as a
22 committee need to discuss whether, I guess because of the long
23 time lags that is necessary, to go back over some of the
24 ground that we have -- went over.

25 MR. MICHELSON: What is really happening is we are

1 beginning to understand the problems a little better I think,
2 and that what we knew in 1983 is quite a bit different than
3 what we know today, and it might even be more interesting in
4 another month or so after we get the results of the current
5 look at the vulnerabilities to fire which are coming up in a
6 March meeting.

7 CHAIRMAN WARD: I see. Let's--Paul, remind me,
8 let's talk specifically about that at the end of the meeting.

9 DR. MAZETIS: Maybe I should mention, remind the
10 agenda plan today really has three speakers. Dr. woods had
11 planned to give the overview leading into where we are into
12 the current reg analysis, and how that relates to the
13 submittal by NUMARC of the EPRI owners group study for Point
14 Beach. We had two speakers to talk about the details of their
15 review of that report, E. Chelliah and Dave Ericson from
16 Sandia laboratories, and as Warren also indicated, there has
17 not been really any give and take yet amongst these
18 individuals, so there may be some redundancy and overlap in
19 what you hear from these gentlemen. Also in the audience we
20 have some other staff members that may be familiar with the
21 reports that they can respond to some questions perhaps.

22 (Slide)

23 DR. MAZETIS: This slide goes over scope of the A-45
24 program to evaluate decay heat removal systems needed to
25 respond to transients and small break LOCAs, and as we have

1 said over the years, this study did not include large break
2 LOCAs or ATWS, and several other areas such as pressurized
3 thermal shock. Also included were an assessment of systems
4 vulnerability to fire, flood, seismic, and insider sabotage
5 where sabotage again was, vulnerability of decay heat removal
6 systems to the insider, and which explicitly did not cover
7 physical security method or the outside or attack from
8 external areas.

9 MR. MICHELSON: What did it cover then on the
10 question of sabotage? How did you evaluate insider
11 vulnerability in some kind of a quantitative way so that you
12 included it in the risk/benefit evaluation which is what you
13 were doing?

14 MR. MINNERS: I don't know how to answer that. I
15 don't think there is a short answer to that question.

16 MR. MICHELSON: I don't think there is an answer to
17 it.

18 CHAIRMAN WARD: Short answer, it wasn't evaluated
19 quantitatively, but it was qualitatively.

20 MR. MICHELSON: What does that do for risk/benefit?

21 CHAIRMAN WARD: They don't use that directly. As I
22 recall, you don't use that directly in the risk/benefit
23 computation.

24 MR. MICHELSON: When you get the risk/benefit you
25 ignore sabotage?

1 DR. MAZETIS: It wasn't ignored.

2 MR. MINNERS: Excludes sabotage.

3 CHAIRMAN WARD: On a page alongside --

4 MR. MICHELSON: The inference here is somehow you
5 evaluated it, and I just don't think you did much on it
6 really.

7 CHAIRMAN WARD: I don't think --

8 MR. MICHELSON: If you did, I didn't find a
9 discussion of it anywhere.

10 MR. EBERSOLE: You say consider. That's a very
11 large word. To me, I hope it means you noticed the
12 vulnerability notably of certain systems and you then, at
13 least you conceived something like crash buttons that would
14 block out the potential for that vulnerability to close in on
15 a safe shutdown. I don't know whether you did that or not.

16 DR. MAZETIS: Perhaps Dave could amplify, but it
17 was, there was, in order to cost out certain aspects of the
18 different alternatives, there were certain assumptions made
19 about insider sabotage probability, and there was no in-depth
20 studies on likely types of probabilities given certain
21 configurations. For costing out. There were certain gross
22 assumptions made.

23 Dave, do you want to amplify on that?

24 DR. ERICSON: I think that's the key point. As we
25 did with several other things, and as the staff has done in

1 the regulatory analysis, some things are presented as a range
2 for the decision-maker to make his own choice. What
3 quantification we did in the sabotage analysis, where we felt
4 systems were particularly vulnerable, we can discuss in a
5 closed meeting, not in this meeting. We did some conditional
6 analyses, Mr. Michelson. We did not say the probability is.
7 We said if you believe it is--

8 MR. MICHELSON: Is that written up somewhere?

9 DR. ERICSON: Those reports are now being, they are
10 appendices to the individual case studies and they are at the
11 printer's now.

12 MR. MICHELSON: We will see those shortly.

13 CHAIRMAN WARD: We have had drafts of those, haven't
14 we?

15 DR. ERICSON: Several of them you have had.

16 CHAIRMAN WARD: Maybe not for each of the ones, but
17 you may have not participated in those subcommittee meetings,
18 Carl.

19 MR. MICHELSON: Most of them, but not all of them.

20 CHAIRMAN WARD: We heard about it. I would like to
21 point out that everyone else in the audience has to use a
22 microphone when they speak from the audience, but Dr. Ericson
23 doesn't because we can hear him.

24 DR. ERICSON: Good!

25 DR. MAZETIS: Okay. Refresh our memory with the

1 A-45 studies, considered several plants, excuse me, six
2 plants, and the idea at the time years ago was to select a
3 group that represented each NSSS vender to try to cover a
4 range of decay heat removal configuration, and
5 architect/engineers, and the, of course, as always when you
6 are looking for plant-specific data, it depends on the
7 cooperation and the interest and how busy the utility is at
8 the time of the data needs.

9 Document studies themselves are all completed, as
10 you know, and have been published this past year in the form
11 of six NUREGs for each of the six plants. The more recent
12 being last August, St. Lucie, and the next report from the
13 contractor is going to be a compilation or consolidation of
14 the findings for each of those six plants sometime early this
15 year when we get that published so I would expect that most
16 people wanting to know the details of the studies would focus
17 on the last report, and to use these as references as needed
18 rather than going right into reading six reports that are
19 three inches thick each.

20 CHAIRMAN WARD: What about the sabotage analyses
21 that are in appendices? What is the status of those?

22 DR. MAZETIS: There is some discussions of the
23 methodology in each of these reports and Appendix I, as you
24 have seen, is left out of the report. I think Dave just
25 mentioned that he is pulling together--

1 DR. ERICSON: Those are in the final sign-off and
2 printing process now, Dave. We should see those within the
3 next month or so much.

4 CHAIRMAN WARD: So they will be coming out as six
5 separate reports?

6 DR. ERICSON: They are a safeguard information
7 appendix to each of the case studies, that is correct. They
8 have to be handled separately in our view.

9 CHAIRMAN WARD: How will that be dealt with in the
10 summary?

11 DR. ERICSON: Some of the detail of why it is
12 particular things are vulnerable are left out.

13 MR. DAVIS: I have a related question. On your
14 slide under the selection criteria, you didn't list what I
15 thought was the primary selection criteria, and that is
16 determination of a potential vulnerability to decay heat
17 removal.

18 DR. MAZETIS: Yes. You are right. I should have
19 mentioned that that, the criteria up on the slide was after a
20 group of maybe 80 or 90 plants that were initially looked at.
21 There was a larger group that was felt to be candidates of
22 trending toward the more vulnerable plants in decay heat
23 removal and out of that group, this was the other criteria.

24 This slide is, goes over a summary of the findings
25 that you will see in the six case studies where the

1 probability--the first bullet. The probability of core melt
2 due to decay heat removal function failure is between two and
3 three, averages between two and three times ten to the minus
4 4th per reactor year total for decay heat removal, including
5 internal, external causes.

6 The second bullet indicates that, an inside
7 observation that support system failures turned out to be a
8 significant contributor to the core melt probability,
9 particularly emergency power, service water, component cooling
10 water areas.

11 MR. MICHELSON: Excuse me. On the support system
12 failures, were those related to just simple equipment failures
13 or were those related to the external event problem?

14 DR. MAZETIS: Both.

15 MR. MICHELSON: Both, yes, but can you give me some
16 kind of feel? Was it predominantly equipment or was it
17 predominantly external event effects or was it about half and
18 half or something?

19 DR. MAZETIS: Depended on the plant. It varied from
20 plant to plant.

21 MR. MINNERS: I think, as a very rough thing, Carl,
22 half of the core melt frequency in decay heat removal was
23 internal and half was external, what are called external
24 events.

25 MR. MICHELSON: The support systems, those are much

1 more vulnerable from external events perhaps than some of the
2 other equipment. I don't know. Generally from experience it
3 seems that they are, if you do a analysis. I just wondered if
4 that is how you came out. So it is 50/50 roughly?

5 MR. MINNERS: It varies from plant to plant a lot
6 of--

7 CHAIRMAN WARD: As I recall on the six, it is a
8 range from 20 to 80 percent.

9 MR. MICHELSON: It never did tell me whether it was
10 coming from the support system effects or whether it was
11 coming from the main line equipment effects. Didn't tell me
12 whether it was the decay heat removal system or was it the
13 electrical power to the decay heat removal that was causing
14 that.

15 DR. MAZETIS: In each of the case study reports and
16 also to be repeated in the summary for each plant, there is a
17 list of the vulnerabilities, the specific system
18 vulnerabilities. For example, for Point Beach, I know there
19 were about 11, and that's a reference where you could get that
20 information. We can maybe the next meeting where we get into
21 a discussion of some of the specific numbers for each case
22 study, we could get into that in as much detail as you like.
23 The observation of, again from insights from the study,
24 redundancy, concerns or lack of redundancy, sharing of
25 systems, support system level, contributed to the risk

1 significantly for some of plants, including independence,
2 separation and physical protection of redundant safeguard
3 trains. Risk from fire, flood, seismic, and sabotage again
4 depending on the plant, was significant. And so that the
5 bottom line you will see that a large number of these areas--I
6 want to make this point now because it leads into the next
7 couple of slides--did vary quite a bit from plant to plant,
8 and was plant-specific.

9 MR. EBERSOLE: Every time you use the term
10 redundancy it brings up the vision of two carbon copies of
11 some function that have common mode potential failures. You
12 don't mention diversity and SCRAMs or sub-systems or even the
13 word at all. Is that deliberate? You don't think diversity
14 is significant?

15 DR. MAZETIS: No. Diversity is significant, but I
16 think that the redundancy, vulnerability comes from
17 observation of walk-throughs at the site, for example, which
18 did see sharing of components and systems, and certain systems
19 that are supposed to be redundant trains are located in the
20 same space side by side, that kind of thing.

21 MR. EBERSOLE: Another aspect of failure, you are
22 talking about functional plant, not to deliver some sort of
23 service in general, you know, step function to zero service of
24 water pressure, air pressure, voltage, whatever; do you
25 consider failure to embody also interactive effects like one

1 pump, for instance, stalls another pump because they can't
2 operate in parallel, or excessive pressure of voltage or
3 frequency as modes of failure or for that matter, a very
4 typical one is failure in the sense of oscillatory performance
5 rather than total step failure?

6 DR. MAZETIS: There was a--maybe Dave can amplify,
7 but there was, I consider what you just went through in the
8 area of common mode concept where the common causes were
9 considered in the studies, and the specific failure rates
10 depended on the system. I don't know what they are, but there
11 is a discussion on what our assumptions were for common cause
12 failures.

13 MR. MICHELSON: Could you clear up for me a general
14 question? For instance, we went through a great deal of
15 efforts under Appendix R to affix spreading rules because of
16 fire vulnerabilities, and we performed certain fixes that were
17 reviewed by the regulators and so forth, and now after having
18 done all of that, we go with you and we do this analysis now,
19 these various plants under this A-45 program, and find some
20 plants have an extremely high vulnerability to fire.

21 Does that mean that Appendix R fixes weren't good
22 enough or because the numbers are also fairly high, the
23 probabilities are fairly high? Does that mean that we just
24 didn't do a good enough job or we didn't do the analysis right
25 to begin with or what happened that says that after all the

1 looking and fixing and reviewing and inspection, and whatever,
2 that we still ended up with high vulnerability on some plants?
3 What went wrong?

4 MR. MINNERS: I think that's your characterization.
5 That is high vulnerability. I mean--

6 MR. MICHELSON: It is fairly high. Ten to the minus
7 5 range is fairly high, and 60 percent of the risk
8 contribution in that plant was fire and spreading, but that
9 percentage doesn't mean much. It is the actual magnitude that
10 counts. It is a fairly high magnitude. Some way on pipe
11 breaks, you know, fire water header, well, that was supposed
12 to have been looked at way back in 1973 when the Gene Busso
13 letter went out and so forth. No energy pipe breaks are
14 supposed to be looked at. They shouldn't be high contributors
15 if they had been looked at carefully and properly reviewed and
16 fixed.

17 MR. MINNERS: I don't agree with that assessment. I
18 think on the fire thing people looked at it; it was, said
19 well, okay, we have given an exception to the full
20 requirements and not have to have spray system. We realized
21 that entails some extra risk, we find it acceptable and when
22 you do the PRA, that qualifies the number.

23 Now I guess you can look again and say is that
24 whatever it is times ten to the minus 5 acceptable or not?

25 MR. MICHELSON: If it is acceptable, then why are we

1 even thinking of adding any additional hardware or whatever to
2 correct the problem? You would think that we already buy off
3 on the numbers, there is no reason to worry about the problem
4 further.

5 MR. MINNERS: Well, one of the problems is, Carl, is
6 that when you add up all of the vulnerabilities in the plant,
7 okay, that may be something that you want to fix. That's a
8 question you have to answer.. Whether you want to go at these
9 individual things and fix them or whether you want to take the
10 big fix and take care of it all.

11 MR. MICHELSON: What bothers me a little bit is that
12 it isn't just a fix. It is a fix again proposition. We have
13 already fixed it once I thought. Didn't the Appendix R work?
14 And now we go back and fix it again because it is a big
15 contributor yet to risk? If it isn't, then we don't do
16 anything I would think.

17 MR. MINNERS: I think it is prudent to go back and
18 look at what you did in the past and say hey, did I do it
19 right? I know more now. I have methods of analyzing it, had
20 more operating experience, should I do something about it. I
21 don't think just because the case study came out with two
22 times ten to the minus 5th for vulnerability that says that it
23 should be fixed. I certainly think it puts it up as a
24 candidate that people ought to think about.

25 MR. MICHELSON: What puzzles me a little bit is I

1 guess we just didn't quite understand the problem well enough
2 to fix it right the first time which was presumably the
3 Appendix R work, which is fairly recent work.

4 DR. MAZETIS: This slide gets into the current
5 summary of where we are in the staff regulatory analysis,
6 which is in essence, of course, a translation of the completed
7 contractor activity, Sandia, into a staff position, and you
8 may recall that in, on September 26th, 1986, we provided a
9 pre-decisional rough draft of the case studies in a regulatory
10 analysis format, and we presented it to you in a closed
11 session, and we described the six alternatives that were being
12 considered. At the moment, we have a, an updated version,
13 revision that is being prepared that will again describe,
14 describe the same six alternatives, and as you heard a couple
15 of months ago from my boss, Brian Sharon, that the thinking
16 still is to propose a resolution focusing on the thrust of
17 alternative 2 that is described in, described in the
18 regulatory analysis, which in essence is a plant-specific
19 studies, PRA studies.

20 And just to refresh your memory here, the six
21 alternatives were the first one, no action. There was a
22 discussion of, there will be a discussion of no action, and
23 obviously if it is determined that the NRC, NRC/Sandia studies
24 are too conservative, then that may be justified. In other
25 words, if the EPRI owners group type of study is concluded to

1 be a more appropriate or more correct, then probably you will
2 end up in this arena.

3 MR. MINNERS: Like Pete said, that is also a problem
4 of goals. Depends what goals are selected. You pick two
5 times ten to the minus 4, I agree with you, you don't have to
6 fix anything.

7 DR. MAZETIS: Alternative 2, of course, we are
8 focusing on as a proposal would direct the resolution and
9 merit to marry it with the severe accident program, in
10 particular individual plant evaluations.

11 Alternative 3 --

12 CHAIRMAN WARD: Could I ask you a question about
13 that? When this was--let's see. In September '86 when this
14 list was, first alternatives described, I don't recall that, I
15 mean I recall alternative 2 was some sort of limited scope
16 PRA, but I don't recall that it was explicitly tied to IPE at
17 that time, because that wasn't very well defined.

18 DR. MAZETIS: You are right, and this next draft is
19 being updated to reflect the marriage of A-45 or actually not
20 A-45 specifically. It is going to be decay heat removal per
21 se, to the severe accident program.

22 Alternative 3 was a, a list or composite of
23 modifications that were focused on the cost-out that were
24 common, more or less common vulnerability seen in the six
25 plants.

1 Alternative 4 was focused on two areas for PWRs. It
2 was feed and bleed, by cost/benefit on feed and bleed and for
3 BWRs venting the containment.

4 MR. EBERSOLE: Call out a non-parallelism or in
5 those two aspects, feed and bleed.

6 DR. MAZETIS: These two?

7 MR. EBERSOLE: Right. There is a large amount of
8 homogeneity in those being in the same place. Feed and bleed
9 does not accommodate containment heat removal, and I, whereas
10 containment venting does.

11 Do you mean containment feed and bleed and still
12 removing heat from the containment via heat exchangers as is
13 normally done? Of course you do. And containment venting,
14 doesn't that always incorporate open cycle boiling out of the
15 primary vessel that is blow-down? So to really make that--

16 CHAIRMAN WARD: Feed and bleed.

17 MR. EBERSOLE: To feed and bleed is open boiling out
18 of the vessel for PWR, but it does not get rid of containment
19 heat whereas the BWR with open boiling contained venting does
20 the whole thing. And I think that ought to be, you know, the
21 differences ought to be stressed. Do you follow me?

22 DR. MAZETIS: Yes. I think they are identified in
23 each case study, a description of the process that was costed
24 out.

25 MR. EBERSOLE: The former is not as comprehensive as

1 the latter.

2 MR. MINNERS: PWRs don't need heat removal with
3 their big containments.

4 MR. EBERSOLE: That's a statement that I find very
5 interesting.

6 MR. MICHELSON: That is.

7 MR. MINNERS: They don't need it for a long time.
8 They are built to take a large break LOCA, okay, so they can
9 go a long time before you have bit of a problem.

10 CHAIRMAN WARD: Pressure pool can, too.

11 MR. EBERSOLE: Sure.

12 CHAIRMAN WARD: It is the same capacity.

13 MR. MINNERS: I agree with you. They are different
14 systems. They are not the same system, but to say that one is
15 bad and one is good --

16 CHAIRMAN WARD: No. I think that Mr. Ebersole is
17 pointing out that, I mean the BWR already has the feed and
18 bleed, and under this you are adding to it a means of getting
19 the heat out of the, you know, abnormal situation out of
20 containment by containment venting. For the PWRs you just are
21 introducing feed and bleed and there is no provision for the
22 second step.

23 MR. EBERSOLE: Exactly. They are not homogeneous
24 objectives.

25 MR. MICHELSON: Could you clear up for me then a

1 point? Don't most PWRs have the inherent capability now of
2 feed and bleed? A few do not I know, but don't most have it
3 already?

4 MR. MINNERS: No. Most, yes, there are some CE
5 plants that don't have PORVs.

6 MR. MICHELSON: Don't the majority already have the
7 hardware and the capability? Maybe not yet the instruction or
8 whatever?

9 MR. MINNERS: They all are supposed to have the
10 procedures for feed and bleed, but they have--

11 MR. MICHELSON: Most of them already have feed and
12 bleed.

13 MR. MINNERS: their capability is different degrees.
14 They have sized PORVs.

15 CHAIRMAN WARD: Reliability of the capacity is
16 different.

17 MR. MICHELSON: That's what I am trying to get down
18 to. Is the reliability differences a matter that you can't
19 get removal of the decay heat by feed and bleed or what?

20 CHAIRMAN WARD: Both.

21 MR. MICHELSON: Depends on what point in time then
22 you are talking about. You are talking about five minutes
23 after the event or talking about an hour after the event or
24 whatever? Most of them have feed and bleed capability within
25 reasonable times.

1 DR. MAZETIS: The importance--it may be of interest,
2 Carl, to take a look at the importance if you were focusing on
3 feed and bleed, for example, to each of the case studies. It
4 varied, of course, with each plant as to its contribution to
5 reducing core melt frequency because the individual accident
6 sequence varied from plant to plant and its contribution to
7 overall core melt frequency varied from plant to plant, so for
8 one plant, this may not have been very important. For another
9 plant, it may have been very important in reducing core melt
10 frequency.

11 Again, the last two alternatives were the two
12 versions of dedicated decay heat or hot shutdown capability,
13 and cold shutdown capability where the last one included both
14 hot and cold shutdown capability.

15 MR. EBERSOLE: Again, there is a disparity. You
16 look at the designs. I don't know what you mean by hot, but
17 in the case of the boiler, at 220 degrees you can zimmer
18 forever if you vent the containment. And I don't know whether
19 you call that hot or not, but it certainly is not hot to, you
20 know, pressurized context, the depressurized boiling system,
21 with the body containment pressure.

22 Ed, is that hot shutdown?

23 DR. MAZETIS: I guess this terminology is probably
24 more appropriate for the PWR where, where the intent would be
25 to--this was a system that did not have the capability, this

1 dedicated system in a separate structure, did not have the
2 capability to continue the plant into cold shutdown. It was
3 in essence the aux feedwater capability with a limited makeup
4 for small breaks, and it was only after you added the shutdown
5 heat removal heat exchanger type pump, heat exchanger
6 structure that we costed out the additional dedicated cold
7 shutdown heat removal.

8 MR. EBERSOLE: One system, of course, has a
9 capability prior to core damage, just direct boiling. The
10 other requires exchangers because of the coolant activity.
11 And it requires, you know, multi-step path to get to
12 atmosphere.

13 You don't develop these differences in these
14 alternative 5 and 6?

15 DR. MAZETIS: No. No. There wasn't really much
16 detail. You may recall that initially we had planned to just
17 cost out five alternatives where the A-45 studies did not
18 intend to cost out the additional capability for long-term
19 decay heat removal, and it wasn't until toward the end of the
20 exercise that it was decided to do our best to tack on the
21 costs associated with adding a cold shutdown capability, so
22 there were some gross assumptions made.

23 MR. EBERSOLE: Cold shutdown capabilities involve
24 sensible heat removal with heat exchangers and pumps.

25 DR. MAZETIS: Yes.

1 CHAIRMAN WARD: Jerry, could I go back? Leave that,
2 the feed and bleed for PWRs again. As I recall the six case
3 studies, well, none of them showed feed and bleed to be as
4 important as perhaps was expected at least by some people
5 before the studies, but there was variability in the
6 importance.

7 DR. MAZETIS: Yes, there was variability.

8 CHAIRMAN WARD: My question, was that variability
9 due to the fact that, the variability and capability for feed
10 and bleed in the various plants, or was it due, just due to
11 the fact that the need for feed and bleed didn't enter into
12 any actual sequences? Do you see what I mean?

13 DR. MAZETIS: My recollection, it is probably more
14 the latter because where you had a plant that maybe had a poor
15 aux feedwater system, with poor reliability, the numbers were
16 not too good, feed and bleed really came out looking great and
17 the contribution of feed and bleed to reducing overall core
18 melt frequency looked more significant than the other plant.
19 You had a great aux feedwater system, so it came into
20 sequences like that. That's why it varied mainly from plant
21 to plant.

22 CHAIRMAN WARD: It could be in those two plants, the
23 actual capability to feed and bleed could be essentially the
24 same. You would still --

25 DR. MAZETIS: Sure.

1 CHAIRMAN WARD: Okay.

2 (Slide)

3 DR. MAZETIS: This again from in the reg analysis
4 that you will see in the near future, emphasizes that for the
5 decision-maker, that it gives him calculations using three
6 methods, and it actually may confuse the decision-maker more
7 than clarify. Anyway, the methods that were presented --

8 CHAIRMAN WARD: Might confuse them. It still might
9 lead to a better decision.

10 DR. MAZETIS: If he understands the three methods;
11 as you will see in the reg analysis or you have seen in
12 earlier versions, that the three methods are A, avert a,
13 considering averted off-site costs only; B, considering
14 averted off-site plus on-site costs; and C, all the above plus
15 the effect of after-decisional special considerations such as
16 the possibility after an accident of reactors being shut down
17 in moratorium or other unquantifiables and using these three
18 methods, you will see and you have seen in reg analysis that,
19 that depending on which method you use, you may come out with
20 a different answer.

21 You use method A, it is possible that alternatives
22 2, 3 and 4 from the previous slide may be cost effective for
23 some plants. If you use method B, of course, now the same
24 alternatives may be cost effective but they would be more cost
25 effective. And of course, if you use the additional, it is

1 very possible averted costs of these special considerations in
2 method C, even alternatives 5 and 6 may be cost effective for
3 some plants.

4 MR. EBERSOLE: In the evolution of these costs, did
5 you give consideration that in the application of say
6 alternatives 5 and 6, you could cut back on the extremely
7 complex and substantial investment in protective features that
8 you could either soft pedal or eliminate which is put there
9 now to cover the extended vulnerability of the plants?

10 DR. MAZETIS: That is certainly a possibility, but
11 the ground rules had to be laid in order to cost things out.

12 MR. EBERSOLE: So you didn't go back and say if you
13 did this then you didn't have to do fourteen other things?

14 DR. MAZETIS: No.

15 MR. EBERSOLE: Why isn't that a substantial--

16 MR. MINNERS: I thought it was surveillance or
17 something we thought could be cut back.

18 MR. EBERSOLE: What about QA, and safety category,
19 categorization, et cetera, in peripheral systems which are now
20 all over the place?

21 DR. MAZETIS: For example, for alternate 5 and 6 the
22 assumption was made. It was installed as safety equipment.

23 MR. EBERSOLE: I know, but you didn't, you didn't
24 take advantage of going back and including up all the
25 peripheral equipment which had to be safety categorized

1 because they formed a part of the overall vulnerability of the
2 plant?

3 DR. MAZETIS: No. No.

4 MR. EBERSOLE: Those savings would be substantial.

5 DR. MAZETIS: Well, in essence that's alternative 2
6 now. Remember alternate 2 were, the rationale for choosing
7 alternate 2 is that here is six plants, and here is for each
8 plant what we see as ten or 11 vulnerabilities to their
9 existing plant, and so we costed out for alternate 2 value
10 impact, a backfit if that plant had backfitted those
11 vulnerabilities, so in that sense, we considered improving the
12 vulnerabilities we found, so it is covered in the scope of
13 alternatives.

14 Yes, sir?

15 DR. MARK: Value impact analysis is a numerical
16 thing. It is arbitrary as may be. You still put in a
17 thousand dollars as if it had anything to do with the man rem
18 and so on.

19 But how you can even, how you can allow yourself to
20 talk about a value impact analysis based on unquantifiables
21 escapes my imagination.

22 That's just a judgment to me. It may be that the
23 method C says we should do it. It will be important to do it.
24 It has got a big point or something, but you can't possibly
25 put it in the bracket of saying it is cost effective.

1 You can put a number on sabotage. It is either one
2 or zero or it is something in between, and the whole list
3 there. It is a value judgment, and I'm not objecting. It may
4 be worth doing, but it can't be called cost effective.

5 DR. MAZETIS: My response to that is yes, there is a
6 lot of uncertainty and vagueness to these areas that I have
7 listed in method C, and we included them because when we asked
8 ourselves the question should we ignore them, the answer was
9 no. That's the decision-maker has to cover, include the
10 spectrum of considerations, and although we may not have as
11 good a handle on all these areas as we have other areas, it's
12 something that shouldn't be ignored, so that's why I was
13 including that.

14 MR. MICHELSON: Question -- the proposed dedicated
15 aux feedwater plus high pressure makeup arrangement, was that
16 considered alternative 5?

17 DR. MAZETIS: Yes.

18 MR. MICHELSON: Thank you.

19 MR. KNIEL: Jerry, could you list which one, which
20 ones were quantified in the alternative C moratorium,
21 quantified in three different ways as I recall, or four
22 different ways?

23 DR. ERICSON: That is correct.

24 MR. KNIEL: Put the slide back up again on
25 the--which of the ones were quantified and which weren't?

1 DR. ERICSON: Okay. Sabotage in the conditional
2 sense allowing you to make the judgment of what likelihood is,
3 but a range was included. The moratorium was quantified in
4 several ways. The resolution or cut was made at the economic
5 impact of the resolution of the other generic issues. Both of
6 those had dollar values assigned. We did not do those. The
7 staff did those.

8 DR. MARK: What you are saying is that they are all
9 subjectively filled in?

10 MR. MINNERS: Sure.

11 MR. KNIEL: We did actually make some dollar values.

12 DR. MARK: You invented numbers to go with them.

13 DR. ERICSON: I wouldn't say we invented them, Dr.
14 Mark.

15 MR. KNIEL: I think the moratorium thing was treated
16 fairly cleverly because we handled it in one, was it three
17 different ways or three different ways, right, so you had your
18 choice of how you wanted to look at it.

19 DR. MARK: That's what I have been saying.

20 MR. KNIEL: Fine.

21 MR. MICHELSON: How did you treat the generic issues
22 then, and there are quite a few of them, and in A-47, A-17 and
23 so forth?

24 DR. MAZETIS: Excuse me?

25 MR. MICHELSON: Proceed. You are going to tell me.

1 DR. MAZETIS: What that means is we looked at the 50
2 or 60 or however many there are generic issues, and using
3 judgment, for example, one of them was A-44, Station Blackout,
4 conditioned on the, a backfit of alternative 6 which was the
5 dedicated heat.

6 MR. MICHELSON: Why don't you take a more difficult
7 one like A-17, which you haven't even resolved yet? That, was
8 that included in this or was that ignored at this point?

9 DR. MAZETIS: I don't recall the specific ones that
10 were included. There may have been about a dozen that are
11 discussed or were considered and--

12 MR. MICHELSON: Did you look at the unresolved ones
13 or only the resolved ones? Maybe that would help.

14 DR. MAZETIS: I think we looked at all of them, but
15 we concentrated in order to come up with a reasonable
16 judgment, as to what the outcome would be, concentrated on
17 those, that some resolution was already perceived on paper.

18 MR. MICHELSON: One of the big ones that keeps
19 coming up as the system interaction A-17, I don't know how you
20 would possibly handle that at this time,

21 MR. MINNERS: Didn't quantify it.

22 MR. MICHELSON: Certain of the generic issues were
23 left out of the quantification?

24 DR. MAZETIS: That's right.

25 MR. MICHELSON: Okay. Thank you.

1 DR. MAZETIS: As I indicated earlier, the
2 alternative 2 is what the reg analysis will focus for future
3 potential improvement of decay heat removal systems where the
4 basis or the reasons that we came up with this proposal is
5 that the studies, the case studies again showed that a large
6 number of the risk contributors are plant-specific because
7 they lie in support systems, balance of plant areas, not in
8 NSSS specific areas.

9 Also use of method C which perhaps could justify
10 even alternative 5 or 6, goes beyond value impact methods
11 previously documented for unresolved safety issues and generic
12 safety issues, and also the insights gained from the six case
13 studies and the EPRI owners group analysis is planned or
14 expected to become guidance to licensees as the severe
15 accident program progresses, and licensees, if what is
16 expected is implemented, turn to their plants for examining
17 for severe accident vulnerabilities.

18 CHAIRMAN WARD: Now we have seen your reg, the
19 results of much of the regulatory analysis, but I'm, I have
20 lost track of what form or when. Did we see a rough draft
21 report or did we just see your earlier --

22 DR. MAZETIS: You saw a rough draft report that we
23 submitted to you prior to the closed session in '86.

24 CHAIRMAN WARD: Okay. Have you changed or have you
25 done any new work since then or--

1 DR. MAZETIS: There has been no change to the
2 contractor's findings, no, but the change is, is going to be
3 in the draft proposed resolution in terms of more definitive
4 as to what direction we feel the A-45 program should take,
5 that you didn't have at that time.

6 CHAIRMAN WARD: Right. Okay.

7 MR. MINNERS: The numbers have changed because we
8 have made errors, and we have made little modifications, but
9 the general idea is the same thing. It is only minor changes.

10 DR. MAZETIS: I think at that time most of the
11 results of the studies had been completed but they hadn't,
12 they hadn't been published yet in final form, and it could
13 have been there was some finetuning.

14 CHAIRMAN WARD: Yes. Well, they are still not
15 published in final form, are they?

16 DR. MAZETIS: Yes. The six case studies from
17 earlier form are in six NUREGs that have been published for
18 the plants.

19 CHAIRMAN WARD: The case studies are?

20 DR. MAZETIS: The case studies.

21 CHAIRMAN WARD: The regulatory analysis is what I am
22 talking about.

23 MR. KNIEL: No.

24 CHAIRMAN WARD: That's what I was talking about. We
25 saw before the September meeting, a rough draft report I

1 thought of the regulatory analysis. Or am I dreaming?

2 DR. MAZETIS: No. You did, and I agree that the
3 major part of that draft remains in tact in terms of the
4 technical findings. I mean they haven't changed. There may
5 have been some finetuning of the numbers, but--

6 CHAIRMAN WARD: What is the status of that report?

7 DR. MAZETIS: Okay. The status -- did you add
8 something to that question?

9 CHAIRMAN WARD: No.

10 MR. MINNERS: Wanted to know what the status was of
11 the regulatory analysis.

12 DR. MAZETIS: As I indicated earlier, that the next
13 revision is essentially in the typewriter, and our plan is
14 sometime within the next couple of weeks to get it distributed
15 internally so that within the next month or two, at the
16 outside, ACRS probably would be a contributor to commenting on
17 that report.

18 DR. SIESS: May I ask a question? What guidance has
19 the staff had from the Commission on the fact that it should
20 be included in the value impact statements?

21 DR. MAZETIS: Well, there is a backfit rule that we
22 have tried to follow with its references to various value
23 impact NUREG guidance that have been published by the staff
24 the past several years, and so the format of this regulatory
25 analysis will track with other recently, other recently

1 submitted backfit analyses. For example, more recently A-4;
2 it follows in general the same backfit format as the A-4
3 format.

4 DR. SIESS: Is that an answer to my question?

5 DR. MAZETIS: Anyone have a better answer?

6 MR. MINNERS: The only explicit guidance, any
7 written guidance that I know you have we have gotten from the
8 Commission, is the backfit rule which lists half a dozen or so
9 specific factors that should be considered in factor analyses,
10 and also has an indirect statement something like in any other
11 relevant factors or something like that.

12 DR. SIESS: Does that give you guidance on off-site
13 versus on-site?

14 MR. MINNERS: No.

15 DR. SIESS: Moratorium?

16 MR. MINNERS: No.

17 DR. SIESS: So we are operating in an area where we
18 don't know what the safety goal is and don't know what the
19 values and impacts should be? Making common law.

20 MR. MINNERS: Well, I guess the direction that I
21 would take is one of reasonableness. I think you ought to
22 discuss all of the relevant significant factors, and I don't
23 think anybody can disagree with that. I don't see any reason
24 for excluding any information except on the basis that it is
25 irrelevant or insignificant.

1 DR. SIESS: So you would you say include everything?

2 MR. MINNERS: Then the decision-maker is going to
3 make his decision on whatever basis he wishes. I have no way
4 of controlling how the decision-maker is going to make--

5 DR. SIESS: Who is the decision-maker?

6 MR. MINNERS: The Commission I presume on the USI.

7 CHAIRMAN WARD: Could we take a--

8 DR. SIESS: You would propose to give the Commission
9 a regulatory analysis that covered the range of strictly
10 off-site up through on-site and moratoria and let them decide?

11 MR. MINNERS: I think they can handle that.

12 DR. SIESS: You said it. I didn't!

13 CHAIRMAN WARD: So in other words--

14 MR. MINNERS: We have had an opinion from OGC on
15 on-site costs, but I haven't heard anything from the
16 Commission on it.

17 CHAIRMAN WARD: Well, if you look at your three A, B
18 and C, methods for value impact analysis, I mean isn't it
19 clear that C, isn't C clearly outside of what would be
20 intended under the backfit rule?

21 MR. MINNERS: No.

22 CHAIRMAN WARD: That isn't clear to you?

23 MR. MINNERS: There is introductory statement in the
24 backfit rule which says you should consider all relevant
25 factors.

1 CHAIRMAN WARD: You don't think, I mean you have
2 made the determination I guess that neither A, B nor C is
3 particularly favored for compliance with the backfit rule? I
4 mean I guess I --

5 MR. MINNERS: If I am making the decision, okay, I
6 would look at method C and I would weight the different
7 factors as to how much I believed them. I would
8 consider--everybody thinks about moratorium. It is ridiculous
9 not to say that. It is a possibility.

10 CHAIRMAN WARD: What would the backfit rule require?
11 I mean what would the lawyers say?

12 MR. MINNERS: What it would require, it has six
13 factors which are basically implementation costs and averted
14 off-site costs, and occupational exposure.

15 CHAIRMAN WARD: So that would be B?

16 MR. MINNERS: That would be A. That would be
17 required. You have to at least address those things. Now in
18 addition to that, the backfit rule as I read it let's you go
19 beyond that and consider other, what I would say is relevant
20 significant factors.

21 CHAIRMAN WARD: Okay. And you say that could then
22 go as far as B and C or C?

23 MR. MINNERS: To me, it goes as far as C, sure.
24 Moratorium is a serious consideration and all we have done is
25 done some number manipulation to try and give you a better

1 perspective on it. No intent to say that our calculations of
2 cost of a moratorium are any estimate of what the actual cost
3 would be. Just trying to give some perspective.

4 Sabotage is the same question. It is a matter of
5 belief. I agree with Dr. Mark. There is no way of knowing
6 what the probability for sabotage with them is, but if you are
7 going to make some estimates you are going to have the balance
8 of cost of sabotage from, against your assessment of risk. It
9 is going to be a very subjective assessment, but it is still
10 going to have to be balanced.

11 CHAIRMAN WARD: Thank you.

12 DR. MAZETIS: This slide is really a review of some
13 of the considerations that are now being given. Obviously it
14 is not cast in concrete yet, but this will give you a feel for
15 the implementation, and as we try to implement the thrust of
16 alternative 2, how we are going to do that specifically.

17 Again, the idea is to require plant-specific
18 reliability analyses to try to focus on plant-specific
19 vulnerabilities, and two questions that are being debated are
20 should, should it be part of IPE or should it be separate PRA
21 requirements concurrent with the IPE program? And there are
22 pros and cons to each as you can see here.

23 One question we are wrestling with now, I really
24 don't have the answer for, is if we marry it to IPE, does it
25 mean we have to require a more rigorous or more thorough PRA

1 methodology than what is being currently contemplated for the
2 utilities to use on IPE?

3 Also not a small consideration is, is somewhere down
4 the road should the staff get involved in either some kind of
5 limited audit efforts or in overall review of these analyses?
6 So that I guess up front here we are thinking there should be
7 some commitment, if we expect to get something, some safety
8 improvement out of the idea of marrying to IPE A-45, there
9 should be some kind of a commitment to review downstream these
10 analyses as a minimum on an audited basis.

11 MR. MICHELSON: Question--if you elect the IPE
12 route, will you be expecting them to look in sufficient detail
13 to understand the effect of fire, flood, external, internal,
14 wind storm, et cetera, which is a part of the question? Would
15 that be now brought--I know IPE can't. I didn't look too
16 closely at those areas. Maybe I am mistaken.

17 MR. MINNERS: If you mean the IDCOR method, that
18 doesn't include external events, but my understanding of the
19 severe accident policy statement is that it says explicitly
20 that external events should be considered.

21 MR. MICHELSON: So you are thinking IPE will include
22 a sufficiently careful examination of external events to
23 satisfy this criteria?

24 MR. MINNERS: We have some people looking at what we
25 should consider in the external events.

1 MR. MICHELSON: From what I have heard today, that
2 would have to be sort of a ground rule if you are going to
3 cover these events by the IPE approach?

4 MR. MINNERS: I said we are investigating how much
5 external events should be included in IPE, and I guess a
6 decision hasn't been made on what is going to be in IPE.

7 MR. DAVIS: On the previous slide, that item under
8 the separate requirement?

9 MR. MINNERS: Where are we, Pete? Slide 8?

10 MR. DAVIS: Nine.

11 DR. MAZETIS: Here?

12 MR. DAVIS: Yes. It indicates you would require, if
13 it is separate, A-45 resolution is separate, this would
14 require each licensee to perform two separate analyses, and I
15 guess that's true.

16 However, I don't see that that is a significant
17 problem because I don't think anything they would do under
18 A-45 could not also be used in the IPE. Is there something
19 more to it than that?

20 DR. MAZETIS: No. I guess the idea was that if they
21 were required under the IPE program to go into their plant and
22 employ a certain methodology to look at the total plant
23 vulnerabilities and that they finished that study and
24 concurrent with that there is a requirement to do the same
25 thing but focusing on just decay heat removal in a more

1 rigorous PRA methodology, it may be an additional burden, and
2 redundant to what they did under IPE, but what you say is
3 true. They may be able to use something they learned from IPE
4 or vice-versa, but it would be two separate burdens on the
5 licensee to respond.

6 MR. DAVIS: Well, they might be separate, but they
7 wouldn't be independent.

8 MR. MINNERS: At least double the paperwork.

9 MR. DAVIS: Okay. Well, to me, that doesn't seem
10 like a significant disadvantage.

11 MR. MINNERS: It is quite possible, too, depending
12 on what order you did it, you seem to be suggesting if we did
13 A-45 first that could be used in IPE or vice-versa.

14 MR. MINNERS: That might not be the case. If IPE
15 didn't include external events, and that's not a decision made
16 yet, then it might not be enough.

17 MR. DAVIS: No. I am not suggesting it wouldn't be
18 enough, but what they would do would be applicable to at least
19 internal events part of of A-45.

20 CHAIRMAN WARD: At least if a licensee knows he is
21 going to have to do both of these things, whatever they are,
22 he should be able to organize his effort.

23 MR. DAVIS: Avoid duplication.

24 CHAIRMAN WARD: Yes. But if you come out with
25 instructions for doing an IPE next month and eight months

1 later come out with instructions for doing something under
2 this, that could cause licensees a lot of problems it would
3 seem to me.

4 DR. MAZETIS: Okay, and the last two slides kind of
5 shifts gears into the next couple of speakers, where maybe now
6 we could point to the submittal by EPRI and the owners group
7 on Point Beach which is the same plant, one of the plants that
8 NRC/Sandia studies concentrated on, and you might ask the
9 question, well, if we are going the way that I just described
10 in our reg analysis why bother? I mean this document may be
11 a nice piece of information to have, but why bother with
12 resources of reviewing this document?

13 I guess that's a good question, and our current
14 thinking is that when the IPE generic letter is published, we
15 would not lose what we have learned on A-45 the past seven
16 years. There is planned and explicit address of, focuses on
17 decay heat removal in the IPE exercise, and we perceive it
18 perhaps as an additional appendix on what we have learned on
19 A-45 through the case study analysis plus in this particular
20 case, the whole breadth of the picture on some additional
21 insights provided from others in the industry and hopefully by
22 the time it is published, some staff comments in the IPE
23 program as to where, what agreements we have had with NUMARC
24 and where our disagreements still lie so that the utility as
25 he goes through this severe accident program and starts

1 looking in his plant can get some specific guidance for decay
2 heat removal vulnerabilities on where to focus his resources
3 and where the areas perhaps for his plant would contain the
4 more vulnerabilities, where the soft spots are and so forth.

5 So we think there is something to be gained by
6 continuing to the dialogue which is planned with the NUMARC
7 sometime within the next one or two months to interface with
8 NUMARC to discuss in essence as you will see a need for
9 additional understanding as to why certain assumptions were
10 made, so that we could at some point down the road form an
11 opinion as to what we feel are the better assumptions. And as
12 I indicated earlier, you might ask is the alternative 1 or the
13 no action, do nothing, justifiable? And again, if the EPRI
14 PRA is, turns out to be correct, and if you like it,
15 and you think that Point Beach was a bounding plant, then
16 again you may think, may end up in this box where doing
17 nothing is justified, but I don't think as far as the staff is
18 concerned that obviously this early that we are convinced that
19 either of these are correct. We have this dialogue to go
20 through on the NUMARC studies, better understand the basis for
21 a lot of their assumptions.

22 MR. MICHELSON: Clarification--when you talk about
23 the EPRI PRA, do you mean the NSAC-113?

24 DR. MAZETIS: Yes.

25 MR. MICHELSON: Okay. Thank you.

1 CHAIRMAN WARD: Jerry, it seems to me that the first
2 one is a, reasonably determinable, that is, the differences
3 between the Sandia PRA and the EPRI revision of that. You
4 know, that's what you are going to discuss. Maybe you can
5 resolve those.

6 DR. MAZETIS: Yes.

7 CHAIRMAN WARD: But the second one, how are you ever
8 going to figure out whether Point Beach is a bounding plant or
9 not?

10 DR. MAZETIS: We are not intending to do that. All
11 I am saying is if someone is asking himself and is convinced
12 that doing nothing is justifiable, as far as the staff is
13 concerned, this may be the bases for them believing that. All
14 I am saying is we disagree. We are not convinced yet that
15 that rationale has a basis.

16 MR. WARD: Okay. You are saying your position is
17 alternative 1 is not justifiable?

18 DR. MAZETIS: That's right. Exactly.

19 CHAIRMAN WARD: Maybe they can convince you on the
20 first part there, but it looks tough on the second one.

21 DR. MAZETIS: I doubt it on the first part, too,
22 after preliminary interface with some of the analysts, but you
23 will hear that in a couple of minutes.

24 (Slide)

25 DR. MAZETIS: And my last slide is--you have seen

1 this table before. It is just a lead-in to the next
2 presenter, from the EPRI owners group document. You can see
3 the difference for the up-front end of the document, the core
4 melt frequency, where the major differences are identified and
5 focus more on the first four areas where you can see the, they
6 are in some cases a large difference between NRC/Sandia
7 reports and the EPRI owners group report.

8 So that completes my presentation, and Mr. Chelliah
9 is the next presenter with 15, 20 minutes discussion of what
10 his observations are so far, and again I remind you that he
11 has not yet closed. There have been no give and take with his
12 observations with Sandia, nor with NUMARC, so there may be a
13 little overlap here.

14 CHAIRMAN WARD: Thank you very much. Let's take a
15 break until 10:30.

16 (A brief recess was taken.)

17 CHAIRMAN WARD: Our next speaker is Mr. Chelliah of
18 the Research Office.

19 DR. MAZETIS: If I can just make a brief comment, I
20 notice from your agenda that you had an additional gentleman,
21 Dave Pyatt, scheduled, and we would like to have his area,
22 which is the back end of the calculation, deferred as far as
23 an actual presentation, but have him available if questions
24 come up, so really we have got two speakers left, Mr. Chelliah
25 and Dr. Ericson, who probably we could get through before

1 lunch.

2 MR. CHELLIAH: Good morning. My name is Chelliah.
3 I am from the Risk Analysis from Research.

4 (Slide)

5 MR. CHELLIAH: As the, as part of this decay heat
6 removal study, the lab, Sandia Laboratory, they performed the
7 decay heat removal type of PRA on the Point Beach facility on
8 the power in cooperation the EPRI. They performed the
9 reanalysis of this particular Sandia study with the EPRI,
10 phone company, of the Point Beach facility in cooperation with
11 the EPRI; they performed the limited review of this Sandia
12 study. They have provided us the reanalysis the staff looked
13 into, and we have the preliminary comments here.

14 In summary, the EPRI report claims that their core
15 damage frequency estimate just allocated to decay heat removal
16 is lower than the Sandia estimate. What we have done here in
17 the presentation is to provide you with a summary differences
18 on all the accident sequences. Here I would like to put the
19 ACRS members to read the sequence. There are a couple of
20 pages on the back side. I have described the sequence with,
21 what this means. Also I will explain to you as I go through
22 here.

23 Here we have two estimates, that is Sandia National
24 Lab, EPRI estimate. And we have here three major bullets I
25 would like to explain one at a time, and I will also try to

1 say whether we concur or don't concur.

2 First the sequence, the frequency of failures. You
3 can see the difference in the frequency estimate. The first
4 difference comes from the frequency in the EPRI study.
5 Basically here what they did, they looked into the Sandia
6 frequency, the smaller frequency; it covers wide range of
7 break, varying from .3 inches all the way up to 1.6 inch, 2
8 inches. It includes all the failures, all those things.

9 What the EPRI did, they did look into the
10 experience, the operating experience. They have decided that
11 those breaks involves the smaller ones, so what they did, they
12 assigned the small LOCA frequency about 1.5 inch, which
13 would--accordingly they are just doing this frequency.

14 MR. MICHELSON: Question--what data base did you use
15 to determine small break frequency?

16 MR. MICHELSON: Or what did Westinghouse use or
17 whoever did the work?

18 MR. CHELLIAH: Yes. In this particular report,
19 there is also one, in the report it is indicated that they
20 used Westinghouse operating experience I assume.

21 MR. MICHELSON: Westinghouse, every time some
22 utility has a small break, does Westinghouse somehow get
23 informed or become aware of it and put it down in their data
24 base? Is that the way it works? Or are they just pulling out
25 some numbers and playing around with them? They are real

1 legitimate scientific data base that they maintain small break
2 LOCA?

3 DR. MAZETIS: I think you are asking some of the
4 questions that when we get with NUMARC that we would expect to
5 gain a better understanding of what the basis for their
6 numbers are.

7 MR. MICHELSON: You haven't done that yet?

8 DR. MAZETIS: However, Sandia could address the
9 basis for the numbers in the six case studies if you want to
10 get into that.

11 MR. MICHELSON: That's a good place. What at
12 Sandia--

13 DR. ERICSON: Generic data base published in the
14 procedures guide.

15 MR. MICHELSON: Where did it come from?

16 DR. ERICSON: Accrued by the staff and by the
17 community over a number of years.

18 MR. MICHELSON: I have seen some of those numbers.
19 I am no PRA expert, and the first to admit it, but a lot of
20 numbers I have seen in the past seem to not have a good
21 scientific base, but rather some, early on they were
22 assumptions because they didn't have good numbers and they
23 began to become accepted even though they weren't necessarily
24 scientifically based. I just wondered, you are using the same
25 numbers everybody else is using? Is what you are saying?

1 DR. ERICSON: That is correct.

2 MR. MICHELSON: And how do our PRA people feel about
3 that? Are they satisfied those are good numbers, or just the
4 numbers everybody uses?

5 MR. DAVIS: According to the EPRI report, the small
6 LOCA frequency that was used by Sandia was dominated by some
7 pump seal LOCA data that is in an internal NRC memo which I
8 haven't seen, and according to the EPRI report, most of those
9 breaks were pieces of small data that would not require
10 recirculation, and that at least my understanding is the basis
11 for the large difference in initiated frequency.

12 CHAIRMAN WARD: Mr. Ericson, is that right? The
13 data you used--

14 DR. ERICSON: He says what I understand to be in the
15 report. I disagree with him. And the S2 data that is
16 published includes all of small break LOCAs below one and a
17 half inch, doesn't throw some of them out. In fact, if you
18 take what is in the EPRI report, the five additional events
19 cited, I think that is correct. Then you come up with
20 something like three times ten to the minus 2 if you add those
21 into the data base they talk about.

22 MR. CHELLIAH: One point, Dr. Michelson--the EPRI--

23 MR. MICHELSON: I am not quite finished with the
24 question yet.

25 MR. CHELLIAH: Okay. I'm sorry.

1 MR. MICHELSON: If the pump seal LOCA is a dominant
2 contributor, which I think is what you are saying, then the
3 NRC is aware of that, it is their data base, is that what you
4 are saying? You said it was an internal NRC memo, so really
5 the NRC is the custodian of small break LOCA predominant
6 contributors at least. And so you people are the ones that
7 are the experts and have the good data base on it I guess.
8 That's what I thought I heard.

9 MR. DAVIS: According to the report, the data that
10 was in the memo was based on a search of LERs.

11 MR. MICHELSON: Now we are getting a little closer.
12 And does NRC maintain a small break LOCA data base which they
13 keep current on all of these? They find, of course, the pump
14 seal is made to contributor. I don't think I necessarily
15 disagree, but you people are the custodian and I can go and
16 find out who is maintaining this data base and see how they do
17 it?

18 DR. MAZETIS: Joe--

19 MR. MINNERS: Joe, you guys--

20 MR. MURPHY: I am unaware of formal data base.

21 MR. BOEHNERT: Would you identify yourself, sir?

22 MR. MURPHY: Joe Murphy from Research; I am unaware
23 of a formal data base in terms of someone surveying the OERs
24 once a month and adding that in.

25 MR. MICHELSON: I am unaware of it, too. That's why

1 I was a little surprised. I am, I am not going to argue if
2 that's what everybody thinks is the source.

3 MR. MURPHY: There was a search done a couple of
4 years ago, on the pump seal LOCAs, and that information was in
5 the memo that was referred to and that has been used in a lot
6 of PRAs sponsored by the staff.

7 Now there is a standard policy in doing a PRA that
8 the analysts usually do surveys of ECRs. If they see an
9 unusual pattern of behavior, they go back and analyze the data
10 more explicitly, but AEOD may do some formal data base, the
11 basic organization for gathering and maintaining the data base
12 for the agency. They may have something explicit in that
13 area, but I'm not aware of it.

14 MR. MICHELSON: I am not either, but I will go back
15 and ask them again for a current answer. Thank you.

16 MR. EBERSOLE: Ask you a question? First I want to
17 thank you for characterizing these sequences because it blows
18 my mind to try to remember them. So in the first one there,
19 you have in the explanation it is a small LOCA followed by
20 failure of low and high pressure recirculation systems.

21 MR. CHELLIAH: Yes.

22 MR. EBERSOLE: I thought a PWR, for that matter BWR,
23 really has no problem with recirculation since it has natural
24 convection and the problem is one of makeup to hold pressure
25 so you would have a thermal differential to carry the heat to

1 the secondary side.

2 I don't know why I say failure of low and high
3 pressure recirculation system. You have got one in natural
4 convection. I can see a problem in actually supplying the
5 pressure to make up the leak to hold the pressure up so you
6 can transfer heat.

7 DR. MAZETIS: I think--this is a different
8 terminology, recirculation.

9 MR. EBERSOLE: You are going on out to recirculating
10 the water. I am talking about the presence of the
11 secondaries.

12 MR. MICHELSON: Are you defining small LOCA for BWRs
13 differently than for PWRs? By definition it is the makeup of
14 the normal, beyond the makeup of the normal system I think is
15 the definition of small break LOCA, and it is very large
16 break.

17 MR. MINNERS: What difference does it make if we
18 define it differently?

19 MR. MICHELSON: Makes quite a difference in what
20 kind of systems are going to address it.

21 MR. MINNERS: Small break LOCA medium, and we do
22 large break LOCAs.

23 MR. MICHELSON: You said 2 inches was the range of
24 your small break LOCA. I think it is considerably bigger than
25 that for the boiling water reactor?

1 DR. MAZETIS: My recollection is that was about the
2 size for the PWR case study. Perhaps Dave could correct me if
3 I'm wrong.

4 DR. ERICSON: I can't pull it out of the top of my
5 head.

6 MR. EBERSOLE: You are taking heat out through the
7 exchangers. You have got for even the boilers, I mean the
8 steam generators--

9 MR. CHELLIAH: Yes.

10 MR. EBERSOLE: Degraded state in the first place;
11 you have lost the secondary.

12 MR. CHELLIAH: The point is the EPRI analysis assume
13 that is the, is needed for breaks more than 1.5 inch
14 breaks. Accordingly, they are just small LOCA frequency, so
15 that is one of the difference here.

16 Dr. Michelson, going back to your question, the PRA
17 does provide a document of all the reported small LOCA events,
18 including the Zion and the Robinson event, and some of the
19 small leaks varying from 20 GPM all the way up to hundred
20 GPMs. It does provide some documentation. If you are
21 interested, you can look into the NSAC-60 report.

22 The second difference is the modified common cooling
23 water success criteria. Basically what it is here, the EPRI,
24 they did look into the cooling system configuration and
25 associated cooling by common cooling water system, but their

1 claim is this. The CCW provides seals rather than it provides
2 the cooling, so the claim is this particular system is not
3 really needed during the injection phase of this particular
4 sequence up to one hours. Accordingly, they have, the
5 frequency here has accounted for some removal dependency due
6 to the CCW system. We do concur with the plant-specific
7 details.

8 We need some additional information on some of the
9 test data on this seal performance related to why it doesn't
10 fail during injection, why it would fail only after one hours
11 because we have more than two-hour time sequence from the time
12 so basically we do have that, but we need some additional
13 information here.

14 The third one is really--

15 CHAIRMAN WARD: How much would that change the
16 numbers?

17 MR. CHELLIAH: I don't have it here. The
18 difference, added to the other thing they have here.

19 DR. ERICSON: Eighty-six percent of the difference
20 in the small break LOCA frequency, in the two numbers; above
21 the CCW and the service water balances are very minor
22 contributors. CCW is like 6 or 7 percent.

23 MR. CHELLIAH: This is the load balancing.
24 Basically this particular sequence used as the hour, there are
25 three series pumping each unit at Point Beach. What EPRI

1 claims based on data, review of their procedures, related to
2 this system, there are two, it is not meant to--operator has
3 reduced some of the heat load. It is not needed so that they
4 can live with the one hour satisfactory, so accordingly, there
5 are some redundancies. That is also one of the reasons we
6 went down.

7 We do have some other differences which I did not
8 list. They did look into some human ratio. One of the things
9 that this frequency involves is the operator failure to
10 establish recirculation following the event. You have two
11 hours to go. The Sandia, they used something like three minus
12 per demand. EPRI claims that there are, 1 E minus 4 would be
13 more appropriate based on the procedures. They have not
14 provided any human analysis. Right now we do, we need more
15 analysis on that particular operator failures.

16 There is one more on the sequence--the tank, because
17 two hour, you are going to dump the water. What they are
18 saying, you bleed from the tank; this particular area you
19 bleed through the tank from spent fuel or you can bleed
20 through the tank, okay, bleed the tank spent fuel or use the
21 boric acid storage tank, about a hundred thousand gallons.

22 EPRI basically claims that the Point Beach facility,
23 they do have procedures which dictates in case of water is 60
24 percent, 30 percent, you can do all these accidents, so based
25 on the plant-specific procedures and training which are in

1 place, they claim, they have taken some--that's also a
2 contributing factor. Other thing, too, you can see the
3 sequence.

4 The next sequence is--

5 MR. DAVIS: Excuse me. A question--have you come to
6 a conclusion about whose frequency of small break LOCA is more
7 valid for this case? I don't believe you said whether you
8 agree or not.

9 MR. CHELLIAH: We do contend the EPRI's frequency
10 because we did look into it--you don't need these below 1.5
11 inch break. They are right. It is right. We do agree with
12 that.

13 Now the second sequence is really that loss of
14 off-site power sequence, basically Station Blackout sequence.

15 DR. MAZETIS: Excuse me. Again, if you ask the same
16 question of Dave when he gets up here, you may or may not get
17 the same answer, and I just want to point out that the staff
18 has yet to close the loop on interfacing back and forth.

19 MR. DAVIS: I understand. Thank you.

20 MR. MICHELSON: Question--if you have a safety
21 relief valve go through an operation and stick, is that
22 considered a small break LOCA under this business?

23 DR. MAZETIS: Yes. PORV open air, sticking open.

24 MR. MICHELSON: Those kind of events do not occur as
25 frequently as pump seal failures? Or if not, why does pump

1 seal failure dominate the data base?

2 MR. CHELLIAH: Dr. Michelson, we do have the
3 sequence. We will come to that. We do have a sequence to
4 answer your question.

5 DR. ERICSON: That is not the initiating event. The
6 stuck open PORV is not the initiating event; subsequent event
7 after transient.

8 MR. MICHELSON: That's why I asked the question. Is
9 it considered a small break LOCA? What you are saying is that
10 only if the pipe breaks first is it in this table in the way
11 it is presented, but a small break LOCA may be involved in
12 some of the other events. The fact is it was a fairly high
13 probability.

14 MR. MINNERS: It is event T3QD1D2!

15 MR. MICHELSON: I really think it is there. That's
16 why I asked the question. I thought it would have been
17 considered a small break LOCA, but I see why such logic is you
18 are looking only at the initiator, finding it that way.

19 MR. CHELLIAH: The second sequence is basically loss
20 of off-site power, the failure of--the L is the failure of aux
21 cooling. I'm sorry--secondary cooling, and E is the, really
22 the failure of feed and bleed, so this sequence is really
23 dominated by some of the Station Blackout concerns, failure
24 combinations. There is some difference you can see close
25 to--there are two major differences here. Updated initiator

1 frequency, loss of off-site power frequency. The Sandia
2 study, they use something like about .zero 8 per site year
3 based on one of the reports, NUREG 1032. At EPRI they did
4 look into the plant-specific operating experience. We did
5 have one event over there in the sixteen-year operating
6 history, so they are just going accordingly.

7 The second one is really a very important one I
8 thought in my view. They added, like they said in the report,
9 they added one of the third time class battery system,
10 seismically qualified. Basically, some start and control
11 failure probabilities, safety equipment, because this
12 particular sequence frequency is really dominated by the
13 battery common mode failure, so this would help now, so they
14 have not provided us--we do concur with this one. We don't
15 have much detail what they did, how they did all these things.
16 We need some information from EPRI, but basically we do
17 concur.

18 There is some other difference also other than these
19 two bullets. EPRI, what they did, they did look into the
20 common mode failure analysis of the D cells and batteries
21 reported in the Sandia. They used a somewhat different
22 method. For example, in the Sandia study we used factor for
23 the common cause failure of common mode failure of the
24 diesels. EPRI, they started using one of the multiple
25 failures. There is a difference, about three difference on

1 the diesel common mode failure. So that comes into this
2 sequence frequency.

3 MR. EBERSOLE: Did they add an engine-driven DC
4 charger by any chance?

5 MR. DAVIS: Just batteries; site qualified.

6 MR. EBERSOLE: They just added more battery
7 capacity?

8 MR. DAVIS: It is an independent battery.

9 MR. EBERSOLE: Rather than putting a small
10 engine-driven charger which has indefinite capacity, storage
11 life; well, okay.

12 MR. CHELLIAH: We need more detail on what the
13 battery does exactly, you know, where does it hook up, all of
14 these things. I think Sandia is going to discuss the data we
15 have on this particular item.

16 So basically, we need some information on this
17 particular bullet.

18 The third and fourth sequence is really transient
19 where you have main feedwater is available. The Q is the
20 stuck open, the relief valve, and these are the recent
21 failures and here is the injection failures.

22 EPRI, they look into this sequence carefully. Their
23 claim is they did look into some of the Westinghouse, some of
24 the operations performed by Westinghouse. They came to the
25 conclusion as long as you have main feedwater available, you

1 don't get into this situation because--I'm sorry--because you
2 don't reach first to the relief valve set point. Therefore,
3 you go on to something, so they are, according to their
4 analysis, the sequence shouldn't exist. so they did not
5 comment.

6 MR. EBERSOLE: That exit is a transient involving a
7 stuck open PORV and failure of recirculation systems.

8 The main feedwater system is assumed to be initially
9 available. Well, and that says no need for recirculation, and
10 that's right, but there is a distinct need for pressurization
11 and supply capability to deepen overpressure on the primary
12 side against the secondary system. Are you with me?

13 MR. CHELLIAH: Yes.

14 MR. EBERSOLE: I have both to have a thermal
15 gradient--maybe you can pull secondary down to 29 inches of
16 vacuum. Does it involve that? You have got to run downhill.
17 Is that what is contemplated, that you will run the secondary
18 pressure down as the primary pressure declines?

19 MR. CHELLIAH: Okay. Answering your question, Dr.
20 Ebersole, we don't have much detail because if you look at the
21 EPRI analysis, they did not even draw a branch point when you
22 come to this particular event.

23 MR. EBERSOLE: It implies they are going to transfer
24 to the secondary somehow, when they say no need for
25 recirculation.

1 MR. CHELLIAH: But their claim is this valve is,
2 won't reach that set point as long as you have initiating
3 feedwater available, so they say you will be able to cool down
4 with the existing, the other ejection systems.

5 MR. EBERSOLE: Feedwater is not worth anything
6 unless you can get heat from the primary to the secondary, and
7 that requires a gradient in temperature and that requires a
8 primary system be at higher pressure than the secondary.

9 MR. ERICSON: If you accept the argument that Q
10 doesn't occur, there is no loss in primary, primary stays
11 pressurized.

12 MR. EBERSOLE: Fine if it does that.

13 DR. ERICSON: That's their argument.

14 MR. CHELLIAH: The question that we are taking
15 basically, here is the similar situation as well as here. The
16 injection is failing, falling this particular event, so you
17 are in the same argument. If the valve doesn't open, you
18 don't bleed the water from the primary system. Basically it
19 is a logical sequence according to them.

20 Right now the question of what position we are
21 taking, we do agree with them, but I think they have to show
22 that the specific analysis for this facility, falling back to
23 some of the analyses or typical Westinghouse analyses to some
24 raising pressure, we haven't seen yet in the report. This is
25 part of the verification of the criteria. Basically we do, we

1 agree with them.

2 CHAIRMAN WARD: You are saying you agree on both of
3 those cases?

4 MR. CHELLIAH: Yes. Then this sequence, the fifth
5 sequence, is very important sequencew. The T is really loss
6 of feedwater event.

7 MR. MINNERS: We have a little.

8 MR. VANDERMOLEN: Harold Vandermolen from Risk
9 Analysis Branch--the ruling means we agree with them
10 contingent upon seeing the thermohydraulic calculation. We
11 are not accepting this unconditionally.

12 MR. CHELLIAH: That's right.

13 MR. VANDERMOLEN: I want to make that clear. When
14 we say we agree, we agree contingent upon some type of
15 receiving thermohydraulic calculation verifying that
16 assumption. Follow me?

17 CHAIRMAN WARD: Right. Thank you for the
18 clarification.

19 MR. CHELLIAH: As part of PRA review we have to
20 verify the criteria so we have to look into those
21 calculations.

22 This fifth sequence is a feedwater event followed by
23 the stuck open, the relief valve.

24 MR. MICHELSON: Which relief valve? That has got a
25 Q in it also.

1 MR. CHELLIAH: I will explain that. Okay. Such
2 sequence also exists in EPRI. They do have some estimate.
3 Have, sometimes have difference. The major difference is the
4 revised PORV probability. I think here it needs a little
5 explanation. When there is, Sandia did, performed their
6 study, based on the information available to them, what they
7 assumed here, the safety valve will open because the PORV is
8 the block valve.

9 Also they made assumption that 7 percent of the time
10 they do open, and they are just also, they gave critically the
11 blocked valve failure. Probably accordingly they computed Q
12 in, but the EPRI, they did look into this particular event
13 under the associated calculation performed by Westinghouse.

14 What their claim is, if you get the feedwater event,
15 the only way you can reach the set point, the PRA set point
16 the PRA set point is with the number 35 pressure, PSIG. This
17 is based on the flow mismatch between the primary and
18 secondary system so they say that there is only 1 percent of
19 the time the valve will challenge because of the rising
20 pressure. So accordingly, they computed this Q. They did
21 also give credit to the blocked valve failure on the PORV.
22 According to them, it will not reach the set point which is
23 over 2485 PSIG. That's a big difference over there, so
24 basically some sense here so they assumed 7 percent of the
25 time it will open. But what the licensee claims based on

1 their operating experience and the Westinghouse with
2 calculations, is only 1 percent of the time it will challenge
3 because of the flow mismatch.

4 We do agree with the EPRI position but we need some
5 additional bases under the assumption 1 percent, how they
6 got--we need some bases on that, but we do concur with that
7 position.

8 Then the last sequence, this is companion sequence
9 here, that's the failure here, the small LOCA followed by the
10 injection failure, so you have this particular bullet, place
11 it here; also this one because this affects it as well, the
12 LOCA frequency. And also doing the injection phase, the CCW
13 is not needed because it prevents the seal rather than the
14 cooling, so that bullet goes into this risk we estimate.

15 MR. EBERSOLE: Let me ask you a question. You have
16 got some pretty low numbers up there, like ten to the minus 8.
17 Isn't there a school of thought that says as you go up--

18 MR. CHELLIAH: Mine he is 79.5.

19 MR. EBERSOLE: As you go up, rather go down in
20 probability like this, that there is a progressive
21 deterioration of the reliability of these numbers because of
22 common mode especially in complex systems, and so as you run
23 down this scale of probability, your accuracy really declines
24 and everything gets rather fuzzy at about ten to the minus
25 5th, or 4th.

1 MR. CHELLIAH: Well, yes. We do agree. When you go
2 to minus 7, you do have substantial amount of uncertainty. In
3 fact, right there the S2 frequency is the frequency itself
4 because here we are talking about break and 1.5 inch, the
5 sequence, because the same initiating frequency is assigned
6 here, so in absence of data, you know, light water reactor,
7 you do have uncertainty.

8 MR. EBERSOLE: A cry for super-simple systems that
9 don't have so many elements to have unreliability.

10 MR. CHELLIAH: The D1, D2 here, we are talking about
11 the LOCA rejection. These systems are ECCS system. Sandia
12 has modeled extensively common mode failures. We need to look
13 into that. That's factored in here. .

14 MR. MICHELSON: I am still trying to sort out the
15 small break as opposed to a relief PORV safety valve being
16 open.

17 The revised PORV probability you show there is
18 really the probability of that having experienced a transient.
19 The relief, the PORV rather will also open. Does it mean it
20 sticks open or remains open indefinitely? Is that what that
21 probability is supposed to be, or just the probability it
22 opens?

23 MR. CHELLIAH: No. This Q is, it is the joint
24 probability of two events. Not only this will fail open, but
25 also this includes some critical for unblocking the blocked

1 valve.

2 MR. MICHELSON: It is the probability that it opens
3 and the flow path remains open for some reason, is that right?

4 M... CHELLIAH: Yes.

5 MR. MICHELSON: When does the flow path finally
6 terminate, or is that yet another calculation? See, relief
7 valves have been known to open at high pressure but reclose.
8 In fact, many of them will reclose at low pressure. The LOCA
9 does not go on forever. In fact, it gives you a worse
10 situation than if the thing remained open.

11 Do you have any probability for experiencing an
12 isolated small break LOCA which might be a worse situation by
13 far than continuous one?

14 MR. CHELLIAH: Maybe Dave probably?

15 DR. ERICSON: The argument is event Q is open, and
16 sticks open. It doesn't reclose.

17 MR. MICHELSON: Never recloses; the real world
18 history is that it is a rarity to ever have a relief safety
19 valve stick open.

20 DR. ERICSON: When you take that into account, the
21 numbers get very small.

22 MR. MICHELSON: But the event changes significantly
23 when, for instance, you have a small break LOCA terminated at
24 the time when you are now using it as heat removal, it
25 suddenly ceases to be the heat removal, and you have to

1 establish communication with the steam generator again. And
2 now it gets real sticky. Now you have got a refuel problem
3 and a natural convection problem, and so forth, regenerated
4 which wasn't there as long as the small break LOCA procedure.
5 That's what TMI did really. They had a small break LOCA for a
6 while in terms of open PORV and later they terminated the
7 break, and it creates a whole new situation at the wrong time.
8 I just wanted to make sure I understood what your probability
9 you plugged in. Thank you.

10 MR. CHELLIAH: Okay.

11 (Slide)

12 MR. CHELLIAH: So the previous slide says some of
13 the sequences. The Sandia study, it is very detailed study.
14 That's my thinking with respect to the other, comparable to
15 some of the industry performed historical analysis on the
16 flooding and seismic events and fire events, and also they did
17 some on the wind analysis and they don't dominate here. So
18 the EPRI, they did also review some of the Sandia study
19 sequences. First one is flood sequences. This is basically,
20 the sequence here is really there is fire in the main pipe.
21 It is running on the top of the room, so basically they have
22 postulated the pipe break and releasing something like about
23 2,000 GPM type flood, what they call moderate flood, and so it
24 is going to result in the failure of the pump. The failure
25 mode was really the spray failure mode.

1 Sometime back, Dr. Michelson, you asked me a
2 question is there the system failure, how this failure as
3 opposed to random failures? Here the spray failure mode, so
4 basically, if you lose the water system, the water does
5 provide cooling to the PCS. Basically you will see a
6 transient now. Also water cools some of the safety equipment
7 like the pump and HVA pump so basically they postulated
8 sequence frequency of this.

9 Now EPRI frequency you can see is almost more than
10 three. Some situations, there are two bullets. First bullet
11 is very, very important. In the estimating this frequency,
12 Sandia, they assigned something like $2 E \text{ minus } 2$ of frequency
13 for the flood frequency for the fire in the pipe. Basically
14 that frequency is not really a pipe frequency. That frequency
15 is what they did look into generic experience. They have
16 extracted what they call moderate flood, 2,000 GPM flood.
17 minus 2 frequency. What the EPRI claims, no, that's not the
18 way to calculate.

19 MR. MICHELSON: Excuse me. From any kind of a break
20 that would give 2,000 GPM? Is that what you are were saying?
21 They look for 2,000 GPM breaks of moderate energy pipes I
22 assume?

23 MR. CHELLIAH: yes.

24 MR. MICHELSON: That is correct.

25 MR. CHELLIAH: Which is beyond the isolation

1 capability in that room, flood isolation capability in, like a
2 draining all those things. So they did some careful review on
3 that.

4 CHAIRMAN WARD: That's a lot of floods, isn't it?

5 MR. CHELLIAH: I haven't seen that facility. Water
6 pumps sitting there are going to be affected according to
7 them. They will tell more explanation in the latter part of
8 the presentation.

9 What EPRI claims is that $2 E$ minus 2 frequency is
10 not appropriate. What they have suggested is this. Postulate
11 the pipe break frequency of the pipe failure, and then
12 postulate the sequence, so the EPRI data turned integral
13 formula which uses not only the pipe failure rates, also some
14 of the quality factor, dynamic load factor, all those things.
15 Something like frequency of, flood frequency, something like
16 about $4 E$ minus 5 type frequency. So right there they are the
17 magnitude difference on the frequency.

18 We did look into some of the Point Beach review,
19 water failure in pump room, $1E$ minus 4 type frequency, at the
20 point we are taking. We do the EPRI matter, but we need more
21 data to assess the reasonableness of the flood frequency
22 because it is still meeting that frequency a little lower.
23 Also we believe the other frequency is a little higher.
24 That's our position right now.

25 MR. EBERSOLE: There is a confusion factor in the

1 matter of identifying floods. Does--as the maximum credible
2 flood or possible flood. There is a flood that overruns
3 grade, which is much higher probability.

4 DR. ERICSON: We are talking internal, Mr. Ebersole.

5 MR. EBERSOLE: It is all internal? Sorry.

6 MR. CHELLIAH: Pump room, we are talking about
7 internal flood here. In the pump room we are talking about.
8 Did I say sitting on the room? We are talking internal
9 flooding.

10 MR. MICHELSON: When people talk about flood, there
11 are various ways that one type of person talks about flood on
12 the floor, what the elevation rises to and whether the
13 equipment is affected. Other people talk about a flood in an
14 upper floor and the water cascading, running, dribbling and
15 whatever down the lower floors.

16 Which kind of flood are we talking about here that
17 was evaluated?

18 DR. ERICSON: This is essentially a spray problem,
19 not submergence. This main is above--the pumps have a certain
20 credibility credited to them for existing even outside. We
21 took that into account. The break we postulated was
22 sufficient to cascade water on to the pumps, not to--

23 MR. MICHELSON: All of them?

24 DR. ERICSON: Any one of them or any combination of
25 them.

1 MR. EBERSOLE: Why don't we say something besides
2 flood because--

3 DR. ERICSON: We did call it spray study.

4 MR. MICHELSON: That particular problem took a
5 unique break I think.

6 DR. ERICSON: Take a break about those pumps, that's
7 right.

8 MR. MICHELSON: And that narrowed the probability
9 quite a bit because it is much lower probability of unique
10 break than general break.

11 DR. ERICSON: The point is all six of those plants
12 see at least 15 feet of the header, and now you are into part
13 of it. That the point.

14 MR. MICHELSON: We will get to it later. We will
15 get to it.

16 MR. EBERSOLE: The more general context of flood, do
17 you find plants that large have capability to drain the
18 various areas compatible with the largest source they might
19 see from a sewer pipe? Has that been designed into the plants
20 or not?

21 DR. ERICSON: We do not do detailed analyses of
22 drains. We looked to see if ruptures in specific rooms could
23 submerge or affect that pump in general, particularly Point
24 Beach. It just goes away, returns out doors, and this sort of
25 thing. You just can't pond it.

1 MR. EBERSOLE: Great. I am not sure that is always
2 the case.

3 DR. ERICSON: In this case it is. You can't find
4 any place you can contain water inside.

5 MR. CHELLIAH: So going back to the previous
6 question, Dr. Michelson, you realize your question is whether
7 any support system failure other than random failures is due
8 to external event? Yes, they did identify the failure, spray
9 failure mode, but I think right now we think that 2E minus 2
10 frequency is a little higher, the EPRI estimate of 3E minus 5
11 on the pipe break frequencies a little lower. We need more
12 data from them right now EPRI. THAT's the position we are
13 taking right now.

14 On the seismic events, the Sandia, they did perform
15 very detailed study on seismic events. Basically what they
16 did, they made use of some of the program. Also they doubled
17 up detail of, for various structures and components, and this
18 is estimate. Three types of sequences; I have listed out on
19 the fourth page some loss of feedwater sequences and some
20 small break LOCA type sequences.

21 EPRI did look into--when I say look into, they sort
22 of did the scant type analysis because they have not performed
23 detailed analysis of what they did like Sandia, but there are
24 three points I would like to mention. One is the RWST tanks
25 here, they are refilling the tank during a seismic event. Now

1 this particular tank is called very low DBR in plant,
2 something like .192 median G as opposed to some other kind
3 like .8 or more than 1 G, so that claim is here that according
4 to EPRI, that tank will not catastrophically fail. Take about
5 30 minutes to deplete the water, so they started giving some
6 credit to refill within the time, you know. At the same time,
7 also refilling the CST, the condensate storage tank, for the
8 secondary site cooling, they took some credit. Here we do, we
9 agree with the EPRI's plant-specific process for seismic
10 events, but I think here we are going to look into very
11 carefully this particular tank. We are finding very unusual,
12 somewhat unique design feature here in this plant. We need
13 some more additional information on this.

14 Of course the third plan, second, third plan, 1E
15 system, we do agree with the EPRI, some of the yearly blocker
16 type sequence frequency comes along here.

17 Sandia, they have some similar ones there on this
18 particular one.

19 Here the EPRI, what they claim, they have doubled up
20 more site specific results using some improved technique.
21 They have not provided the curves, so we have to make some
22 provision here. We need some management information looking
23 to the curve, how they double up on all those things, but
24 basically we do agree, plant-specific, to estimate the
25 plant-specific seismic frequency on looking at those decay

1 heat removal problems. We are doing that, but we need more
2 data on that.

3 The final one on the fire events, Sandia, they did
4 perform some limited study on this looking into various,
5 looking into fires in various critical zones. Here the fire
6 is limited to only transient combustible fires. We are not
7 talking about panel fire or the cable fires like what you see
8 in typical PRAs, the first code PRAs. So within that
9 limitation, they came up with this 3E minus 5 frequency. EPRI
10 did look into--you can see this. It needs some explanation.
11 One of the bullets I thought, the difference here, how you
12 estimate the initiating frequency for fire, Sandia, what they
13 did, the Sandia is consistent with the state of art PRA
14 matter, basically looking at the historical experience, report
15 on fires, and then looking into the amount of available
16 materials in each critical zone and they estimated the fire
17 frequency. That's what Sandia did.

18 Now EPRI, they started deviating from their practice
19 which they followed in other sequences. That is, they didn't
20 make use of the historical experience. What they did, they
21 went to each room like the LW pump room. They postulated just
22 one fire even though the plant doesn't, may have any specific
23 operating experience, and they started estimating the fire
24 frequency based on operational experience, and based on so
25 many critical zones, so they came up with substantial lower

1 frequency.

2 We do not agree with that estimate. We agree with
3 the original estimate. This is based on the consistency with
4 the other review of the PRA review practices.

5 Then the second bullet, second and third and fourth
6 item here, the EPRI, they did look into plant-specific, they
7 identify one of the second train, halon system. I guess the
8 Sandia, they do also agree. They just have probability
9 according to here. And then here, the revised halon system
10 failure probability; Sandia, they looked into some experience,
11 some general experience. Here the EPRI, they did look into
12 some non-nuclear facilities, some facilities like the Rocky
13 Flat, all those things. They came up with something like a
14 one in 17 halon failures, so they had halon system failure
15 probability as one of the automatic systems went down so
16 that's taken care of here.

17 Also there is some human failure probability. They
18 took some additional credit, additional credit for the AWL
19 plant. There is, I realized it is not switch gear room here;
20 the AMWP pump room at Sandia. They assigned something like
21 one in ten chance that you can affect the turbine-driven pump
22 by opening the steam visible valves following the fire at the
23 LW pump. We don't know how far they are located. I'm sure
24 Dave could tell.

25 What Sandia is, what EPRI is saying, these pumps are

1 located far apart. The pump is located far apart from the
2 motor-driven. They have cut down that probability something
3 like .zero 3 by a factor of three. We do not go with that
4 kind of assumption. This is primarily because this, there is
5 some core melt timing involved. Depending on the fire damage,
6 if the core damage has to dry out the steam generator, dry
7 out, and core damage has occurred within about 30 or 40
8 minutes, probably the original estimate is probably .1, which
9 you see in other PRAs also.

10 In other words, if there is a slow fire, if you take
11 about two, three hours, then probably we can say that the EPRI
12 estimate could be justified, a little different situation
13 here. It needs little more detail from EPRI in this case, so
14 basically here what we are saying the staff did look into
15 various contributing factors to the difference of the factor
16 of 30 in EPRI estimate.

17 What we think right now that the Sandia estimate is
18 higher, but it is not lower like what EPRI says. It could be
19 somewhere--we are not quantified. We need additional
20 information. We have asked them for a meeting. After that
21 we will be able to requalify and tell where we stand.

22 That concludes my presentation.

23 MR. MICHELSON: Question--on the fire protection of
24 Point Beach, is it all manual, or is it automatic sprinklers?
25 And if so, what type or what--it wasn't clear in the reports

1 when they talked about manual mitigation, so forth, whether or
2 not it was automatic backed by manual or just what it was.
3 Could you tell me?

4 MR. CHELLIAH: The way the PRA analysis was done
5 using--

6 MR. MICHELSON: What is the plant? I don't care
7 about the PRA analysis. What is the provisions in the plant
8 for fire protection and particularly say in the area of the
9 auxiliary feedwater pumps?

10 MR. CHELLIAH: It has got both, manual as well as
11 automatic.

12 MR. MICHELSON: Does have automatic sprinklers?

13 MR. CHELLIAH: Halon system.

14 MR. MICHELSON: They are using Halon for fire
15 protection around the aux feedwater pump?

16 DR. ERICSON: The pump room, that is one of their
17 main cable routing rooms. That's why it is an issue.

18 MR. MICHELSON: It is a cable routing, okay.

19 MR. CHELLIAH: Yes.

20 MR. MICHELSON: They back the halon with hand-held
21 hoses?

22 DR. ERICSON: If I recall, that's true.

23 MR. MICHELSON: Each pump is in its own separate
24 compartment.

25 MR. ERICSON: It has a wall, but it is a common

1 room.

2 MR. MICHELSON: Ten foot wall?

3 DR. ERICSON: Eight foot, six to eight foot.

4 MR. MICHELSON: There is a very similar arrangement
5 in number of other plants except a lot of plants use water
6 sprinklers over those pumps.

7 DR. ERICSON: In this case, there is considerable
8 cabling on either end of the room running through the room.

9 MR. MICHELSON: This was the case, too, that that's
10 why the staff made them put sprinklers in the room and
11 sprinklers are a real problem like you talk about fire
12 anywhere in that area because the heat and smoke propagate to
13 the sprinkler system and it thinks there is a fire there and
14 it will spray all the aux feedwater pumps and it is no
15 different than that header break that you talked about
16 earlier. You have seen a pretty good example of that lately
17 on something else.

18 MR. CHELLIAH: Thank you.

19 CHAIRMAN WARD: Okay. Any other questions? Have
20 you got any comments you want to make now?

21 MR. DAVIS: No, I don't.

22 CHAIRMAN WARD: Your plans now, you have left us,
23 you know, hanging on an opinion here on a number of these, so
24 your plans are to work with who in resolving these

25 DR. MAZETIS: Again, our near-term goal is, as I

1 have discussed with Jerry Nyles yesterday, of NUMARC, is to
2 sometime over the next month or so, meet with them, the staff
3 meet with them, with Sandia, and discuss these various areas
4 of differing views or need for additional information and
5 understand the basis for their numbers.

6 Now it is not obvious to me that we necessarily are
7 headed in the direction of coming up with a new number per se.
8 Right now, I think our objective is just to understand the
9 reasons for the differences. That's our primary objective, so
10 that eventually, any insights that we gain from this interface
11 with the industry can be disseminated to the rest of the
12 utilities.

13 MR. MICHELSON: Did the industry make any real
14 attempt to look for financials that you might have left out of
15 your analysis that perhaps should have been included?

16 DR. MAZETIS: I noticed there were a couple of
17 places in the report where they explicitly pointed out several
18 areas of possible non-conservatism in the Sandia study. Maybe
19 Dave has some comments on that later, but in answer to your
20 question directly, my observation is yes, they did.

21 MR. MICHELSON: Are you picking up on those to go
22 back to see if perhaps you should revise your numbers upward
23 to reflect these, this lack of conservatism?

24 DR. MAZETIS: Again, I'm not sure our objective is
25 to change any numbers in the future.

1 MR. MICHELSON: If you were to change any numbers,
2 you would then re-evaluate some of these perhaps inadequate
3 conservatisms as well as where they pointed out maybe you were
4 too conservative?

5 DR. MAZETIS: Not necessarily to re-evaluate them,
6 but to identify for the benefit of whoever wants to use the
7 guidance from these studies, to identify that this is an area
8 that they should either explore further, or use new numbers.

9 CHAIRMAN WARD: Parallel question to Mr.
10 Michelson--what about areas of incompleteness that their
11 study--did their study suggest any, you know, new sequences or
12 things that the Sandia study had missed?

13 DR. MAZETIS: Other than the couple of areas where
14 they mentioned because a sequence may have been overlooked or
15 an assumption may have been overlooked the sequence implied,
16 maybe not conservative, I don't remember anything that was
17 significant that sticks out in my mind from the report. Does
18 that answer your question?

19 CHAIRMAN WARD: Yes, I think so. Okay. Thank you,
20 Mr. Chelliah. Now let's see. Mr. Ericson, so you are going
21 to kind of cover the same?

22 DR. ERICSON: Mine will be very short. It has all
23 been covered.

24 CHAIRMAN WARD: Let me point out to the
25 Subcommittee, I think what we have to consider here is not

1 just the specifics of each case, figuring out whether a
2 particular number ought to be adjusted one way or the other,
3 but rather that you know, part of the basis for the
4 decision-making in this whole USI is the understanding of risk
5 in these six plants, to the extent they represent, you know,
6 the total population of plants out there, to the extent that
7 they can. And so I think we have got to be, think about the
8 process here as a means of providing information for the
9 essential decision-making as well as the, just the specifics
10 of this particular case.

11 DR. ERICSON: Well, I said that partly in jest and
12 partly seriously. I have a number of these introductory
13 vignettes I am just going to flip through because we talked
14 about much of it before.

15 (Slide)

16 DR. ERICSON: For those of you who don't know, I am
17 no longer with Sandia, but I am still involved with the A-45
18 study. Mr. Adams, who is here, has been very much involved in
19 looking at the EPRI work and comparison with what we did
20 originally.

21 Just to reiterate, the objectives we set out to do
22 were to set some--and the point I would like to make, we were
23 interested in the industry perspective in these objectives, to
24 try to get as broad a view as we could during this study, and
25 therefore, from day one, we tended to use generic data in the

1 available data bases unless there was some overriding reason
2 at that particular point in time to use plant-specific data.

3 The limits were, as had been stated, to--we only
4 looked essentially at the small LOCA and the transients. We
5 were looking only at DHR, and although again we had specific
6 plants, we were trying to get some broader perspective.

7 Now the EPRI report deals specifically in the
8 analysis with Point Beach. Stated objective is to get the
9 best estimate of Point Beach risk from an industry
10 perspective. And I think that's, that's the important thing.
11 It is from their perspective.

12 I think we should mention that they did no original
13 fault tree analysis. Started with the fault trees that were
14 reported in case study. They did not go back and redo all of
15 those. They did use this risk management query system which
16 is a way of, developed by SAI, of storing event trees, fault
17 trees, system cut sets, and data, and it allows you to ask
18 questions. If I change the quantification, what is the
19 result? And these can be very useful tools. One has to be
20 very careful in doing this. I feel that you have to be
21 careful how much you change, because when the original fault
22 trees are solved, when the reductions are made, you make
23 certain assumptions or review assigned certain values, and if
24 you go back and completely eliminate systems or make gross
25 changes, gross changes in values, you may be led astray.

1 I don't think that has happened here. I think we
2 are all right and that they are all right in using it in this
3 particular application, but it is a caution again in the
4 broader perspective as we look toward what industry may be
5 asked to do as part of the resolution package.

6 (Slide)

7 DR. ERICSON: All of this has been mentioned before.
8 Let me put some numbers with this and I will come back to them
9 again. but new, the internal core melt which includes the
10 long-term Station Blackout, the reduction is a factor of 50,
11 but if you look at this, the big issue or the biggest
12 contributor in this reduction is that small LOCA frequency
13 that we have talked about. The small LOCA reduction takes
14 about 50 percent of the frequency, and then if you add to it
15 the changing relief valve, about 80 percent of the differences
16 is accounted for by those two, so while these other issues
17 were addressed and are addressed in their, in the EPRI report,
18 there are one or two things that dominate.

19 Same way here, and I will just skip through this one
20 and come back to some of these comments on the specific
21 issues. In particular, for example, if you look at the
22 details of the analysis, the biggest difference in the fire is
23 caused by the credit given for suppression reliability. We
24 had a per train of .2. They have something on the order of
25 ten to the minus 3, so when you start multiplying those

1 through, that's your big player. I will say some more about
2 that.

3 MR. EBERSOLE: May I ask you a question back on the
4 other slide? You had in your accident, you dismissed large
5 LOCAs and other things but you did include small ones.

6 DR. ERICSON: That's right.

7 MR. EBERSOLE: Now implicit in that, although I
8 haven't heard anything about how you are going to design a
9 decay heat removal system, is presumably that it will have to
10 have a replenishment system for PWRs, but it really won't have
11 to have any for boilers because they are going to cool by
12 evaporation anyway.

13 DR. ERICSON: We did include one that has the
14 capability of that.

15 MR. EBERSOLE: They add I am sure quite a bit to the
16 cost as you have to cope with a small LOCA. In other words,
17 you have got to provide makeup to get transfer in a PWR
18 whereas it is only a part of the normal evaporative process in
19 the boiler.

20 DR. ERICSON: The capital cost for the high pressure
21 pumping equipment are not the major factor.

22 MR. EBERSOLE: It is not?

23 DR. ERICSON: It is the civil costs associated with
24 building those separate buildings and tank and water supplies.
25 If you look at the details, in fact, as an instance, the BWR,

1 we looked at it without some high pressure makeup, and I think
2 the cost was like 80 some million and it was another million
3 and a half to put a high pressure pump in one. The BWR had
4 been designed, much of the civil costs that just gobble you
5 alive on the add-ons.

6 MR. EBERSOLE: All right.

7 DR. ERICSON: The results, these have been mentioned
8 before; overall the factor of 30. Additionally, they relooked
9 at the core melt or at the containment performance, and the
10 consequence sometimes another factor of seven, and some
11 increases in costs, and we will come back to touch just
12 briefly on those today.

13 (Slide)

14 DR. ERICSON: I will skip the next one. We have
15 talked about the general forms of the accident sequences,
16 transients and small LOCAs, and we have although not
17 specifically listed it as such, the real reasons for the
18 differences are this removal of the CCW in the objection
19 phase; the changing frequencies for various transients, very
20 low numbers for, lower numbers for Point Beach, the
21 cross-connect capabilities and then operator or human error
22 factors in which there is some changes, some areas of
23 disagreement.

24 CHAIRMAN WARD: The second one dominate, right?

25 DR. ERICSON: In the internal, that's a bigger, the

1 initiating event frequencies are multiplied. When when you
2 change those by order of magnitude, you have a tremendous
3 impact on the obvious.

4 MR. DAVIS: Excuse me, James. Put that slide back
5 up.

6 DR. ERICSON: Yes.

7 MR. DAVIS: The biggest single difference in the two
8 studies was the flooding sequence. Now you are talking about
9 internal only?

10 DR. ERICSON: This is pretty much internal.

11 CHAIRMAN WARD: Yes. But what is--this is all
12 internal, isn't it?

13 DR. ERICSON: These are internal, yes; initiating,
14 yes.

15 (Slide)

16 DR. ERICSON: Let me--some things I think we need to
17 talk about, some of which we have already talked about, and
18 those of you who have heard me for four or five years know I
19 am always willing to talk about something again.

20 First, the timeliness of data; in this review, and
21 in several other outside reviews that have taken place over
22 the, for the case studies, we have frequently been chastised
23 for not using data that was available in 1986. Well, I'm
24 sorry. We did the study in 1984 and 1985. It took us a year
25 to get it printed, but that's life in this business, as you

1 all know. So we are dealing with snapshots. You can't
2 continually update just because the new piece of data came out
3 yesterday. It just, you just can't do it.

4 Plant characteristics, in my view, to some extent,
5 this study deals with a different plant than we dealt with.
6 There are seismic one, new seismic one batteries. Now it was
7 said they were added. I don't know whether they added or
8 replaced what was there. I can't tell from what they say in
9 the record, quite frankly. That's an issue that we have to
10 discuss with them, as has been pointed out.

11 The other area that we will talk about, human
12 effectiveness and recovery actions--we have been accused from
13 day one of being very conservative with our recovery. I would
14 suggest to you that the EPRI analysis is very optimistic. Let
15 me give you some specifics. Question of whether a plant will
16 feed and bleed? Now as has been pointed out in the bottom
17 line, whether they do or do not doesn't make a big difference
18 in the core melt frequency when you talk about what operator
19 will or will not do. Davis-Besse, they could have, but they
20 didn't. This report says we talked to a couple of operators
21 and they said they would have no hesitancy. I'm sorry,
22 gentlemen, I have had technicians for many years working for
23 me and I also taught school, and people who have been through
24 training know what the school solution is. If you have asked
25 them in the classroom what are you going to do, they will give

1 me, better give me the right answer or they flunk.

2 What they will do at 3:00 in the morning with, as
3 our former colleague Mr. Reed used to say, the world turning
4 brown, I don't know. I am more sceptical than those who did
5 the study. The times is available. Those are things that are
6 discussable and we will be discussing those.

7 Modification costs--I am surprised that there is
8 such a difference in the cost as I will come back to that in
9 in a minute. So in general, to that extent it was a different
10 plant. I think this is a key issue, and I heard the word
11 "correct" used here a couple of times this morning. I don't
12 think anybody in the PRA business, and I hope Mr. Davis will
13 agree with me, knows whether they have got quote, the correct
14 answer.

15 CHAIRMAN WARD: That is a good place to pause.

16 (A discussion was held off the record.)

17 DR. ERICSON: Wouldn't you agree, Mr. Davis, this is
18 the crux of some of our discussion, what is correct or what is
19 not correct? I wish we had, could go to the grade book and
20 get the right answer!

21 At times, I think even with the new emergency
22 response guidelines, though, we agree and understand they are
23 very specific. At this point I am not sure we have enough
24 experience with them to really know what performance will be.

25 And in our review, and again I think it was--

1 MR. MINNERS: The new guidelines for this plant?

2 DR. ERICSON: In general, but certainly here, and in
3 this particular review, and again as we said preliminarily we
4 haven't had a chance to interact, because you have got to
5 study a report a long time before you know what questions you
6 want to ask or you are going to waste a lot of time. There
7 are times we are not sure exactly what data was changed and
8 where. That is we know pretty much, but in the details. This
9 is then success criteria, this has been commented upon. The
10 EPRI document, EPRI owners group document, says you don't need
11 it for cooling, but in almost all the other PRAs that
12 generally have been used, so this is a point we need to
13 discuss.

14 The balancing of service water, what they have
15 presented certainly sounds like a reasonable thing to do and
16 if the procedures exist and it can be done, we would expect
17 that it does get done.

18 Human reliability quantification, they make the
19 point they have reduced the failure to initiate feed and bleed
20 one times ten to the minus 3. One times ten to the minus 3,
21 that is because they believe we have, the individual event
22 activity, or criteria in our study, was one times ten to the
23 minus 3, but they argue that we have summed those and summed
24 it erroneously as a point we need to discuss, several times,
25 and this is one place they make the point that there are many

1 people in, many people in the control room following the event
2 so something is, so the action has been sure to be taken.
3 Does the mere presence of lots of people mean something will
4 get done? That's something we can discuss.

5 MR. MINNERS: And here we are!

6 DR. ERICSON: I can show you lots of places where
7 lots of people were there and nothing happened.

8 MR. EBERSOLE: Like the Browns Ferry fire, it took
9 them six hours to put water on it.

10 DR. ERICSON: The reduced failure to initiate sump
11 recirculation, as a matter of fact we acknowledge that in the
12 study because we originally were going to require some
13 redundancy and went back and said no, we don't need to. We
14 were assured the training cases and we have suggested maybe
15 another alarm, but then did not make any changes.

16 The reduced failure to depressurize, the big issue
17 here is not in the baseline values, but the application of
18 stress factors, and I would not claim to be a human
19 reliability analyst or specialist. We multiplied and you can
20 see the difference is a factor of five that we had there for a
21 stressful situation.

22 MR. EBERSOLE: Has the operator, did you look at the
23 matter of what the operator can see, validate, that he should
24 depressurize?

25 DR. ERICSON: We did not, not in our study. Again

1 remember we did not do a detailed HRA. We used the--

2 MR. EBERSOLE: I can't find, see does the
3 information flow to him that says that's the last bit I need,
4 now blow it?

5 DR. ERICSON: We certainly did not look at that.

6 MR. EBERSOLE: I think it is hard to find.

7 DR. ERICSON: I think they have, I think in the EPRI
8 as I recall, the way they worded this thing, they have looked
9 at that somebody said A, B, C and D, not in the report, but I
10 think in the procedures that now exist in the ERGs, in fact
11 one of the EPRI people may comment, it gives you a specific
12 point as to what to look for in the, in those new procedures,
13 because they are symptom oriented. And then they have used
14 the new--not new, but SAI approach to the time reliability
15 correlation and in some cases additional actions which we
16 might comment on later.

17 Just to refresh your memory, though, we have been
18 repeatedly accused of only using one recovery. We do in fact
19 have two before two hours. If you include loss of feedwater,
20 either recovering the off-site power or loss of feedwater plus
21 another after two hours, we have had that plus two other
22 things.

23 The study, owners group study looked at the number
24 of options available, the time that they felt required to
25 perform any given action, whether it existed in the procedures

1 or not, and whether there had been training on it, so their
2 application of recovery I would say is certainly more
3 plant-specific and allows for more flexibility.

4 MR. EBERSOLE: May I ask you in the particular case
5 of the boiler, the staff says that loss of containment heat
6 removal, they believe every boiler has a means to vent the
7 containment to prevent disastrous overpressurization before
8 the core is hurt.

9 Are you with me?

10 DR. ERICSON: Yes.

11 MR. EBERSOLE: You find that to be true or not, in
12 terms of equipment and procedures? I don't think it is.

13 DR. ERICSON: I am shifting gears, Mr. Ebersole,
14 because we were not--you keep jumping to the BWRs and I
15 haven't looked at those in a while.

16 MR. EBERSOLE: That has been a curtain that is
17 lifted. Oh, yes, you can dismiss the--

18 DR. MAZETIS: Of the six case studies, two of them
19 were BWRs.

20 CHAIRMAN WARD: Sample is only two of--

21 MR. EBERSOLE: Okay. You only had the two.

22 DR. ERICSON: We gave credit for limited venting.

23 DR. MAZETIS: Limited examination of procedures
24 observing the credit could be given for that.

25 MR. EBERSOLE: Can you, did you find the equipment

1 to be present and the procedures there?

2 DR. MAZETIS: The procedures were there, but I just
3 don't remember about the details of the equipment.

4 MR. EBERSOLE: Conflict is whether in fact even the
5 equipment is there or not.

6 MR. MICHELSON: Or if the equipment will function
7 under the conditions that will likely exist at the time
8 venting is required.

9 DR. MAZETIS: I know that wasn't.

10 MR. MICHELSON: If they won't, then the procedures
11 and equipment are worthless because these can't function.

12 DR. ERICSON: The next slide just recaps those
13 recovery actions that we had in our, in the case study we did.
14 We covered off-site power, main feedwater, battery common
15 cause, battery faults, diesel, and then other things that one
16 can do from the control room or things one can do locally
17 without spelling those out specifically.

18 In the EPRI owners group analysis, again, as was
19 mentioned earlier, the refill of RWST which would allow you to
20 stay in injection mode because you have additional water, I
21 think for internal events if indeed that plumbing system
22 allows you to do that, I would certainly accept that. I have
23 a little trouble with someone telling me that refilling the
24 RWST is a recovery action for a seismic event. We will come
25 back to that in a minute. Cross-connecting buses, those

1 cross-connects do exist. Manual control turbine drive aux
2 feedwater pump, they take considerable credit for this now
3 because of the new batteries, allowing, giving the supply even
4 though it has to be done locally.

5 MR. MICHELSON: Have they ever operated those pumps
6 under that condition? Have as a test?

7 DR. ERICSON: I do not know.

8 MR. MICHELSON: Does anybody know? It would be a
9 fairly--if it is, it is purported to be not that difficult. I
10 have talked to some people on the side as to how difficult it
11 may be, but I just wondered if does it--have the staff ever
12 known of anybody that has actually demonstrated?

13 DR. ERICSON: There is one. I can't think of which
14 plant it was. I have read a report where they, indeed the
15 fact went in and ran some of the stuff manually.

16 MR. MICHELSON: That is the way to put it to bed in
17 a hurry. Otherwise I hear conflicting stories, maybe very
18 equipment specific. The real problem is control, of course.
19 It is all done manually, they can't feed back fast enough to
20 vent the trips.

21 DR. ERICSON: I guess the other one, recovery from
22 common mode failures, they relied heavily on. AEOD study that
23 said significant numbers could be recovered and so they
24 applied, reduced some of the common mode stuff apparently
25 somewhat arbitrarily.

1 (Slide)

2 DR. ERICSON: I think we have beat this one to death
3 at this point. The small break LOCA frequency as to what you
4 count or don't count, we will be discussing that more with
5 them. As has been pointed out, it does make a significant
6 difference.

7 The PORV, the relief valve PORV LOCA situation, I
8 guess I would have to agree that the arguments they present,
9 as the staff has pointed out, when we ourselves take a look at
10 the thermohydraulic analysis, we made, certainly accept that Q
11 or that event as not having occurred given that feedwater is
12 present so that you have got a transfer mechanism for the heat
13 to circulate, reasonable argument.

14 MR. MINNERS: What is RCMF?

15 DR. ERICSON: Reduction core melt frequency.

16 MR. MICHELSON: This statement doesn't pertain I
17 guess to boiling water reactors? Is that what you are saying?

18 DR. ERICSON: We are dealing specifically in our
19 comments here with Point Beach, Point Beach only.

20 MR. MICHELSON: Okay. Thank you.

21 (Slide)

22 DR. ERICSON: I might, I would make the comment in
23 the small break LOCA frequency, this study uses a lot of
24 Westinghouse data and Westinghouse topical reports that
25 so-called WCAPS, to make their point, but the small break

1 frequency argument is not for a Westinghouse plant. They use
2 Oconee, and I don't think that's a Westinghouse plant, but it
3 is a smaller number.

4 (Slide)

5 DR. ERICSON: Common cause failure rates, they have
6 used a number significantly less than ours, taking exception
7 to our use of beta factors in some places. They talk about a
8 design review and that certainly is the method that Carl
9 Flemming has argued for, still that you really need to look at
10 those things, and yet I don't believe based on the way I read
11 this, the EPRI record, that they really did those detailed
12 design reviews on this plant but have used similar sorts of
13 things, and certainly they did use significant amounts of data
14 from the Millstone 3 PRA.

15 (Slide)

16 DR. ERICSON: You can see very quickly that
17 significant differences come in in the batteries. For
18 example, other pumps are down by about a factor of three. The
19 combination of motor driven and turbine driven aux feedwater
20 pump is down order of magnitude and those do have their
21 effects promulgated through the system, and I think this is an
22 area where we will want to have considerable discussion with
23 those folks as to how their numbers were arrived at.

24 MR. MICHELSON: Clarification on common cause--are
25 you dealing here with the common cause perhaps being seismic

1 or flood or a fire, et cetera?

2 DR. ERICSON: In those numbers, no. Those were--

3 MR. MICHELSON: Purely equipment?

4 DR. ERICSON: Equipment failures; in the seismic
5 analysis we did a correlation, though, so that if the pump was
6 in the same room, they both fail, that sort of thing. We
7 certainly understand that they have installed new batteries
8 now and where batteries exist in our seismic sequences, they
9 may have an effect, but it does not appear in the report as we
10 have analyzed it thus far where they looked at these new
11 batteries at the two, three and four times SSE levels where
12 there are significant seismic risks.

13 The refueling water storage tank failure and
14 recovery, I think it has already been mentioned, but I will
15 mention it again. The RWST at Point Beach is unique. I can
16 best describe it as a smokestack. It is very tall, and very
17 short in diameter. Our people have done the fragility
18 analysis. They are convinced that tank will fail relatively
19 catastrophically when it goes. When it buckles, it will
20 buckle. So I am not sure you can refill it.

21 I would also suggest somewhat humerously but very
22 seriously when you talk about recovery actions in seismic
23 events in 30 minutes, I don't think you have ever been in an
24 earthquake. Things are pretty chaotic in those first 30
25 minutes, and--

1 MR. MICHELSON: When dealing with the RWST failure,
2 catastrophic, potential catastrophic failure, are they looking
3 also at the flooding effects of the water release?

4 DR. ERICSON: They did not, but that thing will dump
5 a lot of water in places you don't want it.

6 MR. MICHELSON: The piping arrangement coming into
7 it, there may be a cavern underneath that tank with the piping
8 in it.

9 DR. ERICSON: This tank could get back up in aux
10 building.

11 MR. MICHELSON: Runs into potentially interesting
12 situations.

13 DR. ERICSON: This tank could get water back to the
14 aux building.

15 EPRI has argued seismic hazard curve conservative
16 for factor of two for low accelerations, three to five for
17 high accelerations. We disagree. They have not reanalyzed
18 this particular site. Our approach was to normalize curves to
19 the frequency at the SSE, look at local attenuation factors,
20 local soil, column effects, to get the curve. In talking with
21 our seismic people, they feel that our numbers will be, would
22 be very consistent with the complete site specific curve if
23 one were to take the techniques that now exist and do it,
24 which would take you probably three or four man months in time
25 to generate that analysis.

1 MR. MINNERS: Low accelerations below SSE?

2 DR. ERICSON: They said conservative at one to,
3 factor of two at 2 to 3 SSE and factor of five above as I
4 recall.

5 MR. EBERSOLE: That tank is the source of highly
6 borated water. To simply shut down the--

7 DR. ERICSON: There are, the reactor makeup water is
8 also available on site.

9 MR. EBERSOLE: Is it better off than this?

10 DR. ERICSON: As I recall, it is a squatter tank.
11 Again, the question of how much your recovery action in early
12 on in seismic; we were asked earlier did they identify things
13 that we had? Yes. And this is a specific example. Turns out
14 the way Point Beach opens the CSTs intertied, so if you lose
15 one, you have lost them both because the valving is locked
16 open between them.

17 MR. EBERSOLE: Did you find out by any chance as we
18 did at Diablo Canyon the emergency manuals fall over the
19 floor, you couldn't find them in seismic events?

20 DR. ERICSON: Well, I haven't looked at the book
21 racks in the control room, so I don't know the answer to that
22 question.

23 Internal flood, as has been pointed out earlier, the
24 significant differences in the, occurs in the frequency that
25 is used. We used a generic flooding frequency room by room

1 for aux buildings. EPRI has used a pipe frequency, break
2 frequency correlation by Thomas, which they use and then
3 recompute, or estimate the pipe break frequency for the pipe,
4 service water pipe, over those fire, water pipe over those
5 service water pumps.

6 MR. MICHELSON: Do you know what that number is
7 approximately? Pipe break frequency I guess per foot of
8 length or something?

9 DR. ERICSON: Oh, P--no. This one is a computed
10 number, and when you use their numbers, this is the 3.7 times
11 ten to the minus 5 number.

12 MR. MICHELSON: Per unit length of pipe?

13 DR. ERICSON: Isn't unit length. It is on a--here
14 it is, right here--1.8, one ten to the minus 8 per year per
15 cube. These are the quality factors I would call them.

16 MR. MICHELSON: What is cube?

17 DR. ERICSON: Relates to how thick and how big the
18 pipe is.

19 MR. MICHELSON: So you, somehow that is a per foot
20 of pipe, isn't it? And then you multiply by--

21 DR. ERICSON: Q is ratio of--you look at this
22 product to pipe diameter in feet, times length in feet,
23 divided by thickness squared.

24 MR. MICHELSON: If I have a hundred such lengths, it
25 is a different probability than if I only have one such

1 length.

2 DR. ERICSON: Q is dimensionless parameter.

3 MR. MICHELSON: How do you convert it into, to
4 reflect the number of total length of pipe that you have in
5 your plant?

6 DR. ERICSON: That Q is based on this three-foot
7 lengths. See, EPRI argued that there was only one three-foot
8 section of pipe that could affect you in this particular
9 situation.

10 MR. MICHELSON: They are doing--okay.

11 DR. ERICSON: For that specific location, one
12 three-foot.

13 MR. MICHELSON: That's a strange--

14 DR. ERICSON: We don't understand that because we
15 feel that the pumps can see anywhere from ten to 13 foot.
16 That's a point of discussion.

17 The other problem I had, quite frankly, when I
18 looked at this correlation and went back to the reference, I
19 find that what EPRI reports in the document is not what I
20 found in the original reference. There has been modifications
21 made to it that are not documented. The original work by
22 Thomas doesn't use a dynamic loading factor but uses factors
23 related to age and design learning.

24 They have used a restricted pipe length only three
25 feet which we need we have to discuss that with them why they

1 feel it is only that three-foot length, and these two are
2 related and the definition in terms in the equation, so we
3 have, some discussions have to take place on that correlation.

4 MR. MICHELSON: How did they treat the non-seismic
5 piping that could produce floods versus the seismic that could
6 produce floods? Did they treat those as any different than
7 probability of failure?

8 DR. ERICSON: The only one that was computed was the
9 one we argued, fire main water. They used this as an
10 empirical relationship based on data, on industry-wide data.

11 MR. MICHELSON: Only pipe in the whole plant that
12 could give them a problem if it broke? Is that the idea?

13 DR. ERICSON: Our argument was that given, looking
14 for internal flood sources, this was the one we found.
15 Whether they went and looked for others, I don't know, one of
16 the reasons being, for example, there are significant rooms at
17 Point Beach which have big service water pipes but they are in
18 guard pipes, so if the pipe ruptured, it would go outside the
19 room.

20 MR. EBERSOLE: Tell me, there are three high
21 pressure pipes at least, in a PWR, there is more in others.
22 That have a substantial different potential in others. It is
23 the, I will pick--well, the first one is the steam line that
24 feeds to, the steam to the steam-driven aux feed pump. That
25 is service area either pressurized up to the valve or right up

1 to the stop valve. I don't know. Two other reactor water
2 clean-up systems; if those pipes break, the effect of break is
3 regressive; if the flow continues on out into the machinery
4 area, disables the whole damn plant.

5 One must place dependence on valves operating in an
6 unusual and untested and not in a statistically verified mode.
7 Did you go to that level detail?

8 DR. ERICSON: For clean-up, for example, we did not.

9 MR. EBERSOLE: What about steam on the aux feeds?

10 DR. ERICSON: No. Steam on aux feed can't cause a
11 spray or flooding; causes steam, so we did not look at it.

12 MR. EBERSOLE: Saturates the whole electrical
13 network in the plant. It is a Turkish bath. Everything
14 shorts out.

15 MR. ERICSON: If it is in the right place; no, we
16 did not look at the steam lines, that steam line.

17 MR. EBERSOLE: Those happen to be focal points of
18 severe potential.

19 DR. ERICSON: In the area of containment, success
20 criteria, EPRI argued and the owners group argues that primary
21 system leakage in small LOCAs do not place a significant load
22 on containment, and I think Mr. Minners made that same comment
23 a while ago. They look at recovery. The report says we used
24 criteria for large LOCA. To some extent, that's right. We
25 said originally in the studies that we would use the RESMAP

1 approach because we did not have the resources at the time to
2 go into detailed containment performance.

3 We did, however, modify that as the NUREG 0956 and
4 other reports were coming out, the 1150 work, and reduced the
5 failure probabilities; we have something like a 55 percent
6 non-failure probability for the large containment, so we did
7 not do it sequence by sequence the way EPRI has, and I cannot
8 comment on theirs because at this point we have not had the
9 opportunity to get back through all of those yet.

10 They provide a comparison of using 95 and BMI 2104,
11 the IDCOR data, their judgment, and using our baseline case of
12 .3 times WASH-1400 for the source terms, and get this range of
13 values. You may recall that we, we had an estimated person
14 reactor year of something like 38 I think is what we report in
15 our report based on our analysis and the 3.3 times WASH-1400
16 numbers.

17 (Slide)

18 DR. ERICSON: We have to do some more comparison and
19 work on that one. We have not done that yet.

20 Cost estimate differences, failure to consider all
21 design requirements for specific aspects of modification, I
22 think this is, refers primarily to the add-on system.

23 Failure to account for existing structures and/or
24 buried piping in cable, frankly I find this one very puzzling
25 that they raise this issue since after we did our conceptual

1 designs we went to the plant, walked through the plant with a
2 plant staff, asked if we could do this, can we do that, will
3 this fit there, and what are your local labor costs and what
4 is your experience? So to tell us that we haven't done that
5 and we are way off, I don't understand.

6 Failure to account for iteration between initial
7 design and final installation, and then they argue cost
8 experience and installing new batteries, quite frankly, we
9 have not explored all of this. I am very, very puzzled by it
10 since the architect/engineer who did this work does this kind
11 of thing for the industry all the time, and I know they were
12 very conscientious about checking their costs to make sure
13 they weren't optimistic because somebody might ask them to bid
14 on them, and so it is puzzling just why we have such a marked
15 difference.

16 DR. SIESS: Was there a time difference?

17 DR. ERICSON: The EPRI report doesn't say anything
18 about time, but we were used, we used 1985 dollars and even if
19 you use 1987, I don't think labor rates and that sort of thing
20 have changed that much in the last two years.

21 CHAIRMAN WARD: Is that what you mean? Okay.

22 DR. ERICSON: In fact, some areas, it is cheaper now
23 than it was before.

24 One other thing we have looked at, though, is this
25 question of human reliability and emergency procedures, and

1 there is a NUREG that came out last year that suggests that
2 emergency operating procedures can markedly improve, and
3 perhaps reduce core melt by as much as 12 percent and that
4 there are synergisms. I have no reason to argue with that,
5 and--

6 CHAIRMAN WARD: What NUREG is that? Who wrote that?

7 MR. ADAMS: Idaho.

8 DR. ERICSON: Are you familiar with that one?

9 DR. SIESS: Did you mean what you said by factor of
10 1 percent? This says factor of one eighth up there.

11 DR. ERICSON: Isn't that 1 percent?

12 DR. SIESS: That would be 88 percent if I reduced it
13 by--

14 DR. ERICSON: Reduced it by eight, that is 12
15 percent.

16 DR. SIESS: By an 8th.

17 DR. ERICSON: That's what it said.

18 DR. SIESS: That's practically nothing.

19 DR. ERICSON: Well, I have learned one has to be
20 very careful when people talk about reduced by factors of, and
21 that sort of thing.

22 DR. SIESS: I would multiply it by an 8th if I just
23 read it and hadn't heard what you said.

24 MR. ADAMS: I think you multiply it by one 8th,
25 Dave.

1 DR. ERICSON. Eighty-eight percent, okay; I haven't
2 gone through the whole report yet. We have to be careful of
3 that.

4 DR. SIESS: Twelve percent, you forget about it.
5 Wouldn't even make the slide.

6 CHAIRMAN WARD: Okay.

7 DR. ERICSON: There is one slide.

8 CHAIRMAN WARD: Also, well, whether it is, if it is
9 12 percent, I don't want to say this. If it is 88 percent, I
10 guess I do want to say it, so I don't know. I don't want to
11 take the time. But I don't know what sort of study this was,
12 but you know, reports we have had about the efficacy of EOPs
13 is that it is, maybe it is good in a theoretical study that
14 INEL might be doing, but as far as EOPs, that is actually in
15 the hundred and some plants, there is some question about
16 whether they are doing any, much good or how uniform that good
17 is spread around the plant.

18 DR. ERICSON: I think your latter point is certainly
19 valid. I think it will depend very much on staff, on
20 management attitudes, that sort of thing. Even with the best
21 of procedures, I think, you know, we can talk about simulator
22 experience, but somehow that just isn't quite the same. You
23 know; if you make a mistake on a simulator, can always go do
24 it again.

25 MR. ADAMS: That EG and G report at Idaho,

1 high-level report on the on-site assessment of the
2 effectiveness and impacts of upgraded emergency operating
3 procedures.

4 MR. MICHELSON: What is that name again?

5 MR. ADAMS: On-site assessment of the effectiveness
6 and impacts of upgraded emergency operating procedures.

7 CHAIRMAN WARD: Carl, this is another subject, but I
8 think--

9 MR. MICHELSON: What is the NUREG number?

10 MR. ADAMS: 4617.

11 CHAIRMAN WARD: It is on the sheet.

12 MR. MICHELSON: I missed it. I'm sorry. I'm sorry.

13 CHAIRMAN WARD: This is kind of another subject, but
14 your subcommittee was going to look at this matter.

15 MR. MICHELSON: Yes. I have got it.

16 DR. ERICSON: Let me close with the following
17 additional general comments that aren't in your package.
18 Quite frankly, in the review process, this one and others, one
19 of the problems we have had is people misquoting what we did.
20 This report says we considered only transient combustible
21 fires. That is incorrect. We have responded at least to four
22 different times when people have said that.

23 We only used a calculation of a transient
24 combustible to bound the amount of energy in fires. The
25 frequency, locations are all done by separate analysis. I get

1 frustrated and I know our analysts do, too, when that keeps
2 happening.

3 MR. CATTON: What about the comment about acetone
4 being everywhere?

5 DR. ERICSON: That is not what we assumed. The
6 prior frequency in a room is a function of the historical data
7 for those kinds of rooms. The acetone fire was only looked to
8 see if a fire of certain intensity could propagate to cables
9 and propagate to something else, and I see Mr. Busley smiling
10 over there. He knows what I am saying. The best estimate
11 analysis, EPRI claims to have a best estimate analysis. There
12 is no discussions of uncertainties.

13 DR. SIESS: Uncertainties in the best estimate or
14 uncertainties in the--

15 DR. ERICSON: Uncertainties, how good is that best
16 estimate? We have used a conservative number. If you look at
17 the results coming out of, that have come out of NUREG 1150,
18 and every other PRA where a detailed propagation of
19 uncertainty is taking place, the 95 and five are a long way
20 from the best estimates or means.

21 CHAIRMAN WARD: So you are saying that your PRA
22 numbers are not what you would characterize as best estimate
23 or--

24 DR. ERICSON: We called them point estimates based
25 on available generic data. We also gave you some discussion

1 of the potential effects of uncertainties, but we did not
2 propagate uncertainty through our analysis.

3 CHAIRMAN WARD: But did you cover uncertainty by
4 using conservative, purposefully conservative assumptions?

5 DR. ERICSON: No. We did not say now let's take the
6 top number. What I am saying is in our analysis we have used
7 the generic data which has some conservatism in it I will
8 argue, and we have presented it as a point estimate using
9 generic data; no more or no less.

10 DR. SIESS: What is the difference between that and
11 what EPRI did now?

12 DR. ERICSON: Their argument is best estimate, I
13 interpret to mean they have looked at all the data they can
14 get their hands on and then selected or arrived--

15 DR. SIESS: You don't mean best estimate the way you
16 say point estimate?

17 DR. ERICSON: No, because in the point estimates we
18 did not dig into all potential possible data bases. We did
19 not get deeply into the human, into the EOPs as they did.

20 DR. SIESS: Maybe I don't know what best estimate
21 means. I thought best estimate was the statistical term that
22 gave you the most likely value out of a universe of values.

23 DR. ERICSON: That would be a definition.

24 DR. SIESS: Is that what they mean by best sometime?

25 DR. ERICSON: I assume so.

1 DR. SIESS: In other words, value like a mean or
2 median or something.

3 CHAIRMAN WARD: Some attempt at a central estimate.

4 DR. ERICSON: Some sort of central estimate.

5 CHAIRMAN WARD: My impression is that is what most
6 PRAs are intended to try to do.

7 DR. ERICSON: We treated them as a means whenever we
8 could.

9 DR. SIESS: And your best, your point estimate
10 quantitatively, how would you describe it?

11 DR. ERICSON: We used mean values from the generic
12 data bases.

13 DR. SIESS: Incidentally--

14 CHAIRMAN WARD: So why is there a difference? I
15 mean I don't understand.

16 DR. ERICSON: Because they haven't used mean values
17 from published generic data bases. They have reworked those
18 values and massaged them to get what they consider as the best
19 estimate for this particular plant.

20 MR. MINNERS: Didn't we use median values for the
21 seismic part?

22 DR. ERICSON: Yes. There is a, the problem there is
23 it is off by about a factor of three as a result.

24 MR. MINNERS: Mean value is accepted.

25 DR. ERICSON: That's right. That's a good point.

1 We owe you a piece of paper that is somewhere in the--you will
2 get in.

3 CHAIRMAN WARD: The difference isn't so much that
4 their analysis characteristically used, you know, central
5 best, median, mean, values, and yours didn't, but rather they
6 used data bases or whatever that were specific for this
7 particular plant and you didn't in some cases?

8 DR. ERICSON: Well, in some cases they have chosen
9 to use other data, to change the generic data, and the small
10 break frequency is an example. The values they use are not
11 Point Beach specific. They were derived for Oconee, and
12 that's the number of the Oconee report. They adopted that
13 argument and so used that number, so--

14 DR. SIESS: Mr. Chairman, I think it is very
15 important that we get a copy of that slide because it is the
16 only slide he has used that has the word "uncertainty" on it.
17 I just didn't believe anybody could get through any discussion
18 of PRA FOR that long without the word uncertainty.

19 MR. MINNERS: You almost made it!

20 DR. ERICSON: Schucks! I should have left this one
21 off and I would have set a record!

22 And the other thing that I think needs to be
23 commented about the report is that this report deals with more
24 than just the Point Beach study. Significant comments are
25 made about what is presumed to be the NRC decision on this

1 matter and not the Point Beach specific report.

2 As Mr. Mazetis has said, we will be in an iterative,
3 not necessarily iterative process, but interactive process
4 with the EPRI owner's group people to understand the source of
5 numbers, and argue and fuss about why we use different
6 numbers.

7 MR. EBERSOLE: Can you talk a little bit about a
8 matter that is somewhat in detail? Do you recall the GDC-19
9 required early on the establishment of points of control from
10 the plant at places outside the containment. That resulted in
11 a rash of extension cords stuck out all over the place from
12 the main control room into these discrete other areas, thus
13 extending the fire vulnerability.

14 It is recognized now that those are regressive
15 circuits and we ought to cut them all out because now we can
16 take care of damage in the control room rather than just a
17 stink in it.

18 Did you look at vulnerabilities from fire, including
19 those spread-out circuits all over the place?

20 DR. ERICSON: We looked at the plant with Appendix R
21 in place. We used Appendix R submittals.

22 MR. EBERSOLE: I understand that, but did you look
23 at increment in risk presented by those old circuits that are
24 still there?

25 DR. ERICSON: Specifically, I don't know. I can't

1 answer that question.

2 MR. EBERSOLE: They are still there.

3 CHAIRMAN WARD: Any other questions for Mr. Ericson?
4 Okay. I think as a Subcommittee, we need to discuss what we
5 think about what we have heard, where we want to go
6 particularly. We haven't heard directly on the issue which we
7 can spend some time on this, that the Point Beach analysis, we
8 haven't heard directly from the EPRI group or whomever it is
9 now that is responsible for that and we might want to do that
10 in the future, but I think we need to put that in the context
11 of what we are trying to do.

12 So before we go into that discussion, though, and I
13 am going to suggest that we have that after lunch, I would
14 like to hear from Mr. Minners a little bit more specifically,
15 you know, what is your schedule? When are you going to do
16 what, toward, you know, final resolution of this? What do you
17 need to do, and what would you like to have from the
18 Committee, from the ACRS? What do you see that you need, if
19 anything, from the Committee. Isn't necessarily what you are
20 going to get, but just like to know what you think you would
21 like to get. Could you tell us that?

22 DR. MAZETIS: Let me start and just--Jerry
23 Mazetis--as far as schedule in the near future, I may have
24 indicated in recent conversation with NUMARC, Jerry Nyles
25 yesterday, led to our tentative initial dialogue with, the

1 interface with them perhaps around the first or second week in
2 March, and before then, of course, we would continue amongst
3 ourselves in-house interfacing with completion of the review,
4 and preparing ourselves for that meeting.

5 I would anticipate concurrent with that would be the
6 availability as I indicated earlier of the draft or the
7 updated regulatory analysis distribution, at the moment
8 unknown, but it would be my guess available for the ACRS
9 within that timeframe, the next month or two.

10 CHAIRMAN WARD: Okay.

11 DR. MAZETIS: Let's see. You had another question?
12 Your other question was?

13 MR. MINNERS: What do we want out of the Committee?
14 I think the usual word is that you know, we have brought this
15 down to you. We value any comments that you had. I don't
16 know whether you want to give it your blessing, but we are
17 going to present a proposed resolution and traditionally the
18 ACRS has commented on it, and sometimes said yea or nay, so I
19 guess it is more up to the Committee exactly what you want to
20 provide.

21 CHAIRMAN WARD: I realize that, but I just wanted to
22 know what your perspective was. when you say the draft
23 analysis, regulatory analysis, that's going to present your
24 proposed resolution, and right now you think that is going to
25 be item number whatever it was.

1 MR. MINNERS: Two.

2 CHAIRMAN WARD: And then present the arguments for
3 that; that's what you mean by the regulatory analysis?

4 MR. MINNERS: Well, the purpose of the regulatory
5 analysis is not to present the arguments just for alternative
6 2. The purpose is to discuss all six of the alternatives,
7 okay, so that people can see what basis the decision was made
8 on.

9 CHAIRMAN WARD: Okay.

10 MR. MINNERS: I think--

11 CHAIRMAN WARD: Okay. That's all?

12 MR. MICHELSON: Warren?

13 DR. SIESS: Warren, they have got to do some kind of
14 PRA, right?

15 MR. MINNERS: To do what?

16 DR. SIESS: The individual plants.

17 MR. MINNERS: Yes.

18 DR. SIESS: How is the staff going to handle this?
19 I don't think there has ever been an instance of a licensee
20 making a PRA that the staff didn't think the probability was
21 one to two orders of magnitude higher.

22 Is the staff going to makeup, do a PRA to go along
23 with every one the license does, accept the licensee's value,
24 or are you going to apply a factor of say of ten on it..
25 Conservatism or at empirically ten to 15 seems, ten to 50

1 seems about right.

2 MR. MINNERS: I don't know the answer to your
3 question. It is perfectly possible that the staff might not
4 even review the PRAs done by the licensees. That's a
5 possibility.

6 DR. SIESS: You really think that's a possibility?

7 MR. MINNERS: Anything is possible. Now what is
8 probable is something else again, and I don't think we know
9 the answer to your question because it takes a lot of staff
10 resources. And I guess that's going to be, I mean this is
11 something that is being worked out basically in the IPE
12 process. If we look on to those guys, we come out and it is
13 their worry, but we are, you know, it is something that has
14 been being discussed as we say.

15 One of the purposes of reviewing this
16 EPRI-Westinghouse owners group analysis was because we think
17 it is kind of--I don't know how to say it--one of the
18 precursors to an IPE submittal, okay, and maybe some precedent
19 will be set or at least indicated by our evaluation of their
20 analysis, but I would point out to you is that yes, you do,
21 you get a factor of ten lower, but here is a particular
22 incident that if, a reason you have got some of the difference
23 is because they installed some new equipment, and that's fine
24 by me.

25 DR. SIESS: I saw the Susquehanna IPE evaluation

1 with their ten to the minus 6, ten to the minus 7, and they
2 say it is, all comes not from installing any new equipment but
3 from taking advantage of accident management procedures in
4 site training, based on their PRA.

5 MR. MINNERS: Okay.

6 DR. SIESS: I remember when you had the six choices,
7 one of the objections to No. 2 was opens everything to
8 argument, and No. 3 or 4, whichever it was, prescribed fixes,
9 at least was clear cut, somewhat reminiscent of ATWS. ATWS
10 ended up being prescribed figures, right? Were negotiated or
11 developed let's say in cooperation with the venders.

12 MR. MINNERS: We are going the opposite way here.
13 ATWS, that's right. We said we weren't going to have
14 individual evaluation models. We will paint everybody with
15 one brush. And we are going, seemingly going the other way.

16 I don't know what to do, Dr. Seiss. I think it is
17 recognized that when you get into PRA, you have got this
18 problem. You have got many knobs and switches that you can
19 turn on these analyses, and people have different views of
20 them. And you can--and take different views. I guess that's
21 a problem.

22 The, I guess what you have to look at is your
23 alternatives. Your alternative is a very expensive
24 prescriptive system, or a less expensive prescriptive system
25 which I'm not sure that no matter how you train the operator,

1 he will ever turn it on.

2 DR. SIESS: Well, even on that ATWS you had to have
3 different systems for different plants.

4 MR. MINNERS: For feed and bleed you are talking
5 about?

6 DR. SIESS: Hardware fixes for ATWS, for each
7 vender, the hardware fixes for DHR are likely to be different
8 for every darned plant.

9 MR. MINNERS: That is correct.

10 DR. SIESS: Going to be more variations that affect
11 the SCRAM system.

12 MR. MINNERS: Well, you know, we work with, for the
13 Commission, and I think the Commission set out a severe
14 accident policy, and I think we should be guided by that, and
15 their decision was to do it in a PRA way, and I guess we are
16 going to work out the details of how that gets reviewed, and I
17 think that A-45 is more of a severe accident issue than
18 anything else. I mean kind of falls into that category
19 naturally, so I think, you know, I think there is, to my view,
20 some Commission guidance that's the way they would like to go.

21 Now whether policy statements and that kind of stuff
22 is the proper thing to use for severe accidents is, that was
23 their decision. I think that's what your question is. I
24 think you are more questioning the IPE process than you are
25 our A-45 because that's going to cover more accidents than we

1 have covered. If we went out with a prescriptive solution and
2 fixed decay heat removal, there could still be ATWS, or
3 interfacing LOCAs, or any other, or other sequences that could
4 dominate and all our fixes would be for naught because it
5 would be overridden by these other possible more dominant
6 vulnerabilities at particular plants.

7 MR. DAVIS: Mr. Chairman, I had a question. I think
8 I agree with the alternative you have chosen. It seems to me
9 that your studies have shown that there are significant plant
10 differences, and therefore, we need to look at each one
11 individually.

12 But I guess I am still troubled by how we decide if
13 we have got a problem or not. Both your study and the EPRI
14 study indicated that there were no fixes justified on a
15 cost/benefit basis I thought for Point Beach, and yet you seem
16 to, you seem to have a high core melt frequency that you now
17 think should demand some sort of effect. Am I missing
18 something here?

19 MR. MINNERS: Depends what method. I don't agree
20 with you that there is, that on the cost/benefit method they
21 are not justified. I mean I don't know what you, I mean we
22 presented three and there is probably any number of
23 combination you want to use. My view is that the, you should
24 include on-site costs, and that's in my view, a kind of a
25 negative impact. You subtract that off of the limitation cost

1 and then do your ratio bit, and in most cases that comes out
2 it is worthwhile.

3 Now I don't think you should be regulating on the
4 basis that you are going to reduce on-site costs. That should
5 not be the impetus for the regulation. The impetus should be
6 you are going to have off-site safety improvement, but when
7 you consider the balance and what you put on each side of the
8 billion as you have to put on to the cost, and the affected
9 on-site costs are real costs, somebody is going to pay those
10 costs. Okay. And they have happened and somebody is now
11 paying for them. Okay. So I think they ought to be put in
12 the balance.

13 MR. EBERSOLE: Don't you think it is important who
14 pays those costs?

15 MR. MINNERS: No, I don't care who pays those costs.

16 MR. EBERSOLE: Let me tell you why I bring this up.
17 It is, if it is a corporate cost, there are forces that will
18 come in the direction of saving corporate costs. If they are
19 public costs, that's different. I am putting incentives to
20 fix the incentive, the pocketbook as ever, and the public has
21 no way of reaching in and influencing that incentive, as you
22 know, except the intervenin~~g~~ process.

23 MR. MINNERS: I don't agree with that. I think PUCs
24 have very strong influence on--

25 MR. EBERSOLE: Get down into this?

1 MR. MINNERS: They sure have.

2 DR. SIESS: If we assume that the off-site costs are
3 an industry concern, a business-type concern, is it fair to
4 make the industry consider the on-site costs with your PRA
5 results, which is two orders of magnitude higher than their
6 PRA? They look and say it is on ten to the minus 6
7 probability that it is going to cost me a billion dollars, and
8 you say that is a ten to the minus 4 probability that it is
9 something happened to the public. Make them use the ten to
10 the minus 4, with their billion dollars.

11 MR. MINNERS: I don't think there is any such thing
12 as industry cost, Dr. Seiss. The industry has no way of
13 paying for anything. Only way they get their money is out of
14 people. I mean we are the source of all of their funds, and
15 so eventually, the country pays for those costs.

16 MR. EBERSOLE: There is a--

17 DR. SEISS: That is not NRC's concern.

18 MR. MINNERS: I think it is NRC's concern in making
19 the balance.

20 MR. EBERSOLE: The corporate stockholders can fire
21 the president, chairman of the Board, everybody else, if they
22 don't have a good design. The public can't do that. And I
23 think there is a difference in the incentive. If the cost is
24 seen as corporate costs, management will rise up and pay
25 attention to whatever the plant is designed.

1 MR. MINNERS: I don't think I have any regulatory
2 authority to say who will pay the cost. the Public Utility
3 Commissions will decide in their prudence hearings, prudence
4 hearings who pays what costs. I have no influence on that.

5 MR. EBERSOLE: You believe that can be shunted off
6 to the PUCs?

7 MR. MINNERS: Believe it can be? It is. I don't
8 read anything in the Atomic Energy Act that let's me regulate
9 their costs.

10 MR. EBERSOLE: I am not impressed by PUCs as I dig
11 down this far for details.

12 DR. SIESS: If you were advising the PUC to look at
13 this sort of thing on a cost/benefit basis, what PRA would you
14 advise them to use, the licensee's, or the NRC's or the quote,
15 correct one?

16 MR. MINNERS: I would advise them to use the best
17 PRA they can get.

18 DR. SIESS: But in other words, should they--let's
19 face it. The NRC PRA or Sandia or whoever is always a higher
20 probability than the one that comes from the licensee. I
21 don't think I have ever seen a case where they weren't in that
22 usually by a factor of one to two orders of magnitude. There
23 are conservatisms in the regulatory PRAs. Should the PUC be
24 using a conservative--

25 MR. MINNERS: No.

1 DR. SIESS: Value even by one order of magnitude or
2 be using the most realistic thing they can get?

3 MR. EBERSOLE: Generating their own.

4 MR. MINNERS: For economic calculations, it is clear
5 you should be using the mean value for making any of your
6 economic calculations, so they should try to give a PRA that
7 gives them the mean core melt frequency.

8 DR. SIESS: You wouldn't offer opinion as to which
9 of the two we have looked at is the closest to that?

10 MR. MINNERS: No. I think that this is an honest
11 effort, and I appreciate it, and industry has their new and
12 they tend to take a more optimistic view. Fine. I think
13 that's good because I think we need some balance in looking
14 at that. I think some elements of ours are conservative, but
15 then again, there is always the question that we have missed
16 things in PRAs. It is a very--I tried in the beginning to get
17 people to sit down and write all the assumptions that went
18 into these things, and then from that, make a qualitative
19 assessment on the conservatism or non-conservatism of the
20 PRAs, and we were unable to do that. It is too difficult a
21 task to do I think. It is sounds good ideally, but I think
22 it, as a practical matter, it is not good. But nevertheless,
23 I think decision-makers are going to have to do that. It is
24 going to have to come to some judgment of who has got the
25 appropriate PRA. Some of the stuff can be resolved on

1 technical bases I am sure, go out, get a consensus this is the
2 right number, but I think, on human error rates, what do you
3 pick? That's anybody's guess.

4 DR. SIESS: You think they are both biased?

5 MR. MINNERS: Yes. I do think both, do agree with
6 that, and don't imply from that that I think there is a gross
7 bias, okay? I think that when Sandia came to a point of
8 decision they would tend to go to the conservative. Okay.
9 When they had to make a decision I think when--and disagree
10 with me. I expressed my opinion. I think when industry came
11 to that same decision, they go more the optimistic route.

12 DR. ERICSON: I agree with you, Warren. The answer
13 is that every study that is done is biased, without putting
14 bias in a derogatory or negative fashion. We all are biased
15 by our own experience base, and by our own perception of the
16 problem. That doesn't mean that it is bad or negative or
17 wrong, but we are biased.

18 MR. MINNERS: Well, see I think maybe the point that
19 ought to be made here, I guess it is said all the time with
20 PRAs, don't bottom line it. This is a very interesting set of
21 numbers, okay, but don't get mesmerized by the bottom line
22 numbers, okay. Look more into what the PRA tells you and then
23 start to use your engineering experience and say hey, is that
24 a reasonable thing?

25 CHAIRMAN WARD: I think the bias that we are

1 concerned about is not the bias resulting from your personal
2 experience, but the bias which comes from being interested in
3 the result, having some particular interest in the result.
4 That's the bias you are concerned about, we have to deal with.

5 DR. SIESS: It is conceivable--

6 MR. MINNERS: They both produce bias.

7 DR. SIESS: It is conceivable that the normal
8 regulatory bias, you know, we know it is there. I think we
9 always think a little bit on the conservative side, that the
10 regulatory bias itself could account for a 54 difference.
11 Maybe it only accounts for about 30 and the other 20 is some
12 optimistic bias on the other side.

13 MR. MINNERS: Factor of 50 is well within 1150s
14 feather diagram.

15 DR. SIESS: Everything is within that

16 MR. WARD: Everything is, yes.

17 DR. SEISS: Zero and one, you know, we have about
18 covered that 1150.

19 CHAIRMAN WARD: Okay. Well, thank you very much,
20 gentlemen. Before we--let's see. We will take a break for
21 lunch, but I would like the Subcommittee to come back and we
22 will be in Executive Session, which means we don't need a
23 record, at 1:45. I want to spend about an hour or so in a
24 more general discussion.

25 (Whereupon, at 12:40, the recorded portion of the

1 meeting was adjourned.)

STATUS REPORT ON USI A-45
"SHUTDOWN DECAY HEAT REMOVAL REQUIREMENTS"

PRESENTED TO THE
ACRS SUBCOMMITTEE FOR DECAY HEAT REMOVAL
JANUARY 28, 1987

ROY WOODS, SENIOR TASK MANAGER
DIVISION OF REACTOR AND PLANT SYSTEMS
OFFICE OF NUCLEAR REGULATORY RESEARCH

BACKGROUND

- ° CONCERNS ON RELIABILITY OF DHR FUNCTION:
 - RAISED BY TMI
 - EXTENDED TO SPECIAL EMERGENCIES (E.G., FIRE, FLOOD, SEISMIC, SABOTAGE)
- ° ACRS, TASK FORCES, AND SPECIAL COMMISSIONS RECOMMENDED THAT HIGH PRIORITY BE GIVEN TO STUDIES OF IMPROVING SHUTDOWN DHR FUNCTION (POST-TMI EFFORTS)
- ° UNRESOLVED SAFETY ISSUE (USI A-45) APPROVED DEC. 24, 1980 (SECY-80-325)
- ° KEY QUESTIONS:
 - ° DO CURRENT DESIGNS PROVIDE THE RELIABILITY NEEDED TO MEET CDF GOAL?
 - ° ARE THERE IMPROVEMENTS TO DHR FUNCTION IN OPERATING PLANTS WHICH ARE COST-BENEFICIAL?

USI A-45
SPECIFIC OBJECTIVES

- ° DETERMINE THE SAFETY ADEQUACY OF DECAY HEAT REMOVAL IN EXISTING POWER PLANTS FOR ACHIEVING BOTH HOT SHUTDOWN AND COLD SHUTDOWN CONDITIONS
- ° DEVELOP AND EVALUATE ALTERNATIVE METHODS FOR IMPROVING RELIABILITY OF DECAY HEAT REMOVAL FUNCTION,
- ° ASSESS THE VALUE AND IMPACT OF ALTERNATIVE METHODS
- ° ESTABLISH NEW REQUIREMENTS, IF NECESSARY, TO REACH DHR RELIABILITY COMPATIBLE WITH CDF GOAL

USI A-45 SCOPE

- ° EVALUATED DHR SYSTEMS NEEDED TO RESPOND TO TRANSIENTS AND SMALL-BREAK LOCAs (DID NOT INCLUDE LARGE BREAK LOCAs OR ATWS)
- ° ALSO EVALUATED SUCH SYSTEMS' VULNERABILITY TO FIRE, FLOOD, SEISMIC, INSIDER SABOTAGE
- ° SABOTAGE CONSIDERATIONS:
 - CONSIDERED VULNERABILITY OF DHR SYSTEMS TO "INSIDER" SABOTAGE
 - DID NOT CONSIDER "PHYSICAL SECURITY" METHODS ("OUTSIDER")

A-45 STUDIES

° DHR SPECIFIC STUDIES OF SEVERAL PLANTS

° PLANTS SELECTION CRITERIA:

- REPRESENT EACH NSSS VENDOR
- COVER "RANGE" OF DHR CONFIGURATIONS, AEs
- UTILITY INTEREST IN STUDIES

° PRA CASE STUDIES FOR DECAY HEAT REMOVAL (ALL COMPLETED)

<u>PLANT</u>	<u>TYPE</u>	<u>REPORT NO.</u> (NUREG/CR-)	<u>DATE</u>
POINT BEACH	W2LP	4458	3/87
TURKEY POINT	W3LP	4762	3/87
ST. LUCIE	CE	4710	8/87
ANO-1	B&W	4713	3/87
QUAD CITIES	BWR3	4448	3/87
COOPER	BWR4	4767	7/87
(SUMMARY)	(ALL)	-	(EARLY '88)

SUMMARY OF
FINDINGS FROM SIX CASE STUDIES

- ° PROBABILITY OF CORE MELT DUE TO DHR FUNCTION FAILURE [$P(CM)_{DHR}$] AVERAGES 2 TO 3×10^{-4} PER R-YR (INCLUDES INTERNAL AND EXTERNAL CAUSES)
- ° SUPPORT SYSTEM FAILURES (E.G., EMERGENCY POWER, SERVICE WATER, COMPONENT COOLING) CONTRIBUTE SIGNIFICANTLY TO $P(CM)_{DHR}$
- ° LACK OF REDUNDANCY AND SHARING OF SYSTEMS, PARTICULARLY AT SUPPORT SYSTEM LEVEL, CONTRIBUTE SIGNIFICANT RISK FOR SOME PLANTS
- ° LACK OF INDEPENDENCE, SEPARATION AND PHYSICAL PROTECTION OF REDUNDANT SAFEGUARD TRAINS CONTRIBUTE SIGNIFICANT RISK
- ° RISK FROM FIRE, FLOOD, SEISMIC, SABOTAGE IS SIGNIFICANT
- ° BOTTOM LINE IS THAT RELATIVE IMPORTANCE OF VULNERABILITIES IS PLANT-SPECIFIC

° REGULATORY ANALYSIS

- SEPTEMBER 26, 1986 PRE-DECISIONAL DRAFT PRESENTED TO CLOSED SESSION OF ACRS SUBCOMMITTEE DESCRIBING SIX ALTERNATIVES
- DRAFT REVISION BEING PREPARED. WILL DESCRIBE SAME SIX ALTERNATIVES. WE WILL PROPOSE RESOLUTION WITH ALT. # 2 (PLANT-SPECIFIC ANALYSIS)

ALTERNATIVE 1 - NO ACTION

WOULD BE ACCEPTABLE IF NRC ANALYSIS RESULTS ARE
OVERLY CONSERVATIVE (EPRI/WOG: POINT BEACH)

ALTERNATIVE 2 - LIMITED SCOPE PRAs

SEVERE ACCIDENT PROGRAM IPEs

ALTERNATIVE 3 - SPECIFIED SYSTEMS MODIFICATIONS

USIs AND GIs

ALTERNATIVE 4 - DEPRESSURIZATION AND COOLING

PWR - FEED AND BLEED

BWR - CONTAINMENT VENTING

ALTERNATIVE 5 - DEDICATED HOT SHUTDOWN CAPABILITY

ALTERNATIVE 6 - DEDICATED COLD SHUTDOWN CAPABILITY

REG. ANALYSIS (CONT'D)
DIFFERENT APPROACHES TO VALUE-IMPACT ANALYSIS

- ° VALUE-IMPACT ANALYSIS PERFORMED 3 WAYS:
 - A. AVERTED OFFSITE COSTS ONLY
 - B. AVERTED OFFSITE PLUS ONSITE COSTS
 - C. ABOVE PLUS EFFECTS OF SPECIAL CONSIDERATIONS
(E.G., SABOTAGE, MORATORIUM, RESOLUTION OF OTHER
GENERIC ISSUES, UNQUANTIFIABLES)
- ° RESULTS:
 - ° METHOD A - ALTERNATIVES 2, 3 & 4 MAY BE COST-EFFECTIVE
 - ° METHOD B - ALTERNATIVES 2, 3 & 4 MAY BE MORE COST-EFFECTIVE
 - ° METHOD C - ALTERNATIVES 5 & 6 MAY BE COST-EFFECTIVE

REG. ANALYSIS (CONT'D)

- ° RES ENDORSES ALTERNATIVE 2, PLANT-SPECIFIC ANALYSES AND IMPROVEMENT OF DECAY HEAT REMOVAL SYSTEMS.
- ° BASIS:
 - ° A-45 CASE STUDIES SHOWED MOST RISK CONTRIBUTORS TO BE PLANT-SPECIFIC.
 - ° USE OF "METHOD C" (CREDIT FOR "MORATORIUM AVOIDANCE") GOES BEYOND VALUE/IMPACT METHODS PREVIOUSLY USED FOR USIs/GSIs AND THEREFORE ALTERNATIVES FIVE AND SIX CAN NOT BE JUSTIFIED ON THE BASIS OF CONVENTIONAL VALUE/IMPACT
 - ° INSIGHTS GAINED FROM SIX CASE STUDIES AND EPRI-WOG ANALYSIS (PL'S NRC/SANDIA REVIEW) WILL BECOME GUIDANCE TO LICENSEES.

IMPLEMENTATION DETAILS

(ALTERNATIVE 2)

- ° RES PROPOSES TO REQUIRE PLANT SPECIFIC PRAs TO IDENTIFY PLANT-SPECIFIC VULNERABILITIES
- ° SHOULD BE PART OF THE IPE?
 - GREATER EFFICIENCY, BUT
 - WOULD REQUIRE MORE THOROUGH PRA
 - WOULD OBLIGATE LARGER NRR REVIEW EFFORT FOR IPE ANALYSES
- ° SHOULD BE SEPARATELY REQUIRED?
 - SIGNIFICANT REDUNDANCY WITH IPE, WOULD REQUIRE EACH LICENSEE TO PERFORM TWO SEPARATE ANALYSES
 - COULD PERFORM MORE THOROUGH PRA FOCUSED ON DHR ONLY
- ° COMMITMENT TO REVIEW ANALYSES
 - LARGE EFFORT NEEDED, NOT NECESSARILY AVAILABLE
 - SAFETY IMPROVEMENT DEPENDENT UPON REVIEW COMMITMENT

EPRI/WOG POINT BEACH PRA

° NRC REVIEWING FOR 2 REASONS:

1) GUIDANCE FOR UTILITIES PERFORMING A-45 PRAS

- WHAT METHODS ACCEPTABLE
- WHAT NUMERICAL ASSUMPTIONS ACCEPTABLE

2) IS ALTERNATIVE 1 JUSTIFIABLE?

- IF THEIR PRA CORRECT, AND
- IF PB IS A "BOUNDING" PLANT
(THEN ALT. 1 WOULD BE ACCEPTABLE)
- WE ARE NOT CONVINCED THAT EITHER OF THE ABOVE
ARE CORRECT

° THUS THE REVIEW RESULTS URGENTLY NEEDED

° WILL BE DISCUSSED BY NRC AND SANDIA

COMPARISON OF NRC/SNL AND

SEQUENCE

DESCRIPTION

- | | |
|------------|--|
| S2MH1'H2' | - SMALL LOCA FOLLOWED BY THE FAILURE OF LOW AND HIGH PRESSURE RECIRCULATION SYSTEMS |
| T1MLE | - A LOSS OF OFFSITE POWER EVENT FOLLOWED BY THE COMMON MODE FAILURE OF THE DIESELS, RESULTING IN EARLY CORE MELT |
| T3QH1'H2' | - A TRANSIENT INVOLVING A STUCK OPEN PORV AND FAILURE OF RECIRCULATION SYSTEMS. THE MFW SYSTEM IS ASSUMED TO BE INITIALLY AVAILABLE. |
| T3QD1D2 | - A TRANSIENT INVOLVING A STUCK OPEN PORV AND FAILURE OF BOTH HIGH AND LOW PRESSURE INJECTION SYSTEMS. THE MFW IS ASSUMED TO BE INITIALLY AVAILABLE. |
| T2MQH1'H2' | - A LOSS OF FEEDWATER EVENT FOLLOWED BY A STUCK OPEN PORV AND FAILURE OF RECIRCULATION SYSTEM. |
| S2MD1D2 | - A SMALL LOCA EVENT FOLLOWED BY THE FAILURE OF BOTH HIGH AND LOW PRESSURE INJECTION SYSTEMS. |

POINT BEACH DHR/PRA

- SW FLOOD - A FLOODING EVENT IN SERVICE WATER PUMP ROOM CAUSING INOPERABILITY OF ALL SW PUMPS, RESULTING IN LOSS OF CORE COOLING SYSTEMS. THE FLOOD IS ASSUMED TO RESULT IN A TRANSIENT.
- SEISMIC EVENTS - SEISMIC EVENTS OF LOW TO MODERATE INTENSITY RESULTING IN:
- (A) LOSS OF FEEDWATER SEQUENCES INVOLVING INJECTION FAILURES,
 - (B) SMALL LOCA SEQUENCES INVOLVING INJECTION FAILURES, AND
 - (C) TRANSIENTS INVOLVING THE FAILURE OF BOTH PRIMARY AND SECONDARY COOLING SYSTEMS.
- FIRES - TRANSIENT COMBUSTIBLE FIRES WERE CONSIDERED.
- (A) A FIRE IN AFW PUMP ROOM FOLLOWED BY PRIMARY COOLING SYSTEM FAILURES.
 - (B) A FIRE IN 4.16 KV SWITCHGEAR ROOM FOLLOWED BY PRIMARY AND SECONDARY COOLING SYSTEM FAILURES.

TAP A-45 Shutdown Decay Heat Removal Analysis

**Comparison of SNL/NRC and EPRI/WOG
Results for Point Beach**

**David M. Ericson, Jr
ERCI Incorporated**

**Kenneth G. Adams
Sandia National Laboratories**

**ACRS Subcommittee on Decay Heat Removal
January 28, 1988**

USI A-45 (TAP A-45) Program Objectives

Determine adequacy of DHR in existing NPP

**Evaluate feasibility of methods for improving
DHR, including diverse dedicated systems**

**Assess the value and impact of potential
alternatives**

Limits on Scope of PRA

Initiating events considered did not include
Large LOCA, reactor vessel ruptures,
Interfacing system LOCAs, ATWS

Only plant systems contributing to DHR were
analyzed

Although specific plants were identified for
analysis, the analysis was to provide
representative results for similar plants

EPRI/WOG Analysis

**Best estimate of Point Beach risk
from industry perspective**

Same analysis scope as USI A-45

Primarily used RMQS

Risk Management Query System (RMQS)

Store principle components of a PRA

**Initiators, Accident sequences, System cut
sets, Basic event (component) probabilities,
Risk management factors**

Ask questions of the PRA

Investigate effect of parameter changes

**Initiator frequencies, recovery events,
failure probabilities, new loops**

Internal

Core Melt Frequency

NRC $1.4E-4$ WOG $2.6E-6$

Reduction Factor 54

New Batteries

Small LOCA frequency

CCW success criteria

Operator action

Refill of CST

Diesel generator failure rates

Handling of relief valve LOCA

External

Core Melt Frequency

	NRC	WOG	R/F
Seismic	$6.1E-5$	$7.4E-6$	8

Recovery, new batteries, seismic hazard curve

Fire	$3.2E-5$	$6.3E-8$	500
------	----------	----------	-----

Recovery, new batteries, initiator frequencies

Internal Flood	$7.7E-5$	$<1.0E-8$	>7700
----------------	----------	-----------	---------

Flood frequency, success criteria for cooling of HPI

Wind	$4.0E-6$	$<1.0E-8$	$>>400$
------	----------	-----------	---------

Diesel generator exhaust supports strengthened

Results of Reanalysis

Factor of 30 reduction in core melt frequency

Additional factor of 7 in offsite consequences

50% to 400% increase in cost estimates

General Form of Accident Sequences

Transient with failure of secondary heat removal and feed-and-bleed

Transient with failure of secondary heat removal and successful feed-and-bleed in injection mode, but failure of ECCS recirculation (HPR mode)

Small LOCA with failure of ECCS recirculation

Small LOCA with failure of ECCS injection and failure of either secondary heat removal or LPI

Transient-induced LOCA and failure of ECCS recirculation

Transient-induced LOCA and failure of ECCS injection (and failure of either secondary heat removal or LPI)

Reasons for Differences

HPI does not require CCW

SBLOCA and transient-induced LOCA frequency

Low Point Beach-specific transient frequencies

AC and DC bus cross-connects

Miscellaneous operator recovery actions or
human error in performing normal actions

Areas for Discussion

Timeliness of data (snapshot)

Plant characteristics (inerties/interconnects)
EPRI/WOG included new batteries

Human effectiveness (recovery)

Times available for recovery

Initiator frequencies

Modification costs

General Comments

Different plant based on new batteries and success criteria

Current methodology does not provide a "correct" answer

Difficult to establish effectiveness of human performance (particularly under new ERG)

Difficult to ascertain exactly what data, models and assumption were used

Success Criteria for Support Systems

CCW provides seal rather than bearing cooling
and is therefore not required for HPI operation
in injection mode

SW not required for cooling of CCW and
recovery possible by operator when less
than three of six pumps available
(balance load)

Changes in HRA Quantification

Reduced failure to initiate feed and bleed
9.E-3 to 1.E-3

Reduced failure to initiate sump recirculation
3.E-3 to 1.E-4

Reduced failure to depressurize
1.5E-2 to 3.E-3

Change the human recovery time reliability
correlation, reduction by up to a factor
of 50

Additional Recovery actions

Criteria for Recovery

USI A-45

Two actions before two hours (RA-1 or
RA-2 + another)

Three after two hours (two + RA-1 or
RA-2)

WOG

Number of options available

Time required to perform each action

Presence in procedures and training

(Emergency Response Guidelines or plant
specific procedures)

USI A-45 Recovery

- RA-1 Loss of offsite power
- RA-2 Loss of main feedwater
- RA-8 Battery common cause
- RA-9 Battery fault
- RA-10 Diesel common cause
- RA-11 Diesel fault
- RA-6 Other failures from control room
- RA-7 Other failures locally

EPRI/WOG Recovery

RWST refill using spent fuel pool or
chemical and volume control system
Cross-connect AC or DC buses
Manual control of turbine-driven AFW pump
Provision of backup supply of feedwater
Use of charging system for loss of feedwater
Balancing loads on the service water system
Recovery from common mode failures

Small LOCA Frequency and Modeling

2.0E-2 to 3.0E-3 eliminate seal leaks

Small small break LOCA 0.5 to 1.5 inches

Significantly less injection for makeup

**AFW can delay core uncover, more time
for recovery actions**

**Small enough for recovery by the alternate
sources of water for the RWST**

Relief Valve/PORV LOCA

1.4E-3 to 1.1E-4 RCMF 2.9E-5

**Survey of operational Westinghouse plants
conducted in 1981 showed no failures in
PORVs. Included 163 operational openings**

Common-Cause Failure Rates

Reasons for Changes

Design review for determining beta factors

The design review process has yielded a factor of two lower in EPRI's application than the beta factors calculated using all industry experience. (i.e., Factor of 3 on pump failure)

Recovery from common-cause failures

A review (AEOD report C504) indicates that roughly 60% of both human and hardware failures were recovered within one hour

Used data from Millstone-3 PRA

Common-Cause Failure Rates

	USI A-45	WOG
Batteries	$9.6\text{E-}4$	$4.0\text{E-}4$
MDPs & TDP	$2.0\text{E-}4$	$3.0\text{E-}5$
2 running SWPs & 1 standby	$2.0\text{E-}5$	$4.0\text{E-}6$
Running & standby CCWPs	$8.0\text{E-}5$	$3.0\text{E-}5$
Other pumps	$1.0\text{E-}4$	$3.0\text{E-}5$
MOVs	$4.0\text{E-}4$	$8.0\text{E-}5$
Diesel generators	$1.5\text{E-}3$	$5.0\text{E-}4$

Seismic

New Seismic Category I batteries

RWST tank failure recovery

Seismic hazard curve conservative by factor
of two for low accelerations, and by a factor
of five for high accelerations

Frequency of small break LOCAs

AFW recoveries implemented from control room

Failure of one CST will cause loss of inventory

Internal Flood

(Service Water Pump Room)

USI A-45 study used generic room flood
frequency of auxiliary building moderate flood
 $2.2E-2$

WOG used frequency based on relationship
of break to pipe characteristics
length of pipe
pipe diameter
pipe thickness
weld quality
dynamic loading factor
 $3.73E-5$

Pipe Break Frequency Correlation (EPRI/WOG)

$$P_o = (P_o/P_l) * (Q_p + A * S * Q_w) * BF * P$$

P_o = probability of break over the pipe length

P_o/P_l = percentage of breaks out of leaks (.06)

Q_p = ratio of product of pipe diameter with
length of pipe to square of thickness

A, S = factors related to weld quality (50, 1)

Q_w = same as Q_p but for the welds

BF = dynamic loading factor (2)

P = Global pipe failure rate per Q ($1.E-8/yr/Q$)

Length=3 ft. diameter=10 in. thickness=.5 in.

Issues Related to EPRI/WOG Approach

(Internal Flood)

Correlation modified without explanation

Restricted pipe length considered

Definition of terms

Containment Success Criteria

EPRI/WOG

**RCS leakage and small LOCAs do not place
a significant load on containment
Recovery considered**

USI A-45

**Used criteria for a large LOCA design based
accident**

Source Term Comparisons

Using EPRI/WOG Core Melt Frequencies

	expected dose person-rem/reactor yr
EPRI/WOG 1 BMI-2104 and draft NUREG-0956	0.08
EPRI/WOG 2 IDCOR program	0.16
EPRI/WOG 3 Engineering judgement	0.7
USI A-45 .3 time WASH-1400	1.2

Cost Estimate Differences

**Failure to consider all design requirements
(seismic) for specific aspects of modification**

**Failure to account for existing structures
and/or buried piping or cabling**

**Failure to account for iteration between
initial design and final installation**

Cost experienced in installing new batteries

Upgraded Emergency Operating Procedures

There is evidence NUREG/CR-4617, March 1987
that EOPs markedly improve operator performance
(CMF conservatively estimated to be reduced by a
factor of 1/8)

Synergisms among transient analysis, upgraded
training, and management overview
